Eye height is the distance between  $\mu - 3\sigma$  of the upper eye level and  $\mu + 3\sigma$  of the lower eye level.  $\mu$  is the mean of the eye level, and  $\sigma$  is the standard deviation.

Vertical Opening - Distance between BER threshold points

The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of  $10^{-12}$ , these points correspond to the  $7\sigma$  distance from each eye level.

#### Eye SNR - Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where  $L_1$  and  $L_0$  represent the means of the upper and lower eye levels and  $\sigma_1$  and  $\sigma_0$  represent their standard deviations.

#### Q Factor - Quality factor

The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

#### Crossing Levels - Amplitude levels for eye crossings

The crossing levels are the amplitude levels at which the eye crossings occur.

The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.

Crossing Times - Times for which crossings occur

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

Eye Delay - Mean time between eye crossings

Eye delay is the midpoint between the two crossing times.

Eye Width - Statistical minimum time between eye crossings

Eye width is the horizontal distance between  $\mu + 3\sigma$  of the left crossing time and  $\mu - 3\sigma$  of the right crossing time.  $\mu$  is the mean of the jitter histogram, and  $\sigma$  is the standard deviation.

Horizontal Opening - Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a  $10^{-12}$  BER, these two points correspond to the  $7\sigma$  distance from each crossing time.

Rise Time - Time to transition from low to high

Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

Fall Time - Time to transition from high to low

Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

Deterministic Jitter - Deterministic deviation from ideal signal timing

*Jitter* is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

### Random Jitter - Random deviation from ideal signal timing

RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of  $\sigma$ . The RJ is computed as:

$$RJ = (Q_L + Q_R)\sigma,$$

where

$$Q = \sqrt{2} \operatorname{erfc}^{-1} \left( 2 \frac{BER}{\rho} \right).$$

BER is the specified BER threshold.  $\rho$  is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

### Total Jitter - Deviation from ideal signal timing

Total jitter (TJ) is the sum of the deterministic and random jitter, such that  $TJ = DJ + RJ$ .

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

### RMS Jitter - Standard deviation of jitter

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

### Peak-to-Peak Jitter - Distance between extreme data points of histogram

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

## Version History

**Introduced in R2016b**

**R2022a: comm.EyeDiagram has been removed**

*Errors starting in R2022a*

comm.EyeDiagram has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

### Examples

#### Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...  
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...  
    'ColorScale','Logarithmic','EnableMeasurements',true, ...  
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...  
    'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...  
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar', 'Seed', 5489);
y = awgn(x, 30, 'measured', randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold], [hb.BER], 'b', ...
         [hb.RightThreshold], [hb.BER], 'b')
grid
hb =
```

1x13 struct array with fields:

```
BER
LeftThreshold
RightThreshold
```

Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
         [vb.BER],[vb.UpperThreshold],'b')
grid
vb =
```

1x13 struct array with fields:

```
BER
UpperThreshold
LowerThreshold
```

## Input Arguments

**ed** — Eye Diagram System object  
System object

Eye Diagram System object, where you get the bathtub curve information from.

## Output Arguments

**s** — Structure containing information  
struct

Structure containing information about the horizontal bathtub curve.

**BER** — Bit error rate values  
scalar

Bit error rate values, mapped on the Y-axis of the horizontalBathtub plot against the corresponding LeftThreshold and RightThreshold values on the x-axis, specified as a scalar.

Data Types: double

**LeftThreshold** — Left threshold values  
scalar

Left threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: double

### **RightThreshold – Right threshold values**

scalar

Right threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: double

## Examples

### Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

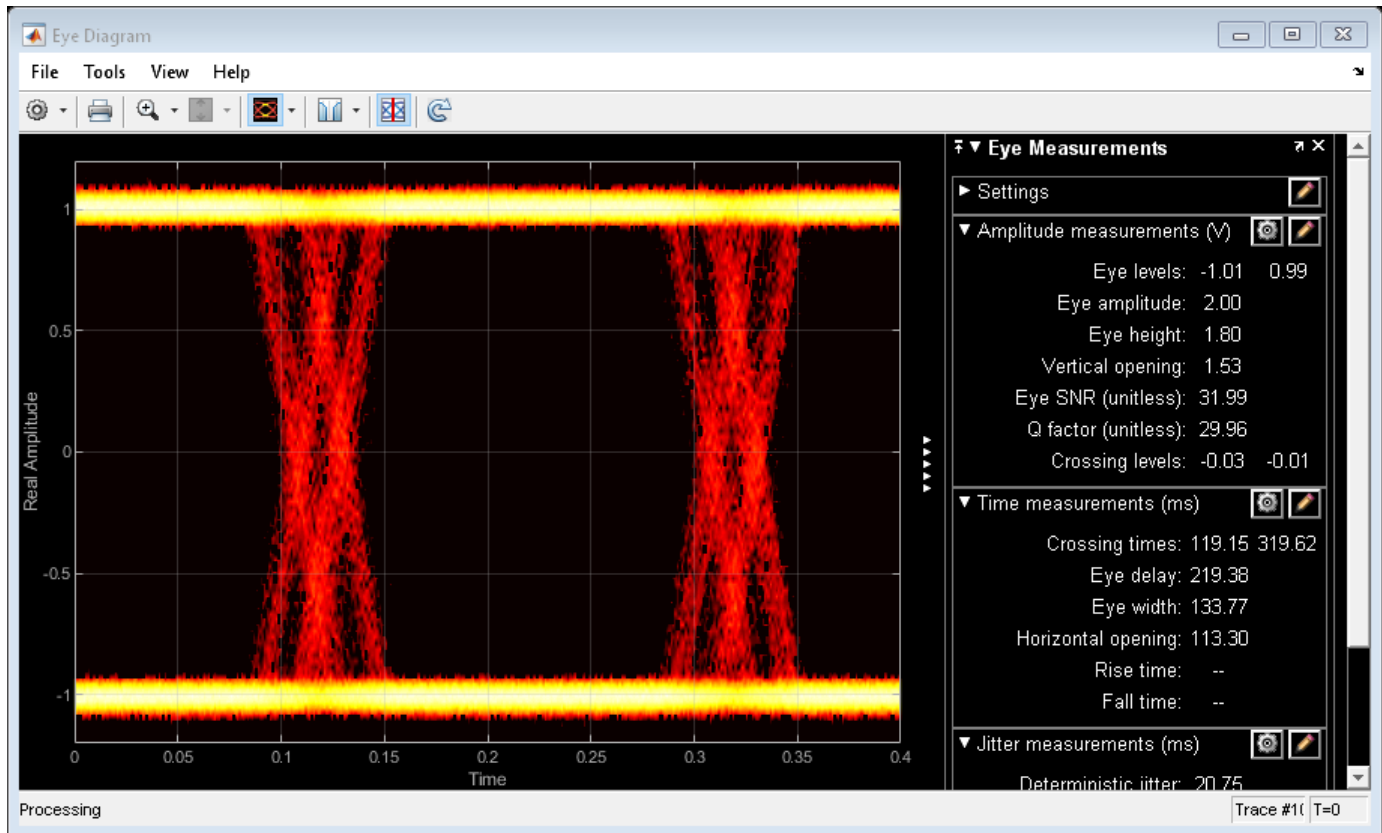

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```

randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)

```

Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```

jbins = jitterHistogram(ed);
plot(jbins)

```

Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);  
plot(nbins)
```

## Input Arguments

### **ed** — Eye Diagram System object

System object

Eye Diagram System object, where the count for decision boundary crossings is set.

## Output Arguments

### **jh** — Jitter histogram

nonnegative integer

Jitter histogram, which represent the counts for decision boundary crossings, specified as a nonnegative integer.

Data Types: `double`

## Version History

**Introduced in R2016b**

**R2022a: `comm.EyeDiagram` has been removed**

*Errors starting in R2022a*

jitterHistogram has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

**See Also**

`noiseHistogram`

## measurements

**Package:** comm

(Removed) Measure eye diagram parameters

### Syntax

```
m = measurements(ed)
```

### Description

`m = measurements(ed)` returns the parameter measurements calculated by eye diagram System object.

---

**Note** This method is available when `EnableMeasurements` is `true`.

---

### Examples

#### Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a  $2e-4$  standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

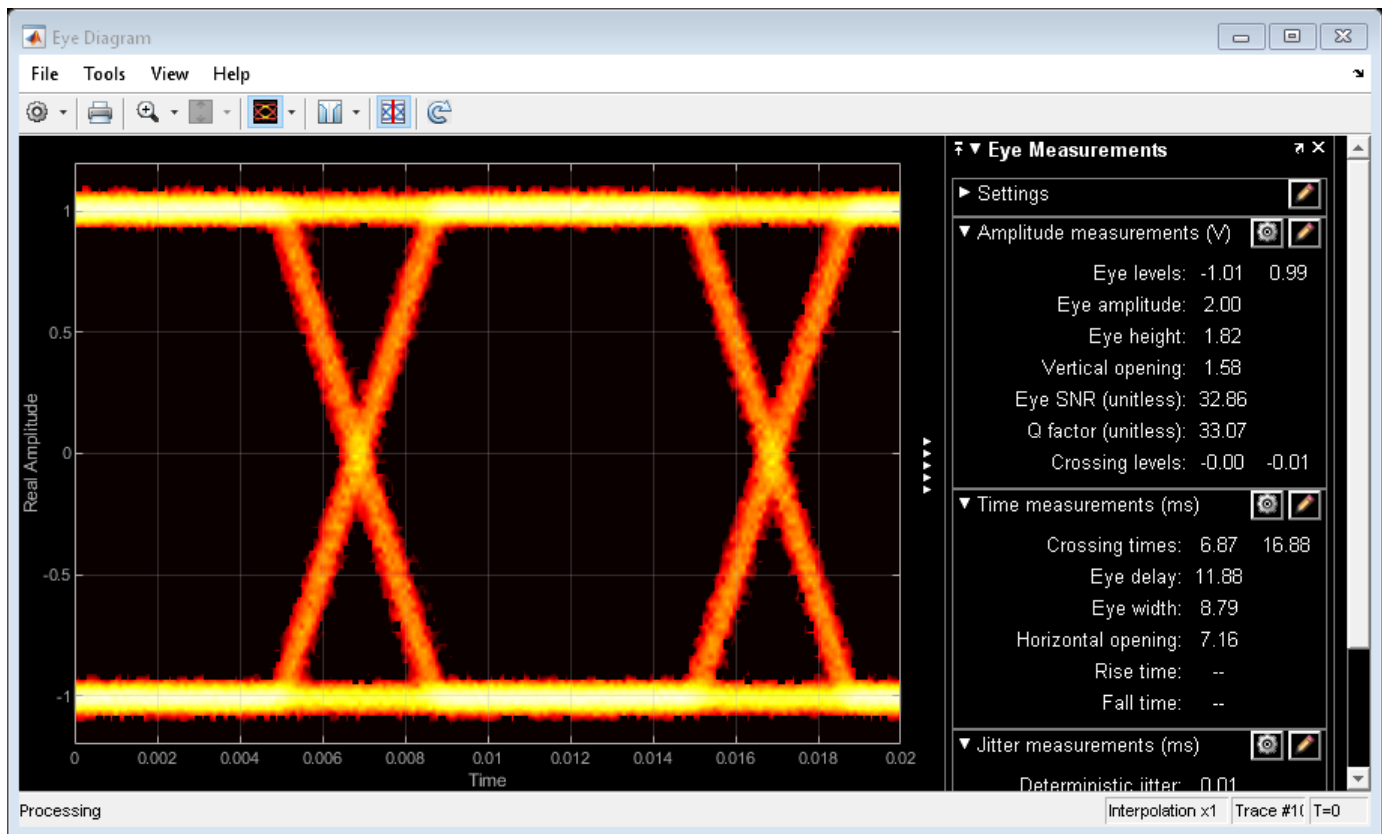

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency, ...
    'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation', ...
    'ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```

Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the measurements method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime
```

```
riseTime =
    0.0030
```

```
fallTime =
    0.0030
```

The measured values match the 3 ms specification.

## Input Arguments

**ed** — Eye Diagram System object  
System object

Eye Diagram System object, where the parameter measurements are calculated.

## Output Arguments

**m** — Eye Diagram parameters measurement  
struct

Eye Diagram parameters measurement, returned as a structure containing all 18 parameters mentioned in “Measurements” on page 3-481, along with their values.

Data Types: double

## Version History

**Introduced in R2016b**

**R2022a: comm.EyeDiagram has been removed**

*Errors starting in R2022a*

measurements has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

# noiseHistogram

**Package:** comm

(Removed) Noise histogram

## Syntax

```
nh = noiseHistogram(ed)
```

## Description

`nh = noiseHistogram(ed)` returns the bin counts for the signal values at the vertical opening (eye delay) as set in eye diagram System object.

---

**Note** This method is available when both of these conditions apply:

- `EnableMeasurements` is true
  - `DisplayMode` is '2D color histogram'
- 

## Examples

### Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2, ...
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```

Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```

Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);  
plot(nbins)
```

## Input Arguments

### **ed** — Eye Diagram System object

System object

Eye Diagram System object, where the counts for signal values at the eye delay is set.

## Output Arguments

### **nh** — Noise histogram

nonnegative integer

Noise histogram, which represent the counts for the signal values at the vertical opening (eye delay), specified as a nonnegative integer.

Data Types: `double`

## Version History

         [vb.BER],[vb.UpperThreshold],'b')
grid
```

vb =

1x13 struct array with fields:

```
BER
UpperThreshold
LowerThreshold
```

## Input Arguments

**ed** — Eye Diagram System object  
System object

Eye Diagram System object, where you get the bathtub curve information from.

## Output Arguments

**s** — Structure containing information  
struct

Structure containing information about the vertical bathtub curve.

**BER** — Bit error rate values  
scalar

Bit error rate values, mapped on the Y-axis of the verticalBathtub plot against the corresponding UpperThreshold and LowerThreshold values on the x-axis, specified as a scalar.

Data Types: double

**UpperThreshold** — Upper threshold value  
scalar

Upper threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: double

#### **LowerThreshold — Lower threshold value**

scalar

Lower threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: double

## comm.FMBroadcastDemodulator

**Package:** comm

Demodulate broadcast FM audio signal

### Description

The `comm.FMBroadcastDemodulator` System object demodulates a complex broadcast FM-modulated signal and filters the signal with a de-emphasis filter to produce an audio signal. For more details, see “Algorithms” on page 3-524.

To demodulate a broadcast FM audio signal:

- 1 Create the `comm.FMBroadcastDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
fmbdemodulator = comm.FMBroadcastDemodulator  
fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)  
fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)
```

#### Description

`fmbdemodulator = comm.FMBroadcastDemodulator` creates an FM broadcast demodulator System object.

`fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)` sets properties using one or more name-value arguments. For example, `fmbdemodulator = comm.FMBroadcastDemodulator('SampleRate',400e3)` specifies a sample rate of 400 kHz.

`fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)` sets properties based on the configuration of the input `comm.FMBroadcastModulator` System object, `fmbmodulator`.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**SampleRate — Sample rate**

240e3 (default) | positive scalar

Sample rate of the input of the demodulator in Hz, specified as a positive scalar. The sample rate must be greater than twice the frequency deviation (that is,  $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$ ).

Data Types: double

**FrequencyDeviation — Peak deviation of the input signal frequency**

75e3 (default) | positive scalar

Peak deviation of the input signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is,  $\text{FrequencyDeviation} < \text{SampleRate}/2$ ).

The system bandwidth  $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$ , where  $B_M$  is the message bandwidth in Hz. For more information, see “Algorithms” on page 3-524.

FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

Data Types: double

**FilterTimeConstant — De-emphasis highpass filter time constant**

7.5e-05 (default) | positive scalar

De-emphasis highpass filter time constant in seconds, specified as a positive scalar. FM broadcast standards specify a value of 75  $\mu\text{s}$  in the United States and 50  $\mu\text{s}$  in Europe.

Data Types: double

**Stereo — Option to enable stereo demodulation**

false or 0 (default) | true or 1

Option to enable stereo demodulation, specified as a logical 0 (false) or 1 (true).

- `false` — The output is mono audio.
- `true` — The object performs stereo decoding and outputs stereo audio.

For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-525.

Data Types: logical

**PlaySound — Option to enable audio playback**

false or 0 (default) | true or 1

Option to enable audio playback, specified as a logical 0 (false) or 1 (true). To playback the output signal on the default audio device connected to the computer, set this property to `true`.

Data Types: logical

**AudioSampleRate — Sample rate of output audio signal**

48000 (default) | positive scalar

Sample rate of the output audio signal in Hz, specified as a positive scalar.

Data Types: `double`

**BufferSize — Size of buffer**

4096 (default) | positive integer

Size of the buffer in samples, specified as a positive integer. This property specifies the size of the buffer used by the System object for communication with the audio device.

**Dependencies**

To enable this property, set the `PlaySound` property to `true`.

Data Types: `double`

**RBDS — Option to enable RDS (or RBDS) waveform demodulation**

false or 0 (default) | true or 1

Option to enable RDS (or RBDS) waveform demodulation, specified as a logical 0 (`false`) or 1 (`true`). If you set this property set to `true`, the object demodulates the RDS (or RBDS) waveform. For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-525.

Data Types: `logical`

**RBDSamplesPerSymbol — Oversampling factor of RDS (or RBDS) output signal**

10 (default) | positive integer

Oversampling factor of the RDS (or RBDS) output signal, specified as a positive integer. The sample rate of RDS (or RBDS) broadcast data is 1187.5 Hz. The RDS (or RBDS) signal sample rate is  $\text{RBDSsamplesPerSymbol} \times 1187.5$  Hz.

**Dependencies**

To enable this property, set the `RBDS` property to `true`.

Data Types: `double`

**RBDSCostasLoop — Option to recover phase of RDS (or RBDS) signal**

false or 0 (default) | true or 1

Option to recover phase of the RDS (or RBDS) signal, specified as a logical 0 (`false`) or 1 (`true`).

To recover the phase of the RDS (or RBDS) signal by using a Costas loop, set this property to `true`. For radio stations that do not lock the 57 kHz RDS (or RBDS) signal in phase with the third harmonic of the 19 kHz pilot tone, a Costas loop helps recover the phase of the RDS (or RBDS) signal.

**Dependencies**

To enable this property, set the `RBDS` property to `true`.

Data Types: `logical`

## Usage

### Syntax

```
audiosig = fmbdemodulator(insig)
[audiosig, rbdssig] = fmbdemodulator(insig)
```

### Description

`audiosig = fmbdemodulator(insig)` demodulates an FM-modulated baseband audio signal and filters this signal with a de-emphasis filter to produce an audio signal.

`[audiosig, rbdssig] = fmbdemodulator(insig)` also demodulates a baseband RBDS signal at 57 kHz. To enable this syntax, set the `RBDS` property to `true`.

### Input Arguments

#### **insig** — FM-modulated baseband audio signal

column vector

FM-modulated baseband audio signal, specified as a column vector. For information about signal length restrictions, see “Limitations” on page 3-524.

Data Types: `double` | `single`

Complex Number Support: Yes

### Output Arguments

#### **audiosig** — Audio signal

$N$ -element column vector |  $M$ -by- $N$  matrix

Audio signal, returned as a column vector or an  $M$ -by- $N$  matrix.  $M$  is the number of stereo channels.  $N$  is the number of samples in the audio signal per channel. The output has the same data type as the input signal, `insig`.

If you set the `Stereo` property to `true`, the audio signal must have at least two channels and the System object performs stereo encoding before de-emphasis filtering. The length of the output is  $N \times (\text{AudioSampleRate}/\text{SampleRate})$ .

#### **rbdssig** — RBDS signal

column vector

RBDS signal, returned as a column vector with the same data type as the input signal.

Data Types: `double` | `single`

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.FMBroadcastDemodulator

info Information about FM broadcast modulator or demodulator

## Common to All System Objects

step Run System object algorithm  
release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### FM Broadcast Streaming Audio Signal

Play back an audio file after applying FM broadcast modulation and demodulation using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™ with the samples per frame set to 4410.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...  
    'SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Set the sample rate of the demodulator to match the specified sample rate of the modulator. Enable audio playback for the broadcast demodulator.

```
fmbMod = comm.FMBroadcastModulator( ...  
    'AudioSampleRate',audiofilereader.SampleRate, ...  
    'SampleRate',240e3);  
fmbDemod = comm.FMBroadcastDemodulator( ...  
    'AudioSampleRate',audiofilereader.SampleRate, ...  
    'SampleRate',240e3, 'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal, and play back the demodulated signal (`demodData`).

```
while ~isDone(audiofilereader)  
    audioData = audiofilereader();  
    modData = fmbMod(audioData);  
    demodData = fmbDemod(modData); % Demodulate and play signal  
end
```

### FM Broadcast Modulate and Demodulate an RBDS Waveform

Generate an RBDS waveform, FM broadcast modulate the RBDS waveform with an audio signal, and FM broadcast demodulate the FM signal.

Specify parameters for an RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by  $1187.5 \times 10$ . Set the audio sample rate to  $1187.5 \times 40$ .

```

groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

```

Load the audio file `guitartune.wav` by using an audio file reader System object™ while setting the samples per frame. Create RBDS waveform generator, FM broadcast modulator, FM broadcast demodulator, and time scope System objects. Configure the modulator and demodulator objects to process a stereo audio file and an RBDS waveform.

```

afr = dsp.AudioFileReader( ...
    'rbds_capture_47500.wav', ...
    'SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame',groupsPerFrame, ...
    'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',afr.SampleRate, ...
    'SampleRate',outRate, ...
    'Stereo',true, ...
    'RBDS',true, ...
    'RBDSsamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    'SampleRate',outRate, ...
    'Stereo',true, ...
    'RBDS',true, ...
    'PlaySound',true);
scope = timescope( ...
    'SampleRate',outRate, ...
    'YLimits',10^-2*[-1 1]);

```

Read the audio signal. Generate RBDS information at the same configured rate as audio. FM broadcast modulate the stereo audio signal with RBDS information. Add additive white Gaussian noise. FM-demodulate the audio signal and RBDS waveforms. View the waveforms in a time scope.

```

for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input],rbdsWave);
    rcv = awgn(yFM,40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end

```

## Limitations

The length of the input signal, `insig`, must be an integer multiple of the `AudioDecimationFactor` property. If you set the `RBDS` property to `true`, the length of the input signal, `insig`, also must be an integer multiple of `RBDSDecimationFactor`. For more information on the `AudioDecimationFactor` and `RBDSDecimationFactor` properties, see the `info` object function.

## Algorithms

The `comm.FMBroadcastDemodulator` System object includes the functionality of the `comm.FMDemodulator` System object, plus de-emphasis filtering and the ability to receive stereophonic signals.

### Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter before FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum. This figure shows the order of processing operations.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 75  $\mu$ s in the United States and 50  $\mu$ s in Europe. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the response shown in this figure.

### Multiplexed Stereo and RDS (or RBDS) FM Signal

FM broadcast supports stereophonic and monophonic operations. To support stereo transmission:

- The Left + Right channel information is assigned to the mono portion of the spectrum (0 to 15 kHz).
- The Left - Right channel information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal.

A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS (or RBDS) signals.

This figure shows the spectrum of the multiplex baseband signal.

The multiplex message signal  $m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1 \cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2 \text{RBDS}(t) \cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $L(t) \pm R(t)$  signals, the 19 kHz pilot tone, and the RDS (or RBDS) subcarrier, respectively.

The demodulator applies  $m(t)$  to three bandpass filters with center frequencies at 19, 38, and 57 kHz and to a lowpass filter with a 3 dB cutoff frequency of 15 kHz. The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the  $(L - R)$  and RDS (or RBDS) signals, respectively. To generate a scaled version of the left and right channels that produces the stereo sound, the object adds and subtracts the  $(L + R)$  and  $(L - R)$  signals. To recover the RDS (or RBDS) signal,  $m(t)$  is mixed with the 57 kHz signal.

This figure shows the multiplexing (MPX) decoder block diagram of the FM broadcast demodulator.  $L(t)$  and  $R(t)$  are the left and right audio signal components of the time-domain waveforms.  $\text{RBDS}(t)$  is the time-domain waveform of the RDS (or RBDS) signal.

Modulate broadcast FM audio signal

## Description

The `comm.FMBroadcastModulator` System object pre-emphasizes an audio signal and modulates it onto a baseband FM signal. For more information, see “Algorithms” on page 3-538.

To modulate a broadcast FM audio signal:

- 1 Create the `comm.FMBroadcastModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fmbmodulator = comm.FMBroadcastModulator
fmbmodulator = comm.FMBroadcastModulator(Name,Value)
fmbmodulator = comm.FMBroadcastModulator(fmbdemodulator)
```

### Description

`fmbmodulator = comm.FMBroadcastModulator` creates a FM broadcast modulator System object.

`fmbmodulator = comm.FMBroadcastModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',400e3` specifies a sample rate of 400 kHz.

`fmbmodulator = comm.FMBroadcastModulator(fmbdemodulator)` sets properties based on configuration of the input `comm.FMBroadcastDemodulator` System object, `fmbdemodulator`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the output of the modulator in Hz, specified as a positive scalar. The sample rate must be greater than twice the frequency deviation (that is,  $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$ ).

Data Types: `double`

**FrequencyDeviation — Peak deviation of the output signal frequency**

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is,  $\text{FrequencyDeviation} < \text{SampleRate}/2$ ).

The system bandwidth  $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$ , where  $B_M$  is the message bandwidth in Hz. For more information, see “Algorithms” on page 3-538.

FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

Data Types: `double`

**FilterTimeConstant — Pre-emphasis highpass filter time constant**

7.5e-05 (default) | positive scalar

Pre-emphasis highpass filter time constant in seconds, specified as a positive scalar. FM broadcast standards specify a value of 75  $\mu\text{s}$  in the United States and 50  $\mu\text{s}$  in Europe.

Data Types: `double`

**AudioSampleRate — Sample rate of input audio signal**

48000 (default) | positive scalar

Sample rate of the input audio signal in Hz, specified as a positive scalar.

Data Types: `double`

**Stereo — Option to enable stereo modulation**

false or 0 (default) | true or 1

Option to enable stereo modulation, specified as a logical 0 (false) or 1 (true).

- Set this property to `false` for monophonic audio signals.
- Set this property to `true` for stereophonic audio signals. The object modulates the audio input ( $L - R$ ) in the 38 kHz band in addition to modulating the audio signal in the baseband ( $L + R$ ).

For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-539.

Data Types: `logical`

**RBDS — Option to enable RDS (or RBDS) waveform modulation**

false or 0 (default) | true or 1

Option to enable RDS (or RBDS) waveform modulation, specified as a logical 0 (false) or 1 (true). If you set this property to `true`, the object accepts the baseband RDS (or RBDS) waveform as its

second input and modulates the RDS (or RBDS) signal at 57 kHz. For more information, see “Multiplexed Stereo and RDS (or RBDS) FM Signal” on page 3-539.

Data Types: `logical`

### **RBDSamplesPerSymbol — Oversampling factor of RDS (or RBDS) input signal**

10 (default) | positive integer

Oversampling factor of the RDS (or RBDS) input signal, specified as a positive integer. The sample rate of RDS (or RBDS) broadcast data is 1187.5 Hz. The RDS (or RBDS) signal sample rate is  $\text{RBDSamplesPerSymbol} \times 1187.5$  Hz.

#### **Dependencies**

To enable this property, set the `RBDS` property to `true`.

Data Types: `double`

## **Usage**

### **Syntax**

```
outsig = fmbmodulator(audiosig)
outsig = fmbmodulator(audiosig, rbdssig)
```

#### **Description**

`outsig = fmbmodulator(audiosig)` pre-emphasizes the input audio signal and modulates the pre-emphasized signal onto an FM-modulated baseband audio signal.

`outsig = fmbmodulator(audiosig, rbdssig)` also modulates a baseband RBDS signal at 57 kHz. To enable this syntax, set the `RBDS` property to `true`.

#### **Input Arguments**

##### **audiosig — Audio signal**

*N*-element column vector | *M*-by-*N* matrix

Audio signal, specified as one of these options.

- *N*-element column vector for mono signals — If you set the `Stereo` property to `false`, you must specify the audio signal as a column vector. *N* is the number of samples in the audio signal.
- *M*-by-*N* matrix for stereo signals — *M* is the number of stereo channels. *N* is the number of samples in the audio signal per channel.

For information about signal length restrictions, see “Limitations” on page 3-538.

If you set the `Stereo` property to `true`, the audio signal must have at least two channels and the `System` object performs stereo encoding after pre-emphasis filtering.

Data Types: `double` | `single`

Complex Number Support: Yes

##### **rbdssig — RBDS signal**

column vector

RBDS signal, specified as a column vector. For information about RBDS signal length restrictions, see “Limitations” on page 3-538.

To generate the RBDS signal, use the `comm.RBDSWaveformGenerator` System object.

Data Types: `double` | `single`  
Complex Number Support: Yes

### Output Arguments

#### **outsig** – FM-modulated baseband signal

column vector

FM-modulated baseband signal, returned as a column vector of complex values of the same data type as the input signal, `audiosig`. The length of this output is  $\text{length}(\text{audiosig}) \times (\text{SampleRate}/\text{AudioSampleRate})$ .

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.FMBroadcastModulator`

info Information about FM broadcast modulator or demodulator

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

### Examples

#### FM Broadcast Streaming Audio Signal

Play back an audio file after applying FM broadcast modulation and demodulation using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™ with the samples per frame set to 4410.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...  
    'SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Set the sample rate of the demodulator to match the specified sample rate of the modulator. Enable audio playback for the broadcast demodulator.

```
fmbMod = comm.FMBroadcastModulator( ...  
    'AudioSampleRate',audiofilereader.SampleRate, ...
```

```

    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);

```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal, and play back the demodulated signal (demodData).

```

while ~isDone(audiofilereader)
    audioData = audiofilereader();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData); % Demodulate and play signal
end

```

### Modulate and Demodulate Streaming Audio Signals Using FM Broadcast Method

Modulate and demodulate an audio signal with the FM broadcast modulator and demodulator System objects. Plot the frequency responses to compare the input and demodulated audio signals.

Load the audio file `guitartune.wav` by using an audio file reader System object™. Set the samples per frame to 44,100, which is large enough to include the entire audio file.

```

audiofilereader = dsp.AudioFileReader("guitartune.wav", ...
    SamplesPerFrame=44100);
x = audiofilereader();

```

Create spectrum analyzer System objects to plot the spectra of the modulated and demodulated signals.

```

saFM = spectrumAnalyzer( ...
    SampleRate=152e3, ...
    Title="FM Broadcast Signal");
saAudio = spectrumAnalyzer( ...
    SampleRate=44100, ...
    ShowLegend=true, ...
    Title="Audio Signal", ...
    ChannelNames=["Input signal" "Demodulated signal"]);

```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Configure the demodulator to match the specified modulator.

```

fmbMod = comm.FMBroadcastModulator( ...
    AudioSampleRate=audiofilereader.SampleRate, ...
    SampleRate=200e3);
fmbDemod = comm.FMBroadcastDemodulator(fmbMod)

fmbDemod =
    comm.FMBroadcastDemodulator with properties:

```

```

        SampleRate: 200000
    FrequencyDeviation: 75000
    FilterTimeConstant: 7.5000e-05
        AudioSampleRate: 44100
            PlaySound: false

```

```
Stereo: false  
RBDS: false
```

The length of the sequence input to the object must be an integer multiple of the decimation factor. To determine the audio decimation factor of the filter in the modulator and demodulator, use the `info` object function.

```
info(fmbMod)
```

```
ans = struct with fields:  
    AudioDecimationFactor: 441  
    AudioInterpolationFactor: 2000  
    RBDSDecimationFactor: 19  
    RBDSInterpolationFactor: 320
```

```
info(fmbDemod)
```

```
ans = struct with fields:  
    AudioDecimationFactor: 50  
    AudioInterpolationFactor: 57  
    RBDSDecimationFactor: 50  
    RBDSInterpolationFactor: 57
```

The audio decimation factor of the modulator is a multiple of the audio frame length of 44,100. The audio decimation factor of the demodulator is an integer multiple of the 200,000 samples data sequence length of the modulator output.

Modulate the audio signal and plot the spectrum of the modulated signal.

```
y = fmbMod(x);  
saFM(y)
```

Demodulate the modulated audio signal and plot the resultant spectrum. Compare the input signal spectrum with the demodulated signal spectrum. The spectra are similar except that the demodulated signal has smaller high-frequency components.

```
z = fmbDemod(y);  
saAudio([x z])
```

### FM Broadcast Modulate and Demodulate an RBDS Waveform

Generate an RBDS waveform, FM broadcast modulate the RBDS waveform with an audio signal, and FM broadcast demodulate the FM signal.

Specify parameters for an RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by  $1187.5 \times 10$ . Set the audio sample rate to  $1187.5 \times 40$ .

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
```

Load the audio file `guitartune.wav` by using an audio file reader System object™ while setting the samples per frame. Create RBDS waveform generator, FM broadcast modulator, FM broadcast demodulator, and time scope System objects. Configure the modulator and demodulator objects to process a stereo audio file and an RBDS waveform.

```
afr = dsp.AudioFileReader( ...
    'rbds_capture_47500.wav', ...
    'SamplesPerFrame', rbdsFrameLen*afrRate/rbdsRate);
```

```

rbds = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame',groupsPerFrame, ...
    'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',afr.SampleRate, ...
    'SampleRate',outRate, ...
    'Stereo',true, ...
    'RBDS',true, ...
    'RBDSsamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    'SampleRate',outRate, ...
    'Stereo',true, ...
    'RBDS',true, ...
    'PlaySound',true);
scope = timescope( ...
    'SampleRate',outRate, ...
    'YLimits',10^-2*[-1 1]);

```

Read the audio signal. Generate RBDS information at the same configured rate as audio. FM broadcast modulate the stereo audio signal with RBDS information. Add additive white Gaussian noise. FM-demodulate the audio signal and RBDS waveforms. View the waveforms in a time scope.

```

for idx = 1:7
    input = afr();
    rbdsWave = rbds();
    yFM = fmMod([input input],rbdsWave);
    rcv = awgn(yFM,40);
    [audioRcv, rbdsRcv] = fmDemod(rcv);
    scope(rbdsRcv);
end

```

## Limitations

- If you set the RBDS to `true`, both the audio and RDS (or RBDS) inputs must satisfy this equation.

$$\frac{\text{audioLength}}{\text{audioSampleRate}} = \frac{\text{RBDSLengh}}{\text{RBDSSampleRate}}$$

- The RDS (or RBDS) signal sample rate is `RBDSSamplesPerSymbol × 1187.5 Hz`.
- The length of the input RDS (or RBDS) signal, `rbdsig`, must be an integer multiple of the `RBDSDecimationFactor` property. The input length of the audio signal, `audiosig`, must be an integer multiple of the `AudioDecimationFactor` property. For more information on `RBDSDecimationFactor` and `AudioDecimationFactor`, see the `info` object function.

## Algorithms

The `comm.FMBroadcastModulator` System object includes the functionality of the `comm.FMModulator` System object, plus de-emphasis filtering and the ability to receive stereophonic signals.

### Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter before FM modulation to amplify the high-frequency

content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum. This figure shows the order of processing operations.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where  $\tau_s$  is the filter time constant. The time constant is 75  $\mu\text{s}$  in the United States and 50  $\mu\text{s}$  in Europe. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the response shown in this figure.

### Multiplexed Stereo and RDS (or RBDS) FM Signal

FM broadcast supports stereophonic and monophonic operations. To support stereo transmission:

- The Left + Right channel information is assigned to the mono portion of the spectrum (0 to 15 kHz).

- The Left - Right channel information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal.

A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS (or RBDS) signals.

This figure shows the spectrum of the multiplex baseband signal.

The multiplex message signal  $m(t)$  is given by

$$m(t) = C_0[L(t) + R(t)] + C_1 \cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2 RBDS(t) \cos(2\pi \times 57\text{kHz} \times t),$$

where  $C_0$ ,  $C_1$ , and  $C_2$  are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the  $L(t) \pm R(t)$  signals, the 19 kHz pilot tone, and the RDS (or RBDS) subcarrier, respectively.

This figure shows the multiplexing (MPX) encoder block diagram of the FM broadcast modulator, which generates the multiplex baseband signal.  $L(t)$  and  $R(t)$  are the left and right audio signal components of the time-domain waveforms.  $RBDS(t)$  is the time-domain waveform of the RDS (or RBDS) signal.

Demodulate baseband FM signal

## Description

The `comm.FMDemodulator` System object demodulates a baseband FM signal.

To demodulate a baseband FM signal:

- 1 Create the `comm.FMDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fmdemodulator = comm.FMDemodulator  
fmdemodulator = comm.FMDemodulator(Name, Value)  
fmdemodulator = comm.FMDemodulator(fmmodulator)
```

### Description

`fmdemodulator = comm.FMDemodulator` creates an FM demodulator System object.

`fmdemodulator = comm.FMDemodulator(Name, Value)` sets properties using one or more name-value arguments. For example, `'SampleRate', 400e3` specifies a sample rate of 400 kHz.

`fmdemodulator = comm.FMDemodulator(fmmodulator)` sets properties based on the configuration of the input `comm.FMModulator` System object, `fmmodulator`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar. This property specifies the sample rate at the output of a modulator or at the input of a demodulator. The sample rate must be greater than twice the frequency deviation (that is,  $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$ ).

Data Types: `double`

### **FrequencyDeviation — Peak deviation of output signal frequency**

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is,  $\text{FrequencyDeviation} < \text{SampleRate}/2$ ).

The system bandwidth is  $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$ , where  $B_M$  is the message bandwidth in Hz. For more information, see “Algorithms” on page 3-549.

Data Types: `double`

## **Usage**

### **Syntax**

```
outsig = fmdemodulator(insig)
```

### **Description**

`outsig = fmdemodulator(insig)` demodulates a baseband FM signal and outputs message data.

### **Input Arguments**

#### **insig — Baseband FM signal**

scalar | column vector

Baseband FM signal, specified as a scalar or column vector.

Data Types: `double` | `single` | `fi`

Complex Number Support: Yes

### **Output Arguments**

#### **outsig — Message data**

scalar | column vector

Message data, returned as a scalar or column vector of the same data type and size as the input `insig`.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### Play FM-Demodulated Audio File

Play back an audio file after applying FM modulation and demodulation by using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',4410);
```

Create an audio device writer System object for audio playback.

```
audioplayer = audioDeviceWriter;
```

Create default FM modulator and demodulator System objects.

```
fmmod = comm.FMModulator;
fmdemod = comm.FMDemodulator;
```

Read the audio data, FM-modulate the audio data, FM-demodulate the FM-modulated signal, and play back the demodulated signal (`z`).

```
while ~isDone(audiofilereader)
    x = audiofilereader();
    y = fmmod(x);
    z = fmdemod(y);
    audioplayer(z);
end
```

### Modulate and Demodulate Sinusoidal Signal Using FM Method

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Initialize parameters for the example.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object™, setting the sample rate and frequency deviation. Then, create an FM demodulator System object, using the FM modulator configuration to set the demodulator properties.

```
fmmodulator = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
fmdemodulator = comm.FMDemodulator(fmmodulator);
```

FM-modulate the signal and plot the real component of the complex signal. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmodulator(x);
plot(t,[x real(y)])
title('Input Sinusoid and FM-Modulated Signals')
xlabel('Time (seconds)'); ylabel('Amplitude')
legend('Input signal','Modulated signal (real component)')
```

Demodulate the FM-modulated signal.

```
z = fmdemodulator(y);
```

Plot the original and demodulated signals. The demodulator output signal exactly aligns with the original signal.

```
plot(t,x,'r',t,z,'ks')
legend('Original signal','Demodulated signal')
```

```
xlabel('Time (s)')
ylabel('Amplitude')
```

### Create FM Demodulator from FM Modulator

Create an FM demodulator System object™ from an FM modulator System object. Modulate and demodulate audio data loaded from a file and compare the spectrum for the demodulated data and the input data.

Initialize parameters for the example.

```
fd = 50e3; % Frequency deviation (Hz)
fs = 300e3; % Sample rate (Hz)
```

Create an FM modulator System object.

```
mod = comm.FMModulator( ...
    FrequencyDeviation=fd, ...
    SampleRate=fs);
```

Create an FM demodulator object by using the modulator to configure it.

```
demod = comm.FMDemodulator(mod);
```

Verify that the properties are identical in the two System objects.

**mod**

```
mod =  
comm.FMModulator with properties:  
    SampleRate: 300000  
    FrequencyDeviation: 50000
```

**demod**

```
demod =  
comm.FMDemodulator with properties:  
    SampleRate: 300000  
    FrequencyDeviation: 50000
```

Load audio data into the workspace.

```
S = load("handel.mat");  
data = S.y;  
fsamp = S.Fs;
```

Create a spectrum analyzer System object.

```
sa = spectrumAnalyzer( ...  
    SampleRate=fsamp, ...  
    ShowLegend=true);
```

FM-modulate and -demodulate the audio data.

```
modData = mod(data);  
demodData = demod(modData);
```

Verify that the spectrum plot of the input data (Channel 1) aligns with that of the demodulated data (Channel 2).

```
sa([data demodData])  
release(sa)
```

## Algorithms

A frequency-modulated passband signal,  $Y(t)$ , is given as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right),$$

where:

- $A$  is the carrier amplitude.
- $f_c$  is the carrier frequency.
- $x(\tau)$  is the baseband input signal.
- $f_\Delta$  is the frequency deviation in Hz.

The frequency deviation is the maximum shift from  $f_c$  in one direction, assuming  $|x(\tau)| \leq 1$ .

A baseband FM signal can be derived from the passband representation by downconverting the passband signal by  $f_c$  such that

$$\begin{aligned} y_s(t) &= Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[ e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t} \\ &= \frac{A}{2} \left[ e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right]. \end{aligned}$$

Removing the component at  $-2f_c$  from  $y_s(t)$  leaves the baseband signal representation,  $y(t)$ , which is given as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for  $y(t)$  can be rewritten as  $y(t) = \frac{A}{2} e^{j\phi(t)}$ , where  $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$ . Expressing  $y(t)$  this way implies that the input signal is a scaled version of the derivative of the phase,  $\phi(t)$ .

To recover the input signal from  $y(t)$ , use a baseband delay demodulator, as this figure shows.

Modulate signal using FM method

### Description

The `comm.FMModulator` System object applies baseband frequency modulation to a signal. For more information, see “Algorithms” on page 3-558.

To modulate a signal using the FM method:

- 1 Create the `comm.FMModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
fmmodulator = comm.FMModulator
fmmodulator = comm.FMModulator(Name,Value)
fmmodulator = comm.FMModulator(fmdemodulator)
```

#### Description

`fmmodulator = comm.FMModulator` creates an FM modulator System object.

`fmmodulator = comm.FMModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate,400e3'` specifies a sample rate of 400 kHz.

`fmmodulator = comm.FMModulator(fmdemodulator)` sets properties based on the configuration of the input `comm.FMDemodulator` System object, `fmdemodulator`.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **SampleRate — Sample rate**

240e3 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar. This property specifies the sample rate at the output of a modulator or at the input of a demodulator. The sample rate must be greater than twice the frequency deviation (that is,  $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$ ).

Data Types: double

### **FrequencyDeviation — Peak deviation of output signal frequency**

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is,  $\text{FrequencyDeviation} < \text{SampleRate}/2$ ).

The system bandwidth is  $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$ , where  $B_M$  is the message bandwidth in Hz. For more information, see “Algorithms” on page 3-558.

Data Types: double

## **Usage**

### **Syntax**

```
outsig = fmmodulator(insig)
```

### **Description**

`outsig = fmmodulator(insig)` modulates the input message signal and outputs a baseband FM signal.

### **Input Arguments**

#### **insig — Input signal**

scalar | column vector

Input signal, specified as a scalar or column vector.

Data Types: double | single | fi

Complex Number Support: Yes

### **Output Arguments**

#### **outsig — Modulated baseband FM signal**

scalar | column vector

Modulated baseband FM signal, returned as a scalar or column vector with complex values. The output signal has the same data type and size as the input `insig`.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### FM-Modulate Sinusoidal Signal

Apply baseband modulation to a sine wave. Plot the sine wave and the modulated signals.

Set parameters for the example.

```
fs = 1e3; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 50; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object™, setting the sample rate and frequency deviation.

```
fmodulator = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
```

FM-modulate the signal and plot its real part. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmodulator(x);
plot(t,[x real(y)])
```

### Plot Spectrum of Baseband FM-Modulated Signal

Apply baseband FM modulation to a white Gaussian noise source and plot the spectrum of the modulated signal.

Initialize parameters for the example.

```
fs = 1e3; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 10; % Frequency deviation (Hz)
```

Create a white Gaussian noise source with a duration of 5 seconds.

```
t = (0:ts:5-ts)';
x = wgn(length(t),1,0);
```

Create two FM modulator System objects, setting the sample rate and frequency deviation. Set the frequency deviation of the second FM modulator object five times higher than the first FM modulator.

```
fmmod1 = comm.FMModulator( ...
    SampleRate=fs, ...
    FrequencyDeviation=fd);
fmmod2 = comm.FMModulator( ...
    SampleRate=fs, ...
    FrequencyDeviation=5*fd);
```

Use the FM modulators to apply FM modulation to the signal  $x$ .

```
y1 = fmod1(x);
y2 = fmod2(x);
```

Plot the spectra of the two modulated signals. The larger frequency deviation associated with channel 2 results in a noise level that is 10 dB higher than the first channel.

```
specanalyzer = spectrumAnalyzer(SampleRate=fs, ShowLegend=true);
specanalyzer([y1 y2])
release(specanalyzer)
```

### Modulate and Demodulate Sinusoidal Signal Using FM Method

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Initialize parameters for the example.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object™, setting the sample rate and frequency deviation. Then, create an FM demodulator System object, using the FM modulator configuration to set the demodulator properties.

```
fmmodulator = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
fmdemodulator = comm.FMDemodulator(fmmodulator);
```

FM-modulate the signal and plot the real component of the complex signal. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmodulator(x);
plot(t,[x real(y)])
title('Input Sinusoid and FM-Modulated Signals')
xlabel('Time (seconds)'); ylabel('Amplitude')
legend('Input signal','Modulated signal (real component)')
```

Demodulate the FM-modulated signal.

```
z = fmdemodulator(y);
```

Plot the original and demodulated signals. The demodulator output signal exactly aligns with the original signal.

```

plot(t,x,'r',t,z,'ks')
legend('Original signal','Demodulated signal')
xlabel('Time (s)')
ylabel('Amplitude')

```

## Algorithms

A frequency-modulated passband signal,  $Y(t)$ , is given as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right),$$

where:

- $A$  is the carrier amplitude.
- $f_c$  is the carrier frequency.
- $x(\tau)$  is the baseband input signal.
- $f_\Delta$  is the frequency deviation in Hz.

The frequency deviation is the maximum shift from  $f_c$  in one direction, assuming  $|x(\tau)| \leq 1$ .

A baseband FM signal can be derived from the passband representation by downconverting the passband signal by  $f_c$  such that

$$y_s(t) = Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[ e^{j(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau)} + e^{-j(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau)} \right] e^{-j2\pi f_c t}$$

$$= \frac{A}{2} \left[ e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right].$$

Removing the component at  $-2f_c$  from  $y_s(t)$  leaves the baseband signal representation,  $y(t)$ , which is given as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for  $y(t)$  can be rewritten as  $y(t) = \frac{A}{2} e^{j\phi(t)}$ , where  $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$ . Expressing  $y(t)$  this way implies that the input signal is a scaled version of the derivative of the phase,  $\phi(t)$ .

To recover the input signal from  $y(t)$ , use a baseband delay demodulator, as this figure shows.

Subtracting a delayed and conjugated copy of the received signal from the signal itself results in this equation.

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where  $T$  is the sample period. In discrete terms,

$$w_n = w(nT),$$

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]}, \text{ and}$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal  $v_n$  is the approximate derivative of  $\phi_n$  such that  $v_n \approx x_n$ .

**Package:** comm

Demodulate using M-ary FSK method

## Description

The `comm.FSKDemodulator` System object noncoherently demodulates a signal that was modulated using the M-ary frequency shift keying (M-FSK) method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. For more information, see “Algorithms” on page 3-567.

To demodulate a signal that was modulated using frequency shift keying:

- 1 Create the `comm.FSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fskdemodulator = comm.FSKDemodulator
fskdemodulator = comm.FSKDemodulator(Name=Value)
fskdemodulator = comm.FSKDemodulator(M,freqSep,RS,Name=Value)
```

### Description

`fskdemodulator = comm.FSKDemodulator` creates a demodulator System object that demodulates an M-FSK modulated signal by using a noncoherent energy detector.

`fskdemodulator = comm.FSKDemodulator(Name=Value)` creates an FSK demodulator object and sets properties using one or more name-value arguments. For example, `comm.FSKDemodulator(BitOutput=true)` configures the object to return binary output values.

`fskdemodulator = comm.FSKDemodulator(M,freqSep,RS,Name=Value)` creates an M-FSK demodulator object with the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `freqSep`, the `SymbolRate` property set to `RS`, and optional name-value arguments.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**ModulationOrder — Number of frequencies in modulated signal**8 (default) | positive integer  $\geq 2$ 

Number of frequencies in the modulated signal, specified as a positive integer  $\geq 2$ .

---

**Note** The modulation order,  $M$ , must be a power of two, such that  $M = 2^K$ , where  $K$  is a positive integer when you set `SymbolMapping` to 'Gray' or you set `BitOutput` to `true`.

---

Data Types: `double`

**BitOutput — Option to provide output as integers or groups of bit values**0 or `false` (default) | 1 or `true`

Option to provide the output as integers or groups of bit values, specified as a numeric or logical 0 (`false`) or 1 (`true`).

Data Types: `logical`

**SymbolMapping — Symbol encoding mapping**

'Gray' (default) | 'Binary'

Symbol encoding mapping, specified as 'Gray' or 'Binary'. Each integer or group of  $\log_2(M)$  bits corresponds to one symbol.  $M$  represents the value of the `ModulationOrder` property.

- When you set this property to 'Gray', the object maps symbols to a Gray-encoded ordering.
- When you set this property to 'Binary', the object maps symbols to a natural binary-encoded ordering.

For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer  $(M - 1)$ . In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

**FrequencySeparation — Frequency separation between successive tones**

6 (default) | positive scalar

Frequency separation between successive tones in the modulated signal in hertz, specified as a positive scalar value. For more information, see "Avoid Output Signal Aliasing" on page 3-567.

Data Types: `double`

**SamplesPerSymbol — Number of samples per input symbol**

17 (default) | positive integer

Number of samples per input symbol, specified as positive integer. For more information, see "Avoid Output Signal Aliasing" on page 3-567.

Data Types: `double`

**SymbolRate — Symbol rate in symbols per second**

100 (default) | positive scalar

Symbol rate in symbols per second, specified as a positive scalar. The symbol duration remains the same, regardless of whether the output signal is bits or integers. For more information, see “Avoid Output Signal Aliasing” on page 3-567.

Data Types: double

#### **OutputDataType — Data type of output**

"double" (default) | "logical" | "int8" | ...

Data type of output, specified as one of "double", "logical", "int8", "uint8", "int16", "uint16", "int32", or "uint32".

- When you set the `BitOutput` property to `false` and the `ModulationOrder` property to 2, you can set this property to "logical".
- When you set the `BitOutput` property to `true`, the output data type must be set to "logical" or "double".

## **Usage**

### **Syntax**

`Y = fskdemodulator(X)`

### **Description**

`Y = fskdemodulator(X)` demodulates the input signal by using the M-FSK method.

### **Input Arguments**

#### **X — Modulated input signal**

column vector

Modulated input signal, specified as a column vector. The length of X must be an integer multiple of the `SamplesPerSymbol` property value.

Data Types: double | single

### **Output Arguments**

#### **Y — Output signal**

column vector

Output signal, returned as an integer or bit-valued column vector.

- When you set `BitOutput` to `false`, the object returns an  $N / N_{\text{SPS}}$ -by-1 vector.  $N$  is the length of the input signal  $x$  and  $N_{\text{SPS}}$  is the value of the `SamplesPerSymbol` property. The elements of the output vector are integers in the range  $[0, (M - 1)]$ .  $M$  represents the value of the `ModulationOrder` property.
- When you set `BitOutput` to `true`, the object returns a column vector of length equal to  $N \times \log_2(M)$ . The output vector contains bit representations of integers in the range  $[0, (M - 1)]$ .

Groups of  $\log_2(M)$  bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

The `OutputDataType` property specifies the data type of the output.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Create FSK modulator and demodulator System objects with modulation order 8 and 100 Hz frequency separation.

```
M = 8;
freqSep = 100;
fskmodulator = comm.FSKModulator(M, freqSep);
fskdemodulator = comm.FSKDemodulator(M, freqSep);
```

Create an additive white Gaussian noise channel with a signal-to-noise ratio of -2 dB.

```
awgnchan = comm.AWGNChannel( ...
    NoiseMethod="Signal to noise ratio (SNR)", ...
    SNR=-2);
```

Create an error rate calculator object.

```
errRate = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK modulation in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1], 50, 1);
    modSignal = fskmodulator(data);
    noisySignal = awgnchan(modSignal);
    receivedData = fskdemodulator(noisySignal);
    errorStats = errRate(data, receivedData);
end
```

Display the error statistics.

```

es1 = 'Error rate = %4.2e\n';
es2 = 'Number of errors = %d\n';
es3 = 'Number of symbols = %d\n';
fprintf([es1 es2 es3],errorStats)

```

```

Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000

```

### Display Lengths for FSK Modulation and Demodulation of Binary and Integer Signals

The FSK modulator System object can be configured to modulate data input as integer values or as binary values. The FSK demodulator System object can be configured to demodulate symbols and output as integer values or as binary values. Each integer or group of  $\log_2(M)$  bits corresponds to one symbol.  $M$  represents the value of the ModulationOrder property. Compute the expected signal lengths for input and output of FSK modulation and demodulation of the integer and binary signals. Display the resulting signal lengths for input and output of the FSK modulated and demodulated integer and binary signals.

Define variable to use when configuring FSK modulator and demodulator objects.

```

M = 8;           % Modulation order
freqSep = 100; % Frequency separation
nspf = 21;      % Number of samples per frame
sps = 10;       % Samples per symbol

fskmod_bit = comm.FSKModulator(M,freqSep, ...
    BitInput=true, ...
    SamplesPerSymbol=sps);
fskmod_bif = comm.FSKModulator(M,freqSep, ...
    BitInput=false, ...
    SamplesPerSymbol=sps);
fskdemod_bot = comm.FSKDemodulator(M,freqSep, ...
    BitOutput=true, ...
    SamplesPerSymbol=sps);
fskdemod_bof = comm.FSKDemodulator(M,freqSep, ...
    BitOutput=false, ...
    SamplesPerSymbol=sps);

```

Generate integer data and modulate data by using an FSK modulator object configured to accept bit data (BitInput=true).

```

bindata = randi([0 1],nspf*M,1);
modSignal = fskmod_bit(bindata);

```

Demodulate the data, and then output binary data from the first demodulator object and integer data from the second demodulator. Compute the expected and resulting input and output signal lengths.

```

rxData_bot = fskdemod_bot(modSignal);
rxData_bof = fskdemod_bof(modSignal);

```

Compute expected input and output lengths for a binary input signal.

```

Nbit = length(bindata);
Nsym = sps*length(bindata)/log2(M);

```

```

Nbot = (length(modSignal)/sps)*log2(M);
Nbof = length(modSignal)/sps;
explen = sprintf(' Nbit  Nsym  Nbot  Nbof\n %d  %d  %d  %d', ...
    length(bindata),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

explen =
    ' Nbit  Nsym  Nbot  Nbof
      168   560   168   56'

```

Display input and output lengths for a binary input signal.

```

sigLen = sprintf(' bit  sym  bot  bof\n %d  %d  %d  %d', ...
    length(bindata),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

sigLen =
    ' bit  sym  bot  bof
      168   560   168   56'

```

Generate integer data and modulate data by using an FSK modulator object configured to accept integer data (BitInput=false).

```

data = randi([0 M-1],nspf,1);
modSignal = fskmod_bif(data);

```

Because the input length changes, you must release the demodulator objects before reusing them. Demodulate the data, and then output binary data from the first demodulator object and integer data from the second demodulator. Compute the expected and resulting input and output signal lengths.

```

release(fskdemod_bot)
release(fskdemod_bof)
rxData_bot = fskdemod_bot(modSignal);
rxData_bof = fskdemod_bof(modSignal);

```

Compute expected input and output lengths for an integer input signal.

```

Nbif = length(data);
Nsym = sps*length(data);
Nbot = (length(modSignal)/sps)*log2(M);
Nbof = length(modSignal)/sps;
explen = sprintf('Nbif  Nsym  Nbot  Nbof\n %d  %d  %d  %d', ...
    length(data),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

explen =
    'Nbif  Nsym  Nbot  Nbof
      21   210   63   21'

```

Display input and output lengths for an integer input signal.

```

sigLen = sprintf(' bif  sym  bot  bof\n %d  %d  %d  %d', ...
    length(data),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

sigLen =
    ' bif  sym  bot  bof

```

21 210 63 21'

## More About

### Avoid Output Signal Aliasing

To avoid output signal aliasing, the output sampling rate (specifically, the product of `SamplesPerSymbol` and `SymbolRate`) must be greater than the product of `ModulationOrder` and `FrequencySeparation`.

## Algorithms

Demodulation of M-FSK modulated signals is performed by using a noncoherent detection, which configures an energy detector that does not exploit phase measurements. The demodulator knows that  $M$  possible waveforms were transmitted and must decide which is received during each time duration  $T$ .

As described in Sklar [1], the general analytical expression for M-FSK modulation is

$$s_i(t) = \sqrt{\frac{2E}{T}} \cos(\omega_i t + \phi) \quad \begin{array}{l} 0 \leq t \leq T \\ i=1, \dots, M \end{array}$$

- $E$  is the symbol energy.
- $T$  is the symbol time duration.
- $\omega_i$  is the frequency term that has  $M$  discrete values.
- $M$  is the modulation order and specifies the number of waveforms.
- $\phi$  is the phase offset.

The noncoherent energy detector of the M-FSK demodulator selects decision regions for each  $\omega_i$  waveform based on which decision region yields the maximum output.

For more details, see the **Noncoherent Detection of FSK** section in Sklar, [1].

# comm.FSKModulator

**Package:** comm

Modulate using M-ary FSK method

## Description

The `comm.FSKModulator` System object modulates a signal using the M-ary frequency shift keying (M-FSK) method. The output is a baseband representation of the modulated signal. For more information, see “Algorithms” on page 3-576.

To modulate a signal using frequency shift keying:

- 1 Create the `comm.FSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fskmodulator = comm.FSKModulator
fskmodulator = comm.FSKModulator(Name=Value)
fskmodulator = comm.FSKModulator(M,freqSep,RS,Name=Value)
```

### Description

`fskmodulator = comm.FSKModulator` creates a modulator System object that modulates the input signal using the M-ary frequency shift keying method.

`fskmodulator = comm.FSKModulator(Name=Value)` creates an FSK modulator object and sets properties using one or more name-value arguments. For example, `comm.FSKModulator(BitInput=true)` that specifies input values must be binary.

`fskmodulator = comm.FSKModulator(M,freqSep,RS,Name=Value)` creates an M-FSK modulator object with the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `freqSep`, the `SymbolRate` property set to `RS`, and optional name-value arguments.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**ModulationOrder — Number of frequencies in modulated signal**

8 (default) | positive integer

Number of frequencies in the modulated signal, specified as a positive integer  $\geq 2$ .

---

**Note** The modulation order,  $M$ , must be a power of two, such that  $M = 2^K$ , where  $K$  is a positive integer when you set `SymbolMapping` to 'Gray' or you set `BitInput` to `true`.

---

Data Types: `double`

**BitInput — Option to provide input in bits**

0 or false (default) | 1 or true

Option to provide input in bits, specified as a numeric or logical 0 (false) or 1 (true).

- When you set this property to `false`, the input values must be integers in the range  $[0, (M - 1)]$ . If  $M$  equals 2, the input vector can be logical values.  $M$  represents the value of the `ModulationOrder` property.
- When you set this property to `true`, the input values must be a column vector of bit values. The data type of the input values must be double-precision or logical. The input vector length must be an integer multiple of the number of bits per symbol,  $\log_2(M)$ . This vector contains bit representations of integers in the range  $[0, (M - 1)]$  and  $M$  must be a power of two. Groups of  $\log_2(M)$  bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `logical`

**SymbolMapping — Symbol encoding mapping**

'Gray' (default) | 'Binary'

Symbol encoding mapping, specified as 'Gray' or 'Binary'. Each integer or group of  $\log_2(M)$  bits corresponds to one symbol.  $M$  represents the value of the `ModulationOrder` property.

- When you set this property to 'Gray', the object maps symbols to a Gray-encoded ordering.
- When you set this property to 'Binary', the object maps symbols to a natural binary-encoded ordering.

For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer  $M - 1$ . In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

**FrequencySeparation — Frequency separation between successive tones**

6 (default) | positive scalar

Frequency separation between successive tones in the modulated signal in hertz, specified as a positive scalar value. For more information, see "Avoid Output Signal Aliasing" on page 3-576.

Data Types: `double`

**ContinuousPhase — Phase continuity**

1 or true (default) | 0 or false

Phase continuity, specified as a numeric or logical 0 (false) or 1 (true).

- When you set this property to true, the modulated signal maintains continuous phase, even when its frequency changes.
- When you set this property to false, the modulated signal comprises portions of  $M$  sinusoids of different frequencies. In this case, a change in the input value can cause a discontinuous change in the phase of the modulated signal.  $M$  represents the value of the ModulationOrder property.

Data Types: logical

**SamplesPerSymbol — Number of samples per output symbol**

17 (default) | positive integer

Number of samples per output symbol for each integer or binary word in the input, specified as a positive integer. For more information, see “Avoid Output Signal Aliasing” on page 3-576.

Data Types: double

**SymbolRate — Symbol rate in symbols per second**

100 (default) | positive scalar

Symbol rate in symbols per second, specified as a positive scalar. The symbol duration remains the same, regardless of whether the input signal is bits or integers. For more information, see “Avoid Output Signal Aliasing” on page 3-576.

Data Types: double

**OutputDataType — Data type of output**

"double" (default) | "single"

Data type of output, specified as either "double" or "single".

**Usage****Syntax**

```
y = fskmodulator(x)
```

**Description**

$y = \text{fskmodulator}(x)$  modulates the input signal by using the FSK method. The output is the modulated FSK baseband signal.

**Input Arguments****x — Input signal**

column vector

Input signal, specified as an integer or bit-valued column vector with numeric or logical data types. The `BitInput` property specifies the expected input type and vector length constraints.

### Output Arguments

#### **y** — Modulated output signal

column vector

Modulated output signal, returned as a column vector.

- When you set `BitInput` to `false`, the object returns a column vector with  $(N \times N_{\text{SPS}})$  elements.  $N$  represents the length of the input signal `x` and  $N_{\text{SPS}}$  represents the value of the `SamplesPerSymbol` property.
- When you set `BitInput` to `true`, the object returns a column vector with  $(N \times N_{\text{SPS}}) / \log_2(M)$  elements.  $M$  represents the value of the `ModulationOrder` property.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

### Examples

#### FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Create FSK modulator and demodulator System objects with modulation order 8 and 100 Hz frequency separation.

```
M = 8;
freqSep = 100;
fskmodulator = comm.FSKModulator(M, freqSep);
fskdemodulator = comm.FSKDemodulator(M, freqSep);
```

Create an additive white Gaussian noise channel with a signal-to-noise ratio of -2 dB.

```
awgnchan = comm.AWGNChannel( ...
    NoiseMethod="Signal to noise ratio (SNR)", ...
    SNR=-2);
```

Create an error rate calculator object.

```
errRate = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK modulation in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = fskmodulator(data);
    noisySignal = awgnchan(modSignal);
    receivedData = fskdemodulator(noisySignal);
    errorStats = errRate(data,receivedData);
end
```

Display the error statistics.

```
es1 = 'Error rate = %4.2e\n';
es2 = 'Number of errors = %d\n';
es3 = 'Number of symbols = %d\n';
fprintf([es1 es2 es3],errorStats)
```

```
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

### Visualize FSK Modulated Symbol Mapping

Visualize symbol mapping of an FSK modulated signal with a spectrogram.

Specify 20 samples for each symbol. The symbol 0 maps to -50 kHz (negative phase slope) and the symbol 1 maps to +50 kHz (positive phase slope).

```
mod = comm.FSKModulator(ModulationOrder=2, ...
    FrequencySeparation=1e5, ...
    SamplesPerSymbol=20, ...
    SymbolRate=1e4);
x = mod([0 1 0 1 0 1]');
figure
subplot(1,2,1)
plot(unwrap(angle(x)),0:length(x)-1)
grid on
xlabel("Phase")
ylabel("Samples")
subplot(1,2,2)
spectrogram(x,20,0,[], ...
    mod.SymbolRate*mod.SamplesPerSymbol,"centered")
```

### Display Lengths for FSK Modulation and Demodulation of Binary and Integer Signals

The FSK modulator System object can be configured to modulate data input as integer values or as binary values. The FSK demodulator System object can be configured to demodulate symbols and output as integer values or as binary values. Each integer or group of  $\log_2(M)$  bits corresponds to one symbol.  $M$  represents the value of the `ModulationOrder` property. Compute the expected signal lengths for input and output of FSK modulation and demodulation of the integer and binary signals. Display the resulting signal lengths for input and output of the FSK modulated and demodulated integer and binary signals.

Define variable to use when configuring FSK modulator and demodulator objects.

```
M = 8;           % Modulation order
freqSep = 100;  % Frequency separation
nspf = 21;      % Number of samples per frame
sps = 10;       % Samples per symbol

fskmod_bit = comm.FSKModulator(M, freqSep, ...
    BitInput=true, ...
    SamplesPerSymbol=sps);
fskmod_bif = comm.FSKModulator(M, freqSep, ...
    BitInput=false, ...
    SamplesPerSymbol=sps);
fskdemod_bot = comm.FSKDemodulator(M, freqSep, ...
```

```

    BitOutput=true, ...
    SamplesPerSymbol=sps);
fskdemod_bof = comm.FSKDemodulator(M,freqSep, ...
    BitOutput=false, ...
    SamplesPerSymbol=sps);

```

Generate integer data and modulate data by using an FSK modulator object configured to accept bit data (BitInput=true).

```

bindata = randi([0 1],nspf*M,1);
modSignal = fskmod_bit(bindata);

```

Demodulate the data, and then output binary data from the first demodulator object and integer data from the second demodulator. Compute the expected and resulting input and output signal lengths.

```

rxData_bot = fskdemod_bot(modSignal);
rxData_bof = fskdemod_bof(modSignal);

```

Compute expected input and output lengths for a binary input signal.

```

Nbit = length(bindata);
Nsym = sps*length(bindata)/log2(M);
Nbot = (length(modSignal)/sps)*log2(M);
Nbof = length(modSignal)/sps;
explen = sprintf(' Nbit  Nsym  Nbot  Nbof\n %d  %d  %d  %d', ...
    length(bindata),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

explen =
    ' Nbit  Nsym  Nbot  Nbof
      168   560   168   56'

```

Display input and output lengths for a binary input signal.

```

sigLen = sprintf(' bit  sym  bot  bof\n %d  %d  %d  %d', ...
    length(bindata),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

sigLen =
    ' bit  sym  bot  bof
      168   560   168   56'

```

Generate integer data and modulate data by using an FSK modulator object configured to accept integer data (BitInput=false).

```

data = randi([0 M-1],nspf,1);
modSignal = fskmod_bif(data);

```

Because the input length changes, you must release the demodulator objects before reusing them. Demodulate the data, and then output binary data from the first demodulator object and integer data from the second demodulator. Compute the expected and resulting input and output signal lengths.

```

release(fskdemod_bot)
release(fskdemod_bof)
rxData_bot = fskdemod_bot(modSignal);
rxData_bof = fskdemod_bof(modSignal);

```

Compute expected input and output lengths for an integer input signal.

```
Nbif = length(data);
Nsym = sps*length(data);
Nbot = (length(modSignal)/sps)*log2(M);
Nbof = length(modSignal)/sps;
explen = sprintf('Nbif Nsym Nbot Nbof\n %d %d %d %d', ...
    length(data),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

explen =
    'Nbif  Nsym  Nbot  Nbof
     21   210   63   21'
```

Display input and output lengths for an integer input signal.

```
sigLen = sprintf(' bif sym bot bof\n %d %d %d %d', ...
    length(data),length(modSignal), ...
    length(rxData_bot),length(rxData_bof))

sigLen =
    ' bif  sym  bot  bof
     21  210  63  21'
```

## More About

### Avoid Output Signal Aliasing

To avoid output signal aliasing, the output sampling rate (specifically, the product of `SamplesPerSymbol` and `SymbolRate`) must be greater than the product of `ModulationOrder` and `FrequencySeparation`.

## Algorithms

As described in Sklar [1], the general analytical expression for M-FSK modulation is

$$s_i(t) = \sqrt{\frac{2E}{T}} \cos(\omega_i t + \phi) \quad \begin{matrix} 0 \leq t \leq T \\ i=1,\dots,M \end{matrix}$$

- $E$  is the symbol energy.
- $T$  is the symbol time duration.
- $\omega_i$  is the frequency term that has  $M$  discrete values.
- $M$  is the modulation order and specifies the number of waveforms.
- $\phi$  is the phase offset.

## comm.GeneralQAMDemodulator

**Package:** comm

Demodulate using arbitrary QAM constellation

### Description

The `GeneralQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your QAM demodulator object. See “Construction” on page 3-578.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.GeneralQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMDemodulator(Name,Value)` creates a general QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMDemodulator(CONST,Name,Value)` creates a general QAM demodulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

### Properties

#### Constellation

Signal constellation

Specify the constellation points as a real or complex, double-precision data type vector. The default is `exp(2 ×  $\pi$  × 1i × (0:7)/8)`. The length of the vector determines the modulation order.

When you set the `BitOutput` property to `false`, the `step` method outputs a vector with integer values. These integers are between 0 and  $M-1$ , where  $M$  is the length of this property vector. The length of the output vector equals the length of the input signal.

When you set the `BitOutput` property to `true`, the output signal contains bits. For bit outputs, the size of the signal constellation requires an integer power of two and the output length is an integer multiple of the number of bits per symbol.

### **BitOutput**

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to  $\log_2(M)$  times the number of demodulated symbols, where  $M$  is the length of the signal constellation specified in the `Constellation` property. The length  $M$  determines the modulation order.

When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector. The vector contains integer symbol values between 0 and  $M-1$ .

### **DecisionMethod**

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` property to `false` the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a nonzero, real scalar value. The default is 1.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- `Inf` to `-Inf` if the variance is very high
- `NaN` if the variance and signal power are both very small

In such cases, use approximate LLR because the algorithm does not involve computing exponentials.

This property applies when you set the `VarianceSource` property to `Property`. This property is nontunable for fixed-point inputs.

**Tips**

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

**OutputDataType**

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

This property applies only when you set the `BitOutput` property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Hard decision` or `Approximate log-likelihood ratio`. In this case, when you set the `OutputDataType` property to `Full precision`, the output data type is the same as that of the input when the input data has a single or double-precision data type.

When the input data is of a fixed-point type, the output data type works as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set the `BitOutput` property to `true`, and the `DecisionMethod` property to `Hard Decision` the data type `logical` becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Approximate log-likelihood ratio` you may only set this property to `Full precision` | `Custom`.

If you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`, the output data has the same type as that of the input. In this case, that value can be only single or double precision.

**Fixed-Point Properties****FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled

through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-585.

### **RoundingMethod**

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration. This property does not apply when you set `BitOutput` to true and `DecisionMethod` to `Log-likelihood ratio`.

### **OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

### **ConstellationDataType**

Data type of signal constellation

Specify the constellation fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

### **CustomConstellationDataType**

Fixed-point data type of signal constellation

Specify the constellation fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `ConstellationDataType` property to `Custom`.

### **Accumulator1DataType**

Data type of accumulator 1

Specify the accumulator 1 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to false. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

### **CustomAccumulator1DataType**

Fixed-point data type of accumulator 1

Specify the accumulator 1 fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([], 32, 30)`. This property applies when you set the `Accumulator1DataType` property to `Custom`.

### **ProductInputDataType**

Data type of product

Specify the product input fixed-point data type as one of `Same as accumulator 1 | Custom`. The default is `Same as accumulator 1`. This property applies when you set the `FullPrecisionOverride` property to `false`, the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`.

### **CustomProductInputDataType**

Fixed-point data type of product

Specify the product input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to `false` and the `ProductInputDataType` property to `Custom`.

### **ProductOutputDataType**

Data type of product output

Specify the product output fixed-point data type as one of `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to `false`, the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`.

### **CustomProductOutputDataType**

Fixed-point data type of product output

Specify the product output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to `false` and the `ProductOutputDataType` property to `Custom`.

### **Accumulator2DataType**

Data type of accumulator 2

Specify the accumulator 2 fixed-point data type as one of `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to `false`, the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`.

### **CustomAccumulator2DataType**

Fixed-point data type accumulator 2

Specify the accumulator 2 fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to `false` and the `Accumulator2DataType` property to `Custom`.

### **Accumulator3DataType**

Data type of accumulator 3

Specify the accumulator 3 fixed-point data type as one of `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to `false`, the `BitOutput` property to `true` and the `DecisionMethod` property to `Approximate log-likelihood ratio`.

### **CustomAccumulator3DataType**

Fixed-point data type of accumulator 3

Specify the accumulator 3 fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to `false` and the `Accumulator3DataType` property to `Custom`.

### **NoiseScalingInputDataType**

Data type of noise-scaling input

Specify the noise-scaling input fixed-point data type as one of `Same as accumulator 3 | Custom`. The default is `Same as accumulator 3`. This property applies when you set the `FullPrecisionOverride` property to `false`, the `BitOutput` property to `true` and the `DecisionMethod` property to `Approximate log-likelihood ratio`.

### **CustomNoiseScalingInputDataType**

Fixed-point data type of noise-scaling input

Specify the noise-scaling input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to `false` and the `NoiseScalingInputDataType` property to `Custom`.

### **InverseVarianceDataType**

Data type of inverse noise variance

Specify the inverse noise variance fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio`, and the `VarianceSource` property to `Property`.

### CustomInverseVarianceDataType

Fixed-point data type of inverse noise variance

Specify the inverse noise variance fixed-point type as a `numericType` object with a Signedness of Auto. The default is `numericType([],16,8)`. This property applies when you set the `InverseVarianceDataType` property to Custom.

### CustomOutputDataType

Data type of output

Specify the output fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([],32,30)`. This property applies when you set the `FullPrecisionOverride` property to false and the `OutputDataType` property to Custom.

## Methods

`step` Demodulate using arbitrary QAM constellation

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

Modulate and demodulate data using an arbitrary three-point constellation.

```
% Setup a three point constellation
c = [1 1i -1];
hQAMMod = comm.GeneralQAMModulator(c);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR',15,'SignalPower',0.89);
hQAMDemod = comm.GeneralQAMDemodulator(c);

%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 2],50,1);
    modSignal = step(hQAMMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hQAMDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `Variance` property is nontunable when using code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### Objects

`comm.GeneralQAMModulator` | `comm.RectangularQAMDemodulator`

## step

**System object:** comm.GeneralQAMDemodulator

**Package:** comm

Demodulate using arbitrary QAM constellation

### Syntax

$Y = \text{step}(H, X)$

$Y = \text{step}(H, X, \text{VAR})$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  demodulates the input data,  $X$ , with the general QAM demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to true and the `DecisionMethod` property to 'Log-likelihood ratio' the input data type must be single or double precision. Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

$Y = \text{step}(H, X, \text{VAR})$  uses soft decision demodulation and noise variance  $\text{VAR}$ . This syntax applies when you set the `BitOutput` property to true, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to 'Input port'.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

# comm.GeneralQAMModulator

**Package:** comm

Modulate using arbitrary QAM constellation

## Description

The `GeneralQAMModulator` object modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your QAM modulator object. See “Construction” on page 3-587.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GeneralQAMModulator` creates a modulator System object, `H`. This object modulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMModulator(Name, Value)` creates a QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.GeneralQAMModulator(CONST, Name, Value)` creates a General QAM modulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

## Properties

### Constellation

Signal constellation

Specify the constellation points as a vector of real or complex double-precision data type. The default is  $\exp(2 \times \pi \times 1i \times (0:7)/8)$ . The length of the vector determines the modulation order. The `step` method inputs requires integers between 0 and  $M-1$ , where  $M$  indicates the length of this property vector. The object maps an input integer  $m$  to the  $(m+1)^{\text{st}}$  value in the `Constellation` vector.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

**Fixed-Point Properties**

**CustomOutputDataType**

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

**Methods**

`step` Modulate using arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

**Examples**

Modulate data using an arbitrary 3-point constellation. Then, visualize the data in a scatter plot

```

hQAMMod = comm.GeneralQAMModulator;
% Setup a three point constellation
hQAMMod.Constellation = [1 1i -1];
data = randi([0 2],100,1);
modData = step(hQAMMod, data);
scatterplot(modData)
    
```

**Algorithms**

This object implements the algorithm, inputs, and outputs described on the General QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

# comm.GeneralQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

## Description

The `GeneralQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

To demodulate a signal that was modulated using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 3-591.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GeneralQAMTCMDemodulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an arbitrary QAM constellation.

`H = comm.GeneralQAMTCMDemodulator(Name, Value)` creates a general QAM TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.GeneralQAMTCMDemodulator(TRELLIS, Name, Value)` creates a general QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the value that results from `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

### **TracebackDepth**

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The `TracebackDepth` parameter influences the decoding accuracy and delay. The decoding delay indicates the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`×*K* zero bits for a rate *K/N* convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

### **ResetInputPort**

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

### **Constellation**

Signal constellation

Specify a double- or single-precision complex vector. This vector lists the points in the signal constellation that were used to map the convolutionally encoded data. The constellation must be specified in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to  $2^N$  for a rate *K/N* convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed as  $\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$ .

## OutputDataType

Data type of output

Specify output data type as one of `logical` | `double`. The default is `double`.

## Methods

`step` Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Modulate and Demodulate Data Using QAM TCM

Modulate and demodulate noisy data using QAM TCM modulation with an arbitrary 4-point constellation. Estimate the resultant BER.

Define a trellis structure with two input symbols and four output symbols using a [171 133] generator polynomial. Define an arbitrary four-point constellation.

```
qamTrellis = poly2trellis(7,[171 133]);
refConst = exp(pi*1i*[1 2 3 6]/4);
```

Create a QAM TCM modulator and demodulator System object™ pair using `qamTrellis` and `refConst`.

```
qamtcmod = comm.GeneralQAMTCModulator( ...
    qamTrellis, ...
    Constellation=refConst);
qamtcdemod = comm.GeneralQAMTCMDemodulator( ...
    qamTrellis, ...
    Constellation=refConst);
```

Create an AWGN channel object in which the noise is set by using a signal-to-noise ratio.

```
awgnchan = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (SNR)', ...
    SNR=4);
```

Create an error rate calculator with delay (in bits) equal to the product of `TracebackDepth` and the number of bits per symbol

```
errorrate = comm.ErrorRate( ...
    ReceiveDelay=qamtcdemod.TracebackDepth * ...
    log2(qamTrellis.numInputSymbols));
```

Generate random binary data and apply QAM TCM modulation. Pass the signal through an AWGN channel and demodulate. Collect the error statistics.

```
for counter = 1:10
    % Generate binary data
    data = randi([0 1],500,1);
    % Modulate
    modSignal = qamtcmod(data);
    % Pass through an AWGN channel
    noisySignal = awgnchan(modSignal);
    % Demodulate
    receivedData = qamtcodemod(noisySignal);
    % Calculate the error statistics
    errorStats = errorrate(data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 1.16e-02
Number of errors = 58
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Decoder block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## Extended Capabilities

## step

**System object:** comm.GeneralQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

### Syntax

$Y = \text{step}(H,X)$

$Y = \text{step}(H,X,R)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates the general QAM modulated input data,  $X$ , and uses the Viterbi algorithm to decode the resulting demodulated convolutionally encoded bits.  $X$  must be a complex double or single precision column vector. The `step` method outputs a demodulated binary column data vector,  $Y$ . When the convolutional encoder represents a rate  $K/N$  code, the length of the output vector equals  $K \times L$ , where  $L$  is the length of the input vector,  $X$ .

$Y = \text{step}(H,X,R)$  resets the decoder states of the general QAM TCM demodulator System object to the all-zeros state when you input a non-zero reset signal,  $R$ .  $R$  must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

## comm.GeneralQAMTCMModulator

**Package:** comm

Convolutionally encode binary data and map using arbitrary QAM constellation

### Description

The `GeneralQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal. The object then maps the result to an arbitrary signal constellation. The `SignalConstellation` property lists the signal constellation points in set-partitioned order.

To modulate a signal using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 3-596.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.GeneralQAMTCMModulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result using QAM modulation with a signal constellation specified in the `Constellation` property.

`H = comm.GeneralQAMTCMModulator(Name, Value)` creates a general QAM TCM modulator System object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.GeneralQAMTCMModulator(TRELLIS, Name, Value)` creates a general QAM TCM modulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

### Properties

#### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

## TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with length  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength} - 1$ . In the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i) - 1)$ .  $L$  represents the length of the input to the `step` method.

## ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

## Constellation

Signal constellation

Specify a double- or single-precision complex vector that lists the points in the signal constellation that were used to map the convolutionally encoded data. You must specify the constellation in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to  $2^N$  for a rate  $K/N$  convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed  $\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$ .

## OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## Methods

step Convolutionally encode binary data and map using arbitrary QAM constellation

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

## Examples

### Modulate Data Using QAM TCM with an Arbitrary Constellation

Modulate data using QAM TCM modulation with an arbitrary 4-point constellation. Display a scatter plot of the modulated data.

Create binary data.

```
data = randi([0 1],1000,1);
```

Use the trellis structure with generating polynomial [171 133] and 4-point arbitrary constellation  $\{ e^{j\pi/4}, e^{j\pi/2}, e^{j3\pi/4}, e^{j3\pi/2} \}$  to perform QAM TCM modulation.

```
t = poly2trellis(7,[171 133]);  
hMod = comm.GeneralQAMTCModulator(t,...  
    'Constellation',exp(pi*1i*[1 2 3 6]/4));
```

Modulate and plot the data.

```
modData = step(hMod,data);  
scatterplot(modData);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Encoder block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## step

**System object:** comm.GeneralQAMTCMModulator

**Package:** comm

Convolutionally encode binary data and map using arbitrary QAM constellation

### Syntax

$Y = \text{step}(H,X)$

$Y = \text{step}(H,X,R)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  convolutionally encodes and modulates the input data,  $X$ , and returns the encoded and modulated data,  $Y$ .  $X$  must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector,  $X$ , must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector,  $Y$ , of length  $L$ .

$Y = \text{step}(H,X,R)$  resets the encoder of the general QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal,  $R$ .  $R$  must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.GMSKDemodulator

**Package:** comm

Demodulate GMSK-modulated signal using Viterbi algorithm

## Description

The `comm.GMSKDemodulator` System object uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying (GMSK) method. The input is a baseband representation of the modulated signal.

To demodulate a GMSK-modulated signal using the Viterbi algorithm:

- 1 Create the `comm.GMSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
gmskdemodulator = comm.GMSKDemodulator
gmskdemodulator = comm.GMSKDemodulator(Name, Value)
```

### Description

`gmskdemodulator = comm.GMSKDemodulator` creates a demodulator System object that demodulates the input GMSK-modulated data by using the Viterbi algorithm.

`gmskdemodulator = comm.GMSKDemodulator(Name, Value)` sets properties on page 3-601 using one or more name-value pairs. For example, `gmskdemodulator = comm.GMSKDemodulator('PulseLength', 6)` specifies the length of the Gaussian pulse shape as 6 symbol intervals.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **BitOutput** — Option to output data as bits

false or 0 (default) | true or 1

Option to output data as bits, specified as a numeric or logical 0 (false) or 1 (true).

- When you set this property to `false`, the output of the System object call is a column vector of elements -1 or 1.
- When you set this property to `true`, the output of the System object call is a binary column vector of elements 0 or 1.

Data Types: `logical`

### **BandwidthTimeProduct — Product of bandwidth and symbol time**

0.3 (default) | positive scalar

Product of the bandwidth and symbol time for the Gaussian pulse shape, specified as a positive scalar value. For more details, see Algorithms on page 3-605.

Data Types: `double`

### **PulseLength — Pulse length**

4 (default) | positive integer

Pulse length, specified as a positive integer. The pulse length value represents the length of the Gaussian pulse shape in symbol intervals.

Data Types: `double`

### **SymbolPrehistory — Symbol prehistory**

1 (default) | -1 | vector

Symbol prehistory, specified as -1, 1, or a vector with elements equal those values. The symbol prehistory indicates the data symbols that the modulator uses prior to the first call of the object, in reverse chronological order.

- A scalar value expands to a vector of length `PulseLength - 1`.
- For a vector, the length must be `PulseLength - 1`.

Data Types: `double`

### **InitialPhaseOffset — Initial phase offset**

0 (default) | numeric scalar

Initial phase offset of the modulated waveform in radians, specified as a numeric scalar.

Data Types: `double`

### **SamplesPerSymbol — Number of samples per output symbol**

8 (default) | positive integer

Number of samples per symbol, specified as a positive integer. The number of samples per symbol represents the upsampling factor from input samples to output samples.

Data Types: `double`

**TracebackDepth — Traceback depth**

16 (default) | positive integer

Traceback depth for the Viterbi algorithm, specified as a positive integer.

The traceback depth is the number of trellis branches that the Viterbi algorithm uses to construct each traceback path. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay.

Data Types: `double`

**OutputDataType — Output data type**`double` (default) | `int8` | `int16` | `int32` | `logical`

Output data type, specified as one of these values.

- `int8`, `int16`, `int32`, or `double` — Use one of these values when you set the `BitOutput` property to `false`.
- `logical` or `double` — Use one of these values when you set the `BitOutput` property to `true`.

**Usage****Syntax**

$$Y = \text{gmskdemodulator}(X)$$
**Description**

$Y = \text{gmskdemodulator}(X)$  applies GMSK demodulation to the GMSK-modulated waveform and returns the demodulated input signal.

**Input Arguments****X — GMSK-modulated baseband signal**

column vector

GMSK-modulated input signal, specified as a column vector.

The length of the input signal must be an integer multiple of the `SamplesPerSymbol` property.

Data Types: `double` | `single`

**Output Arguments****Y — Demodulated signal**

column vector

Demodulated signal, returned as a column vector with length equal to  $N / \text{SamplesPerSymbol}$ .  $N$  is the length of the input signal,  $X$ . For more information about the output datatype, see the `OutputDataType` property.

- When you set the `BitOutput` property to `false`,  $Y$  is returned as a column vector of elements `-1` or `1`.

- When you set the `BitOutput` property to `true`, `Y` is returned as a binary column vector of elements `0` or `1`.

Data Types: `double` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### GMSK Signal in AWGN

Create a GMSK modulator and demodulator pair. Create an AWGN channel object.

```
gmskmodulator = comm.GMSKModulator('BitInput',true, ...  
                                   'InitialPhaseOffset',pi/4);  
channel = comm.AWGNChannel('NoiseMethod', ...  
                           'Signal to noise ratio (SNR)', ...  
                           'SNR',0);  
gmskdemodulator = comm.GMSKDemodulator('BitOutput',true, ...  
                                       'InitialPhaseOffset',pi/4);
```

Create an error rate calculator and account for the delay between the modulator and demodulator, caused by the Viterbi algorithm.

```
errorRate = comm.ErrorRate('ReceiveDelay', ...  
                           gmskdemodulator.TracebackDepth);
```

Process 100 frames of data looping through these steps.

- 1 Generate vectors with 300 elements of random binary data.
- 2 GMSK-modulate the data.
- 3 Pass the modulated data through the AWGN channel.
- 4 GMSK-demodulate the data.
- 5 Collect error statistics on the frames of data.

```
for counter = 1:100  
    % Transmit 100 3-bit words  
    data = randi([0 1],300,1);  
    modSignal = gmskmodulator(data);  
    noisySignal = channel(modSignal);  
    receivedData = gmskdemodulator(noisySignal);
```

```

    errorStats = errorRate(data, receivedData);
end

```

Display the error statistics.

```

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

```

```

Error rate = 0.000133
Number of errors = 4

```

## Algorithms

The `BandwidthTimeProduct` property represents bandwidth multiplied by time. Use this property to reduce the bandwidth at the expense of increased intersymbol interference. The `PulseLength` property measures the length of the Gaussian pulse shape in symbol intervals. These equations define the frequency pulse shape.  $B_b$  represents the bandwidth of the pulse and  $T$  is the symbol durations.  $Q(t)$  is the complementary cumulative distribution function.

$$g(t) = \frac{1}{2T} \left\{ Q \left[ 2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln(2)}} \right] - Q \left[ 2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln(2)}} \right] \right\}$$

$$Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$$

For this System object, an input symbol of 1 causes a phase shift of  $\pi/2$  radians, which corresponds to a modulation index of 0.5.

Modulate using GMSK method

## Description

The `comm.GMSKModulator` System object modulates using the Gaussian minimum shift keying (GMSK) method. The output is a baseband representation of the modulated signal. For more detail, see “Algorithms” on page 3-617.

To modulate a signal by using the GMSK method:

- 1 Create the `comm.GMSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
gmskmodulator = comm.GMSKModulator
gmskmodulator = comm.GMSKModulator(Name, Value)
```

### Description

`gmskmodulator = comm.GMSKModulator` creates a modulator System object that modulates the input signal using the GMSK modulation method.

`gmskmodulator = comm.GMSKModulator(Name, Value)` sets properties on page 3-607 using one or more name-value arguments. For example, `'PulseLength', 6` specifies the length of the Gaussian pulse shape as 6 symbol intervals.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### BitInput — Option to provide input in bits

false or 0 (default) | true or 1

Option to provide input in bits, specified as a numeric or logical 0 (false) or 1 (true).

- When you set this property to `false`, the input to the System object call requires a double-precision or signed integer data type column vector with values of -1 or 1.
- When you set this property to `true`, the input to the System object call requires a double-precision or logical data type column vector of 0s and 1s.

Data Types: `logical`

**BandwidthTimeProduct — Product of bandwidth and symbol time**

0.3 (default) | positive scalar

Product of the bandwidth and symbol time for the Gaussian pulse shape, specified as a positive scalar value. For more detail, see “Algorithms” on page 3-617.

To observe the effect of this property on the modulated signal, see the “Effect of Bandwidth Time Product on GMSK Modulated Signal” on page 3-612 example.

Data Types: `double`

**PulseLength — Pulse length**

4 (default) | positive integer

Pulse length, specified as a positive integer. The pulse length value represents the length of the Gaussian pulse shape in symbol intervals.

Data Types: `double`

**SymbolPrehistory — Symbol prehistory**

1 (default) | -1 | vector

Symbol prehistory, specified as -1, 1, or a vector with elements equal those values. This property defines the data symbols that the modulator uses prior to the first call of the object, in reverse chronological order.

- A scalar value expands to a vector of length `PulseLength - 1`.
- For a vector, the length must be `PulseLength - 1`.

Data Types: `double`

**InitialPhaseOffset — Initial phase offset**

0 (default) | numeric scalar

Initial phase offset of the modulated waveform in radians, specified as a numeric scalar.

Data Types: `double`

**SamplesPerSymbol — Number of samples per output symbol**

8 (default) | positive integer

Number of samples per symbol, specified as a positive integer. The number of samples per symbol represents the upsampling factor from input samples to output samples.

Data Types: `double`

### **OutputDataType — Output data type**

`double` (default) | `single`

Output data type, specified as either `double` or `single`.

## **Usage**

### **Syntax**

`Y = gmskmodulator(X)`

### **Description**

`Y = gmskmodulator(X)` applies GMSK modulation to the input data and returns the modulated GMSK baseband signal.

### **Input Arguments**

#### **X — Input data**

`integer` | `column vector`

Input data, specified as an integer or column vector of integers or bits.

The setting of the `BitInput` property determines the interpretation of the input data.

Data Types: `double` | `logical`

### **Output Arguments**

#### **Y — GMSK-modulated baseband signal**

`vector`

GMSK-modulated baseband signal, returned as a vector.

The length of the vector is equal to the number of input samples times the `SamplesPerSymbol` property. For more information about the output data type, see the `OutputDataType` property.

Data Types: `double` | `single`

## **Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

`step` Run `System` object algorithm

`release` Release resources and allow changes to `System` object property values and input characteristics

reset     Reset internal states of System object

## Examples

### Map Binary Data to GMSK Signal

Map binary sequences of zeros and ones to the output of a GMSK modulator. This mapping also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs and has pulse length and samples per symbol values of 1.

```
gmskmodulator = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...  
                                   'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);  
y = gmskmodulator(x)
```

*y = 5×1 complex*

```
1.0000 + 0.0000i  
-0.0000 - 1.0000i  
-1.0000 + 0.0000i  
0.0000 + 1.0000i  
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

*theta = 5×1*

```
0  
-1.5708  
-3.1416  
-4.7124  
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmskmodulator)  
x = ones(5,1);  
y = gmskmodulator(x)
```

*y = 5×1 complex*

```
1.0000 + 0.0000i  
-0.0000 + 1.0000i  
-1.0000 - 0.0000i  
0.0000 - 1.0000i
```

```
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1
```

```
0
1.5708
3.1416
4.7124
6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

### GMSK Signal in AWGN

Create a GMSK modulator and demodulator pair. Create an AWGN channel object.

```
gmskmodulator = comm.GMSKModulator('BitInput',true, ...
    'InitialPhaseOffset',pi/4);
channel = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',0);
gmskdemodulator = comm.GMSKDemodulator('BitOutput',true, ...
    'InitialPhaseOffset',pi/4);
```

Create an error rate calculator and account for the delay between the modulator and demodulator, caused by the Viterbi algorithm.

```
errorRate = comm.ErrorRate('ReceiveDelay', ...
    gmskdemodulator.TracebackDepth);
```

Process 100 frames of data looping through these steps.

- 1 Generate vectors with 300 elements of random binary data.
- 2 GMSK-modulate the data.
- 3 Pass the modulated data through the AWGN channel.
- 4 GMSK-demodulate the data.
- 5 Collect error statistics on the frames of data.

```
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1],300,1);
    modSignal = gmskmodulator(data);
    noisySignal = channel(modSignal);
    receivedData = gmskdemodulator(noisySignal);
    errorStats = errorRate(data, receivedData);
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

### Effect of Bandwidth Time Product on GMSK Modulated Signal

This example demonstrates the effect of bandwidth time (BT) product on a GMSK modulated signal.

Create a binary data vector and apply GMSK modulation to the data.

```
d = [0 1 1 0 1 0 0 1 1 1]';
a = comm.GMSKModulator(BitInput=true,SamplesPerSymbol=10)
```

```
a =
comm.GMSKModulator with properties:
```

```
        BitInput: true
BandwidthTimeProduct: 0.3000
        PulseLength: 4
        SymbolPrehistory: 1
InitialPhaseOffset: 0
        SamplesPerSymbol: 10
        OutputDataType: 'double'
```

```
x = a(d);
BTa = sprintf('BT=%2.1f',a.BandwidthTimeProduct);
```

Plot the phase angles and use the unwrap function to show the trend better.

```
plot(unwrap(angle(x)), 'red-');
title('Bandwidth Time Product Effect')
hold on;
plot(1:10:length(x),unwrap(angle(x(1:10:end))), '*');
grid on
```

Set the BT product to 1 and plot the phase angles in the same plot.

```
a = comm.GMSKModulator(BitInput=true, ...
        SamplesPerSymbol=10,BandwidthTimeProduct=1)
```

```
a =
comm.GMSKModulator with properties:
```

```
        BitInput: true
BandwidthTimeProduct: 1
        PulseLength: 4
        SymbolPrehistory: 1
InitialPhaseOffset: 0
        SamplesPerSymbol: 10
        OutputDataType: 'double'
```

```
x = a(d);
BTb = sprintf('BT=%2.1f',a.BandwidthTimeProduct);
```

```
plot(unwrap(angle(x)), 'blue-.');
plot(1:10:length(x),unwrap(angle(x(1:10:end))), 'o');
```

Set the BT product to 0.1 and plot the phase angles in the same plot.

```
a = comm.GMSKModulator(BitInput=true, ...
    SamplesPerSymbol=10,BandwidthTimeProduct=0.1)
```

```
a =
comm.GMSKModulator with properties:
```

```
        BitInput: true
BandwidthTimeProduct: 0.1000
        PulseLength: 4
        SymbolPrehistory: 1
InitialPhaseOffset: 0
        SamplesPerSymbol: 10
        OutputDataType: 'double'
```

```
BTc = sprintf('BT=%2.1f',a.BandwidthTimeProduct);
```

The spread of this pulse is inversely proportional to the BT product and a lower BT causes a wider spread over the bit symbol period. The peak amplitude of the pulse is directly proportional to the BT product and a lower peak amplitude causes narrower spread over the bit symbol period. As the bandwidth of the pulse decreases, the pulse duration increases.

```
x = a(d);
plot(unwrap(angle(x)), 'green--');
plot(1:10:length(x),unwrap(angle(x(1:10:end))), 'x');
legend(BTa, '',BTb, '',BTc, '')
hold off;
```

### Compare GMSK and MSK Modulation

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to 1.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
    'SamplesPerSymbol',sps);
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of 30 dB.

```
rxSigGMSK = awgn(modSigGMSK,30);  
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to 1, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

```
eyediagram(rxSigMSK,sps,1,sps/2)
```

Set the `PulseLength` property for the GMSK modulator object to 3. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GMSK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to  $\pi/4$  and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “View CPM Phase Tree Using Simulink” example.

## Algorithms

The `BandwidthTimeProduct` property represents the bandwidth multiplied by time. Use this property to reduce the bandwidth at the expense of increased intersymbol interference. The `PulseLength` property measures the length of the Gaussian pulse shape in symbol intervals. These equations define the frequency pulse shape.  $B_b$  represents the bandwidth of the pulse and  $T$  is the symbol durations.  $Q(t)$  is the complementary cumulative distribution function.

$$g(t) = \frac{1}{2T} \left\{ Q \left[ 2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln(2)}} \right] - Q \left[ 2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln(2)}} \right] \right\}$$

$$Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$$

For this System object, an input symbol of 1 causes a phase shift of  $\pi/2$  radians, which corresponds to a modulation index of 0.5.

Recover symbol timing phase using fourth-order nonlinearity method

## Description

The `GMSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method. This timing synchronization is a non-data-aided feedback method that is independent of carrier phase recovery, but requires prior compensation for the carrier frequency offset. You can use this block for systems that use Gaussian minimum shift keying (GMSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your GMSK timing synchronizer object. See “Construction” on page 3-619.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.GMSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.GMSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the GMSK input signal using a fourth-order nonlinearity method.

`H = comm.GMSKTimingSynchronizer(Name,Value)` creates a GMSK timing synchronizer object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### SamplesPerSymbol

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar value greater than 1. The default is 4.

### ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive real scalar value. Typically, this number is less than  $1/\text{SamplesPerSymbol}$  on page 3-0, which corresponds to a slowly varying timing phase. The default is 0.05. This property is tunable.

### ResetInputPort

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When you specify a nonzero value as the reset input, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

### ResetCondition

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every frame`. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. In this case, the restart occurs at each `step` method call. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

## Methods

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Recover Timing Phase of GMSK Signal

Create GMSK modulator, variable fractional delay, and GMSK timing synchronizer System objects.

```
gmskMod = comm.GMSKModulator('BitInput', true, ...
    'SamplesPerSymbol', 14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
gmskTimingSync = comm.GMSKTimingSynchronizer('SamplesPerSymbol', 14, ...
    'ErrorUpdateGain', 0.05);
```

Main processing loop:

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = gmskMod(data); % Modulate data

    % Apply timing offset error
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery
    [~,phase] = gmskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end
```

Plot the results.

```
plot(1:50,[0.2*ones(50,1) phEst])
legend('Original','Estimated')
title('Original and Estimated timing phases')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to GMSK.
- The **Reset** parameter corresponds to the `ResetInputPort` on page 3-0 and `ResetCondition` on page 3-0 properties.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

**System object:** comm.GMSKTimingSynchronizer

**Package:** comm

Recover symbol timing phase using fourth-order nonlinearity method

### Syntax

`[Y,PHASE] = step(H,X)`

`[Y,PHASE] = step(H,X,R)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[Y,PHASE] = step(H,X)` performs timing phase recovery and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

## comm.GoldSequence

**Package:** comm

Generate Gold sequence from set of sequences

### Description

The `comm.GoldSequence` System object generates a binary sequence with small periodic cross-correlation properties from a bounded set of sequences. For more information, see “Gold Sequences” on page 3-634.

To generate a Gold sequence from set of sequences:

- 1 Create the `comm.GoldSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
goldseq = comm.GoldSequence  
goldseq = comm.GoldSequence(Name, Value)
```

#### Description

`goldseq = comm.GoldSequence` creates a Gold sequence generator System object. This object generates a pseudorandom Gold sequence of binary numbers.

`goldseq = comm.GoldSequence(Name, Value)` sets properties using one or more name-value arguments. Enclose each property name in quotes. For example, `goldseq = comm.GoldSequence('Shift', 1)` specifies a one sample offset of the output sequence from the starting point.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **FirstPolynomial — Generator polynomial for first preferred PN sequence**

'z<sup>6</sup> + z + 1' (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial for the first preferred PN sequence, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be  $N + 1$ , where  $N$  is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree  $N$  and a constant term of 1.
- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

This property determines the feedback connections for the shift register of the first preferred PN sequence generator. The degree of the first generator polynomial must equal the degree of the second generator polynomial specified by the `SecondPolynomial` property. For more information, see “Preferred Pairs of Sequences” on page 3-635.

Example: `'z^8 + z^2 + 1'`, `[1 0 0 0 0 0 1 0 1]`, and `[8 2 0]` represent the same polynomial,  $p(z) = z^8 + z^2 + 1$ .

Data Types: `double` | `char`

### **FirstInitialConditions** — Initial conditions used for shift register of first preferred PN sequence generator

`[0 0 0 0 0 1]` (default) | binary-valued scalar | binary-valued vector

Initial conditions used for the shift register of the first preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `FirstPolynomial` property.

---

**Note** For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

Data Types: `double`

### **SecondPolynomial** — Generator polynomial for second preferred PN sequence

`'z^6 + z^5 + z^2 + z + 1'` (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial for the first preferred PN sequence, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.

- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be  $N + 1$ , where  $N$  is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree  $N$  and a constant term of 1.
- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

This property determines the feedback connections for the shift register of the second preferred PN sequence generator. The degree of the second generator polynomial must equal the degree of the first generator polynomial specified by the `FirstPolynomial` property. For more information, see “Preferred Pairs of Sequences” on page 3-635.

Data Types: `double` | `char`

**SecondInitialConditionsSource — Source of initial conditions used for shift register of second preferred PN sequence generator**

'Property' (default) | 'Input port'

Source of the initial conditions used for the shift register of the second preferred PN sequence generator, specified as one of these values:

- 'Property' — Specify PN sequence generator initial conditions by using the `SecondInitialConditions` property.
- 'Input port' — Specify PN sequence generator initial conditions by using the `secondinitcond` input argument.

Data Types: `string` | `char`

**SecondInitialConditions — Initial conditions used for shift register of second preferred PN sequence generator**

[0 0 0 0 0 1] (default) | binary-valued scalar | binary-valued vector

Initial conditions used for the shift register of the second preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `SecondPolynomial` property.

---

**Note** For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

**Dependencies**

To enable this property set the `SecondInitialConditionsSource` property to 'Property'.

Data Types: `double`

**Index — Sequence index**

0 (default) | integer

Sequence index of the output sequence from the set of Gold sequences, specified as an integer in the range  $[-2, 2^n-2]$ .  $n$  is the degree of the preferred polynomials. For more information, see “Sequence Index” on page 3-636 and “Gold Sequences” on page 3-634.

Data Types: double

**Shift — Offset of output sequence from starting point**

0 (default) | integer

Offset of the output sequence from the starting point, specified as an integer. Units are in samples. The object wraps shift values that are negative or greater than the length of the Gold sequence. For an example using shift, see “Generate Gold Sequences with Various Shift Values” on page 3-631.

---

**Note** Calculate the mask vector by using the `shift2mask` function.

---

Data Types: double

**VariableSizeOutput — Enable variable-size outputs**

false (default) | true

Enable variable-size outputs, specified as a numeric or logical 0 (false) or 1 (true). To enable variable-size outputs by using the `outputsize` input argument, set this property to `true`. The enabled input specifies the output size of the Gold sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to `false`, the `SamplesPerFrame` property specifies the number of output samples.

Data Types: logical | double

**MaximumOutputSize — Maximum output frame size**

[10 1] (default) | vector of the form [m 1]

Maximum output frame size, specified as a vector of the form  $[m 1]$ , where  $m$  is a positive integer. The first element of the vector indicates the maximum length of the output frame and the second element of the vector must be 1.

Example: `[20 1]` specifies a maximum frame output size of 20-by-1.

**Dependencies**

To enable this property, set the `VariableSizeOutput` property to `true`.

Data Types: double

**SamplesPerFrame — Number of samples output per frame**

1 (default) | positive integer

Number of samples output per frame, specified as a positive integer. If you set this property to a value of  $M$ , the object outputs  $M$  samples of a Gold sequence that has a period of  $N = 2^n - 1$ , where  $n$

is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties.

**Dependencies**

To enable this property, set the `VariableSizeOutput` property to `false`.

Data Types: `double`

**ResetInputPort — Enable generator reset input**

`false` (default) | `true`

Enable the generator reset input, specified as a numeric or logical 0 (`false`) or 1 (`true`). To enable the ability to reset the sequence generator using the `resetseq` input argument, set this property to `true`. This input resets the states of the two shift registers of the Gold sequence generator to the initial conditions specified by the `FirstInitialConditions` and `SecondInitialConditions` properties. For an example using the `resetseq` input, see “Generate Gold Sequences with Various Reset Values” on page 3-632.

**Dependencies**

To enable this property, set the `SecondInitialConditionsSource` property to `'Property'`.

Data Types: `logical` | `double`

**OutputDataType — Data type of output**

`'double'` (default) | `'logical'` | `'Smallest unsigned integer'` | `'Smallest integer'`

Data type of the output, specified as `'double'`, `'logical'`, `'Smallest unsigned integer'`, or `'Smallest integer'`.

To use the `Smallest unsigned integer` option, you must have the Fixed-Point Designer product.

Data Types: `string` | `char`

**Usage****Syntax**

```
outSequence = goldseq()  
outSequence = goldseq(secondinitcond)  
outSequence = goldseq(outputsize)  
outSequence = goldseq(resetseq)  
outSequence = goldseq(secondinitcond,outputsize)  
outSequence = goldseq(outputsize,resetseq)
```

**Description**

`outSequence = goldseq()` outputs a frame of the Gold sequence in a column vector based on the configured object.

`outSequence = goldseq(secondinitcond)` uses `secondinitcond` as the initial conditions for the second PN sequence.

To enable this syntax, set the `SecondInitialConditionsSource` property to 'Input port' and the `ResetInputPort` property to false.

`outSequence = goldseq(outputsize)` uses `outputsize` as the output size.

To enable this syntax, set the `VariableSizeOutput` property to true.

`outSequence = goldseq(resetseq)` uses `resetseq` as the reset signal.

To enable this syntax, set the `ResetInputPort` property to true and the `SecondInitialConditionsSource` property to 'Property'.

`outSequence = goldseq(secondinitcond,outputsize)` specifies inputs for the second PN sequence initial conditions and the output size.

To enable this syntax, set the `SecondInitialConditionsSource` property to 'Input port', the `ResetInputPort` property to false, and set the `VariableSizeOutput` property to true.

`outSequence = goldseq(outputsize,resetseq)` specifies inputs for the output size and a reset signal.

To enable this syntax, set the `VariableSizeOutput` property to true, the `SecondInitialConditionsSource` property to 'Property', and the `ResetInputPort` property to true.

### Input Arguments

**secondinitcond** — Initial conditions used for shift register of second sequence polynomial  
binary scalar | binary vector

Initial conditions used for the shift register of the second preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this input to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this input to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `SecondPolynomial` property.

---

**Note** For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

### Dependencies

To enable this input argument, set the `SecondInitialConditionsSource` property to 'Input port'.

Data Types: double

**outputsize** — Length of output sequence  
nonnegative integer | vector of the form  $[n \ 1]$

Length of the output sequence, specified as a nonnegative integer,  $n$ , or a vector of the form  $[n \ 1]$ , where  $n$  is a positive integer. The first element of the vector indicates the length of the output frame and the second element of the vector must be 1.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

#### **Dependencies**

To enable this input argument, set the `VariableSizeOutput` property to `true`.

Data Types: `double`

#### **resetseq — Reset sequence generator**

scalar | column vector

Reset sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the object resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a column vector, the object resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in the reset vector.

For an example using `reset`, see “Generate Gold Sequences with Various Reset Values” on page 3-632.

#### **Dependencies**

To enable this input argument, set the `ResetInputPort` property to `true`.

Data Types: `double` | `logical`

#### **Output Arguments**

##### **outSequence — Gold sequence**

column vector

Gold sequence, returned as a column vector. For more information, see “Gold Sequences” on page 3-634.

### **Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

## Examples

### Generate Gold Sequence Samples

Generate 10 samples of a Gold sequence with a period of  $2^5 - 1$ .

```
goldseq = comm.GoldSequence('FirstPolynomial','x^5+x^2+1', ...
    'SecondPolynomial','x^5+x^4+x^3+x^2+1', ...
    'FirstInitialConditions',[0 0 0 0 1], ...
    'SecondInitialConditions',[0 0 0 0 1], ...
    'Index',4,'SamplesPerFrame',10);
x = goldseq()
```

x = 10×1

```
1
1
1
0
0
0
0
0
0
0
1
```

### Generate Gold Sequences with Various Shift Values

Generate Gold sequences using different values for the shift input to demonstrate that the object wraps shift values that are negative or greater than the sequence length.

Create a Gold sequence System object™, specifying 15 samples per frame and no shift. Generate the 7-sample Gold sequence. The output frame begins at the start of the Gold sequence.

```
goldseq = comm.GoldSequence( ...
    "FirstPolynomial","x^3+x^2+1", ...
    "SecondPolynomial","x^3+x+1", ...
    "FirstInitialConditions",[0 0 1], ...
    "SecondInitialConditions",[0 1 1], ...
    "Index",3, ...
    "SamplesPerFrame",15)
```

```
goldseq =
  comm.GoldSequence with properties:
    FirstPolynomial: "x^3+x^2+1"
    FirstInitialConditions: [0 0 1]
    SecondPolynomial: "x^3+x+1"
    SecondInitialConditionsSource: 'Property'
    SecondInitialConditions: [0 1 1]
    Index: 3
    Shift: 0
    VariableSizeOutput: false
```

```
SamplesPerFrame: 15
ResetInputPort: false
OutputDataType: 'double'
```

```
outseq = goldseq()'
```

```
outseq = 1×15
```

```
1 1 0 0 0 0 0 1 1 0 0 0 0 0 1
```

Release the object, adjust the shift to -1, and generate the shifted output. Repeat this process for shift values of 6 and 13. For each of these shift settings, the output frame begins at the 6th sample of this 7-sample long Gold sequence.

```
release(goldseq);
goldseq.Shift = -1;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 1 1 0 0 0 0 0
```

```
release(goldseq);
goldseq.Shift = 6;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 0 1 1 0 0 0 0
```

```
release(goldseq);
goldseq.Shift = 13;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 0 1 1 0 0 0 0
```

### Generate Gold Sequences with Various Reset Values

Generate Gold sequences using different values for the reset input.

Create a Gold sequence System object™, specifying 15 samples per frame and enabling the reset input. Generate the 7-sample Gold sequence. To observe the starting point of frames output by the object relative to the generated Gold sequence, the samples per frame value includes one sample more than two times the sequence length.

```
goldseq = comm.GoldSequence( ...
    "FirstPolynomial", "x^3+x^2+1", ...
    "SecondPolynomial", "x^3+x+1", ...
    "FirstInitialConditions", [0 0 1], ...
```

```

"SecondInitialConditions",[0 1 1], ...
"Index",3, ...
"ResetInputPort",true, ...
"SamplesPerFrame",15);

```

So that the object does not reset the sequence to the initial conditions, specify a scalar reset input value of 0. Display consecutive 15-sample frames of the sequence. The second frame continues the sequence from where the first frame left off, with the second element of the Gold sequence.

```

resetseq = 0;
x1 = goldseq(resetseq)'

```

```

x1 = 1×15

```

```

     1     1     0     0     0     0     0     1     1     0     0     0     0     0     1

```

```

x2 = goldseq(resetseq)'

```

```

x2 = 1×15

```

```

     1     0     0     0     0     0     1     1     0     0     0     0     0     1     1

```

To reset the sequence to the initial conditions, specify a scalar reset input value of 1. Display consecutive 15-sample frames of the sequence. The second frame now begins with the first element of the Gold sequence.

```

resetseq = 1;
x3 = goldseq(resetseq)'

```

```

x3 = 1×15

```

```

     1     1     0     0     0     0     0     1     1     0     0     0     0     0     1

```

```

x4 = goldseq(resetseq)'

```

```

x4 = 1×15

```

```

     1     1     0     0     0     0     0     1     1     0     0     0     0     0     1

```

To reconfigure the reset input of the object to accept a vector, release the object. Specify a reset input vector filled with 0s. Display consecutive 15-sample frames of the sequence. Since the object does not reset the sequence to the initial conditions, the second frame begins with the second element of the Gold sequence.

```

release(goldseq)
resetseq = [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]';
x5 = goldseq(resetseq)'

```

```

x5 = 1×15

```

```

     1     1     0     0     0     0     0     1     1     0     0     0     0     0     1

```

```

x6 = goldseq(resetseq)'

```

```
x6 = 1×15
```

```
1 0 0 0 0 0 1 1 0 0 0 0 0 1 1
```

Specify a reset input vector that has two elements with nonzero values. Display consecutive 15-sample frames of the sequence. The second and third frames continue the sequence from the prior frame but reset the sequence at the third and ninth samples of the frame due to the position of the nonzero entries in the vector specified for the reset input.

```
resetseq = [0 0 1 0 0 0 0 0 1 0 0 0 0 0 0]';
x7 = goldseq(resetseq)'
```

```
x7 = 1×15
```

```
0 0 1 1 0 0 0 0 1 1 0 0 0 0 0
```

```
x8 = goldseq(resetseq)'
```

```
x8 = 1×15
```

```
1 1 1 1 0 0 0 0 1 1 0 0 0 0 0
```

```
x9 = goldseq(resetseq)'
```

```
x9 = 1×15
```

```
1 1 1 1 0 0 0 0 1 1 0 0 0 0 0
```

## More About

### Gold Sequences

The characteristic cross-correlation properties of Gold sequences make them useful when multiple devices are broadcasting in the same frequency range. The Gold sequences are defined using a specified pair of sequences,  $u$  and  $v$ , called a preferred pair, as defined in “Preferred Pairs of Sequences” on page 3-635. The  $u$  and  $v$  pair of sequences has a period  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties. The set  $G(u, v)$  of Gold sequences is defined by

$$G(u, v) = \{u, v, u \oplus v, u \oplus Tv, u \oplus T^2v, \dots, u \oplus T^{N-1}v\}$$

$T$  represents the operator that shifts vectors cyclically to the left by one place, and  $\oplus$  represents addition modulo 2.  $G(u, v)$  contains  $N + 2$  sequences of period  $N$ .

Gold sequences have the property that the cross-correlation between any two sequences or between shifted versions of the sequences takes on one of three values:  $-t(n)$ ,  $-1$ , or  $t(n) - 2$ , where

$$t(n) = \begin{cases} 1 + 2^{(n+1)/2} & n \text{ even} \\ 1 + 2^{(n+2)/2} & n \text{ odd} \end{cases}$$

The object uses two PN sequence generators to generate a preferred pair of sequences. The object then XORs these sequences to produce the output Gold sequence, as shown in this figure.

The `FirstPolynomial` and `SecondPolynomial` properties determine the preferred pair of sequences and the feedback connections for the shift registers used by the PN sequence generators to generate their output. For more details on PN sequence generation, see the “Simple Shift Register Generator” on page 3-1041 section on the `comm.PNSequenceSystem` object reference page.

This table provides examples of preferred pairs.

Degree of Generator Polynomials ( $n$ )	Pair of Sequences Period ( $N$ )	FirstPolynomial Property Value	SecondPolynomial Property Value
5	31	[5 2 0]	[5 4 3 2 0]
6	63	[6 1 0]	[6 5 2 1 0]
7	127	[7 3 0]	[7 3 2 1 0]
9	511	[9 4 0]	[9 6 4 3 0]
10	1023	[10 3 0]	[10 8 3 2 0]
11	2047	[11 2 0]	[11 8 5 2 0]

The `FirstInitialConditions` property and `SecondInitialConditions` property (or `secondinitcond` input argument) are values that specify the initial values of the shift registers corresponding to `FirstPolynomial` and `SecondPolynomial`, respectively.

---

**Note** For the object to generate a nonzero sequence, at least one element of one of the initial conditions vectors must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

You can offset the starting point of the Gold sequence by setting the `Shift` property to a nonzero value. For an example that adjusts the shift setting, see “Generate Gold Sequences with Various Shift Values” on page 3-631.

### Preferred Pairs of Sequences

Preferred pairs of sequences,  $u$  and  $v$ , comprise the set of Gold sequences  $G(u, v)$ .

For a pair of sequences,  $u$  and  $v$ , of period  $N = 2^n - 1$  to be a preferred pair, they must satisfy these requirements:

- $n$  is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties.
- $n$  is not divisible by 4.
- $v = u[q]$ , where
  - $q$  is odd.
  - $q = 2^k + 1$  or  $q = 2^{2k} - 2^k + 1$ .
  - $v$  is obtained by sampling every  $q$ th symbol of  $u$ .
- $\text{gcd}(n, k) = \begin{cases} 1 & n \equiv 1 \pmod{2} \\ 2 & n \equiv 2 \pmod{4} \end{cases}$

For more details on PN sequence generation, see the “Simple Shift Register Generator” on page 3-1041 section on the `comm.PNSequenceSystem` object reference page.

### Sequence Index

The sequence index specified by the `Index` property specifies which Gold sequence in the set  $G(u, v)$  is output.

The set of available Gold sequences is

$$G(u, v) = \{u, v, u \oplus v, u \oplus Tv, u \oplus T^2v, \dots, u \oplus T^{N-1}v\}$$

$u$  and  $v$  are the two preferred PN sequences,  $T$  is the operator that shifts vectors cyclically to the left by one place, and  $\oplus$  represents addition modulo 2.  $G(u, v)$  contains  $N+2$  Gold sequences of period  $N = 2^n - 1$ .

The range of `Index` is  $[-2, 2^n - 2]$ , where  $n$  is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties. The index values -2 and -1 correspond to the first and second preferred PN sequences as generated by `FirstPolynomial` and `SecondPolynomial`, respectively. This table shows the correspondence between the sequence index and the output sequence.

Index Property Value	Output Sequence
-2	$u$
-1	$v$
0	$u \oplus v$
1	$u \oplus Tv$
2	$u \oplus T^2v$
...	...
$2^n - 2$	$u \oplus T^{2^n - 2}v$

## comm.gpu.AWGNChannel

**Package:** comm

Add white Gaussian noise to input signal with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.AWGNChannel` System object adds white Gaussian noise to an input signal using a graphics processing unit (GPU).

To add white Gaussian noise to an input signal:

- 1 Create the `comm.gpu.AWGNChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpuawgnchan = comm.gpu.AWGNChannel  
gpuawgnchan = comm.gpu.AWGNChannel(Name=Value)
```

#### Description

`gpuawgnchan = comm.gpu.AWGNChannel` creates a GPU-based channel System object that adds white Gaussian noise to the input signal.

`gpuawgnchan = comm.gpu.AWGNChannel(Name=Value)` sets properties using one or more name-value arguments. For example, `SamplesPerSymbol=4` specifies the samples per symbol value as 4.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**NoiseMethod — Noise level method**

"Signal to noise ratio (Eb/No)" (default) | "Signal to noise ratio (Es/No)" | "Signal to noise ratio (SNR)" | "Variance"

Noise level method, specified as "Signal to noise ratio (Eb/No)", "Signal to noise ratio (Es/No)", "Signal to noise ratio (SNR)", or "Variance". For more information, see "Relationship Between Eb/No, Es/No, and SNR Modes" on page 3-644 and "Specifying Variance Directly or Indirectly" on page 3-645.

**EbNo — Ratio of energy per bit to noise power spectral density**

10 (default) | scalar | row vector

Ratio of energy per bit to noise power spectral density (Eb/No) in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

To enable this property, set NoiseMethod to "Signal to noise ratio (Eb/No)".

Data Types: double

**EsNo — Ratio of energy per symbol to noise power spectral density**

10 (default) | scalar | row vector

Ratio of energy per symbol to noise power spectral density (Es/No) in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

To enable this property, set NoiseMethod to "Signal to noise ratio (Es/No)".

Data Types: double

**SNR — Ratio of signal power to noise power**

10 (default) | scalar | row vector

Ratio of signal power to noise power in decibels, specified as a scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

To enable this property, set NoiseMethod to "Signal to noise ratio (SNR)".

Data Types: double

**BitsPerSymbol — Number of bits per symbol**

1 (default) | positive integer

Number of bits per symbol, specified as a positive integer.

**Dependencies**

To enable this property, set NoiseMethod to "Signal to noise ratio (Eb/No)".

Data Types: double

**SignalPower — Input signal power**

1 (default) | positive scalar | row vector

Input signal power in watts, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels. The object assumes a nominal impedance of 1 ohms.

**Tunable:** Yes

**Dependencies**

To enable this property, set `NoiseMethod` to "Signal to noise ratio (Eb/No)", "Signal to noise ratio (Es/No)", or "Signal to noise ratio (SNR)".

Data Types: double

**SamplesPerSymbol — Number of samples per symbol**

1 (default) | positive integer | row vector

Number of samples per symbol, specified as a positive integer or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Dependencies**

To enable this property, set `NoiseMethod` to "Signal to noise ratio (Eb/No)" or "Signal to noise ratio (Es/No)".

Data Types: double

**VarianceSource — Source of noise variance**

"Property" (default) | "Input port"

Source of noise variance, specified as "Property" or "Input port".

- To specify the noise variance value using the `Variance` property, set `VarianceSource` to "Property".
- To specify the noise variance value using an input to the object, when you call it as a function, set `VarianceSource` to "Input port".

For more information, see "Specifying Variance Directly or Indirectly" on page 3-645.

**Dependencies**

To enable this property, set `NoiseMethod` to "Variance".

**Variance — White Gaussian noise variance**

1 (default) | positive scalar | row vector

White Gaussian noise variance, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels.

**Tunable:** Yes

**Dependencies**

To enable this property, set `NoiseMethod` to "Variance" and set `VarianceSource` to "Property".

Data Types: double

### RandomStream — Source of random number stream

"Global stream" (default)

Source of random number stream, specified as "Global stream". When you set RandomStream to "Global stream", the object uses the MATLAB default random stream to generate random numbers. To generate reproducible numbers using this object, use the `rng` function.

For a complex input signal, the object creates the random data as follows:

```
noise = randn(NS,NC)+1i(randn(NS,NC))
```

$N_S$  is the number of samples and  $N_C$  is the number of channels.

#### Dependencies

To enable this property, set `NoiseMethod` to "Variance".

### Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. For each call to the `reset` function, the object reinitializes the mt19937ar random number stream to the `Seed` value.

#### Dependencies

To enable this property, set `RandomStream` to "mt19937ar with seed".

Data Types: double

## Usage

### Syntax

```
y = gpuawgnchan(x)
y = gpuawgnchan(x,var)
```

### Description

`y = gpuawgnchan(x)` adds white Gaussian noise, as specified by `gpuawgnchan`, to the input signal. The result is returned in `y`.

`y = gpuawgnchan(x,var)` specifies the variance of the white Gaussian noise. This syntax applies when you set `NoiseMethod` to "Variance" and `VarianceSource` to "Input port".

For example:

```
gpuawgnchan = comm.AWGNChannel('NoiseMethod','Variance', ...
    'VarianceSource','Input port');
var = 12;
...
y = gpuawgnchan(x,var);
```

### Input Arguments

#### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an  $N_S$ -element vector, or an  $N_S$ -by- $N_C$  matrix.  $N_S$  is the number of samples and  $N_C$  is the number of channels.

Data Types: double | single

Complex Number Support: Yes

#### **var** — Variance of additive white Gaussian noise

positive scalar | row vector

Variance of additive white Gaussian noise, specified as a positive scalar or 1-by- $N_C$  vector.  $N_C$  is the number of channels, as determined by the number of columns in the input signal matrix.

Data Types: double | single

### Output Arguments

#### **y** — Output signal

matrix

Output signal, returned with the same dimensions as **x**.

Data Types: double | single

Complex Number Support: Yes

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

`step`     Run System object algorithm

`release`   Release resources and allow changes to System object property values and input characteristics

`reset`     Reset internal states of System object

### Examples

#### GPU AWGN Channel

Specify the modulation order and generate PSK-modulated random data.

```
M = 8;  
modData = pskmod(randi([0 M-1],1000,1),M,pi/M);
```

Create an AWGN channel object that uses a GPU. Pass the modulated data through the channel.

```
gpuChannel = comm.gpu.AWGNChannel('EbNo',15,'BitsPerSymbol', ...  
    log2(M));  
channelOutput = gpuChannel(modData);
```

Visualize the noiseless and noisy data in scatter plots.

```
scatterplot(modData)  
scatterplot(channelOutput)
```

## More About

### Array Processing with GPU-Based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## Algorithms

### Relationship Between $E_b/N_0$ , $E_s/N_0$ , and SNR Modes

For uncoded complex input signals, `comm.gpu.AWGNChannel` relates  $E_b/N_0$ ,  $E_s/N_0$ , and SNR according to these equations:

$$E_s/N_0 = N_{\text{sps}} \times \text{SNR}$$

$$E_s/N_0 = E_b/N_0 + 10\log_{10}(k) \text{ in dB}$$

where

- $E_s$  represents the signal energy in joules.
- $E_b$  represents the bit energy in joules.
- $N_0$  represents the noise power spectral density in watts/Hz.
- $N_{\text{sps}}$  represents the number of samples per symbol, `SamplesPerSymbol`.
- $k$  represents the number of information bits per input symbol, `BitsPerSymbol`.

For real signal inputs, the `comm.gpu.AWGNChannel` relates  $E_s/N_0$  and SNR according to this equation:

$$E_s/N_0 = 0.5 (N_{\text{sps}}) \times \text{SNR}$$

---

### Note

- All values of power assume a nominal impedance of 1 ohm.
  - The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of  $N_0/2$  watts/Hz for real input signals, versus  $N_0$  watts/Hz for complex signals.
- 

For more information, see [AWGN Channel Noise Level](#).

### Specifying Variance Directly or Indirectly

To directly specify the variance of the noise generated by `comm.gpu.AWGNChannel`, specify `VarianceSource` as:

- "Property", then set `NoiseMethod` to "Variance" and specify the variance with the `Variance` property.
- "Input port", then specify the variance level for the object as an input with an input argument, `var`.

To specify variance indirectly, that is, to have it calculated by `comm.gpu.AWGNChannel`, specify `VarianceSource` as "Property" and the `NoiseMethod` as:

- "Signal to noise ratio (Eb/No)", where the object uses these properties to calculate the variance:
  - `EbNo`, the ratio of bit energy to noise power spectral density
  - `BitsPerSymbol`
  - `SignalPower`, the actual power of the input signal samples
  - `SamplesPerSymbol`
- "Signal to noise ratio (Es/No)", where the object uses these properties to calculate the variance:
  - `EsNo`, the ratio of signal energy to noise power spectral density
  - `SignalPower`, the actual power of the input signal samples
  - `SamplesPerSymbol`

- "Signal to noise ratio (SNR)", where the object uses these properties to calculate the variance:
  - SNR, the ratio of signal power to noise power
  - SignalPower, the actual power of the input signal samples

Changing the number of samples per symbol (`SamplesPerSymbol`) affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$\text{NoiseVariance} = \text{SignalPower} \times \text{SamplesPerSymbol} / 10^{(E_s N_o / 10)}$$

---

**Tip** Select the number of samples per symbol based on what constitutes a symbol and the oversampling applied to it. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see AWGN Channel Noise Level.

# comm.gpu.BlockDeinterleaver

**Package:** comm

Restore original ordering of block interleaved sequence with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

## Description

The `comm.gpu.BlockDeinterleaver` System object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

To deinterleave the input vector:

- 1 Create the `comm.gpu.BlockDeinterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
gpublockdeinterleaver = comm.gpu.BlockDeinterleaver
gpublockdeinterleaver = comm.gpu.BlockDeinterleaver(Name=Value)
gpublockdeinterleaver = comm.gpu.BlockDeinterleaver(permvec)
```

### Description

`gpublockdeinterleaver = comm.gpu.BlockDeinterleaver` creates a GPU-based block deinterleaver System object that restores the original ordering of a sequence that was block interleaved.

`gpublockdeinterleaver = comm.gpu.BlockDeinterleaver(Name=Value)` creates a GPU-based block deinterleaver object and sets properties using one or more name-value arguments. For example, `gpublockdeinterleaver = comm.gpu.BlockDeinterleaver(PermutationVector=[2;1;4;3])` specifies the permutation vector for a four-element input signal.

`gpublockdeinterleaver = comm.gpu.BlockDeinterleaver(permvec)` creates a GPU-based block deinterleaver object and sets the `PermutationVector` property to `permvec`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **PermutationVectorSource** — Permutation vector source

'Property'

This property is read-only.

Permutation vector source, specified as 'Property'.

### **PermutationVector** — Permutation vector

[5;4;3;2;1] (default) | column vector of integers

Permutation vector, specified as a column vector of integers. This input vector specifies the mapping used to permute the input signal. The permutation vector length must equal the input signal length and contain each integer in the range [1 length(x)].

Data Types: `double`

## Usage

### Syntax

```
y = gpublockdeinterleaver(x)
```

### Description

`y = gpublockdeinterleaver(x)` restores the original ordering of the input signal, which was interleaved using a block interleaver as specified by the `PermutationVector` property.

### Input Arguments

#### **x** — Input signal

column vector

Input signal, specified as column vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`  
Complex Number Support: Yes

### Output Arguments

#### **y** — Output signal

column vector

Output signal, returned as a column vector with the same length and data type as the input signal,  $x$ . The output contains the element from the input signal mapped as  $y(\text{PermutationVector}(k)) = x(k)$  for each integer  $k$  in the range  $[1 \text{ length}(x)]$ .

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics

## Examples

### Block Interleaving and Deinterleaving with GPU

Create GPU-based interleaver and deinterleaver objects.

#### Set Specific Permutation Vector

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver. The length of the input data vector must equal the length of the `PermutationVector` property. Generate a 4-by-1 column vector of input data filled with integer values in the range  $[1, 7]$  by using the `randi` function.

```
data = randi(7,length(interleaver.PermutationVector),1);
intData = interleaver(data);
deintData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deintData]
```

```
ans = 4×3
```

```
     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm that the original and deinterleaved data are identical.

```
isequal(data,deintData)
```

```
ans = logical
     1
```

### Set Random Permutation Vector

Generate a random 8-by-1 vector of unique integers to use as the permutation vector by using the `randperm` function.

```
permVec = randperm(8)';
```

Specify `permVec` as the permutation vector for GPU-based interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);  
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,length(interleaver.PermutationVector),1);  
intData = interleaver(data);  
deintData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deintData]
```

```
ans = 8×3
```

```
    10     5    10  
     5     8     5  
     9     9     9  
     2     2     2  
     5    10     5  
    10     5    10  
     8    10     8  
    10    10    10
```

Confirm that the original and deinterleaved data are identical.

```
isequal(data,deintData)
```

```
ans = logical  
     1
```

**Package:** comm

Create block interleaved sequence with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.BlockInterleaver` System object permutes the input signal using a graphics processing unit (GPU).

To interleave the input signal:

- 1 Create the `comm.gpu.BlockInterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpublockinterleaver = comm.gpu.BlockInterleaver  
gpublockinterleaver = comm.gpu.BlockInterleaver(Name=Value)  
gpublockinterleaver = comm.gpu.BlockInterleaver(permvec)
```

#### Description

`gpublockinterleaver = comm.gpu.BlockInterleaver` creates a GPU-based block interleaver System object that permutes the input signal based on a permutation vector.

`gpublockinterleaver = comm.gpu.BlockInterleaver(Name=Value)` creates a GPU-based block interleaver object and sets properties using one or more name-value arguments. For example, `gpublockinterleaver = comm.gpu.BlockInterleaver(PermutationVector=[2;1;4;3])` specifies the permutation vector for a four-element input signal.

`gpublockinterleaver = comm.gpu.BlockInterleaver(permvec)` creates a GPU-based block interleaver object and sets the `PermutationVector` property to `permvec`.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **PermutationVectorSource — Permutation vector source**

'Property'

This property is read-only.

Permutation vector source, specified as 'Property'.

### **PermutationVector — Permutation vector**

[5;4;3;2;1] (default) | column vector of integers

Permutation vector, specified as a column vector of integers. This input vector specifies the mapping used to permute the input signal. The permutation vector length must equal the input signal length and contain each integer in the range [1 length(x)].

Data Types: double

## **Usage**

### **Syntax**

`y = gpublockinterleaver(x)`

### **Description**

`y = gpublockinterleaver(x)` permutes the input signal as specified by the `PermutationVector` property.

### **Input Arguments**

#### **x — Input signal**

column vector

Input signal, specified as column vector.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see “Array Processing with GPU-Based System Objects” on page 3-655.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | fi  
Complex Number Support: Yes

### **Output Arguments**

#### **y — Output signal**

column vector

Output signal, returned as a column vector with the same length and data type as the input signal, `x`. The output contains elements from the input signal mapped as  $y(k) = x(\text{PermutationVector}(k))$  for each integer `k` in the range [1 length(x)].

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

## Examples

### Block Interleaving and Deinterleaving with GPU

Create GPU-based interleaver and deinterleaver objects.

#### Set Specific Permutation Vector

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');  
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver. The length of the input data vector must equal the length of the `PermutationVector` property. Generate a 4-by-1 column vector of input data filled with integer values in the range [1, 7] by using the `randi` function.

```
data = randi(7,length(interleaver.PermutationVector),1);  
intData = interleaver(data);  
deintData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deintData]
```

```
ans = 4×3
```

```
    6     1     6  
    7     7     7  
    1     6     1  
    7     7     7
```

Confirm that the original and deinterleaved data are identical.

```
isequal(data,deintData)
```

```
ans = logical  
     1
```

#### Set Random Permutation Vector

Generate a random 8-by-1 vector of unique integers to use as the permutation vector by using the `randperm` function.

```
permVec = randperm(8)';
```

Specify `permVec` as the permutation vector for GPU-based interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,length(interleaver.PermutationVector),1);
intData = interleaver(data);
deintData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deintData]
```

```
ans = 8×3
```

```
    10     5    10
     5     8     5
     9     9     9
     2     2     2
     5    10     5
    10     5    10
     8    10     8
    10    10    10
```

Confirm that the original and deinterleaved data are identical.

```
isequal(data,deintData)
```

```
ans = logical
     1
```

## More About

### Array Processing with GPU-Based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## Description

The `comm.gpu.ConvolutionalEncoder` System object convolutionally encodes a sequence of binary input vectors to produce a sequence of binary output vectors by using a graphics processing unit (GPU).

To convolutionally encode a binary signal:

- 1 Create the `comm.gpu.ConvolutionalEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
gpuConvEncoder = comm.gpu.ConvolutionalEncoder
gpuConvEncoder = comm.gpu.ConvolutionalEncoder(trellis)
gpuConvEncoder = comm.gpu.ConvolutionalEncoder( ___,Name,Value)
```

### Description

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder` creates a GPU-based convolutional encoder System object.

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder(trellis)` sets the `TrellisStructure` property to `trellis`.

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder( ___,Name,Value)` sets “Properties” on page 3-658 using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, `'TerminationMethod','Continuous'` specifies the termination method as continuous to retain the encoder states at the end of each input vector for use with the next input vector.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **TrellisStructure** — Trellis structure of convolutional code

`poly2trellis(7,[171 133])` (default) | structure

Trellis structure of the convolutional code, specified as a structure that contains the trellis description for a rate  $K / N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

#### **numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

#### **numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

#### **numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

#### **nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

#### **outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: `struct`

**TerminationMethod — Termination method of encoded frame**

'Continuous' (default) | 'Truncated' | 'Terminated'

Termination method of the encoded frame, specified as one of these values.

- 'Continuous' — The System object retains the encoder states at the end of each input vector for use with the next input vector.
- 'Truncated' — The System object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the `InitialStateInputPort` property to 0 (`false`), the object resets its states to the all-zeros state. If you set the `InitialStateInputPort` property to 1 (`true`), the object resets its states to the values you specify in the `InitialStateInputPort` input.
- 'Terminated' — The System object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to the all-zeros states at the end of the vector. For a rate  $K/N$  code, the object outputs a vector of length  $(N \times (L + S))/K$ . In this calculation,  $S = \text{constraintLength} - 1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i) - 1)$ ).  $L$  is the length of the input.  $\text{constraintLength} - 1$  is defined as  $\log_2(\text{NumStates})$ .

Data Types: char | string

**ResetInputPort — Option to enable encoder reset input**

false or 0 (default)

Option to enable the encoder reset input, specified as a numeric or logical 0 (`false`). The only valid setting is `false`.

Data Types: logical | numeric

**DelayedResetAction — Option to delay output reset**

false or 0 (default)

Option to delay the output reset, specified as a numeric or logical 0 (`false`). The only valid setting is `false`.

Data Types: logical | numeric

**InitialStateInputPort — Option to enable initial state input**

false or 0 (default)

Option to enable the initial state input, specified as a numeric or logical 0 (`false`). The only valid setting is `false`.

Data Types: logical | numeric

**FinalStateOutputPort — Option to enable final state output**

false or 0 (default)

Option to enable the final state output, specified as a numeric or logical 0 (`false`). The only valid setting is `false`.

Data Types: `logical` | `numeric`

### **PuncturePatternSource — Source of puncture pattern**

'None' (default) | 'Property'

Source of the puncture pattern, specified as one of these values.

- 'None' — The object does not apply puncturing.
- 'Property' — The object punctures the code. This puncturing is based on the puncture pattern vector that you specify for the `PuncturePattern` property.

#### **Dependencies**

To enable this property, set the `TerminationMethod` property to 'Continuous' or 'Truncated'.

Data Types: `char` | `string`

### **PuncturePattern — Puncture pattern vector**

[1; 1; 0; 1; 0; 1] (default) | column vector

Puncture pattern vector to puncture the encoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of punctured bits or excluded bits.

#### **Dependencies**

To enable this property, set the `TerminationMethod` property to 'Continuous' or 'Truncated' and the `PuncturePatternSource` property to 'Property'.

Data Types: `double`

### **NumFrames — Number of independent frames**

1 (default) | integer

Number of independent frames present in the input and output data vectors, specified as an integer.

The object segments the input vector into `NumFrames` segments and encodes them independently. The output contains `NumFrames` encoded segments.

#### **Dependencies**

To enable this property, set the `TerminationMethod` property to 'Truncated' or 'Terminated'.

Data Types: `double`

## **Usage**

### **Syntax**

`codeword` = `gpuConvEncoder`(`message`)

## Description

`codeword = gpuConvEncoder(message)` convolutionally encodes the input message specified by the trellis structure and returns the encoded codeword.

## Input Arguments

### message — Input message

binary-valued column vector

Input message, specified as a binary-valued column vector.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see “Array Processing with GPU-based System Objects” on page 3-662.

Data Types: `double` | `single` | `logical`

## Output Arguments

### codeword — Convolutionally encoded message

binary-valued column vector

Convolutionally encoded message, returned as a binary-valued column vector. This output vector has the same data type and orientation as `message`.

When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector equals  $K \times L$  for some positive integer  $L$ . The object sets the length of this output vector to  $L \times N$ .

Data Types: `double` | `single` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### GPU-Based Convolutionally Encode and Viterbi Decode 8-PSK Modulated Data

Create a GPU-based convolutional encoder System object.

```
conEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based phase shift keying (PSK) modulator System object that accepts a bit input signal.

```
modPSK = comm.gpu.PSKModulator(BitInput=true);
```

Create a GPU-based additive white Gaussian noise (AWGN) channel System object with a signal-to-noise ratio of seven.

```
chan = comm.gpu.AWGNChannel( ...  
    NoiseMethod='Signal to noise ratio (SNR)', ...  
    SNR=7);
```

Create a GPU-based PSK demodulator System object that outputs a column vector of bit values.

```
demodPSK = comm.gpu.PSKDemodulator(BitOutput=true);
```

Create a GPU-based Viterbi decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
vDec = comm.gpu.ViterbiDecoder(InputFormat='Hard');
```

Create an error rate System object that ignores 3 data samples before making comparisons. The received data lags behind the transmitted data by 34 samples.

```
error = comm.ErrorRate(ComputationDelay=3,ReceiveDelay=34);
```

Run the simulation by using this for-loop to process data.

```
for counter = 1:20  
    data = randi([0 1],30,1);  
    encodedData = conEnc(gpuArray(data));  
    modSignal = modPSK(encodedData);  
    receivedSignal = chan(modSignal);  
    demodSignal = demodPSK(receivedSignal);  
    receivedBits = vDec(demodSignal);  
    errors = error(data,gather(receivedBits));  
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 26
```

## comm.gpu.ConvolutionalInterleaver

**Package:** comm

Permute input symbols using shift registers with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.ConvolutionalInterleaver` System object permutes the symbols in the input sequence with a graphics processing unit (GPU).

To permute the symbols in the input sequence:

- 1 Create the `comm.gpu.ConvolutionalInterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
intrlvr = comm.gpu.ConvolutionalInterleaver  
intrlvr = comm.gpu.ConvolutionalInterleaver(Name=Value)  
intrlvr = comm.gpu.ConvolutionalInterleaver(m,b,ic)
```

#### Description

`intrlvr = comm.gpu.ConvolutionalInterleaver` creates a GPU-based convolutional interleaver System object.

`intrlvr = comm.gpu.ConvolutionalInterleaver(Name=Value)` sets properties using one or more name-value arguments. For example, `NumRegisters=10` specifies the number of internal shift registers.

`intrlvr = comm.gpu.ConvolutionalInterleaver(m,b,ic)` sets the `NumRegisters` property to `m`, the `RegisterLengthStep` property to `b`, and the `InitialConditions` property to `ic`.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **NumRegisters — Number of internal shift registers**

6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: `double`

### **RegisterLengthStep — Number of additional symbols that fit in each successive shift register**

2 (default) | positive integer

Number of additional symbols that fit in each successive shift register, specified as a positive integer. The first register holds zero symbols.

Data Types: `double`

### **InitialConditions — Initial conditions of shift registers**

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these values.

- Scalar — All shift registers, except the first one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the  $k$ th shift register stores the  $k$ th element of the specified vector.

You do not need to specify a value for the first shift register, which has zero delay. Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: `double`

## **Usage**

### **Syntax**

```
intrlvseq = intrlvr(inputseq)
```

### **Description**

`intrlvseq = intrlvr(inputseq)` permutes the input sequence of symbols `inputseq` by using a set of shift registers. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. The output is the interleaved sequence.

For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-667.

## Input Arguments

### **inputseq** — Sequence of symbols

column vector

Sequence of symbols, specified as a column vector.

Data Types: `double` | `single` | `uint32` | `int32` | `logical`

## Output Arguments

### **intrlvseq** — Interleaved sequence of symbols

column vector

Interleaved sequence of symbols, returned as a column vector with the same data type and size as the `inputseq` input.

Data Types: `double` | `single` | `uint32` | `int32` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### GPU-Based Convolutionally Interleave and Deinterleave Sequence

Create GPU-based convolutional interleaver and deinterleaver System objects.

```
intrlvr = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...  
    'RegisterLengthStep',3);  
deintrlvr = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...  
    'RegisterLengthStep',3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';  
intrlvData = intrlvr(data);  
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21x3
      0      0      0
      1      0      0
      2      2      0
      3      0      0
      4      4      0
      5      0      0
      6      6      0
      7      1      1
      8      8      2
      9      3      3
      :
```

The delay through the interleaver and deinterleaver pair is equal to the product of the NumRegisters and RegisterLengthStep properties.

```
intrlvDelay = intrlvr.NumRegisters * intrlvr.RegisterLengthStep
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...
    deintrlvData(1+intrlvDelay:end))

numSymErrors = 0
```

## More About

### Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is  $N \times slope \times (N - 1)$ .

- $N$  is the number of registers and equals the value of the NumRegisters property
- $slope$  is the register length step and equals the value of the RegisterLengthStep property

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as  $D(1), D(2), \dots, D(N)$ , and a commutator to switch input and output symbols through registers. The  $k$ th shift register holds  $D(k)$  symbols, where  $k = 1, 2, 3, \dots, N$ . The  $k$ th shift register has a delay value of  $((k-1) \times slope)$ . With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the  $N$ th register, upon the next new input, the commutator returns to the first register.

### Array Processing with GPU-based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## comm.gpu.ConvolutionalDeinterleaver

**Package:** comm

Deinterleave symbols using set of shift registers with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.ConvolutionalDeinterleaver` System object deinterleaves the symbols in the input sequence with a graphics processing unit (GPU).

To deinterleave the symbols in the input sequence with GPU:

- 1 Create the `comm.gpu.ConvolutionalDeinterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
deintrlvr = comm.gpu.ConvolutionalDeinterleaver
deintrlvr = comm.gpu.ConvolutionalDeinterleaver(Name=Value)
intrlvr = comm.gpu.ConvolutionalDeinterleaver(m,b,ic)
```

#### Description

`deintrlvr = comm.gpu.ConvolutionalDeinterleaver` creates a default convolutional deinterleaver System object.

`deintrlvr = comm.gpu.ConvolutionalDeinterleaver(Name=Value)` sets “Properties” on page 3-670 using one or more name-value arguments. For example, `NumRegisters=10` specifies the number of internal shift registers.

`intrlvr = comm.gpu.ConvolutionalDeinterleaver(m,b,ic)` sets the `NumRegisters` property to `m`, the `RegisterLengthStep` property to `b`, and the `InitialConditions` property to `ic`.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **NumRegisters — Number of internal shift registers**

6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: `double`

### **RegisterLengthStep — Number of additional symbols that fit in each successive shift register**

2 (default) | positive integer

Number of additional symbols that fit in each successive shift register, specified as a positive integer. The first register holds zero symbols.

Data Types: `double`

### **InitialConditions — Initial conditions of shift registers**

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these values.

- Scalar — All shift registers, except the last one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the  $k$ th shift register stores the  $(N-k+1)$ th element of the specified vector.  $N$  is the total number of shift registers.

You do not need to specify a value for the first shift register, which has zero delay. Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: `double`

## **Usage**

### **Syntax**

```
deintrlvseq = deintrlvr(intrlvseq)
```

### **Description**

`deintrlvseq = deintrlvr(intrlvseq)` deinterleaves the input sequence of symbols `inputseq` by using a set of shift registers. The output is the deinterleaved sequence.

For information about delays, see “Delays of Convolutional Interleaving and Deinterleaving” on page 3-673.

## Input Arguments

### **intrlvseq — Interleaved sequence of symbols**

column vector

Interleaved sequence of symbols, specified as a column vector. This sequence must be one that was interleaved using the `comm.gpu.ConvolutionalInterleaver` System object or `comm.ConvolutionalInterleaver` System object.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see “Array Processing with GPU-based System Objects” on page 3-674.

Data Types: `double` | `single` | `uint32` | `int32`

## Output Arguments

### **deintrlvseq — Deinterleaved sequence of symbols**

column vector

Deinterleaved sequence of symbols, returned as a column vector with the same data type and size as the `intrlvseq` input.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### **GPU-Based Convolutionally Interleave and Deinterleave Sequence**

Create GPU-based convolutional interleaver and deinterleaver System objects.

```
intrlvr = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...  
    'RegisterLengthStep',3);  
deintrlvr = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...  
    'RegisterLengthStep',3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';  
intrlvData = intrlvr(data);  
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21x3
```

```

0     0     0
1     0     0
2     2     0
3     0     0
4     4     0
5     0     0
6     6     0
7     1     1
8     8     2
9     3     3
:

```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties.

```
intrlvDelay = intrlvr.NumRegisters * intrlvr.RegisterLengthStep
```

```
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...
    deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

## More About

### Delays of Convolutional Interleaving and Deinterleaving

The total delay due to a convolutional interleaver and deinterleaver pair is  $N \times slope \times (N - 1)$ .

- $N$  is the number of registers and equals the value of the `NumRegisters` property
- $slope$  is the register length step and equals the value of the `RegisterLengthStep` property

This diagram shows the structure of a general convolutional interleaver comprised of a set of shift registers, each having a specified delay shown as  $D(1), D(2), \dots, D(N)$ , and a commutator to switch input and output symbols through registers. The  $k$ th shift register holds  $D(k)$  symbols, where  $k = 1, 2, 3, \dots, N$ . The  $k$ th shift register has a delay value of  $((k-1) \times slope)$ . With each new input symbol, the commutator switches to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the  $N$ th register, upon the next new input, the commutator returns to the first register.

### Array Processing with GPU-based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## comm.gpu.LDPCDecoder

**Package:** comm

Decode binary low-density parity-check (LDPC) code with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-682.

To decode an LDPC-encoded signal:

- 1 Create the `comm.gpu.LDPCDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpu_ldpcdecoder = comm.gpu.LDPCDecoder
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)
gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ___,Name,Value)
```

#### Description

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder` creates a GPU-based binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates a GPU-based LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ___,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type double. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2,  $\text{gf}(2)$ .

You can also specify the parity-check matrix as a two-column nonsparse index matrix,  $I$ , that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where  $R$  is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

### OutputValue — Output value format

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a  $K$ -by-1 column vector containing only the information-part of the received log-likelihood ratio vector.  $K$  is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an  $N$ -by-1 column vector containing the whole log-likelihood ratio vector.  $N$  is the length of the received signal.

$N$  and  $K$  must align with the dimension of the  $(N-K)$ -by- $K$  parity-check matrix.

Data Types: `char`

### DecisionMethod — Decision method

`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- 'Hard decision' — The object outputs decoded data of data type `logical`.
- 'Soft decision' — The object outputs log-likelihood ratios of data type `double`.

Data Types: `char`

**IterationTerminationCondition — Condition for iteration termination**

'Maximum iteration count' (default) | 'Parity check satisfied'

Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count' — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- 'Parity check satisfied' — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: `char`

**MaximumIterationCount — Maximum number of decoding iterations**

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: `double`

**NumIterationsOutputPort — Output number of iterations performed**

false (default) | true

Output number of iterations executed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: `logical`

**FinalParityChecksOutputPort — Output final parity checks**

false (default) | true

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: `logical`

## Usage

## Syntax

```
y = gpu_ldpcdecoder(x)
[y,numiter] = gpu_ldpcdecoder(x)
[y,parity] = gpu_ldpcdecoder(x)
[y,numiter,parity] = gpu_ldpcdecoder(x)
```

## Description

`y = gpu_ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = gpu_ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

## Input Arguments

### **x** — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an  $N$ -by-1 column vector containing the soft-decision output from demodulation.  $N$  is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first  $K$  elements correspond to the information-part of the input message.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see “Array Processing with GPU-based System Objects” on page 3-682.

Data Types: `double`

## Output Arguments

### **y** — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

### **numiter** — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

## Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

### **parity** — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an  $(N-K)$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword before modulation.  $K$  is the length of the uncoded message.

### Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### LDPC Encode and Decode QPSK-Modulated Signal Using GPU

Using a `comm.gpu.LDPCDecoder` System Object™ to decode the signal, transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. After adding AWGN, demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals. For more information, see “Accelerate Simulation Using GPUs”.

Define simulation variables. Create an LDPC encoder configuration object and System objects for the LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
gpuldpcDecoder = comm.gpu.LDPCDecoder;
encoderCfg = ldpcEncoderConfig(gpuldpcDecoder.ParityCheckMatrix);
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
```

```

% Transmit and receiver uncoded signal data
mod_uncSig = pskMod(data);
rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
demod_uncSig = pskuDemod(rx_uncSig);
numErrUnc = biterr(data,demod_uncSig);
ttlErrUnc = ttlErrUnc + numErrUnc;
% Transmit and receive LDPC coded signal data
encData = ldpcEncode(data,encoderCfg);
modSig = pskMod(encData);
rxSig = awgn(modSig,snr(ii),'measured');
demodSig = pskDemod(rxSig);
rxBits = gpuldpcDecoder(demodSig);
numErr = biterr(data,rxBits);
ttlErr = ttlErr + numErr;
end
ttlBits = numFrames*length(rxBits);
uncErrRate(ii) = ttlErrUnc/ttlBits;
errRate(ii) = ttlErr/ttlBits;
end

```

Plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

## Limitations

- The `comm.gpu.LDPCDecoder` System object cannot be included in MATLAB System blocks.

## More About

### Array Processing with GPU-based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

### Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value  $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)}\right)$ .

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in \mathcal{V}_{j|i}} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in \mathcal{C}_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

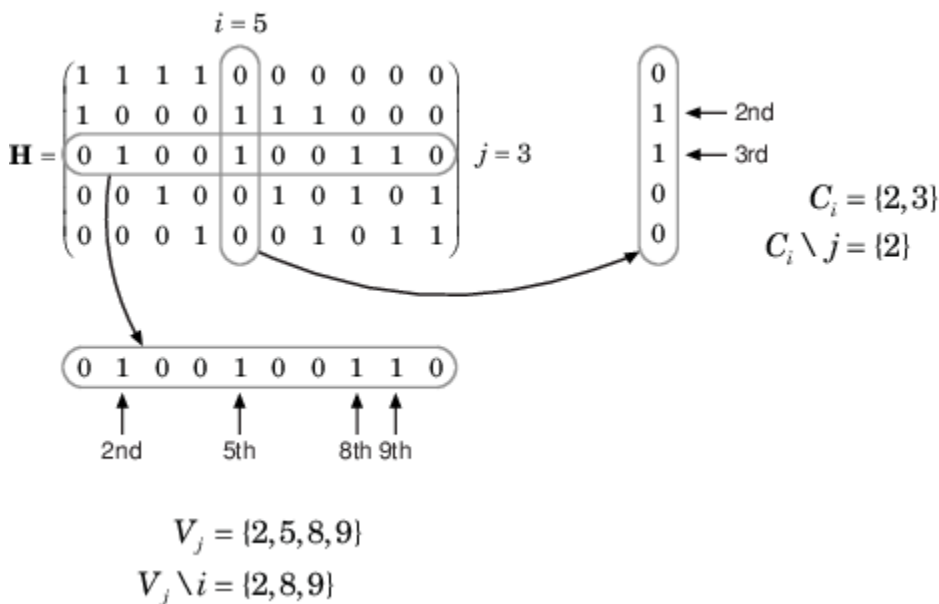

$$L(Q_i) = L(c_i) + \sum_{j' \in \mathcal{C}_i} L(r_{ji'}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ( $H c' = 0$ ) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\operatorname{atanh}(1)$  and  $\operatorname{atanh}(-1)$  are set to 19.07 and  $-19.07$ , respectively. Due to finite precision, MATLAB returns 1 for  $\tanh(19.07)$  and  $-1$  for  $\tanh(-19.07)$ .

# comm.gpu.PSKDemodulator

**Package:** comm

Demodulate signals using M-ary PSK method with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

## Description

The `comm.gpu.PSKDemodulator` object demodulates a signal that was modulated using the M-ary phase shift keying (M-PSK) method implemented on a graphics processing unit (GPU). The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the M-PSK method:

- 1 Create the `comm.gpu.PSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
gpumpskdemod = comm.PSKDemodulator
gpumpskdemod = comm.PSKDemodulator(Name=Value)
gpumpskdemod = comm.PSKDemodulator(M,phase,Name=Value)
```

### Description

`gpumpskdemod = comm.PSKDemodulator` creates a GPU-based demodulator System object that demodulates the input signal using the M-PSK method.

`gpumpskdemod = comm.PSKDemodulator(Name=Value)` sets properties using one or more name-value arguments. For example, `comm.gpu.PSKDemodulator(DecisionMethod="Hard decision")` specifies demodulation using the hard-decision method.

`gpumpskdemod = comm.PSKDemodulator(M,phase,Name=Value)` sets the `ModulationOrder` property to `M`, sets the `PhaseOffset` property to `phase`, and sets optional name-value arguments. Specify `phase` in radians.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **ModulationOrder** — Number of points in signal constellation

8 (default) | positive integer

Number of points in signal constellation, specified as a positive integer.

Data Types: `double`

### **PhaseOffset** — Phase of zeroth point in constellation

$\pi/8$  (default) | scalar

Phase of the zeroth point in the constellation in radians, specified as a scalar.

Example: `PhaseOffset=0` aligns the QPSK signal constellation points on the axes  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: `double`

### **BitOutput** — Option to output data as bits

0 or false (default) | 1 or true

Option to output data as bits, specified as a logical 0 (false) or 1 (true).

- Set this property to `false` to output data as integer values in the range  $[0, (\text{ModulationOrder} - 1)]$  with length equal to the input data vector.
- Set this property to `true` to output data as a column vector of bit values with length equal to  $\log_2(\text{ModulationOrder})$  times the number of demodulated symbols.

Data Types: `logical`

### **SymbolMapping** — Symbol encoding mapping of constellation bits

'Gray' (default) | 'Binary' | 'Custom'

Symbol encoding mapping of the constellation bits, specified as 'Gray', 'Binary', or 'Custom'. Each integer or group of  $\log_2(\text{ModulationOrder})$  bits corresponds to one symbol.

- When you set this property to 'Gray', the object maps symbols to a Gray-encoded signal constellation.
- When you set this property to 'Binary', the object maps symbols to a natural binary-encoded signal constellation. Specifically, the complex value  $e^{j(\text{PhaseOffset} + (2\pi m/\text{ModulationOrder}))}$ , where  $m$  is an integer in the range  $[0, (\text{ModulationOrder} - 1)]$ .

- When you set this property to 'Custom', the object maps symbols to the signal constellation defined in the CustomSymbolMapping property.

### CustomSymbolMapping — Custom symbol encoding

0:7 (default) | integer vector

Custom symbol encoding, specified as an integer vector with length equal to the value of ModulationOrder and unique values in the range [0, (ModulationOrder - 1)]. The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$ .

#### Dependencies

To enable this property, set the SymbolMapping property to 'Custom'.

Data Types: double

### DecisionMethod — Demodulation decision method

'Hard decision' (default) | 'Log-likelihood ratio' | 'Approximate log-likelihood ratio'

Demodulation decision method, specified as 'Hard decision', 'Log-likelihood ratio', or 'Approximate log-likelihood ratio'. When you set the BitOutput property to false, the object always performs hard-decision demodulation.

#### Dependencies

To enable this property, set the BitOutput property to true.

### VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

#### Dependencies

To enable this property, set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio'.

### Variance — Noise variance

1 (default) | positive scalar

Noise variance, specified as a positive scalar.

#### Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

### Dependencies

To enable this property, set the `BitOutput` property to `true`, the `DecisionMethod` property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', and the `VarianceSource` property to 'Property'.

Data Types: `double`

### OutputDataType — Data type of output

'Full precision' (default)

This property is read-only.

Data type of the output, specified as 'Full precision'. The output data type matches the input data type.

## Usage

### Syntax

```
y = gpumpskdemod(x)
y = gpumpskdemod(x,var)
```

### Description

`y = gpumpskdemod(x)` applies M-PSK demodulation to the input signal and returns the demodulated signal.

`y = gpumpskdemod(x,var)` uses soft decision demodulation and noise variance `var`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio', and the `VarianceSource` property to 'Input port'.

### Input Arguments

#### **x** — M-PSK-modulated signal

scalar | column vector

M-PSK-modulated signal, specified as a scalar or column vector.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see "Array Processing with GPU-Based System Objects" on page 3-698.

Data Types: `double` | `single`

#### **var** — Noise variance

scalar

Noise variance, specified as a scalar.

## Dependencies

To enable this argument, set the `VarianceSource` property to 'Input port', the `BitOutput` property to true, and the `DecisionMethod` property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio'.

Data Types: `single` | `double`

## Output Arguments

### **y** — Output signal

`scalar` | `column vector`

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. The output data type matches the input data type.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `comm.gpu.PSKDemodulator`

`constellation` Calculate or plot ideal signal constellation

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### GPU PSK Demodulator

Create a GPU PSK modulator and demodulator pair.

```
gpuMod = comm.gpu.PSKModulator;
gpuDemod = comm.gpu.PSKDemodulator;
```

Generate random data symbols. Modulate the data.

```
txData = randi([0 7],1000,1);
txSig = gpuMod(txData);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,20);
```

Demodulate the received signal.

```
rxData = gpuDemod(rxSig);
```

Determine the number of symbol errors.

```
numSymErrors = symerr(txData,rxData)
```

```
numSymErrors =  
    0
```

### Pass Data to GPU-Based System Objects Using gpuarray Input

In this example, you transmit 1/2 rate convolutionally encoded 16-PSK-modulated data through an AWGN channel, demodulate and decode the received data, and assess the error rate of the received data. For this implementation, you use the GPU-based Viterbi decoder System object™ to process multiple signal frames in a single call and then use `gpuArray` (Parallel Computing Toolbox) objects to pass data into and out of the GPU-based System objects.

Create GPU-based System objects for PSK modulation and demodulation, convolutional encoding, Viterbi decoding, and AWGN. Create a System object for error rate calculation.

```
M = 16; % Modulation order  
numframes = 100;  
  
gpuconvenc = comm.gpu.ConvolutionalEncoder;  
gpupskmod = comm.gpu.PSKModulator(M,pi/16,BitInput=true);  
gpupskdemod = comm.gpu.PSKDemodulator(M,pi/16,BitOutput=true);  
gpuawgn = comm.gpu.AWGNChannel( ...  
    NoiseMethod='Signal to noise ratio (SNR)',SNR=30);  
gpuvitdec = comm.gpu.ViterbiDecoder( ...  
    InputFormat='Hard', ...  
    TerminationMethod='Truncated', ...  
    NumFrames=numframes);  
errorrate = comm.ErrorRate(ComputationDelay=0,ReceiveDelay=0);
```

Due to the computational complexity of the Viterbi decoding algorithm, loading multiple frames of signal data on the GPU and processing them in one call can reduce overall simulation time. To enable this implementation, the GPU-based Viterbi decoder System object contains a `NumFrames` property. Instead of using an external `for`-loop to process individual frames of data, you use the `NumFrames` property to configure the GPU-based Viterbi decoder System object to process multiple data frames. Generate `numframes` of binary data frames. To efficiently manage the data frames for processing by the GPU-based System objects, represent the transmission data frames as a `gpuArray` object.

```
numsymbols = 50;  
rate = 1/2;  
dataA = gpuArray.randi([0 1],rate*numsymbols*log2(M),numframes);
```

The error rate object does not support `gpuArray` objects or multichannel data, so you must retrieve the array from the GPU by using the `gather` (Parallel Computing Toolbox) function to compute the error rate on each frame of data in a `for`-loop. Perform the GPU-based encoding, modulation, AWGN, and demodulation inside a `for`-loop.

```
for ii = 1:numframes  
    encodedData = gpuconvenc(dataA(:,ii));  
    modsig = gpupskmod(encodedData);
```

```

    noisysig = gpuawgn(modsig);
    demodsig(:,ii) = gpupskdemod(noisysig);
end

```

The GPU-based Viterbi decoder performs multiframe processing without a for-loop.

```

rxbits = gpuvitdec(demodsig(:));

errorStats = errorrate(gather(dataA(:)),gather(rxbits));
fprintf('BER = %f\nNumber of errors = %d\nTotal bits = %d', ...
        errorStats(1), errorStats(2), errorStats(3))

```

```

BER = 0.009800
Number of errors = 98
Total bits = 10000

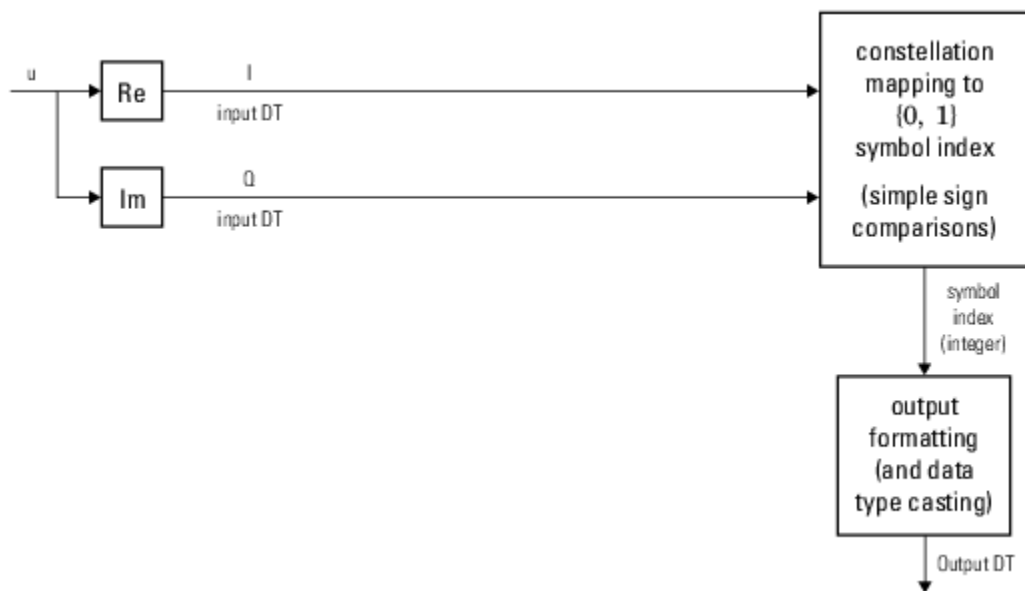

```

## More About

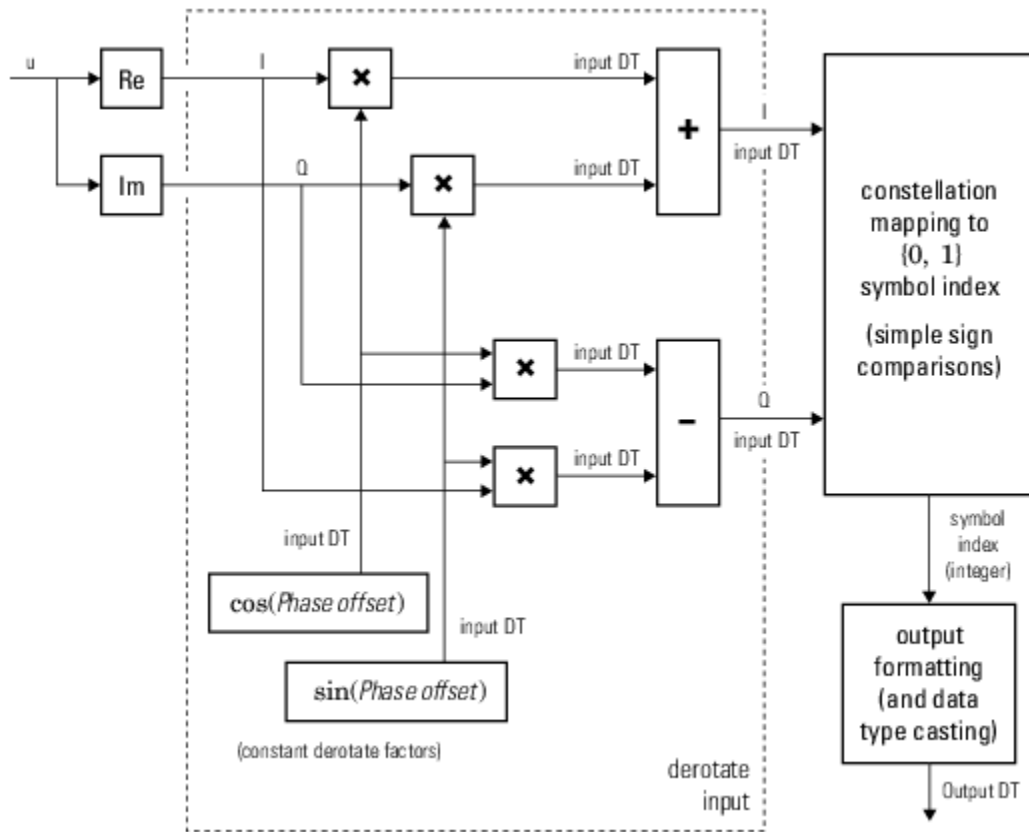

### Hard-Decision BPSK Demodulation

The signal preprocessing required for BPSK demodulation depends on the configuration.

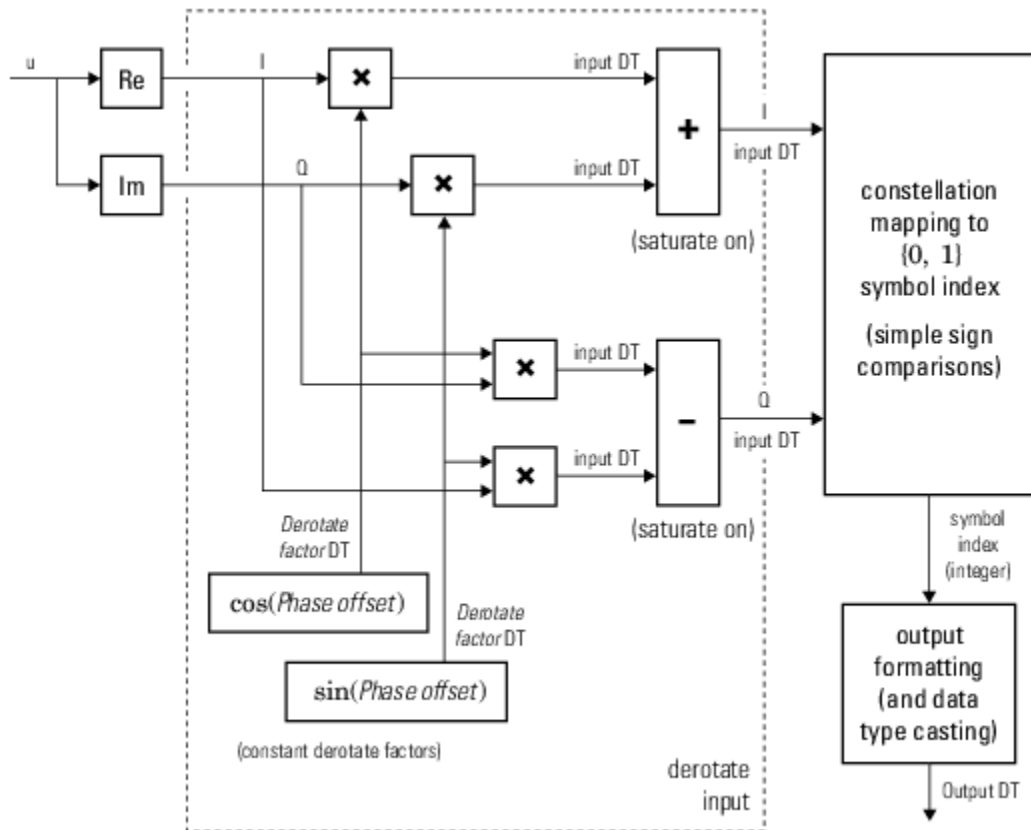

This figure shows the hard-decision BPSK demodulation signal diagram for the trivial phase offset (multiple of  $\pi/2$ ) configuration.

This figure shows the hard-decision BPSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

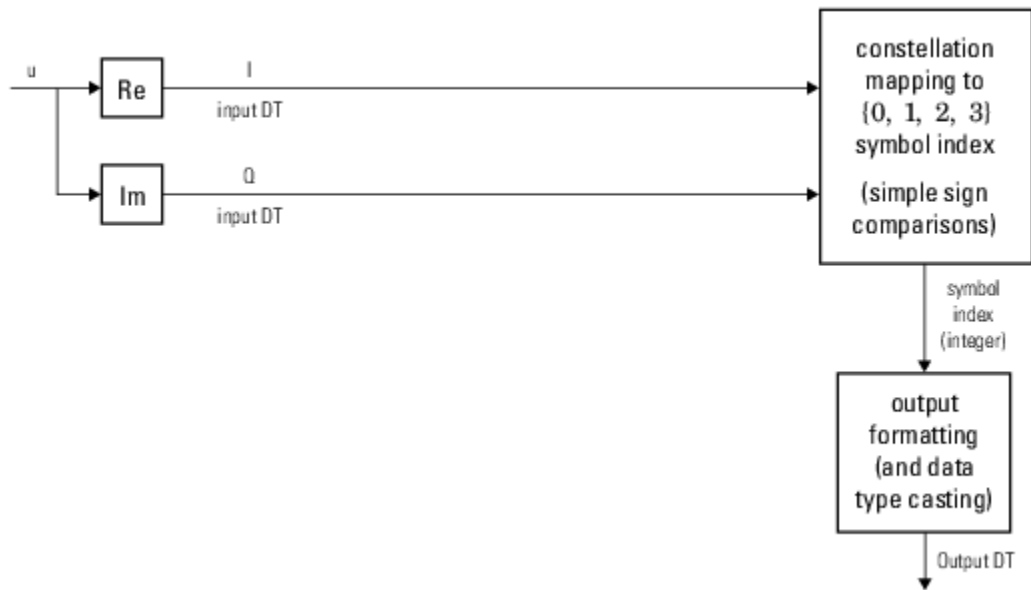

This figure shows the hard-decision BPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

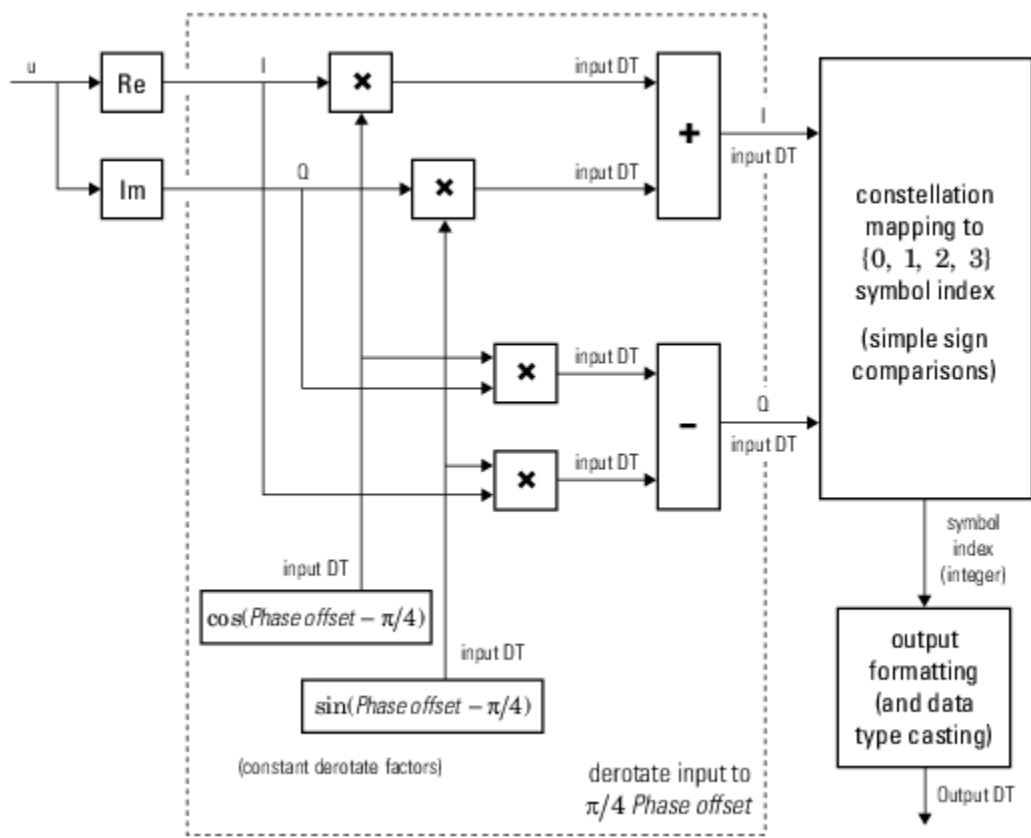

### Hard-Decision QPSK Demodulation

The signal preprocessing required for QPSK demodulation depends on the configuration.

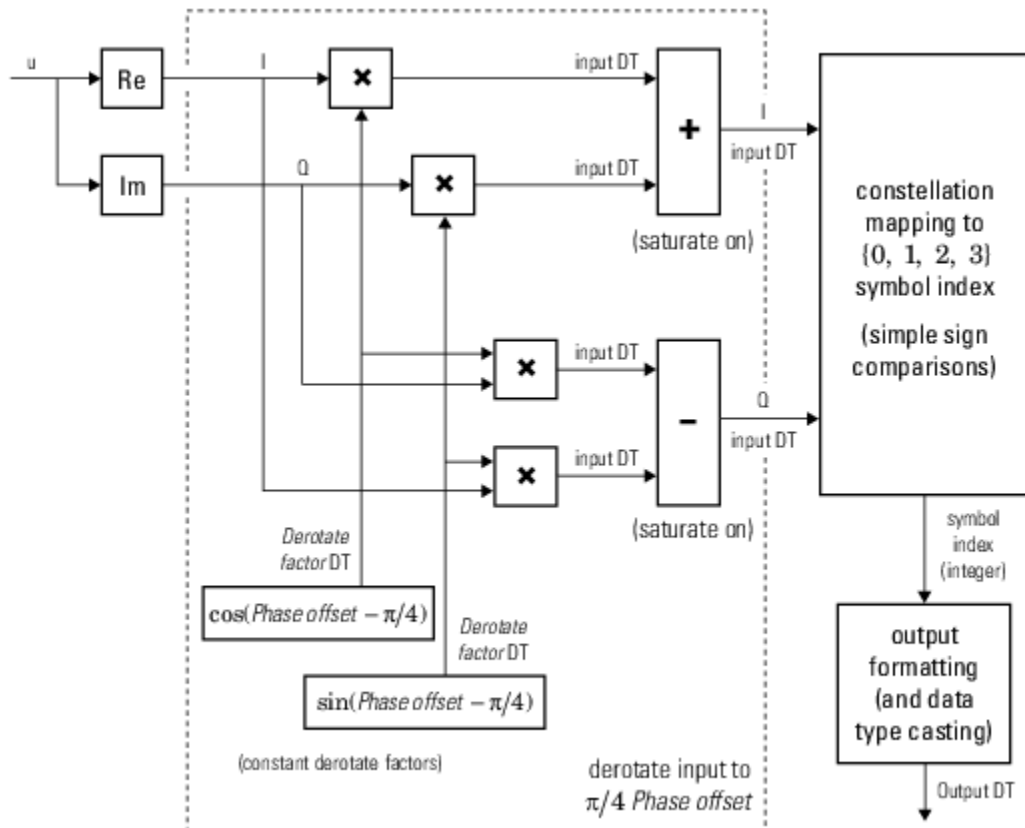

This figure shows the hard-decision QPSK demodulation signal diagram for the trivial phase offset (odd multiple of  $\pi/4$ ) configuration.

This figure shows the hard-decision QPSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

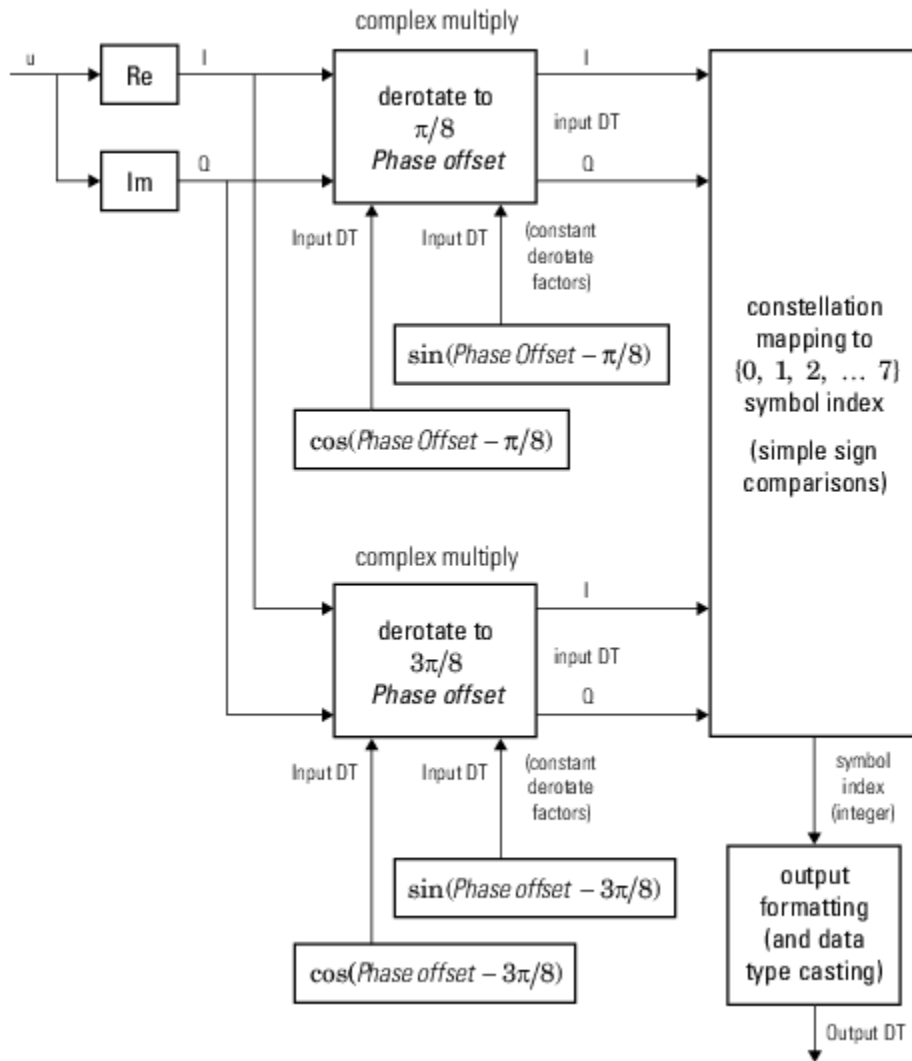

This figure shows the hard-decision QPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

### Hard-Decision Higher-Order PSK

The signal preprocessing required for higher order PSK demodulation depends on the configuration.

This figure shows the hard-decision 8-PSK demodulation signal diagram for the trivial phase offset (odd multiple of  $\pi/8$ ) configuration.

This figure shows the hard-decision 8-PSK demodulation fixed-point signal diagram for trivial phase offset (odd multiple of  $\pi/8$ ) configuration.

This figure shows the hard-decision M-PSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

For  $M > 8$ , to improve speed and implementation costs, no derotation arithmetic is performed for trivial case (specifically, when phase offset is  $0$ ,  $\pi/2$ ,  $\pi$ , or  $3\pi/2$ ).

Also, for  $M > 8$ , only double and single input types are supported.

### Array Processing with GPU-Based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see "Establish Arrays on a GPU" (Parallel Computing Toolbox).

- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## comm.gpu.PSKModulator

**Package:** comm

Modulate signals using M-PSK method with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.PSKModulator` object modulates a signal using the M-ary phase shift keying (M-PSK) method implemented on a graphics processing unit (GPU). The output is a baseband representation of the modulated signal.

To modulate a signal by using the M-PSK method:

- 1 Create the `comm.gpu.PSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpumpskmod = comm.gpu.PSKModulator
gpumpskmod = comm.gpu.PSKModulator(Name=Value)
gpumpskmod = comm.gpu.PSKModulator(M,Name=Value)
gpumpskmod = comm.gpu.PSKModulator(M,phase,Name=Value)
```

#### Description

`gpumpskmod = comm.gpu.PSKModulator` creates a GPU-based modulator System object, that modulates the input signal using the M-PSK method.

`gpumpskmod = comm.gpu.PSKModulator(Name=Value)` sets properties using one or more name-value arguments. For example, `comm.gpu.PSKModulator(BitInput=true)` specifies that input values must be binary.

`gpumpskmod = comm.gpu.PSKModulator(M,Name=Value)` sets the `ModulationOrder` property to `M` and sets optional name-value arguments.

`gpumpskmod = comm.gpu.PSKModulator(M,phase,Name=Value)` sets the `ModulationOrder` property to `M`, sets the `PhaseOffset` property to `phase`, and sets optional name-value arguments. Specify `phase` in radians.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### ModulationOrder — Number of points in signal constellation

8 (default) | positive integer

Number of points in the signal constellation, specified as a positive integer.

Data Types: `double`

### PhaseOffset — Phase of zeroth point of constellation

$\pi/8$  (default) | scalar

Phase of the zeroth point of the constellation in radians, specified as a scalar.

Example: `PhaseOffset=0` aligns the QPSK signal constellation points on the axes  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: `double`

### BitInput — Option to provide input in bits

0 or false (default) | 1 or true

Option to provide input in bits, specified as a numeric or logical 0 (false) or 1 (true).

- If you set this property to `false`, the input values must be integers in the range  $[0, (\text{ModulationOrder} - 1)]$ .
- If you set this property to `true`, the input values must be binary and the input vector length must be an integer multiple of the number of bits per symbol,  $\log_2(\text{ModulationOrder})$ .

Data Types: `logical`

### SymbolMapping — Symbol encoding mapping of constellation bits

'Gray' (default) | 'Binary' | 'Custom'

Symbol encoding mapping of the constellation bits, specified as 'Gray', 'Binary', or 'Custom'. Each integer or group of  $\log_2(\text{ModulationOrder})$  bits corresponds to one symbol.

- When you set this property to 'Gray', the object maps symbols to a Gray-encoded signal constellation.
- When you set this property to 'Binary', the object maps symbols to a natural binary-encoded signal constellation. Specifically, the complex value  $e^{j(\text{PhaseOffset} + (2m/\text{ModulationOrder}))}$ , where  $m$  is an integer in the range  $[0, (\text{ModulationOrder} - 1)]$ .

- When you set this property to 'Custom', the object maps symbols to the signal constellation defined in the CustomSymbolMapping property.

**CustomSymbolMapping — Custom constellation encoding**

0:7 (default) | integer vector

Custom symbol encoding, specified as an integer vector with length equal to the value of ModulationOrder and unique values in the range [0, (ModulationOrder - 1)]. The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$ .

**Dependencies**

To enable this property, set the SymbolMapping property to 'Custom'.

Data Types: double

**OutputDataType — Output datatype**

'double' (default) | 'single'

Output data type, specified as either 'double' or 'single'.

**Usage****Syntax**

```
y = gpumpskmod(x)
```

**Description**

`y = gpumpskmod(x)` modulates the input signal by using the M-PSK method. The output is the modulated M-PSK baseband signal.

**Input Arguments****x — Input signal**

column vector

Input signal, specified as a column vector of integers or bits. The BitInput property specifies the expected input values and vector length.

To decrease data transfer latency, format the input signal as a gpuArray object. For more information, see “Array Processing with GPU-Based System Objects” on page 3-706.

Data Types: double | single

**Output Arguments****y — M-PSK modulated baseband signal**

vector

M-PSK modulated baseband signal, returned as a scalar or vector of complex-valued constellation symbols. The OutputDataType property specifies the data type of the output.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.gpu.PSKModulator`

`constellation` Calculate or plot ideal signal constellation

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### GPU PSK Modulator

Create binary data for 100, 4-bit symbols.

```
data = randi([0 1],400,1);
```

Create a 16-PSK modulator System object™ with bits as inputs and Gray-coded signal constellation. Change the phase offset to  $\pi/16$ .

```
gpupskmod = comm.gpu.PSKModulator(16,'BitInput',true);
gpupskmod.PhaseOffset = pi/16;
```

Modulate and plot the data. Also, use the `constellation` object function to display the configured constellation.

```
modData = gpupskmod(data);
scatterplot(modData)
```

constellation(gpupskmod)

### Pass Data to GPU-Based System Objects Using gpuarray Input

In this example, you transmit 1/2 rate convolutionally encoded 16-PSK-modulated data through an AWGN channel, demodulate and decode the received data, and assess the error rate of the received data. For this implementation, you use the GPU-based Viterbi decoder System object™ to process multiple signal frames in a single call and then use `gpuArray` (Parallel Computing Toolbox) objects to pass data into and out of the GPU-based System objects.

Create GPU-based System objects for PSK modulation and demodulation, convolutional encoding, Viterbi decoding, and AWGN. Create a System object for error rate calculation.

```
M = 16; % Modulation order
numframes = 100;
```

```
gpuconvenc = comm.gpu.ConvolutionalEncoder;
gpupskmod = comm.gpu.PSKModulator(M,pi/16,BitInput=true);
gpupskdemod = comm.gpu.PSKDemodulator(M,pi/16,BitOutput=true);
```

```
gpuawgn = comm.gpu.AWGNChannel( ...  
    NoiseMethod='Signal to noise ratio (SNR)',SNR=30);  
gpuvitdec = comm.gpu.ViterbiDecoder( ...  
    InputFormat='Hard', ...  
    TerminationMethod='Truncated', ...  
    NumFrames=numframes);  
errorrate = comm.ErrorRate(ComputationDelay=0,ReceiveDelay=0);
```

Due to the computational complexity of the Viterbi decoding algorithm, loading multiple frames of signal data on the GPU and processing them in one call can reduce overall simulation time. To enable this implementation, the GPU-based Viterbi decoder System object contains a NumFrames property. Instead of using an external for-loop to process individual frames of data, you use the NumFrames property to configure the GPU-based Viterbi decoder System object to process multiple data frames. Generate numframes of binary data frames. To efficiently manage the data frames for processing by the GPU-based System objects, represent the transmission data frames as a gpuArray object.

```
numsymbols = 50;  
rate = 1/2;  
dataA = gpuArray.randi([0 1],rate*numsymbols*log2(M),numframes);
```

The error rate object does not support gpuArray objects or multichannel data, so you must retrieve the array from the GPU by using the gather (Parallel Computing Toolbox) function to compute the error rate on each frame of data in a for-loop. Perform the GPU-based encoding, modulation, AWGN, and demodulation inside a for-loop.

```
for ii = 1:numframes  
    encodedData = gpuconvenc(dataA(:,ii));  
    modsig = gpupskmod(encodedData);  
    noisysig = gpuawgn(modsig);  
    demodsig(:,ii) = gpupskdemod(noisysig);  
end
```

The GPU-based Viterbi decoder performs multiframe processing without a for-loop.

```
rxbits = gpuvitdec(demodsig(:));  
  
errorStats = errorrate(gather(dataA(:)),gather(rxbits));  
fprintf('BER = %f\nNumber of errors = %d\nTotal bits = %d', ...  
    errorStats(1), errorStats(2), errorStats(3))
```

```
BER = 0.009800  
Number of errors = 98  
Total bits = 10000
```

## More About

### Array Processing with GPU-Based System Objects

A GPU-based System object accepts typical MATLAB arrays or gpuArray objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a gpuArray object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a gpuArray object. Passing gpuArray arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## Algorithms

For binary-encoding, the output baseband signal maps input bits or integers to complex symbols according to:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \{0, 1, \dots, M-1\}.$$

When the input is configured for bits, groups of  $\log_2(M)$  bits represent the complex symbols for the configured symbol mapping. The mapping can be binary encoded, Gray encoded, or custom encoded.

Gray coding has the advantage that only one bit changes between adjacent constellation points, which results in better bit error rate performance. This table shows the mapping between the input and output symbols for 8-PSK modulation with Gray coding.

Input	Output
0	0 (000)
1	1 (001)
2	3 (011)
3	2 (010)
4	6 (110)
5	7 (111)
6	5 (101)
7	4 (100)

This constellation diagram shows the corresponding symbols and their binary values.

**Package:** comm.gpu

Decode input signal using turbo decoding with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.TurboDecoder` System object decodes the input signal by using a parallel concatenated decoding scheme on a graphics processing unit (GPU). This decoding scheme uses the a-posteriori probability (APP) decoder as the constituent decoder. The constituent decoders use the same trellis structure and algorithm.

To decode an input signal using a turbo decoding scheme:

- 1 Create the `comm.gpu.TurboDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpuTurboDec = comm.gpu.TurboDecoder  
gpuTurboDec = comm.gpu.TurboDecoder(trellis,interlvrIndices,numIter)  
gpuTurboDec = comm.gpu.TurboDecoder( ___,Name,Value)
```

#### Description

`gpuTurboDec = comm.gpu.TurboDecoder` creates a GPU-based turbo decoder System object. This object uses an APP constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`gpuTurboDec = comm.gpu.TurboDecoder(trellis,interlvrIndices,numIter)` sets the `TrellisStructure` property to `trellis`, the `InterleaverIndices` property to `interlvrIndices`, and the `NumIterations` property to `numIter`.

`gpuTurboDec = comm.gpu.TurboDecoder( ___,Name,Value)` sets properties using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, `'NumIterations',10` specifies the number of decoding iterations used for each call to the System object.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **TrellisStructure** — Trellis description of constituent convolutional code

`poly2trellis(4, [13 15], 13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate  $K/N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

---

**Note**  $K$  must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1345.

---

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

#### **numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

#### **numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

#### **numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

#### **nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

#### **outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: struct

**InterleaverIndicesSource — Source of interleaver indices**

'Property' (default)

Source of interleaver indices, specified as 'Property'. The only valid setting for this property is Property, which uses the interleaver indices that you specify in the InterleaverIndices property.

Data Types: char | string

**InterleaverIndices — Interleaver indices**

(64:-1:1)' (default) | column vector of integers

Interleaver indices that define the mapping used to permute the codeword bits input to the decoder, specified as a column vector of integers. The vector must be of length  $L$ . Each element of the vector must be an integer in the range  $[1, L]$  and must be unique.  $L$  is the length of the decoded output message, dec.

Data Types: double

**Algorithm — Decoding algorithm**

'True APP' (default)

Decoding algorithm, specified as 'True APP'. The only valid setting is 'True APP', which implements true APP decoding.

Data Types: char | string

**NumIterations — Number of decoding iterations**

6 (default) | positive integer

Number of decoding iterations, specified as a positive integer. This property sets the number of decoding iterations used for each call to the object.

Data Types: double

**NumFrames — Number of independent frames**

1 (default) | positive integer

Number of independent frames present in the input and output data vectors, specified as a positive integer.

The object segments the input vector into NumFrames segments and decodes them independently. The output contains NumFrames decoded segments.

Data Types: double

## Usage

### Syntax

```
dec = gpuTurboDec(codeword)
```

### Description

`dec = gpuTurboDec(codeword)` decodes the input data by using the parallel concatenated convolutional coding scheme. If the host computer has a GPU configured, the processing utilizes the GPU. Otherwise, the processing uses the CPU. The output is the decoded data.

### Input Arguments

#### **codeword** — Parallel concatenated codeword

column vector

Parallel concatenated codeword, specified as a column vector.

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see “Array Processing with GPU-based System Objects” on page 3-715.

Data Types: `double` | `single`

### Output Arguments

#### **dec** — Decoded message

binary-valued column vector

Decoded message, returned as a binary-valued column vector. The output signal is the same data type as the input. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the object is the hard-decision output of the final LLR update.

When the constituent convolutional code represents a rate  $1/N$  code, the object sets the length `dec` to  $(M-2 \times N_{\text{Tails}})/(2 \times N-1)$ .  $M$  is the input vector length, and  $N_{\text{Tails}}$  is given by  $\log_2(\text{TrellisStructure.numStates}) \times N$ . The length of `dec` equals the length of the interleaver indices.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### GPU-Based Turbo Decode BPSK Modulated Data

Transmit turbo-encoded blocks of BPSK-modulated data over a AWGN channel. Decode individual data frames by using a GPU-based turbo decoder System object and accumulate error statistics. Display the errors statistics after processing all of the data frames.

Specify the frame length. To produce repeatable results, use the random stream property with the seed set.

```
framelen = 256;
s = RandStream('mt19937ar',Seed=11);
```

Create a turbo encoder System object and GPU-based turbo decoder System object. Define the trellis structure for the constituent convolutional code by using the `poly2trellis` function. Generate the interleaver indices as a random column vector of unique integers that define the mapping used to permute the input bits at the encoder and decoder by using the `randperm` function.

```
intrlvrIndices = randperm(s,framelen);
trellis = poly2trellis(4,[13 15 17],13);
turboEnc = comm.TurboEncoder( ...
    TrellisStructure=trellis, ...
    InterleaverIndices=intrlvrIndices);
turboDec = comm.gpu.TurboDecoder( ...
    TrellisStructure=trellis, ...
    InterleaverIndices=intrlvrIndices, ...
    NumIterations=4);
```

Define the modulation order for BPSK modulation. Define the SNR level for the AWGN channel. Create an error rate System object to calculate error statistics. Run the simulation and calculate error results by comparing the original data to the received data.

```
M = 2; % BPSK modulation
snr = 2; % dB
numframes = 100;
errorRate = comm.ErrorRate;

for ii = 1:numframes
    data = randi(s,[0 1],framelen,1);
    encodedData = turboEnc(data);
    modSignal = pskmod(encodedData,M);
    rxsig = awgn(modSignal,2);
    demodsig = pskdemod(rxsig,M);
    rxbits = turboDec(demodsig);
    errorStats = errorRate(data,rxbits);
end
fprintf('BER = %f\nNumber of errors = %d\nTotal bits = %d\n', ...
    errorStats(1),errorStats(2),errorStats(3))

BER = 0.001680
Number of errors = 43
Total bits = 25600
```

## More About

### Array Processing with GPU-based System Objects

A GPU-based System object accepts typical MATLAB arrays or `gpuArray` objects. The output signal data type matches the input signal data type.

- When the input signal to the GPU-based System object is a `gpuArray` object, calculations take place entirely on the GPU, the data remains on the GPU, and the output signal is a `gpuArray` object. Passing `gpuArray` arguments minimizes data transfer latency by limiting the number of data transfers between the CPU and the GPU when your simulation runs. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).
- When the input signal is a MATLAB array, the GPU-based System object transfers the data between the CPU and the GPU for each object call. The output signal is a MATLAB array and data transfer latency occurs.

## Version History

Introduced in R2012a

## Extended Capabilities

### GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Accelerate Simulation Using GPUs”.

## comm.gpu.ViterbiDecoder

**Package:** comm

Decode convolutionally encoded data using Viterbi algorithm with GPU

---

**Note** To use this object, you must install Parallel Computing Toolbox™ and have access to a supported GPU. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. For more information about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

---

### Description

The `comm.gpu.ViterbiDecoder` System object decodes convolutionally encoded input symbols to produce binary output symbols by using Viterbi algorithm with a graphics processing unit (GPU).

To decode convolutionally encoded data using the Viterbi algorithm:

- 1 Create the `comm.gpu.ViterbiDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
gpuViterbiDec = comm.gpu.ViterbiDecoder
gpuViterbiDec = comm.gpu.ViterbiDecoder(trellis)
gpuViterbiDec = comm.gpu.ViterbiDecoder( ____,Name,Value)
```

#### Description

`gpuViterbiDec = comm.gpu.ViterbiDecoder` creates a GPU-based Viterbi decoder System object.

`gpuViterbiDec = comm.gpu.ViterbiDecoder(trellis)` sets the `TrellisStructure` property to `trellis`.

`gpuViterbiDec = comm.gpu.ViterbiDecoder( ____,Name,Value)` sets properties using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, `gpuViterbiDec = comm.gpu.ViterbiDecoder(TerminationMethod="Continuous")` specifies the termination method as continuous and saves the internal state metric at the end of each frame for use with the next frame.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### TrellisStructure — Trellis structure of convolutional code

`poly2trellis(7,[171 133])` (default) | structure

Trellis description of the convolutional code, specified as a structure that contains the trellis description for a rate  $K / N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

#### **numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

#### **numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

#### **numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

#### **nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

#### **outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: `struct`

**InputFormat — Input format to decoder**

"Unquantized" (default) | "Hard" | "Soft"

Input format to the decoder, specified as one of these values.

- "Unquantized" — The input data must be a real-valued vector of double- or single-precision soft decision values that are unquantized. The object maps positive values to logical 0s and negative values to logical 1s.
- "Hard" — The input must be a vector of hard decision values, which are 0s or 1s. The data type of the inputs must be double precision or single precision.
- "Soft" — The input requires a vector of quantized soft decision values that are represented as integers between 0 and  $2^{\text{SoftInputWordLength}} - 1$ . The data type of the inputs must be double precision or single precision.

**SoftInputWordLength — Soft decision input word length**

4 (default) | integer

Soft decision input word length that represents the number of bits for each quantized soft input value, specified as an integer.

**Dependencies**

To enable this property, set the InputFormat property to "Soft".

Data Types: double

**InvalidQuantizedInputAction — Option to take action for invalid quantized input**

"Ignore" (default)

Option to take action for an invalid quantized input, specified as "Ignore". The only valid setting is "Ignore", which ignores out-of-range inputs.

**TracebackDepth — Traceback depth**

34 (default) | integer in the range [0, 256]

Traceback depth, specified as an integer in the range [0, 256]. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay. For more information, see "Traceback and Decoding Delay" on page 3-1370 and "Traceback Depth Estimates" on page 3-1370.

When you set the TerminationMethod property to "Continuous", the decoding delay consists of TracebackDepth zero symbols or TracebackDepth zero bits for a rate 1/N convolutional code.

When you set the TerminationMethod property to "Truncated" or "Terminated", no output delay is present. The TracebackDepth value must be less than or equal to the number of symbols in each input. If the code rate is 1/2, a typical traceback depth value is about five times the constraint length of the code.

Data Types: double

**TerminationMethod — Termination method of encoded frame**

"Continuous" (default) | "Truncated" | "Terminated"

Termination method of the encoded frame, specified as one of these values.

- "Continuous" — The System object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently. Use this option when the input signal contains only one symbol.
- "Truncated" — The System object treats each frame independently. The traceback path starts at the state with the best metric and ends in the all-zeros state.
- "Terminated" — The System object treats each frame independently. The traceback path starts and ends in the all-zeros state.

### **ResetInputPort — Option to enable decoder reset input**

false or 0 (default) | true or 1

Option to enable the decoder reset input, specified as a numeric or logical 0 (false) or 1 (true). Set this property to true to enable additional input to the object. When this additional reset input is a nonzero value, the internal states of the decoder reset to their initial conditions.

#### **Dependencies**

To enable this property, set the TerminationMethod property to "Continuous".

Data Types: logical | numeric

### **DelayedResetAction — Option to delay output reset**

false or 0 (default)

Option to delay the output reset, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

### **PuncturePatternSource — Source of puncture pattern**

"None" (default) | "Property"

Source of the puncture pattern, specified as one of these values.

- "None" — The object does not apply puncturing.
- "Property" — The object decodes the punctured codewords based on a puncture pattern vector that you specify in the PuncturePattern property.

### **PuncturePattern — Puncture pattern vector**

[1; 1; 0; 1; 0; 1] (default) | column vector

Puncture pattern vector to puncture the decoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of the punctured bits. This puncture pattern must match the puncture pattern used by the convolutional encoder.

#### **Dependencies**

To enable this property, set the PuncturePatternSource property to "Property".

Data Types: double

**ErasuresInputPort** — Option to enable specification of erasures in input symbols

false or 0 (default)

Option to enable the specification of erasures in the input symbols, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

**OutputDataType** — Data type of output

"Full precision" (default)

Data type of the output, specified as "Full precision". The only valid setting is "Full precision", which makes the output data type match the input data type.

**NumFrames** — Number of independent frames

1 (default) | integer

Number of independent frames present in the input and output data vectors, specified as an integer.

The object segments the input vector into NumFrames segments and decodes them independently. The output contains NumFrames decoded segments.

**Dependencies**

To enable this property, set the TerminationMethod property to "Truncated" or "Terminated".

Data Types: double

## Usage

### Syntax

```
decmsg = gpuViterbiDec(codeword)  
decmsg = gpuViterbiDec(codeword, resetstate)
```

**Description**

decmsg = gpuViterbiDec(codeword) decodes the convolutionally encoded input data by using the GPU-based Viterbi decoding algorithm. The output is the decoded data.

decmsg = gpuViterbiDec(codeword, resetstate) specifies the input to reset the internal states of the decoder. To enable this syntax, set the TerminationMethod property to "Continuous" and the ResetInputPort property to true.

**Input Arguments****codeword** — Convolutionally encoded message

column vector

Convolutionally encoded message, specified as a column vector. The data type and element value in the codeword depend on the value of the InputFormat property.

If the convolutional code uses an alphabet of  $2^N$  possible output symbols, the length of this input vector must be  $L \times N$  for some positive integer  $L$ .

To decrease data transfer latency, format the input signal as a `gpuArray` object. For more information, see "Array Processing with GPU-based System Objects" on page 3-722.

Data Types: `double` | `single`

### **resetstate — Reset internal states of decoder**

`false` or `0` (default) | `true` or `1`

Reset for internal states of the decoder, specified as a logical `0` (`false`) or `1` (`true`).

#### **Dependencies**

To enable this argument, set the `TerminationMethod` property to "Continuous" and the `ResetInputPort` property to `true`.

Data Types: `double` | `logical`

#### **Output Arguments**

##### **decmsg — Decoded message**

binary-valued column vector

Decoded message, returned as a binary-valued column vector. This output vector has the same data type as input `codeword`.

If the decoded data uses an alphabet of  $2^K$  possible output symbols, the length of this output vector is  $L \times K$ .  $L$  is the length of the input message.

Data Types: `double` | `single`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Specific to comm.gpu.ViterbiDecoder**

`info` Characteristic information of GPU-based Viterbi decoder

## **Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## **Examples**

### GPU-Based Convolutionally Encode and Viterbi Decode 8-PSK Modulated Data

Create a GPU-based convolutional encoder System object.

```
conEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based phase shift keying (PSK) modulator System object that accepts a bit input signal.

```
modPSK = comm.gpu.PSKModulator(BitInput=true);
```

Create a GPU-based additive white Gaussian noise (AWGN) channel System object with a signal-to-noise ratio of seven.

```
chan = comm.gpu.AWGNChannel( ...  
    NoiseMethod='Signal to noise ratio (SNR)', ...  
    SNR=7);
```

Create a GPU-based PSK demodulator System object that outputs a column vector of bit values.

```
demodPSK = comm.gpu.PSKDemodulator(BitOutput=true);
```

Create a GPU-based Viterbi decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
vDec = comm.gpu.ViterbiDecoder(InputFormat='Hard');
```

Create an error rate System object that ignores 3 data samples before making comparisons. The received data lags behind the transmitted data by 34 samples.

```
error = comm.ErrorRate(ComputationDelay=3,ReceiveDelay=34);
```

Run the simulation by using this for-loop to process data.

```
for counter = 1:20  
    data = randi([0 1],30,1);  
    encodedData = conEnc(gpuArray(data));  
    modSignal = modPSK(encodedData);  
    receivedSignal = chan(modSignal);  
    demodSignal = demodPSK(receivedSignal);  
    receivedBits = vDec(demodSignal);  
    errors = error(data,gather(receivedBits));  
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 26
```

## gsmDownlinkConfig

Create GSM downlink TDMA frame configuration object

### Description

The `gsmDownlinkConfig` object is a GSM downlink TDMA frame configuration object. Use `gsmDownlinkConfig` objects to create GSM downlink waveforms.

### Creation

#### Syntax

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl = gsmDownlinkConfig( ____, Name, Value)
```

#### Description

`cfggsmdl = gsmDownlinkConfig` creates a GSM downlink TDMA frame configuration object.

`cfggsmdl = gsmDownlinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmdl = gsmDownlinkConfig( ____, Name, Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime', 4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

### Properties

#### **SamplesPerSymbol** — Samples per symbol

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

#### **BurstType** — Burst types

`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB" | "FB" | "SB" | "Dummy" | "Off"`

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"FB"`, `"SB"`, `"Dummy"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"FB"` — Transmit data using a frequency correction burst for every time slot.

- "SB" — Transmit data using a time synchronization burst for every time slot.
- "Dummy" — Transmit data using a dummy burst for every time slot.
- "Off" — All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-737.

---

**Note** The `BurstType` property is an enumeration. To perform code generation, see "Code Generation" on page 3-758 and the "MEX Generation for GSM Downlink Waveform" on page 3-732 example.

---

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

### TSC — Training sequence code

[0 1 2 3 4 5 6 7] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-739.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

### Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

### Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

### RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration

$(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$  must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-737.

Data Types: `double`

#### **RiseDelay — Burst rise delay**

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range  $[-10, 10]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration  $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$  must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-737.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude  $\text{RiseDelay}$  symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude  $\text{RiseDelay}$  symbols before the start of the useful part.

Data Types: `double`

#### **FallTime — Burst fall time**

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range  $[1/\text{SamplesPerSymbol}, 29]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration  $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$  must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-737.

Data Types: `double`

#### **FallDelay — Burst fall delay**

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range  $[-10, 10]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration  $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$  must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-737.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude  $\text{FallDelay}$  symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude  $\text{FallDelay}$  symbols before the end of the useful part.

Data Types: `double`

## **Examples**

## Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig

cfggsmdl =
  gsmDownlinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
BurstLengthInSamples: 2500
FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Downlink Waveform with Specified Samples per Symbol

Create a GSM downlink TDMA frame configuration object that specifies 8 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object, specifying 8 samples per symbols.

```
sps = 8;
cfggsmdl = gsmDownlinkConfig(sps)

cfggsmdl =
  gsmDownlinkConfig with properties:
    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 8
    TSC: [0 1 2 3 4 5 6 7]
    Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 2.1667e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 1250
    FrameLengthInSamples: 10000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Downlink Waveform with Specified Attenuation

Create two GSM downlink TDMA frame configuration objects. Specify default settings for the first `gsmDownlinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```

cfggsmdl = gsmDownlinkConfig

cfggsmdl =
    gsmDownlinkConfig with properties:
        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
        SamplesPerSymbol: 16
        TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 0]
        RiseTime: 2
        RiseDelay: 0
        FallTime: 2
        FallDelay: 0
    
```

Create another GSM downlink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmdl2 = gsmDownlinkConfig('Attenuation',[1 0 3 4 5 6 4 2])

cfggsmdl2 =
  gsmDownlinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [1 0 3 4 5 6 4 2]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames have are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
waveform2 = gsmFrame(cfggsmdl2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### MEX Generation for GSM Downlink Waveform

Generate and run a GSM waveform MEX function from the helper function `createDownlinkWaveform`. The `createDownlinkWaveform` helper function creates a GSM downlink waveform.

### Write MATLAB Function

Open `createDownlinkWaveform.m` to see the code. The `createDownlinkWaveform` helper function generates a GSM downlink waveform by using the `gsmDownlinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

### Generate GSM Waveform

Use the `createDownlinkWaveform` helper function to create a GSM waveform containing two TDMA frames, and then plot the waveform.

```
[x,t] = createDownlinkWaveform(2);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Downlink Waveform - Amplitude');
```

```

xlabel('Time (ms)');
ylabel('Amplitude');
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

### Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function `createDownlinkWaveform_mex`. Generate a MEX function from the `createDownlinkWaveform` helper function, and then run the MEX function to create two TDMA frames.

```
codegen createDownlinkWaveform -args 3
```

Code generation successful.

### Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateDownlinkFrame` helper function or `createDownlinkWaveform_mex` function.

```
[x,t] = createDownlinkWaveform_mex(2);
```

```

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Downlink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

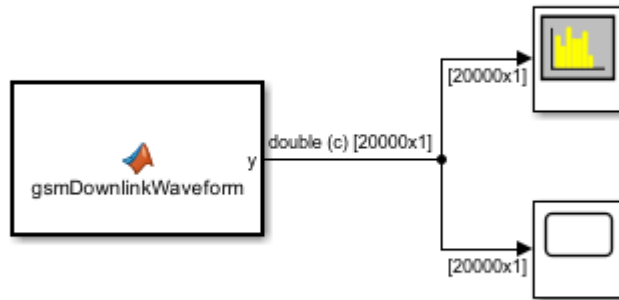

### GSM Downlink Waveform Generation in Simulink

Model a GSM waveform generator in Simulink® by using the MATLAB® Function block and Communications Toolbox™ functions.

#### GSM Downlink Waveform Generation

The MATLAB Function (Simulink) block contains the `gsmDownlinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmDownlinkConfig` object and the `gsmFrame` function.

## GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmDownlinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM downlink TDMA frame shown is this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	FrequencyCorrection burst	0 dB
2	Normal burst	3 dB
3	Synchronization burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Dummy burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

### Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmDownlinkWaveform` function code is set to the GSM symbol rate of  $1625e3/6$  symbols per second. Display the current `gsmDownlinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo =
  struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
      BandwidthTimeProduct: 0.3000
      BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
      BurstLengthInSamples: 2500
```

FrameLengthInSamples: 20000

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

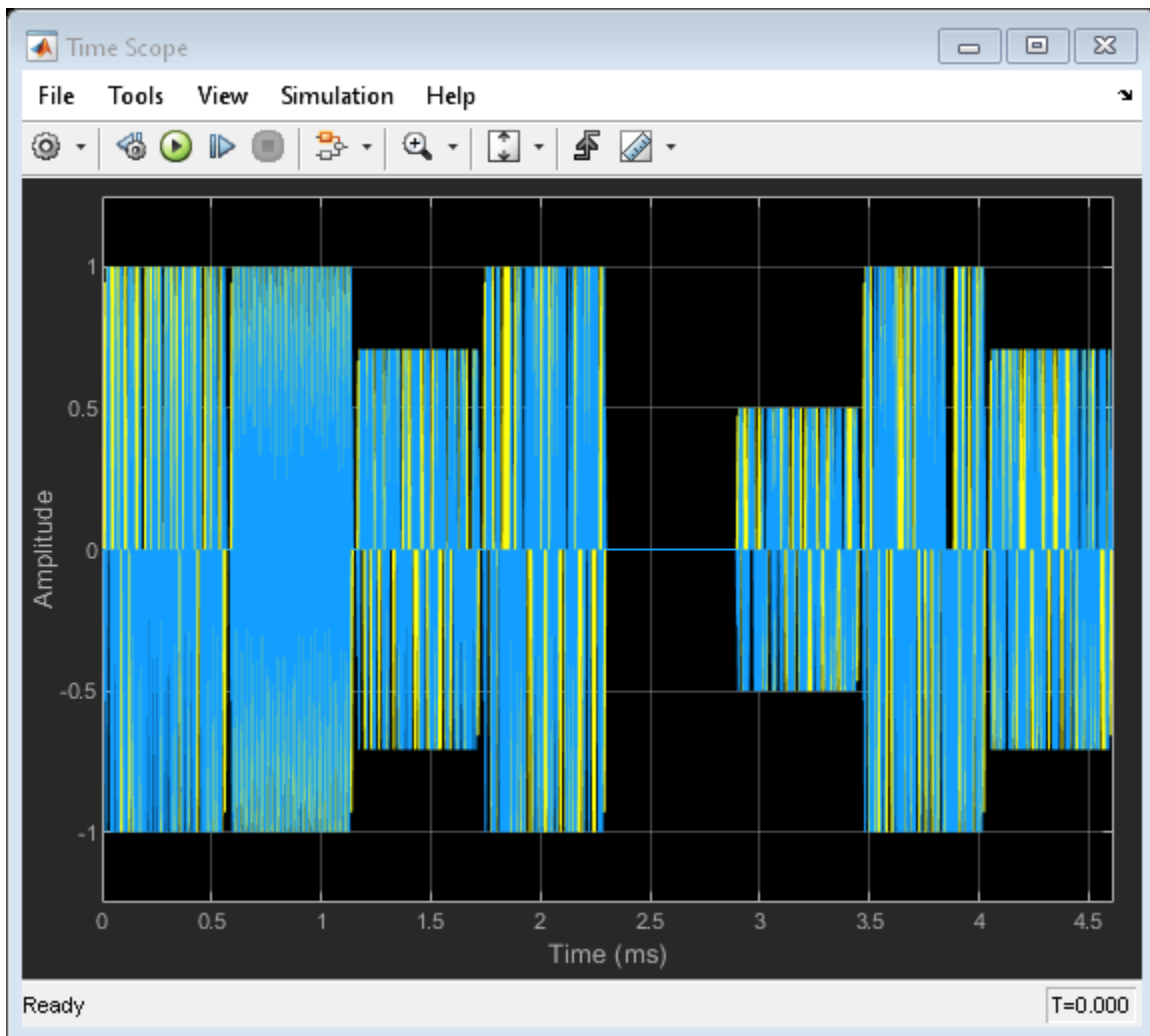

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmDownlinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

### Results

Display the time domain signal and the spectrogram by running the simulation.

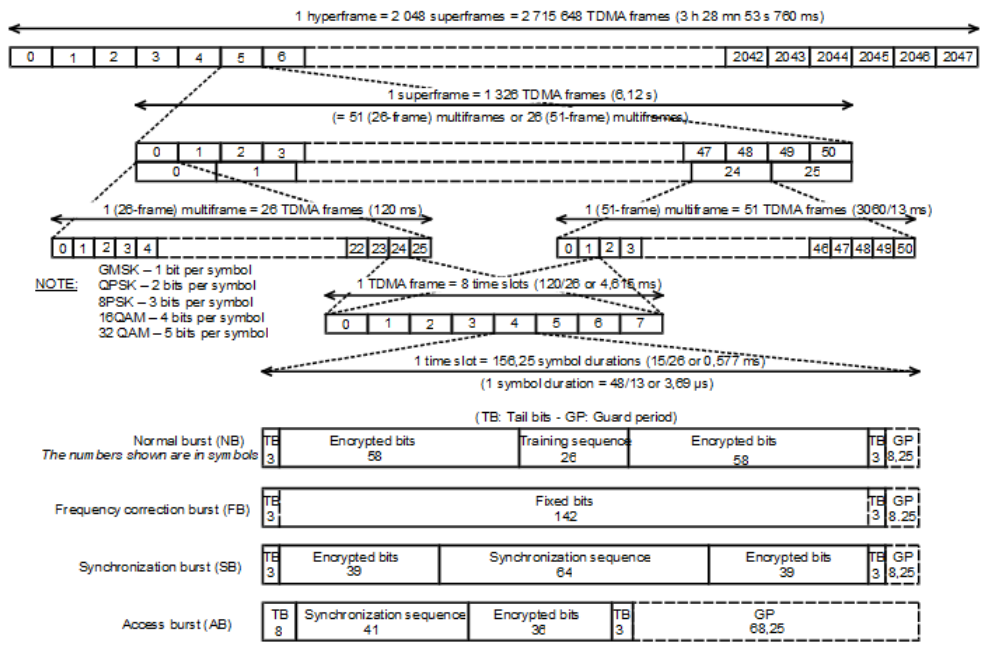

## More About

### GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of  $15/26$  ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

*Useful duration*, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

### Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` [property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.FB`, `gsmDownlinkBurstType.SB`, `gsmDownlinkBurstType.Dummy`, and `gsmUplinkBurstType.Off`. For example, this code assigns a frequency correction burst in time slot 2 and 5.

```
cfg = gsmDownlinkConfig
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```

    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

```
cfg.BurstType([2 5] +1) = gsmDownlinkBurstType.FB
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```

    BurstType: [NB    NB    FB    NB    NB    FB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

## **gsmUplinkConfig**

Create GSM uplink TDMA frame configuration object

### **Description**

The `gsmUplinkConfig` object is a GSM uplink TDMA frame configuration object. Use `gsmUplinkConfig` objects to create GSM uplink waveforms.

### **Creation**

#### **Syntax**

```
cfggsmul = gsmUplinkConfig
cfggsmul = gsmUplinkConfig(sps)
cfggsmul = gsmUplinkConfig( ____, Name, Value)
```

#### **Description**

`cfggsmul = gsmUplinkConfig` creates a GSM uplink TDMA frame configuration object.

`cfggsmul = gsmUplinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmul = gsmUplinkConfig( ____, Name, Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime', 4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

### **Properties**

#### **SamplesPerSymbol — Samples per symbol**

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

#### **BurstType — Burst types**

`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB" | "AB" | "Off"`

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"AB"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"AB"` — Transmit data using an access burst for every time slot.

- "Off" — All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-755

---

**Note** The `BurstType` property is an enumeration. To perform code generation, see "Code Generation" on page 3-758 and the "MEX Generation for GSM Uplink Waveform" on page 3-750 example.

---

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

### TSC — Training sequence code

[0 1 2 3 4 5 6 7] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-757.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

### Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

### Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB of attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

### RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range  $[1/\text{SamplesPerSymbol}, 29]$ , where the increment resolution is  $1/\text{SamplesPerSymbol}$ . The total ramp-up and ramp-down duration ( $\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay}$ ) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-755.

Data Types: `double`

**RiseDelay – Burst rise delay**

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-755.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude `RiseDelay` symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude `RiseDelay` symbols before the start of the useful part.

Data Types: `double`

**FallTime – Burst fall time**

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range [`1/SamplesPerSymbol`, 29], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-755.

Data Types: `double`

**FallDelay – Burst fall delay**

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-755.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude `FallDelay` symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude `FallDelay` symbols before the end of the useful part.

Data Types: `double`

**Examples**

## Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig

cfggsmul =
  gsmUplinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
BurstLengthInSamples: 2500
FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Uplink Waveform with Specified Samples per Symbol

Create a GSM uplink TDMA frame configuration object that specifies 4 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms separates each time slot. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 4 samples per symbols.

```
sps = 4;
cfggsmul = gsmUplinkConfig(sps)

cfggsmul =
  gsmUplinkConfig with properties:
    BurstType: [NB  NB  NB  NB  NB  NB  NB  NB]
    SamplesPerSymbol: 4
    TSC: [0 1 2 3 4 5 6 7]
    Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 1.0833e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 625
    FrameLengthInSamples: 5000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### Create GSM Uplink Waveform with Specified Attenuation

Create two GSM uplink TDMA frame configuration objects. Specify default settings for the first `gsmUplinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```

cfggsmul = gsmUplinkConfig

cfggsmul =
    gsmUplinkConfig with properties:
        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
        SamplesPerSymbol: 16
        TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [0 0 0 0 0 0 0 0]
        RiseTime: 2
        RiseDelay: 0
        FallTime: 2
        FallDelay: 0
    
```

Create another GSM uplink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmul2 = gsmUplinkConfig('Attenuation',[1 2 3 4 5 4 3 2])

cfggsmul2 =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [1 2 3 4 5 4 3 2]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames are eight time slots, each separated by a guard period of 8.25 symbols or about  $30.46 \times 10^{-3}$  ms. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmul);
waveform2 = gsmFrame(cfggsmul2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

### MEX Generation for GSM Uplink Waveform

Generate and run a GSM waveform MEX function from the helper function `createUplinkWaveform`. The `createUplinkWaveform` helper function creates a GSM uplink waveform.

### Write MATLAB Function

Open `createUplinkWaveform.m` to see the code. The `createUplinkWaveform` helper function generates a GSM uplink waveform by using the `gsmUplinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

### Generate GSM Waveform

Use the `createUplinkWaveform` helper function to create a GSM waveform containing three TDMA frames, and then plot the waveform.

```
[x,t] = createUplinkWaveform(3);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Uplink Waveform - Amplitude');
```

```

xlabel('Time (ms)');
ylabel('Amplitude');
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

### Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function `createUplinkWaveform_mex`. Generate a MEX function from the `createUplinkWaveform` helper function, and then run the MEX function to create three TDMA frames.

```
codegen createUplinkWaveform -args 3
```

Code generation successful.

### Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateUplinkFrame` helper function or `createUplinkWaveform_mex` function.

```
[x,t] = createUplinkWaveform_mex(3);
```

```

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Uplink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

### GSM Uplink Waveform Generation in Simulink

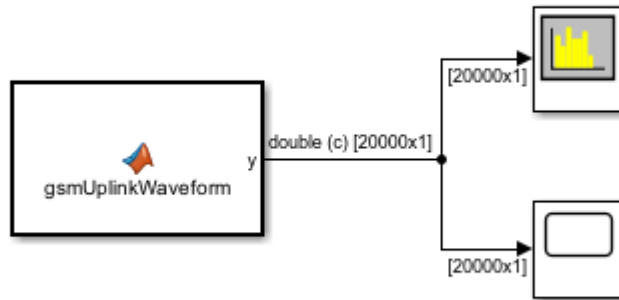

Model a GSM waveform generator in Simulink® by using the MATLAB® Function block and Communications Toolbox™ functions.

#### GSM Uplink Waveform Generation

The MATLAB Function (Simulink) block contains the `gsmUplinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmUplinkConfig` object and the `gsmFrame` function.

## GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmUplinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM uplink TDMA frame shown is this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	Access burst	0 dB
2	Normal burst	3 dB
3	Normal burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Normal burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

### Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmUplinkWaveform` function code is set to the GSM symbol rate of  $1625e3/6$  symbols per second. Display the current `gsmUplinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo =
```

```
struct with fields:
```

```

    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500

```

FrameLengthInSamples: 20000

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmUplinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

### Results

Displays the time domain signal and the spectrogram by running the simulation.

## More About

### GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of  $15/26$  ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

*Useful duration*, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

### Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.AB`, and `gsmUplinkBurstType.Off`. For example, this code assigns an access burst in time slot 2 and 5.

```
cfg = gsmUplinkConfig
```

```
cfg =
```

```
gsmUplinkConfig with properties:
```

```

    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

```
cfg.BurstType([2 5] +1) = gsmUplinkBurstType.AB
```

```
cfg =
```

## comm.HadamardCode

**Package:** comm

Generate Hadamard code

### Description

The `HadamardCode` object generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. You can use orthogonal codes for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, because the codes decorrelate completely.

To generate a Hadamard code:

- 1 Define and set up your Hadamard code object. See “Construction” on page 3-760.
- 2 Call `step` to generate a Hadamard according to the properties of `comm.HadamardCode`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

### Construction

`H = comm.HadamardCode` creates a Hadamard code generator System object, `H`. This object generates Hadamard codes from a set of orthogonal codes.

`H = comm.HadamardCode(Name, Value)` creates a Hadamard code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

### Properties

#### Length

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value with a power of two. The default is 64.

#### Index

Row index of Hadamard matrix

Specify the row index of the Hadamard matrix as a numeric, integer scalar value in the range  $[0, 1, \dots, N-1]$ .  $N$  is the value of the `Length` on page 3-0 property. The default is 60. An  $N \times N$

Hadamard matrix, denoted as  $P(N)$ , is defined recursively as follows:  $P(1) = [1]$   $P(2N) = [P(N) \ P(N); P(N) \ -P(N)]$  The  $N \times N$  Hadamard matrix has the property that  $P(N) \times P(N)' = N \times \text{eye}(N)$ . The `step` method outputs code samples from the row of the Hadamard matrix that you specify in this property.

When you set this property to an integer  $k$ , the output code has exactly  $k$  zero crossings, for  $k = 0, 1, \dots, N-1$ .

### SamplesPerFrame

Number of output samples per frame

Specify the number of Hadamard code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1.

When you set this property to a value of  $M$ , the `step` method outputs  $M$  samples of a Hadamard code of length  $N$ .  $N$  equals the length of the code that you specify in the `Length` on page 3-0 property.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `int8`. The default is `double`.

## Methods

`step` Generate Hadamard code

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Hadamard Code Sequence

Generate 10 samples of a Hadamard code sequence having a length of 128.

```
hadamard = comm.HadamardCode('Length',128,'SamplesPerFrame',10)
```

```
hadamard =  
    comm.HadamardCode with properties:
```

```
        Length: 128  
        Index: 60  
    SamplesPerFrame: 10  
    OutputDataType: 'double'
```

```
seq = hadamard()
```

```
seq = 10×1
```

```
1  
1  
1  
1  
-1  
-1  
-1  
-1  
-1  
-1
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Hadamard Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

## Version History

## step

**System object:** comm.HadamardCode

**Package:** comm

Generate Hadamard code

### Syntax

$Y = \text{step}(H)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the Hadamard code in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property. The Hadamard code corresponds to one of the rows of an  $N \times N$  Hadamard matrix, where  $N$  is a nonnegative power of 2, which you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The `step` method outputs the code in a bi-polar format with 0 and 1 mapped to 1 and -1, respectively.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.HDLCRCDetector

**Package:** comm

Detect errors in input data using CRC

### Description

This HDL-optimized cyclic redundancy code (CRC) detector System object computes a checksum on the input data and compares the result against the input checksum. Instead of frame processing, the `HDLCRCDetector` System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To compute and compare checksums:

- 1 Create the `comm.HDLCRCDetector` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
CRCDet = comm.HDLCRCDetector  
CRCDet = comm.HDLCRCDetector(Name,Value)  
CRCDet = comm.HDLCRCDetector(poly,Name,Value)
```

#### Description

`CRCDet = comm.HDLCRCDetector` creates an HDL-optimized CRC detector System object, `CRCDet`, that detects errors in the input data according to a specified generator polynomial.

`CRCDet = comm.HDLCRCDetector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCDet = comm.HDLCRCDetector('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCDet = comm.HDLCRCDetector(poly,Name,Value)` creates an HDL-optimized CRC detector System object, `CRCDet`, with the `Polynomial` property set to `poly`, and the other specified property names set to the specified values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **Polynomial — Generator polynomial**

[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

#### **InitialState — Initial conditions of shift register**

0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

#### **DirectMethod — Method of calculating checksum**

false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “[Cyclic Redundancy Check Codes](#)”.

#### **ReflectInput — Input byte order**

false (default) | true

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bitwise basis before it enters the shift register.

#### **ReflectCRCChecksum — Checksum byte order**

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

#### **FinalXORValue — Checksum mask**

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## **Usage**

### **Syntax**

```
[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)
```

**Description**

`[Y, startOut, endOut, validOut, err] = CRCn(X, startIn, endIn, validIn)` computes CRC checksums for an input message `X` based on the control signals and compares the computed checksum with input checksum. If the two checksums are not equal, the output `err` is set to 1 (`true`).

**Input Arguments****X — Input message and appended checksum**

binary column vector | scalar integer

Input message and appended checksum, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0, 0, 0, 1, 0, 0, 1, 1]` is equivalent to `uint8` input 19.

If the input is a vector, the data type can be `double` or `logical`. If the input is a scalar, the data type can be `unsigned integer` or `unsigned fixed-point` with 0 fractional bits (`fi([], 0, N, 0)`).

`X` can be part or all of the message to be checked.

The length of `X` must be less than or equal to the CRC length, and the CRC length must be divisible by the length of `X`.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

**startIn — Start of input message**

logical scalar

Start of the input message, specified as a logical scalar.

**endIn — End of input message**

logical scalar

End of the input message, specified as a logical scalar.

**validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input `X`.

**Output Arguments****Y — Message with checksum removed**

binary column vector | scalar integer

Message with checksum removed, returned as a scalar integer or binary column vector with the same width and data type as input `X`.

**startOut — Start of input message**

logical scalar

Start of the input message, returned as a logical scalar.

**endOut — End of input message**

logical scalar

End of the input message, returned as a logical scalar.

### **validOut — Validity of input data**

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

### **err — Checksum mismatch**

logical scalar

Checksum mismatch, returned as a logical scalar. `err` is 1 (`true`) when the input checksum does not match the calculated checksum.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## **Examples**

### **CRC Encode and Decode for HDL**

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcg16;
if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
    [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
        HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

crcg16 =

comm.HDLCRCGenerator with properties:

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end
```

```
crcd16 =
```

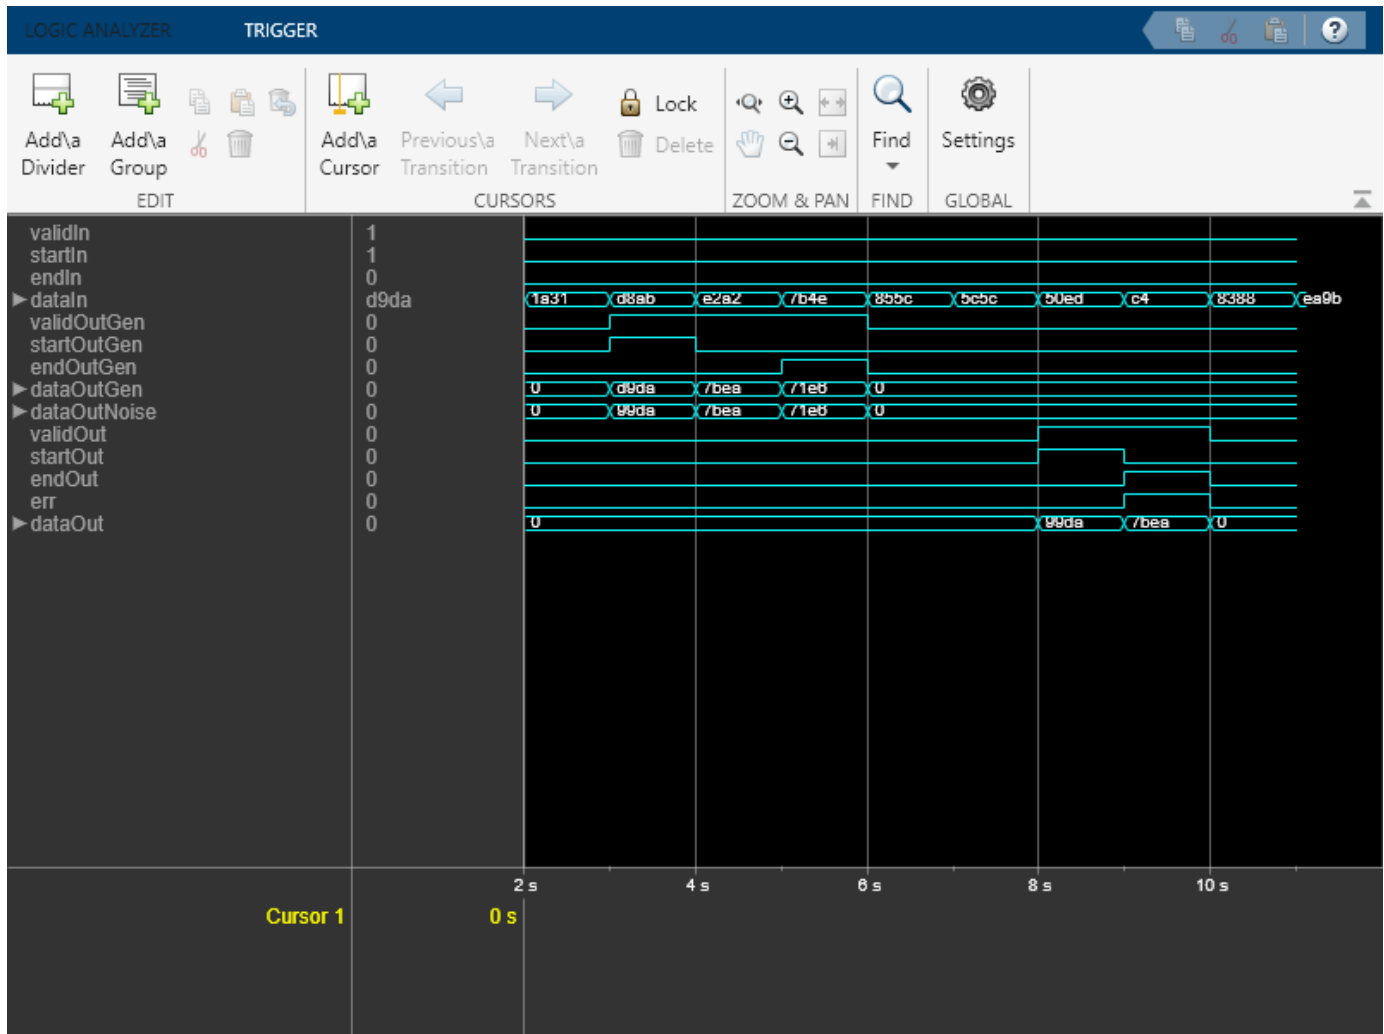

```
comm.HDLCRCDetector with properties:
```

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Use the **Logic Analyzer** to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    {'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    {'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
    'BackgroundColor','Black','DisplayChannelHeight',8);

for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        cVal = eval(c{1});
        dat2 = uint16(bit2int(cVal,size(cVal,1)));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii}));
    end
end
la(chanData{:})

## Algorithms

### Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous. The output frames include space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

### **Initial Delay**

The HDLCRCDetector System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

$$\text{initialDelay} = 3 * (\text{CRCLength}/\text{inputDataWidth}) + 2$$

## **Version History**

**Introduced in R2012b**

### **Extended Capabilities**

#### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

#### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The software supports `double` and `single` data types for simulation, but not for HDL code generation.

## comm.HDLCRCGenerator

**Package:** comm

Generate CRC code bits and append to input data

### Description

This HDL-optimized cyclic redundancy code (CRC) generator System object generates cyclic redundancy code (CRC) bits. Instead of frame processing, the HDLCRCGenerator System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To generate cyclic redundancy code bits:

- 1 Create the `comm.HDLCRCGenerator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
CRCGen = comm.HDLCRCGenerator  
CRCGen = comm.HDLCRCGenerator(Name,Value)  
CRCGen = comm.HDLCRCGenerator(poly,Name,Value)
```

#### Description

`CRCGen = comm.HDLCRCGenerator` creates an HDL-optimized CRC generator System object, `CRCGen`. This object generates CRC bits according to a specified generator polynomial and appends them to the input data.

`CRCGen = comm.HDLCRCGenerator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCGen = comm.HDLCRCGenerator('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCGen = comm.HDLCRCGenerator(poly,Name,Value)` sets the `Polynomial` property to `poly`, and the other specified property names to the specified values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

#### **Polynomial — Generator polynomial**

[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

#### **InitialState — Initial conditions of shift register**

0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

#### **DirectMethod — Method of calculating checksum**

false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

#### **ReflectInput — Input byte order**

false (default) | true

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bitwise basis before it enters the shift register.

#### **ReflectCRCChecksum — Checksum byte order**

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

#### **FinalXORValue — Checksum mask**

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

## **Usage**

### **Syntax**

[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)

**Description**

`[Y, startOut, endOut, validOut] = CRCn(X, startIn, endIn, validIn)` generates CRC checksums for input message `X` based on control signals and appends the checksums to `X`.

**Input Arguments****X — Input message**

binary column vector | scalar integer

Input message, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0, 0, 0, 1, 0, 0, 1, 1]` is equivalent to `uint8` input `19`.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([], 0, N, 0)`).

`X` can be part or all of the message to be encoded.

The length of `X` must be less than or equal to the CRC length, and the CRC length must be divisible by the length of `X`.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

**startIn — Start of input message**

logical scalar

Start of the input message, specified as a logical scalar.

**endIn — End of input message**

logical scalar

End of the input message, specified as a logical scalar.

**validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input `X`.

**Output Arguments****Y — Output message with appended checksum**

binary column vector | scalar integer

Output message, consisting of `X` with appended checksum, returned as a scalar integer or binary column vector with the same width and data type as input `X`.

**startOut — Start of input message**

logical scalar

Start of the input message, returned as a logical scalar.

**endOut — End of input message**

logical scalar

End of the input message, returned as a logical scalar.

### **validOut — Validity of input data**

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## **Examples**

### **CRC Encode and Decode for HDL**

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
```

```
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcg16;
if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end

function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
    [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
        HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

```
crcg16 =
```

```
comm.HDLCRCGenerator with properties:
```

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```

for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end

```

```
crcd16 =
```

```
comm.HDLCRCDetector with properties:
```

```

    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0

```

Use the **Logic Analyzer** to view the input and output signals.

```

channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
    'BackgroundColor','Black','DisplayChannelHeight',8);

for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        cVal = eval(c{1});
        dat2 = uint16(bit2int(cVal,size(cVal,1)));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii}));
    end
end
la(chanData{:})

```

## Algorithms

### Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with an 8-bit binary vector input. To insert the checksum word, input frames must have enough space between them.

This waveform diagram shows continuous input data. The block also supports noncontinuous data. The output valid signal matches the input valid pattern.

### Initial Delay

The HDLCRCGenerator System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

$$\text{initialDelay} = (\text{CRCLength}/\text{inputDataWidth}) + 2$$

## Version History

Introduced in R2012a

### Extended Capabilities

## comm.HDLRSDecoder

**Package:** comm

Decode message using Reed-Solomon decoder

### Description

The HDL-optimized HDLRSDecoder System object recovers a message vector from a Reed-Solomon (RS) codeword vector. For proper decoding, the code and polynomial property values for this object must match those values in the corresponding encoder.

To recover a message vector from a Reed-Solomon codeword vector:

- 1 Create the `comm.HDLRSDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Troubleshooting

- Each input frame must contain more than  $(N-K)*2$  symbols and fewer than or exactly  $N$  symbols. The object infers a shortened code when the number of valid data samples between `startIn` and `endIn` is less than  $N$ . A shortened code still requires  $N$  cycles to perform the Chien search. If the input message is less than  $N$  symbols, leave a guard interval of at least  $N - \text{size}$  inactive cycles before starting the next frame, where `size` is the message length.
- The decoder can operate on up to four messages at a time. If the object receives the start of a fifth message before completely decoding the first message, the object drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, the message length, and the  $B$  value for the starting exponent of the roots. To get the value of  $B$  from a generator polynomial, use the `genpoly2b` function.

## Creation

### Syntax

```
RSDec = comm.HDLRSDecoder  
RSDec = comm.HDLRSDecoder(Name,Value)  
RSDec = comm.HDLRSDecoder(N,K,Name,Value)
```

### Description

`RSDec = comm.HDLRSDecoder` creates an HDL-optimized RS decoder System object, `RSDec`, that performs Reed-Solomon decoding.

`RSDec = comm.HDLRSDecoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSDecoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSDec = comm.HDLRSDecoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### B — Starting power for roots of primitive polynomial

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

#### Dependencies

The object uses this value when you set `BSource` to `'Property'`.

### BSource — Source of starting power for roots of primitive polynomial

'Auto' (default) | 'Property'

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses  $B = 1$ .

### CodewordLength — Number of symbols, N, in RS codeword

7 (default) | positive integer

Number of symbols,  $N$ , in the RS codeword, specified as a positive integer. This value is rounded up to  $2^M - 1$ .  $M$  is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` - `MessageLength` must be an even integer.

If the value of this property is less than  $2^M - 1$ , the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to `'Auto'`, then `CodewordLength` must be in the range  $3 < \text{CodewordLength} \leq 2^{16} - 1$ .

If you set `PrimitivePolynomialSource` to `'Property'`, then `CodewordLength` must be in the range  $3 \leq \text{CodewordLength} \leq 2^M - 1$ .  $M$  must be in the range  $3 \leq M \leq 16$ .

### MessageLength — Message length, K

3 (default) | positive integer

Message length,  $K$ , specified as a positive integer. The difference of `CodewordLength` - `MessageLength` must be an even integer.

**NumErrorsOutputPort — Enable number of errors output argument**`false (default) | true`

When you set this property to `true`, the object returns the number of corrected errors. The number of corrected errors is not valid when `errOut` is `true`, since there were more errors than could be corrected.

**PrimitivePolynomialSource — Source of primitive polynomial**`'Auto' (default) | 'Property'`

Source of the primitive polynomial, specified as either `'Property'` or `'Auto'`.

- When you set this property to `'Auto'`, the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength}+1))$ , which is the result of `int2bit(primpoly(M),bpi)`, where  $bpi$  is the number of bits per integer.
- When you set this property to `'Property'`, you must specify a polynomial using the `PrimitivePolynomial` property.

**PrimitivePolynomial — Primitive polynomial**`[1 0 1 1] (default) | binary row vector`

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$ , in descending order of powers. The polynomial defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords.

**Dependencies**

The object uses this value when you set `PrimitivePolynomialSource` to `'Property'`.

**Usage****Syntax**

```
[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)
[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,
validIn)
```

**Description**

`[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)` decodes one encoded message symbol,  $X$ , and returns the decoded symbol  $Y$ . The `start` and `end` signals indicate the message frame boundaries. If `errOut` is `1 (true)`, then the object detected uncorrectable errors in the input frame.

`[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,validIn)` decodes the input data, and also returns the number of errors detected and corrected. To use this syntax, set the `NumErrorsOutputPort` property to `true`. If `errOut` is `1 (true)`, then the object detected uncorrectable errors in the output frame, and `numErrors` is invalid.

## Input Arguments

### **X — Input message data or parity symbols**

integer

Input message data and parity symbols, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

### **startIn — Start of input data frame**

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

### **endIn — End of input data frame**

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

### **validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

## Output Arguments

### **Y — Message data symbols**

integer

Message data symbols, returned one symbol at a time, as an integer with the same data type as the input message, `X`.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

### **startOut — Start of output data frame**

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`

### **endOut — End of output data frame**

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

### **validOut — Validity of output data**

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

### **errOut — Uncorrectable error in output data frame**

logical scalar

Uncorrectable error in output data frame, returned as a logical scalar. This signal is 1 (`true`) when the message frame contains uncorrectable errors. In this case, the output data symbols are corrupted. This value is valid when `endOut` is 1 (`true`).

Data Types: `logical`

### **numErrors — Number of errors detected and corrected**

integer

Number of errors detected and corrected, returned as an integer. This value is valid when `endOut` is 1 (`true`) and `errOut` is 0 (`false`).

Data Types: `uint8`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## **Examples**

### **Reed-Solomon Coding and Error Detection for HDL**

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;  
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
```

```

%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsEnc80216;
if isempty(rsEnc80216)
    rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
end
[dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end

% Copyright 2019-2022 The MathWorks, Inc.

```

Call the function to encode the message.

```

for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end

```

rsEnc80216 =

comm.HDLRSEncoder with properties:

```

        CodewordLength: 255
        MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
        BSource: 'Property'
         B: 0

```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to  $(N - K)/2$  errors in each  $N$  symbols. So, in this example, the error correction capability is  $(255 - 239)/2=8$  symbols.

```

numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end

```

```

Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb

```

```
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88
```

Write a function that creates and calls a `HDLRSDecoder` System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsDec80216;
if isempty(rsDec80216)
    rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
end
[dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end

% Copyright 2019-2022 The MathWorks, Inc.
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 =
```

```
comm.HDLRSDecoder with properties:
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    BSource: 'Property'
    B: 0
    NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOut(jj))
        end
    end
end
```

All 188 message symbols were correctly decoded.

## Version History

Introduced in R2012b

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

#### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The software supports `double` and `single` data types for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

Integer-Output RS Decoder HDL Optimized

## comm.HDLRSEncoder

**Package:** comm

Encode message using Reed-Solomon encoder

### Description

The HDL-optimized HDLRSEncoder System object creates a Reed-Solomon (RS) code with message and codeword lengths that you specify.

To encode a message using a Reed-Solomon code:

- 1 Create the `comm.HDLRSEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
RSEnc = comm.HDLRSEncoder  
RSEnc = comm.HDLRSEncoder(Name,Value)  
RSEnc = comm.HDLRSEncoder(N,K,Name,Value)
```

#### Description

`RSEnc = comm.HDLRSEncoder` creates an HDL-optimized block encoder System object, `RSEnc`, that performs Reed-Solomon encoding in a streaming fashion for HDL.

`RSEnc = comm.HDLRSEncoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSEncoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSEnc = comm.HDLRSEncoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**B — Starting power for roots of primitive polynomial**

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

**Dependencies**

The object uses this value when you set BSource to 'Property'.

**BSource — Source of starting power for roots of primitive polynomial**

'Auto' (default) | 'Property'

Source of the starting power for roots of the primitive polynomial, specified as either 'Property' or 'Auto'. When you select 'Auto', the object uses  $B = 1$ .**CodewordLength — Number of symbols, N, in RS codeword**

7 (default) | positive integer

Number of symbols,  $N$ , in the RS codeword, specified as a positive integer. This value is rounded up to  $2^M - 1$ .  $M$  is the degree of the primitive polynomial, as specified by the PrimitivePolynomialSource and PrimitivePolynomial properties. The difference of CodewordLength - MessageLength must be an even integer.If the value of this property is less than  $2^M - 1$ , the object assumes a shortened RS code.If you set PrimitivePolynomialSource to 'Auto', then CodewordLength must be in the range  $3 < \text{CodewordLength} \leq 2^{16} - 1$ .If you set PrimitivePolynomialSource to 'Property', then CodewordLength must be in the range  $3 \leq \text{CodewordLength} \leq 2^M - 1$ .  $M$  must be in the range  $3 \leq M \leq 16$ .**MessageLength — Message length, K**

3 (default) | positive integer

Message length,  $K$ , specified as a positive integer. The difference of CodewordLength - MessageLength must be an even integer.**PrimitivePolynomialSource — Source of primitive polynomial**

'Auto' (default) | 'Property'

Source of the primitive polynomial, specified as either 'Property' or 'Auto'.

- When you set this property to 'Auto', the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$ , which is the result of  $\text{int2bit}(\text{primpoly}(M, bpi))$ , where  $bpi$  is the number of bits per integer.
- When you set this property to 'Property', you must specify a polynomial using the PrimitivePolynomial property.

**PrimitivePolynomial — Primitive polynomial**

[1 0 1 1] (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$ , in descending order of powers. The polynomial defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords.

**Dependencies**

The object uses this value when you set `PrimitivePolynomialSource` to 'Property'.

**PuncturePatternSource — Source of puncture pattern**

'None' (default) | 'Property'

Source of the puncture pattern, specified as 'None' or 'Property'. If you set this property to 'None', then the object does not apply puncturing to the code. If you set this property to 'Property', then the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` property.

**PuncturePattern — Pattern used to puncture encoded data**

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Pattern used to puncture the encoded data, specified as a double-precision, binary column vector with a length of `CodewordLength - MessageLength`. The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

**Dependencies**

This property applies when you set the `PuncturePatternSource` property to 'Property'.

**Usage****Syntax**

```
[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)
```

**Description**

`[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)` encodes one input message symbol,  $X$ , and returns one symbol of encoded data,  $Y$ . The `start` and `end` signals indicate the message frame boundaries. The object returns associated parity symbols at the end of each message frame.

**Input Arguments****X — Input message symbol**

integer

Input message data, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling. The word length of each symbol must be `ceil(log2(CodewordLength+1))`.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double | uint8 | uint16 | uint32 | fi`

### **startIn — Start of input data frame**

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

### **endIn — End of input data frame**

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

### **validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

## **Output Arguments**

### **Y — Output message data and parity symbols**

integer

Message data and parity symbols, returned one symbol at a time, as an integer with the same data type as the input message, X.

Data Types: `double | uint8 | uint16 | uint32 | fi`

### **startOut — Start of output data frame**

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`

### **endOut — End of output data frame**

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

### **validOut — Validity of output data**

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

```
step      Run System object algorithm
release   Release resources and allow changes to System object property values and input
          characteristics
reset     Reset internal states of System object
```

## Examples

### Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)
%HDLRSEnc80216
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

    persistent rsEnc80216;
    if isempty(rsEnc80216)
        rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end

% Copyright 2019-2022 The MathWorks, Inc.
```

Call the function to encode the message.

```
for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end

rsEnc80216 =
```

comm.HDLRSEncoder with properties:

```

        CodewordLength: 255
        MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
        BSource: 'Property'
        B: 0

```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to  $(N - K)/2$  errors in each  $N$  symbols. So, in this example, the error correction capability is  $(255 - 239)/2=8$  symbols.

```

numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end

```

```

Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88

```

Write a function that creates and calls a HDLRSDecoder System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```

function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

    persistent rsDec80216;
    if isempty(rsDec80216)
        rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end

% Copyright 2019-2022 The MathWorks, Inc.

```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

```
rsDec80216 =
```

```
    comm.HDLRSDecoder with properties:
```

```
        CodewordLength: 255
        MessageLength: 239
        PrimitivePolynomialSource: 'Auto'
        BSource: 'Property'
        B: 0
        NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOut(jj))
        end
    end
end
```

All 188 message symbols were correctly decoded.

## comm.HelicalDeinterleaver

**Package:** comm

Restore ordering of symbols using helical array

### Description

The `HelicalDeinterleaver` object permutes the symbols in the input signal by placing them in a row-by-row array and then selecting groups helically to send to the output port.

To helically deinterleave input symbols:

- 1 Define and set up your helical deinterleaver object. See “Construction” on page 3-796.
- 2 Call `step` to deinterleave input symbols according to the properties of `comm.HelicalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.HelicalDeinterleaver` creates a helical deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the helical interleaver System object.

`H = comm.HelicalDeinterleaver(Name,Value)` creates a helical deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

### Properties

#### NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

#### GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

#### StepSize

Helical array step size

Specify number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires a positive integer scalar value. The default is 1.

### InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

## Methods

step      Restore ordering of symbols using a helical array

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

## Examples

### Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)

intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))
```

```
ans = logical  
     1
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Deinterleaver block reference page. The object properties correspond to the block parameters.

### Version History

**Introduced in R2012a**

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

## step

**System object:** comm.HelicalDeinterleaver

**Package:** comm

Restore ordering of symbols using a helical array

### Syntax

$Y = \text{step}(H, X)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X)$  restores the original ordering of the sequence,  $X$ , that was interleaved using a helical interleaver and returns  $Y$ . The input  $X$  must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The helical deinterleaver object uses an array for its computations. If you set the `NumColumns` property of the object to  $C$ , then the array has  $C$  columns and unlimited rows. If you set the `GroupSize` property to  $N$ , then the object accepts an input of length  $C \times N$  and inserts it into the next  $N$  rows of the array. The object also places the value of the `InitialConditions` property into certain positions in the top few rows of the array. This accommodates the helical pattern and also preserves the vector indices of symbols that pass through the `HelicalInterleaver` and `HelicalDeinterleaver` objects. The output consists of consecutive groups of  $N$  symbols. The object selects the  $k$ -th output group in the array from column  $k \bmod C$ . This selection is of type helical because of the reduction modulo  $C$  and because the first symbol in the  $k$ -th group is in row  $1 + (k-1) \times s$ , where  $s$  is the value for the `StepSize` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.HelicalInterleaver

**Package:** comm

Permute input symbols using helical array

### Description

The `HelicalInterleaver` object permutes the symbols in the input signal by placing them in an array in a helical arrangement and then sending rows of the array to the output port.

To helically interleave input symbols:

- 1 Define and set up your helical interleaver object. See “Construction” on page 3-800.
- 2 Call `step` to interleave input symbols according to the properties of `comm.HelicalInterleaver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.HelicalInterleaver` creates a helical interleaver System object, `H`. This object permutes the input symbols in the input signal by placing them in an array in a helical arrangement.

`H = comm.HelicalInterleaver(Name,Value)` creates a helical interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

### Properties

#### NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

#### GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

#### StepSize

Helical array step size

Specify the number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires as a positive integer scalar value . The default is 1.

### InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

## Methods

step      Permute input symbols using a helical array

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

## Examples

### Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)

intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))
```

```
ans = logical  
     1
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Interleaver block reference page. The object properties correspond to the block parameters.

### Version History

**Introduced in R2012a**

## step

**System object:** comm.HelicalInterleaver

**Package:** comm

Permute input symbols using a helical array

### Syntax

$Y = \text{step}(H,X)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  permutes input sequence,  $X$ , and returns interleaved sequence,  $Y$ . The input  $X$  must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects).  $Y$  has the same data type as  $X$ . The helical interleaver object places the elements of  $X$  in an array in a helical fashion. If you set the `NumColumns` property of the object to  $C$ , then the array has  $C$  columns and unlimited rows. If you set the `GroupSize` property to  $N$ , then the object accepts an input of length  $C \times N$  and partitions the input into consecutive groups of  $N$  symbols. The object places the  $k$ -th group in the array along column  $k \bmod C$ . This placement is of type helical because of the reduction modulo  $C$  and because the first symbol in the  $k$ -th group is in the row  $1 + (k-1) \times s$ , where  $s$  is the value for the `StepSize` property. Positions in the array that do not contain input symbols have default contents specified by the `InitialConditions` property. The object outputs  $C \times N$  symbols from the array by reading the next  $N$  rows sequentially.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

## comm.IntegrateAndDumpFilter

**Package:** comm

Integrate discrete-time signal with periodic resets

### Description

The `IntegrateAndDumpFilter` object creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the object discards the number of samples specified in the `Offset` property. After this initial period, the object sums the input signal along columns and resets the sum to zero every `Ninput` samples, set by the `IntegrationPeriod` property. The reset occurs after the object produces output at that time step.

To integrate discrete-time signals with periodic resets:

- 1 Define and set up your integrate and dump filter object. See “Construction” on page 3-804.
- 2 Call `step` to integrate discrete-time signals according to the properties of `comm.IntegrateAndDumpFilter`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.IntegrateAndDumpFilter` creates an integrate and dump filter System object, `H`. This object integrates over a number of samples in an integration period, and then resets at the end of that period.

`H = comm.IntegrateAndDumpFilter(Name,Value)` creates an integrate and dump filter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.IntegrateAndDumpFilter(PERIOD,Name,Value)` creates an integrate and dump filter object, `H`. This object has the `IntegrationPeriod` property set to `PERIOD` and the other specified properties set to the specified values.

### Properties

#### IntegrationPeriod

Integration period

Specify the integration period, in samples, as a positive, integer scalar value greater than 1. The integration period defines the length of the sample blocks that the object integrates between resets. The default is 8.

## Offset

Number of offset samples

Specify a nonnegative, integer vector or scalar specifying the number of input samples that the object discards from each column of input data at the beginning of data processing. Discarding begins when you call the `step` method for the first time. The default is 0.

When you set the `Offset` on page 3-0 property to a nonzero value, the object outputs one or more zeros during the initial period while discarding input samples.

When you specify this property as a vector of length  $L$ , the  $i$ -th element of the vector corresponds to the offset for the  $i$ -th column of the input data matrix, which has  $L$  columns.

When you specify this property as a scalar value, the object applies the same offset to each column of the input data matrix. The offset creates a transient effect, rather than a persistent delay.

## DecimateOutput

Decimate output

Specify whether the `step` method returns intermediate cumulative sum results or decimates intermediate results. The default is `true`.

When you set this property to `true`, the `step` method returns one output sample, consisting of the final integration value, for each block of `IntegrationPeriod` on page 3-0 input samples. If the inputs are  $(K \times \text{IntegrationPeriod}) \times L$  matrices, then the outputs are  $K \times L$  matrices.

When you set this property to `false`, the `step` method returns `IntegrationPeriod` output samples, comprising the intermediate cumulative sum values, for each block of `IntegrationPeriod` input samples. In this case, inputs and outputs have the same dimensions.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-808.

### RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

### **OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### **AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object automatically calculates the accumulator output word and fraction lengths. Set this property to `Custom` to specify the accumulator data type using the `CustomAccumulatorDataType` on page 3-0 property. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

### **CustomAccumulatorDataType**

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `AccumulatorDataType` on page 3-0 property to `Custom`.

### **OutputDataType**

Data type of output

Specify the output fixed-point type as one of `Same as accumulator` | `Same as input` | `Custom`. The default is `Same as accumulator`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

### **CustomOutputDataType**

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `OutputDataType` on page 3-0 property to `Custom`.

## Methods

step Integrate discrete-time signal with periodic resets

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Pass Noisy Pulses Through Integrate and Dump Filter

Create an integrate and dump filter having an integration period of 20 samples.

```
intdump = comm.IntegrateAndDumpFilter(20);
```

Generate binary data.

```
d = randi([0 1],50,1);
```

Upsample the data, and pass it through an AWGN channel.

```
x = upsample(d,20);
y = awgn(x,25, 'measured');
```

Pass the noisy data through the filter.

```
z = intdump(y);
```

Plot the original and filtered data. The integrate and dump filter removes most of the noise effects.

```
stairs([d z])
legend('Original Data','Filtered Data')
xlabel('Samples')
ylabel('Amplitude')
grid
```

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Integrate and Dump block reference page. The object properties correspond to the block parameters, except: The **Output intermediate values** parameter corresponds to the `DecimateOutput` on page 3-0 property.

## **Version History**

**Introduced in R2012a**

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## step

**System object:** `comm.IntegrateAndDumpFilter`

**Package:** `comm`

Integrate discrete-time signal with periodic resets

### Syntax

`Y = step(H,X)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` periodically integrates blocks of `N` samples from the input data, `X`, and returns the result in `Y`. `N` is the number of samples that you specify in the `IntegrationPeriod` property. `X` is a column vector or a matrix and the data type is double, single or fixed-point (fi objects). `X` must have `K*N` rows for some positive integer `K`, with one or more columns. The object treats each column as an independent channel with integration occurring along every column. The dimensions of output `Y` depend on the value you set for the `DecimateOutput` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.KasamiSequence

**Package:** comm

Generate Kasami sequence

## Description

The `comm.KasamiSequence` System object generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have cross-correlation properties. For more information, see “Kasami Sequences” on page 3-816.

To generate a Kasami sequence:

- 1 Create the `comm.KasamiSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
kasamiseq = comm.KasamiSequence
kasamiseq = comm.KasamiSequence(Name, Value)
```

### Description

`kasamiseq = comm.KasamiSequence` creates a `KasamiSequence` System object. This object generates a Kasami sequence.

`kasamiseq = comm.KasamiSequence(Name, Value)` sets “Properties” on page 3-811 using one or more name-value arguments. For example, `'Polynomial', 'z^8 + z^4 + z^3 + z^2 + 1'` specifies the generator polynomial.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **Polynomial — Generator polynomial**

`'z^6 + z + 1'` (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of a polynomial in order of descending powers. The length of this vector must be  $N + 1$ , where  $N$  is the degree of the polynomial. The first and last entries must be 1, indicating a leading term with degree  $N$  and a constant term of 1.
- Integer-valued row vector of elements that represents the exponents for the nonzero terms of a polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

You can specify the primitive generator polynomial as a row vector of elements that represents the exponents for the nonzero terms of the polynomial in order of descending powers. Alternatively, you can also use the `primpoly` function to find the primitive polynomials for a Galois field or use the `gfprimck` function to check if a polynomial is a valid primitive polynomial.

Example: `'z^8 + z^4 + z^3 + z^2 + 1'`, `[1 0 0 0 1 1 1 0 1]`, and `[8 4 3 2 0]` represent the same polynomial:  $z^8 + z^4 + z^3 + z^2 + 1$ .

Data Types: `double` | `char` | `string`

### **InitialConditions — Initial conditions of shift register**

`[0 0 0 0 0 1]` (default) | binary-valued scalar | binary-valued row vector

Initial conditions of the shift register, specified as one of these options:

- Binary-valued scalar — This value specifies the initial conditions of all cells in the shift register.
- Binary-valued row vector of length equal to the degree of the generator polynomial — Each element of the vector corresponds to the initial value of the corresponding cell in the shift register.

---

**Note** The scalar, or at least one element of the specified vector, requires a nonzero value for the object to generate a nonzero sequence.

---

Data Types: `double`

### **Index — Sequence index**

0 (default) | integer | vector of the form `[k m]`

Sequence index, specified as an integer or vector of the form `[k m]` to select a Kasami sequence of interest from the set of possible sequences. Kasami sequences have a period equal to  $N = 2^n - 1$ , where  $n$  is a nonnegative even integer equal to the degree of the generator polynomial that you specify in the `Polynomial` property.

Two classes of Kasami sequences exist: those obtained from a small set and those obtained from a large set. You can choose a Kasami sequence from the small set by setting this property to an integer in the range `[0, 2n/2-2]`. You can choose a sequence from the large set by setting this property to a vector of the form `[k m]`.  $k$  must be an integer in the range `[-2, 2n-2]`, and  $m$  must be an integer in the range `[-1, 2n/2-2]`. For more information, see “Kasami Sequences” on page 3-816.

Data Types: `double`

**Shift — Sequence offset from starting point**

0 (default) | integer

Sequence offset from the starting point, specified as an integer. The Kasami sequence has a period of  $N = 2^n - 1$ , where  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property. The shift value is wrapped with respect to the sequence period.

Data Types: double

**VariableSizeOutput — Option to enable variable-size outputs**

false (default) | true

Option to enable variable-size outputs, specified as one of these numeric or logical values:

- `false` (0) -- Use the `SamplesPerFrame` property to specify the number of output samples per frame.
- `true` (1) -- Use the `outputsize` input argument to specify the output size of the Kasami sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

Data Types: logical | double

**MaximumOutputSize — Maximum output size**

[10 1] (default) | vector of the form [m 1]

Maximum output size of the Kasami sequence, specified as a vector of the form [m 1], where  $m$  is a positive integer. The first element of the vector indicates the maximum size of the sequence, and the second element of the vector must be 1.

Example: [10 1] specifies a maximum output size of 10-by-1.

**Dependencies**

To enable this property, set the `VariableSizeOutput` property to 1 (true).

Data Types: double

**SamplesPerFrame — Number of output samples per frame**

1 (default) | positive integer

Number of output samples per frame, specified as a positive integer.

If you set this property to a value of  $M$ , then the output, which contains  $M$  samples of a Kasami sequence, has a period of  $N = 2^n - 1$ . The value  $n$  is the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property.

**Dependencies**

To enable this property, set the `VariableSizeOutput` property to false (0).

Data Types: double

**ResetInputPort — Option to enable input to reset sequence generator**

false (default) | true

Option to enable generator reset input, specified as a logical or numeric `false (0)` or `true(1)`. Set this property to `true (1)` to enable the `resetseq` input argument. The input argument resets the states of the Kasami sequence generator to the initial conditions that you specify in the `InitialConditions` on page 3-0 property.

Data Types: `logical` | `double`

### **OutputDataType — Data type of output Kasami sequence**

`'double'` (default) | `'logical'`

Data type of the output Kasami sequence, specified as `'double'` or `'logical'`.

Data Types: `char` | `string`

## **Usage**

### **Syntax**

```
outsequence = kasamiseq()  
outsequence = kasamiseq(outputsize)  
outsequence = kasamiseq(resetseq)  
outsequence = kasamiseq(outputsize, resetseq)
```

### **Description**

`outsequence = kasamiseq()` generates a Kasami sequence.

`outsequence = kasamiseq(outputsize)` specifies the length of the output sequence.

To enable this syntax, set the `VariableSizeOutput` property to `1 (true)`.

`outsequence = kasamiseq(resetseq)` specifies a reset signal for the sequence generator.

To enable this syntax, set the `ResetInputPort` property to `1 (true)`.

`outsequence = kasamiseq(outputsize, resetseq)` specifies the length of the output sequence and the reset signal for the sequence generator.

To enable this syntax, set the `VariableSizeOutput` property to `1 (true)` and the `ResetInputPort` property to `1 (true)`.

### **Input Arguments**

#### **outputsize — Length of output sequence**

`nonnegative integer` | `vector of the form [n 1]`

Length of the output sequence, specified as a nonnegative integer or a vector of the form `[n 1]`, where `n` is a positive integer. The first element of the vector indicates the length of the output frame, and the second element of the vector must be `1`.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

**Dependencies**

To enable this input argument, set the `VariableSizeOutput` property to `1 (true)`.

Data Types: `double`

**resetseq — Reset signal for sequence generator**

nonzero scalar | numeric column vector

Reset signal for the sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the sequence generator resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a numeric column vector, the sequence generator resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in this vector.

**Dependencies**

To enable this input argument, set the `ResetInputPort` property to `1 (true)`.

Data Types: `double`

**Output Arguments****outSequence — Kasami sequence**

column vector

Kasami sequence, returned as a column vector.

Data Types: `double`

**Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

**Examples****Spread BPSK Data with Kasami Sequence**

Generate binary data, and then apply BPSK modulation to that data.

```
data = randi([0 1],10,1);
modData = pskmod(data,2);
```

Create a Kasami sequence generator System object, specifying a generator polynomial  $x^8 + x^4 + x^3 + x^2 + 1$ , initial conditions of the shift register, and a Kasami sequence of length 255.

```
kasamiseq = comm.KasamiSequence('Polynomial',[8 4 3 2 0], ...
    'InitialConditions',[0 0 0 0 0 0 0 1], 'SamplesPerFrame',255);
```

Generate the Kasami sequence, and then convert it to bipolar form.

```
kasSeq = kasamiseq();
kasSeq = 2*kasSeq - 1;
```

Apply a gain of  $1/\sqrt{255}$  to ensure that the spreading operation does not increase the overall signal power.

```
kasSeq = kasSeq/sqrt(255);
```

Spread the BPSK data using the Kasami sequence.

```
spreadData = modData*kasSeq';
spreadData = spreadData(:);
```

Verify that the spread data sequence is 255 times longer than the input data sequence.

```
spreadingFactor = length(spreadData)/length(data)
```

```
spreadingFactor = 255
```

Verify that the spreading operation did not increase the signal power.

```
modSigPwr = sum(abs(modData).^2)/length(data)
```

```
modSigPwr = 1
```

```
spreadSigPwr = sum(abs(spreadData).^2)/length(data)
```

```
spreadSigPwr = 1.0000
```

## More About

### Kasami Sequences

Two sets of Kasami sequences exist: the *small set* and the *large set*. The large set contains all of the sequences in the small set. Only the small set is optimal in the sense of matching Welch's lower bound for correlation functions.

Kasami sequences have a period of  $N = 2^n - 1$ , where  $n$  is a nonnegative even integer. Let  $u$  be a binary sequence of length  $N$ , and let  $w$  be the sequence obtained by decimating  $u$  by  $2^{n/2} + 1$ . This piecewise function defines the small set of Kasami sequences.  $T$  is the left shift operator,  $m$  is the shift parameter for  $w$ , and  $\oplus$  denotes addition modulo 2.

$$K_s(u, n, m) = \begin{cases} u & m = -1 \\ u \oplus T^m w & m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

The small set contains  $2^{n/2}$  sequences.

For  $\text{mod}(n, 4) = 2$ , this piecewise function defines the large set of Kasami sequences. Let  $v$  be the sequence formed by decimating the sequence  $u$  by  $2^{(n/2 + 1)} + 1$ .  $k$  and  $m$  are the shift parameters for the sequences  $v$  and  $w$ , respectively.

$$K_L(u, n, k, m) = \begin{cases} u & k = -2; m = -1 \\ v & k = -1; m = -1 \\ u \oplus T^k v & k = 0, \dots, 2^n - 2; m = -1 \\ u \oplus T^m w & k = -2; m = 0, \dots, 2^{n/2} - 2 \\ v \oplus T^m w & k = -1; m = 0, \dots, 2^{n/2} - 2 \\ u \oplus T^k v \oplus T^m w & k = 0, \dots, 2^n - 2; m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

The sequences described in the first three rows of  $K_L$  correspond to the Gold sequences for  $\text{mod}(n, 4) = 2$ . For a description of Gold sequences, see the `comm.GoldSequence` System object reference page. However, the Kasami sequences form a larger set than the Gold sequences alone.

The correlation functions for the sequences take on the values

$$\{-t(n), -s(n), -1, s(n) - 2, t(n) - 2\},$$

where

$$t(n) = 1 + 2^{(n+2)/2}, \text{ when } n \text{ is even and} \\ s(n) = \frac{1}{2}(t(n) + 1).$$

### Polynomials for Generating Kasami sequences

Kasami sequences have a period of  $N = 2^n - 1$ , where  $n$  is a nonnegative even integer. This table lists some of the polynomials that you can use to generate the set of Kasami sequences.

$n$	$N$	Polynomial	Set
4	15	'z <sup>4</sup> + z + 1'	Small
6	63	'z <sup>6</sup> + z + 1'	Large
8	255	'z <sup>8</sup> + z <sup>4</sup> + z <sup>3</sup> + z <sup>2</sup> + 1'	Small
10	1023	'z <sup>10</sup> + z <sup>3</sup> + 1'	Large
12	4095	'z <sup>12</sup> + z <sup>6</sup> + z <sup>4</sup> + z + 1'	Small

# comm.LDPCDecoder

**Package:** comm

(Not recommended) Decode binary low-density parity-check (LDPC) code

---

**Note** is not recommended. Instead, use the `ldpcDecode` function. For more information, see “Compatibility Considerations”.

---

## Description

The `comm.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-824.

To decode an LDPC-encoded signal:

- 1 Create the `comm.LDPCDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ldpcdecoder = comm.LDPCDecoder
ldpcdecoder = comm.LDPCDecoder(parity)
ldpcdecoder = comm.LDPCDecoder( ____,Name,Value)
```

### Description

`ldpcdecoder = comm.LDPCDecoder` creates a binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`ldpcdecoder = comm.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcdecoder = comm.LDPCDecoder( ____,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the received signal and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

### OutputValue — Output value format

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a  $K$ -by-1 column vector containing only the information-part of the received log-likelihood ratio vector.  $K$  is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an  $N$ -by-1 column vector containing the whole log-likelihood ratio vector.  $N$  is the length of the received signal.

$N$  and  $K$  must align with the dimension of the  $(N-K)$ -by- $K$  parity-check matrix.

Data Types: `char`

### DecisionMethod — Decision method

`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.

- 'Soft decision' — The object outputs log-likelihood ratios of data type double.

Data Types: char

### **IterationTerminationCondition — Condition for iteration termination**

'Maximum iteration count' (default) | 'Parity check satisfied'

Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count' — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- 'Parity check satisfied' — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: char

### **MaximumIterationCount — Maximum number of decoding iterations**

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

### **NumIterationsOutputPort — Output number of iterations executed**

false (default) | true

Output number of iterations performed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: logical

### **FinalParityChecksOutputPort — Output final parity checks**

false (default) | true

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: logical

## **Usage**

### **Syntax**

```
y = ldpcdecoder(x)
[y,numiter] = ldpcdecoder(x)
[y,parity] = ldpcdecoder(x)
[y,numiter,parity] = ldpcdecoder(x)
```

### **Description**

`y = ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

### Input Arguments

#### **x** — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an  $N$ -by-1 column vector containing the soft-decision output from demodulation.  $N$  is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first  $K$  elements correspond to the information-part of the input message.

Data Types: `double`

### Output Arguments

#### **y** — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

#### **numiter** — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

### Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

#### **parity** — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an  $(N-K)$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword before modulation.  $K$  is the length of the uncoded message.

### Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCEncoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals. The outer for loop processes each SNR value. The inner for loop processes frames of input data.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10);
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
```

```

    encData = ldpcEncoder(data);
    modSig = pskMod(encData);
    rxSig = awgn(modSig, snr(ii), 'measured');
    demodSig = pskDemod(rxSig);
    rxBits = ldpcDecoder(demodSig);
    numErr = biterr(data, rxBits);
    ttlErr = ttlErr + numErr;
end
ttlBits = numFrames*length(rxBits);
uncErrRate(ii) = ttlErrUnc/ttlBits;
errRate(ii) = ttlErr/ttlBits;
end

```

Run this code to plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr, uncErrRate, snr, errRate)
legend('Uncoded', 'LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

## Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

### Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value  $L(c_i) = \log \left( \frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)} \right)$ .

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in V_{j \setminus i}} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ( $Hc' = 0$ ) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\operatorname{atanh}(1)$  and  $\operatorname{atanh}(-1)$  are set to 19.07 and  $-19.07$ , respectively. Due to finite precision, MATLAB returns 1 for  $\tanh(19.07)$  and  $-1$  for  $\tanh(-19.07)$ .

## Version History

Introduced in R2012a

**R2021b: comm.LDPCDecoder is not recommended. Use ldpcDecode instead.**

*Not recommended starting in R2021b*

Use `ldpcDecode` instead of `comm.LDPCDecoder`. To specify the LDPC code applied by the `ldpcDecode` function, use the configuration object returned by the `ldpcDecoderConfig` object.

The code in this table shows LDPC decoding inputs using the recommended function and configuration object.

Discouraged Feature	Recommended Replacement
<pre>% Decode using parity-check matrix (pcmatrix) dec = comm.LDPCDecoder(pcmatrix); dec.OutputValue = 'Whole codeword'; dec.DecisionMethod = 'Soft decision'; dec.MaximumIterationCount = 10; dec.IterationTerminationCondition = 'Parity check satisfied'; output = dec(LLR);</pre>	<pre>% Decode using parity-check matrix (pcmatrix) cfg = ldpcDecoderConfig(pcmatrix); output = ldpcDecode(LLR, cfg, 10, ...     'OutputFormat', 'whole', ...     'DecisionType', 'soft', ...     'Termination', 'early');</pre>

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Using default settings, `comm.LDPCDecoder` does not support code generation. To generate code, specify the `ParityCheckMatrix` property as a nonsparse index matrix.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# comm.LDPCEncoder

**Package:** comm

(Not recommended) Encode binary low-density parity-check (LDPC) code

---

**Note** is not recommended. Instead, use the `ldpcEncode` function. For more information, see “Compatibility Considerations”.

---

## Description

The `comm.LDPCEncoder` System object applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

To encode a binary LDPC code:

- 1 Create the `comm.LDPCEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ldpcencoder = comm.LDPCEncoder
ldpcencoder = comm.LDPCEncoder(parity)
ldpcencoder = comm.LDPCEncoder( ___,Name,Value)
```

### Description

`ldpcencoder = comm.LDPCEncoder` creates a binary LDPC encoder System object. This object performs LDPC encoding based on the default parity-check matrix.

`ldpcencoder = comm.LDPCEncoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC encoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcencoder = comm.LDPCEncoder( ___,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCEncoder('ParityCheckMatrix',sparse(I(:,1),I(:,2),1))` configures an LDPC encoder System object to encode data using the parity matrix `sparse(I(:,1),I(:,2),1)`. Enclose each property name in quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse  $(N - K)$ -by- $N$  binary-valued matrix.  $N$  is the length of the output `codeword` vector, and must be in the range  $(0, 2^{31})$ .  $K$  is the length of the uncoded message and must be less than  $N$ . The last  $(N - K)$  columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

---

### Note

- When the last  $(N - K)$  columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
  - When the last  $(N - K)$  columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.
- 

Example: `dvbs2ldpc(R,'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

## Usage

### Syntax

```
codeword = ldpcencoder(message)
```

## Description

`codeword = ldpcencoder(message)` codes the input message using an LDPC code based on a parity-check matrix. The LDPC codeword output is a solution to the parity-check equation.

## Input Arguments

### message — Input message

binary column vector

Input message, specified as a  $K$ -by-1 column vector containing binary-valued elements.  $K$  is the length of the uncoded message.

Data Types: `double` | `logical`

## Output Arguments

### codeword — LDPC codeword

column vector

LDPC codeword, returned as an  $N$ -by-1 column vector.  $N$  is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first  $K$  bits of the LDPC codeword output, and the parity check comprises the remaining  $(N - K)$  bits.

Data Types: `double` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
```

```

numFrames = 10;
ldpcEncoder = comm.LDPCDecoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));

```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals. The outer for loop processes each SNR value. The inner for loop processes frames of input data.

```

for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10);
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end

```

Run this code to plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

## Version History

### Blocks

LDPC Encoder

## ldpcDecoderConfig

Create LDPC decoder configuration

### Description

The `ldpcDecoderConfig` object is a configuration object for the `ldpcDecode` function. The object specifies the low-density parity-check (LDPC) matrix and read-only properties to provide information about the configured matrix.

### Creation

#### Syntax

```
decodercfg = ldpcDecoderConfig
decodercfg = ldpcDecoderConfig(H)
decodercfg = ldpcDecoderConfig(H,alg)
decodercfg = ldpcDecoderConfig(encodercfg)
decodercfg = ldpcDecoderConfig(encodercfg,alg)
```

#### Description

`decodercfg = ldpcDecoderConfig` creates an LDPC decoder configuration object that specifies a rate 5/6 LDPC code from the WLAN 802.11 standard [1].

`decodercfg = ldpcDecoderConfig(H)` configures the output object setting the `ParityCheckMatrix` property `H`.

`decodercfg = ldpcDecoderConfig(H,alg)` configures the output object setting the `ParityCheckMatrix` property to `H` and the `Algorithm` property to `alg`.

`decodercfg = ldpcDecoderConfig(encodercfg)` sets properties based on the input `ldpcEncoderConfig` configuration object, `encodercfg`.

`decodercfg = ldpcDecoderConfig(encodercfg,alg)` sets properties based on the input `ldpcEncoderConfig` configuration object, `encodercfg`, and sets the `Algorithm` property to `alg`.

Validation of the object settings is performed when the `ldpcDecode` function is called with the object as an input.

### Properties

#### **ParityCheckMatrix** — Parity-check matrix

sparse logical 108-by-648 matrix (default) | sparse logical  $(N - K)$ -by- $N$  matrix

Parity-check matrix, specified as a sparse logical  $(N - K)$ -by- $N$  matrix, where  $N > K > 0$ .  $N$  is the LDPC codeword block length.  $K$  is the number of information bits in the LDPC codeword. The default is the parity-check matrix of rate 5/6 LDPC code with a block length of 648 as specified in the WLAN

802.11 standard [1]. Specifically, the default is the sparse logical 108-by-648 matrix  $H$  output by the `ldpcQuasiCyclicMatrix` function in this code.

```
P = [
    17 13  8 21  9  3 18 12 10  0  4 15 19  2  5 10 26 19 13 13  1  0 -1 -1
     3 12 11 14 11 25  5 18  0  9  2 26 26 10 24  7 14 20  4  2 -1  0  0 -1
    22 16  4  3 10 21 12  5 21 14 19  5 -1  8  5 18 11  5  5 15  0 -1  0  0
     7  7 14 14  4 16 16 24 24 10  1  7 15  6 10 26  8 18 21 14  1 -1 -1  0
];
blockSize = 27;
H = ldpcQuasiCyclicMatrix(blockSize,P);
```

Data Types: `logical`

### Algorithm — LDPC decoding algorithm

'bp' (default) | 'layered-bp' | 'norm-min-sum' | 'offset-min-sum'

LDPC decoding algorithm, specified as one of these values:

- 'bp' — Use “Belief Propagation Decoding” on page 3-836 algorithm.
- 'layered-bp' — Use “Layered Belief Propagation Decoding” on page 3-837 algorithm.
- 'norm-min-sum' — Use “Normalized Min-Sum Decoding” on page 3-838 algorithm.
- 'offset-min-sum' — Use “Offset Min-Sum Decoding” on page 3-838 algorithm.

Data Types: `char` | `string`

### BlockLength — Block length

648 (default) | positive scalar

This property is read-only.

Block length of the LDPC codeword ( $N$ ), specified as a positive scalar.  $N$  equals the number of columns in the parity-check matrix.

Data Types: `double`

### NumInformationBits — Number of information bits

540 (default) | positive scalar

This property is read-only.

Number of information bits in the LDPC codeword ( $K$ ), specified as a positive scalar.  $K$  equals the number of columns of the parity-check matrix minus the number of rows of the parity-check matrix.

Data Types: `double`

### NumParityCheckBits — Number of parity-check bits

108 (default) | positive scalar

This property is read-only.

Number of parity-check bits in the LDPC codeword ( $N - K$ ), specified as a positive scalar.  $N - K$  equals the number of rows in the parity-check matrix.

Data Types: `double`

**CodeRate — Code rate of LDPC code**

5/6 (default) | positive scalar

This property is read-only.

Code rate of the LDPC code, specified as a positive scalar that is equal to NumInformationBits/BlockLength.

Data Types: double

**NumRowsPerLayer — Number of rows per layer**

108 (default) | positive scalar

This property is read-only.

Number of rows per layer, specified as a positive scalar. This property indicates the number of rows per layer when you use a layered decoding algorithm. Specifically, this property is the largest integer such that ParityCheckMatrix can be evenly split into consecutive submatrices in which at most one 1 exists in any column in any one of these submatrices.

ParityCheckMatrix(1:NumRowsPerLayer,:)

ParityCheckMatrix((NumRowsPerLayer + 1):2\*NumRowsPerLayer,:)

ParityCheckMatrix((2\*NumRowsPerLayer + 1):3\*NumRowsPerLayer,:)

...

ParityCheckMatrix((end - NumRowsPerLayer + 1):end,:)

**Dependencies**

To enable this property set the Algorithm property to 'layered-bp', 'norm-min-sum', or 'offset-min-sum'.

Data Types: double

**Examples****Decode Rate 3/4 LDPC Codewords**

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the ldpcQuasiCyclicMatrix function.

```
P = [
    16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
    25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
    25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
     9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
    24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
     2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create LDPC encoder and decoder configuration objects, displaying their properties.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =
  ldpcEncoderConfig with properties:

    ParityCheckMatrix: [162x648 logical]

  Read-only properties:
    BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
    CodeRate: 0.7500
```

```
cfgLDPCDec = ldpcDecoderConfig(pcmatrix)
```

```
cfgLDPCDec =
  ldpcDecoderConfig with properties:

    ParityCheckMatrix: [162x648 logical]
    Algorithm: 'bp'

  Read-only properties:
    BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
    CodeRate: 0.7500
```

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate the signal, decode the received codewords, and then count bit errors. Use nested `for` loops to process multiple SNR settings and frames with and without LDPC forward error correction (FEC) coding of the transmitted data.

```
M = 4;
maxnumiter = 10;
snr = [3 6 20];
numframes = 10;

ber = comm.ErrorRate;
ber2 = comm.ErrorRate;

for ii = 1:length(snr)
    for counter = 1:numframes
        data = randi([0 1],cfgLDPCEnc.NumInformationBits,1,'int8');
        % Transmit and receive with LDPC coding
        encodedData = ldpcEncode(data, cfgLDPCEnc);
        modSignal = pskmod(encodedData, M, InputType='bit');
        [rxsig, noisevar] = awgn(modSignal, snr(ii));
        demodSignal = pskdemod(rxsig, M, ...
            OutputType='approxllr', ...
            NoiseVariance=noisevar);
        rxbits = ldpcDecode(demodSignal, cfgLDPCDec, maxnumiter);
        errStats = ber(data, rxbits);
        % Transmit and receive with no LDPC coding
        noCoding = pskmod(data, M, InputType='bit');
```

```

    rxNoCoding = awgn(noCoding,snr(ii));
    rxBitsNoCoding = pskdemod(rxNoCoding,M,OutputType='bit');
    errStatsNoCoding = ber2(data,int8(rxBitsNoCoding));
end
fprintf(['SNR = %2d\n   Coded: Error rate = %1.2f, ' ...

        snr(ii),errStats(1),errStats(2))
fprintf(['Noncoded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        errStatsNoCoding(1),errStatsNoCoding(2))
reset(ber);
reset(ber2);
end
SNR = 3
    Coded: Error rate = 0.06, Number of errors = 315
Noncoded: Error rate = 0.08, Number of errors = 366
SNR = 6
    Coded: Error rate = 0.00, Number of errors = 0
Noncoded: Error rate = 0.02, Number of errors = 112
SNR = 20
    Coded: Error rate = 0.00, Number of errors = 0
Noncoded: Error rate = 0.00, Number of errors = 0

```

## Algorithms

LDPC decoding using one of these message-passing algorithms.

### Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword  $c = c_0, c_1, \dots, c_{n-1}$ , the input to the LDPC decoder is the log-likelihood ratio (LLR) value  $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)}\right)$ .

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left( \prod_{i' \in \mathcal{V}_j \setminus i} \tanh \left( \frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in \mathcal{C}_i \setminus j} L(r_{ji}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

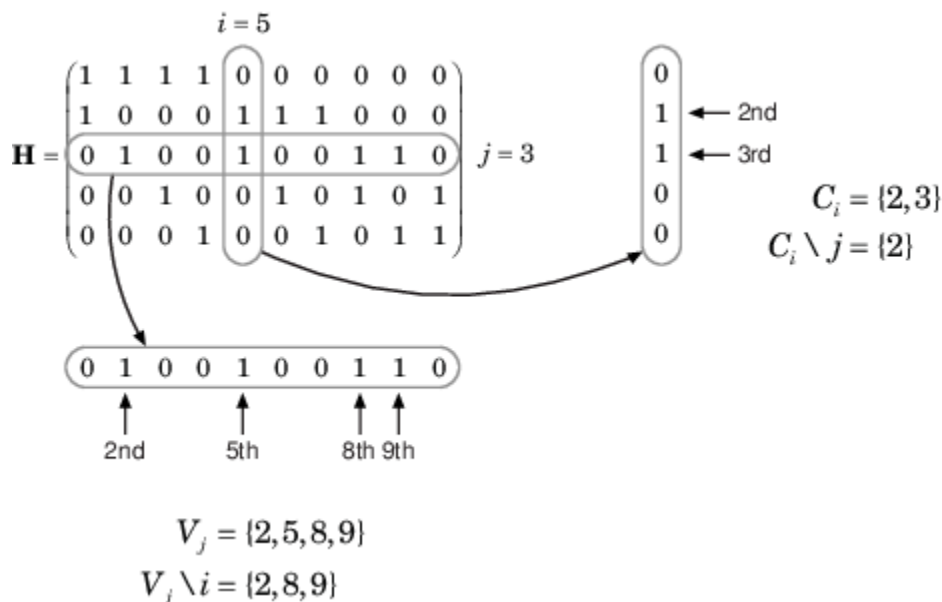

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}).$$

At the end of each iteration,  $L(Q_i)$  contains the updated estimate of the LLR value for transmitted bit  $c_i$ . The value  $L(Q_i)$  is the soft-decision output for  $c_i$ . If  $L(Q_i) < 0$ , the hard-decision output for  $c_i$  is 1. Otherwise, the hard-decision output for  $c_i$  is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ( $H c' = 0$ ) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets  $C_i \setminus j$  and  $V_j \setminus i$  are based on the parity-check matrix (PCM). Index sets  $C_i$  and  $V_j$  correspond to all nonzero elements in column  $i$  and row  $j$  of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for  $i = 5$  and  $j = 3$ .

To avoid infinite numbers in the algorithm equations,  $\text{atanh}(1)$  and  $\text{atanh}(-1)$  are set to 19.07 and  $-19.07$ , respectively. Due to finite precision, MATLAB returns 1 for  $\tanh(19.07)$  and  $-1$  for  $\tanh(-19.07)$ .

### Layered Belief Propagation Decoding

The implementation of the layered belief propagation algorithm is based on the decoding algorithm presented in Hocevar [3], Section II.A. The decoding loop iterates over subsets of rows (layers) of the PCM. For each row,  $m$ , in a layer and each bit index,  $j$ , the implementation updates the key components of the algorithm based on these equations:

$$(1) L(q_{mj}) = L(q_j) - R_{mj},$$

$$(2) A_{mj} = \sum_{\substack{n \in N(m) \\ n \neq j}} \psi(L(q_{mn})),$$

$$(3) s_{mj} = \prod_{\substack{n \in N(m) \\ n \neq j}} \text{sign}(L(q_{mn})),$$

$$(4) R_{mj} = -s_{mj}\psi(A_{mj}), \text{ and}$$

$$(5) L(q_j) = L(q_{mj}) + R_{mj}.$$

For each layer, the decoding equation (5) works on the combined input obtained from the current LLR inputs  $L(q_{mj})$  and the previous layer updates  $R_{mj}$ .

Because only a subset of the nodes is updated in a layer, the layered belief propagation algorithm is faster compared to the belief propagation algorithm. To achieve the same error rate as attained with belief propagation decoding, use half the number of decoding iterations when you use the layered belief propagation algorithm.

### Normalized Min-Sum Decoding

The implementation of the normalized min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| \cdot \alpha),$$

where  $\alpha$  is in the range (0, 1] and is the scaling factor specified by the `MinSumScalingFactor` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (4) presented in Chen [4].

### Offset Min-Sum Decoding

The implementation of the offset min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \max\left(\min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| - \beta), 0\right),$$

where  $\beta \geq 0$  and is the offset specified by the `MinSumOffset` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (5) presented in Chen [4].

### Objects

ldpcEncoderConfig

## ldpcEncoderConfig

Create LDPC encoder configuration

### Description

The `ldpcEncoderConfig` object is a configuration object for the `ldpcEncode` function. The object specifies the low-density parity-check (LDPC) matrix and read-only properties to provide information about the configured matrix.

### Creation

#### Syntax

```
encoderCfg = ldpcEncoderConfig
encoderCfg = ldpcEncoderConfig(H)
encoderCfg = ldpcEncoderConfig(decoderCfg)
```

#### Description

`encoderCfg = ldpcEncoderConfig` creates an LDPC encoder configuration object that specifies a rate 5/6 LDPC code from the WLAN 802.11 standard [1].

`encoderCfg = ldpcEncoderConfig(H)` configures the output object setting the `ParityCheckMatrix` property to `H`.

`encoderCfg = ldpcEncoderConfig(decoderCfg)` sets properties based on the input `ldpcDecoderConfig` configuration object, `decoderCfg`.

Validation of the object settings is performed when the `ldpcEncode` function is called with the object as an input.

### Properties

#### ParityCheckMatrix — Parity-check matrix

sparse logical 108-by-648 matrix (default) | sparse logical  $(N - K)$ -by- $N$  matrix

Parity-check matrix, specified as a sparse logical  $(N - K)$ -by- $N$  matrix, where  $N > K > 0$ . The last  $N - K$  rows of the parity-check matrix must be invertible in a Galois field of order 2.  $N$  is the LDPC codeword block length.  $K$  is the number of information bits in the LDPC codeword. The default is the parity-check matrix of rate 5/6 LDPC code with a block length of 648 as specified in the WLAN 802.11 standard [1]. Specifically, the default is the sparse logical 108-by-648 matrix `H` output by the `ldpcQuasiCyclicMatrix` function in this code.

```
P = [
17 13 8 21 9 3 18 12 10 0 4 15 19 2 5 10 26 19 13 13 1 0 -1 -1
3 12 11 14 11 25 5 18 0 9 2 26 26 10 24 7 14 20 4 2 -1 0 0 -1
22 16 4 3 10 21 12 5 21 14 19 5 -1 8 5 18 11 5 5 15 0 -1 0 0
7 7 14 14 4 16 16 24 24 10 1 7 15 6 10 26 8 18 21 14 1 -1 -1 0
```

```
];
blockSize = 27;
H = ldpcQuasiCyclicMatrix(blockSize,P);
```

Data Types: logical

### BlockLength — Block length

648 (default) | positive scalar

This property is read-only.

Block length of the LDPC codeword ( $N$ ), specified as a positive scalar.  $N$  equals the number of columns in the parity-check matrix.

Data Types: double

### NumInformationBits — Number of information bits

540 (default) | positive scalar

This property is read-only.

Number of information bits in the LDPC codeword ( $K$ ), specified as a positive scalar.  $K$  equals the number of columns of the parity-check matrix minus the number of rows of the parity-check matrix.

Data Types: double

### NumParityCheckBits — Number of parity-check bits

108 (default) | positive scalar

This property is read-only.

Number of parity-check bits in the LDPC codeword ( $N - K$ ), specified as a positive scalar.  $N - K$  equals the number of rows in the parity-check matrix.

Data Types: double

### CodeRate — Code rate of LDPC code

5/6 (default) | positive scalar

This property is read-only.

Code rate of the LDPC code, specified as a positive scalar that is equal to `NumInformationBits/BlockLength`.

Data Types: double

## Examples

### Encode Information Bits Using Rate 3/4 LDPC Code

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [16 17 22 24 9 3 14 -1 4 2 7 -1 26 -1 2 -1 21 -1 1 0 -1 -1 -1 -1
      25 12 12 3 3 26 6 21 -1 15 22 -1 15 -1 4 -1 -1 16 -1 0 0 -1 -1 -1
```

```
    25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
    9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
    24 5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
    2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create an LDPC encoder configuration object, displaying its properties. Generate random information bits by using the `NumInformationBits` property of the configuration object to specify the number of information bits in an LDPC codeword. Encode the information bits by the LDPC code specified by the LDPC encoder configuration object.

```
cfgLDPCenc = ldpcEncoderConfig(pcmatrix)

cfgLDPCenc =
  ldpcEncoderConfig with properties:

    ParityCheckMatrix: [162x648 logical]

  Read-only properties:
    BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
    CodeRate: 0.7500

infoBits = rand(cfgLDPCenc.NumInformationBits,1) < 0.5;
codeword = ldpcEncode(infoBits, cfgLDPCenc);
```

## comm.LTEMIMOChannel

**Package:** comm

(Removed) Filter input signal through LTE MIMO multipath fading channel

---

**Note** `comm.LTEMIMOChannel` has been. Use `comm.MIMOChannel` instead. For information on updating your code, see “Version History”.

---

### Description

The `comm.LTEMIMOChannel` System object filters an input signal through an LTE multiple-input multiple-output (MIMO) multipath fading channel.

A specialization of the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System objects offers pre-set configurations for use with LTE link level simulations. In addition to the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System object also corrects the correlation matrix to be positive semi-definite, after rounding to 4-digit precision. This System object models Rayleigh fading for each of its links.

To filter an input signal using an LTE MIMO multipath fading channel:

- 1 Define and set up your LTE MIMO multipath fading channel object. See “Construction” on page 3-844.
- 2 Call `step` to filter the input signal using an LTE MIMO multipath fading channel according to the properties of `comm.LTEMIMOChannel`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.LTEMIMOChannel` creates a 3GPP Long Term Evolution (LTE) Release 10 specified multiple-input multiple-output (MIMO) multipath fading channel System object, `H`. This object filters a real or complex input signal through the multipath LTE MIMO channel to obtain the channel impaired signal.

`H = comm.LTEMIMOChannel(Name, Value)` creates an LTE MIMO multipath fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

## Properties

### SampleRate

Input signal sample rate (Hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 30.72 MHz, as defined in the LTE specification.

### Profile

Channel propagation profile

Specify the propagation conditions of the LTE multipath fading channel as one of EPA 5Hz | EVA 5Hz | EVA 70Hz | ETU 70Hz | ETU 300Hz, which are supported in the LTE specification Release 10. The default value of this property is EPA 5Hz.

This property defines the delay profile of the channel to be one of EPA, EVA, and ETU. This property also defines the maximum Doppler shift of the channel to be 5 Hz, 70 Hz, or 300 Hz. The Doppler spectrum always has a Jakes shape in the LTE specification. The EPA profile has seven paths. The EVA and ETU profiles have nine paths.

The following tables list the delay and relative power per path associated with each profile.

#### Extended Pedestrian A Model (EPA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.0
70	-2.0
90	-3.0
110	-8.0
190	-17.2
410	-20.8

#### Extended Vehicular A Model (EVA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.5
150	-1.4
310	-3.6
370	-0.6
710	-9.1
1090	-7.0

Excess tap delay [ns]	Relative power [db]
1730	-12.0
2510	-16.9

**Extended Typical Urban Model (ETU)**

Excess tap delay [ns]	Relative power [db]
0	-1.0
50	-1.0
120	-1.0
200	0.0
230	0.0
500	0.0
1600	-3.0
2300	-5.0
5000	-7.0

**AntennaConfiguration**

Antenna configuration

Specify the antenna configuration of the LTE MIMO channel as one of 1x2 | 2x2 | 4x2 | 4x4. These configurations are supported in the LTE specification Release 10. The default value of this property is 2x2.

The property value is in the format of  $N_t$ -by- $N_r$ .  $N_t$  represents the number of transmit antennas and  $N_r$  represents the number of receive antennas.

**CorrelationLevel**

Spatial correlation strength

Specify the spatial correlation strength of the LTE MIMO channel as one of Low | Medium | High. The default value of this property is Low. When you set this property to Low, the MIMO channel is spatially uncorrelated.

The transmit and receive spatial correlation matrices are defined from this property according to the LTE specification Release 10. See the Algorithms section for more information.

**AntennaSelection**

Antenna selection

Specify the antenna selection scheme as one of Off | Tx | Rx | Tx and Rx, where Tx represents transmit antennas and Rx represents receive antennas. When you select Tx and/or Rx, additional input(s) are required to specify which antennas are selected for signal transmission. The default value of this property is Off.

## RandomStream

Source of random number stream

Specify the source of random number stream as one of `Global stream` | `mt19937ar with seed`. The default value of this property is `Global stream`. When you set this property to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar with seed`, the object uses the `mt19937ar` algorithm for normally distributed random number generation. In this case, the `reset` method resets the filters and reinitializes the random number stream to the value of the `Seed` property.

## Seed

Initial seed of `mt19937ar` random number stream

Specify the initial seed of an `mt19937ar` random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is `73`. This property applies when you set the `RandomStream` property to `mt19937ar with seed`. The `Seed` reinitializes the `mt19937ar` random number stream in the `reset` method.

## NormalizePathGains

Normalize path gains (logical)

Set this property to `true` to normalize the fading processes so that the total power of the path gains, averaged over time, is `0` dB. The default value of this property is `true`. When you set this property to `false`, there is no normalization for path gains.

## NormalizeChannelOutputs

Normalize channel outputs (logical)

Set this property to `true` to normalize the channel outputs by the number of receive antennas. The default value of this property is `true`. When you set this property to `false`, there is no normalization for channel outputs.

## PathGainsOutputPort

Enable path gain output (logical)

Set this property to `true` to output the channel path gains of the underlying fading process. The default value of this property is `false`.

## Methods

`reset` (Removed) Reset states of the `LTEMIMOChannel` object

`step` (Removed) Filter input signal through LTE MIMO multipath fading channel

Common to All System Objects	
release	Allow System object property value changes

## Examples

### Configure MIMO Channel Object Using LTE MIMO Channel Object

Configure an equivalent MIMOChannel System Object using the LTEMIMOChannel System Object. Then, verify that the channel output and the path gain output from the two objects are the same.

Create a PSK Modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],2e3,1));
```

Split modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 1e3]).';
```

Create an LTEMIMOChannel System object with a 2-by-2 antenna configuration and a medium correlation level.

```
lteChan = comm.LTEMIMOChannel(...
    'Profile', 'EVA 5Hz',...
    'AntennaConfiguration', '2x2',...
    'CorrelationLevel', 'Medium',...
    'AntennaSelection', 'Off',...
    'RandomStream', 'mt19937ar with seed',...
    'Seed', 99,...
    'PathGainsOutputPort', true);
```

Error: COMM.LTEMIMOCHANNEL has been removed. Use COMM.MIMOCHANNEL or LTEFADINGCHANNEL instead.

Filter the modulated data using the LTEMIMOChannel System object, lteChan.

```
[LTEChanOut,LTEPathGains] = lteChan(channelInput);
```

Create an equivalent MIMOChannel System object, mimoChannel, using the properties of the LTEMIMOChannel System object, lteChan.

The KFactor, DirectPathDopplerShift and DirectPathInitialPhase properties only exist for the MIMOChannel System object. All other MIMOChannel System object properties also exist for the LTEMIMOChannel System object; however, some properties are hidden and read-only.

```
mimoChannel = comm.MIMOChannel( ...
    'SampleRate',lteChan.SampleRate, ...
    'PathDelays',lteChan.PathDelays, ...
    'AveragePathGains',lteChan.AveragePathGains, ...
    'NormalizePathGains',lteChan.NormalizePathGains, ...
    'FadingDistribution',lteChan.FadingDistribution, ...
    'MaximumDopplerShift',lteChan.MaximumDopplerShift, ...
    'DopplerSpectrum',lteChan.DopplerSpectrum, ...
    'SpatialCorrelationSpecification', ...
        lteChan.SpatialCorrelationSpecification, ...
    'SpatialCorrelationMatrix',lteChan.SpatialCorrelationMatrix, ...
```

```
'AntennaSelection',lteChan.AntennaSelection, ...
'NormalizeChannelOutputs',lteChan.NormalizeChannelOutputs, ...
'RandomStream',lteChan.RandomStream, ...
'Seed',lteChan.Seed, ...
'PathGainsOutputPort',lteChan.PathGainsOutputPort);
```

Filter the modulated data using the equivalent mimoChannel object.

```
[MIMOChanOut, MIMOPathGains] = mimoChannel(channelInput);
```

Verify that the channel output and the path gain output from the two objects are the same.

```
sameChOutput = isequal(LTEChanOut,MIMOChanOut)
```

```
sameChOutput = logical
    1
```

```
samePathGains = isequal(LTEPathGains,MIMOPathGains)
```

```
samePathGains = logical
    1
```

You can repeat the preceding process with AntennaConfiguration set to 4x2 or 4x4 and CorrelationLevel set to Medium or High for lteChan.

## Algorithms

This System object is a specialized implementation of the comm.MIMOChannel System object. For additional algorithm information, see the comm.MIMOChannel System object help page.

### Spatial Correlation Matrices

The following table defines the transmitter eNodeB correlation matrix.

	One Antenna	Two Antennas	Four Antennas
eNodeB Correlation	$R_{eNB} = 1$	$R_{eNB} = \begin{pmatrix} 1 & \alpha \\ \alpha^* & 1 \end{pmatrix}$	$R_{eNB} = \begin{pmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{pmatrix}$

The following table defines the receiver UE correlation matrix.

	One Antenna	Two Antennas	Four Antennas
UE Correlation	$R_{UE} = 1$	$R_{UE} = \begin{pmatrix} 1 & \beta \\ \beta^* & 1 \end{pmatrix}$	$R_{UE} = \begin{pmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{pmatrix}$

The following table describes the  $R_{\text{spat}}$  channel spatial correlation matrix between the transmitter and receiver antennas.

Tx-by-Rx Configuration	Correlation Matrix
1-by-2	$R_{\text{spat}} = R_{UE} = \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$

Tx-by-Rx Configuration	Correlation Matrix
2-by-2	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha \\ \alpha^* & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$ $= \begin{bmatrix} 1 & \beta & \alpha & \alpha\beta \\ \beta^* & 1 & \alpha\beta^* & \alpha \\ \alpha^* & \alpha^*\beta & 1 & \beta \\ \alpha^*\beta^* & \alpha^* & \beta^* & 1 \end{bmatrix}$
4-by-2	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix}$ $\otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$
4-by-4	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix}$ $\otimes \begin{bmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{bmatrix}$

### Spatial Correlation Correction

Low Correlation		Medium Correlation		High Correlation	
$\alpha$	$\beta$	$\alpha$	$\beta$	$\alpha$	$\beta$
0	0	0.3	0.9	0.9	0.9

To insure the correlation matrix is positive semi-definite after round-off to 4 digit precision, this System object uses the following equation:

$$R_{high} = [R_{spatial} + aI_n]/(1 + a)$$

Where

$\alpha$  represents the scaling factor such that the smallest value is used to obtain a positive semi-definite result.

For the 4-by-2 high correlation case,  $\alpha=0.00010$ .

For the 4-by-4 high correlation case,  $\alpha=0.00012$ .

The object uses the same method to adjust the 4-by-4 medium correlation matrix to insure the correlation matrix is positive semi-definite after rounding to 4 digit precision with  $\alpha = 0.00012$ .

## Version History

### Introduced in R2012a

#### **R2022b: Function has been removed**

*Errors starting in R2022b*

The `comm.LTEMIMOChannel System` object has been removed. Use `comm.MIMOChannel System` object to filter the input signal through MIMO multipath fading channel.

#### **R2018b: Function issues a warning**

*Warns starting in R2018b*

The `comm.LTEMIMOChannel System` object issues a warning that it will be removed in a future release.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**See Also**

comm.MIMOChannel

## reset

**System object:** `comm.LTEMIMOChannel`

**Package:** `comm`

(Removed) Reset states of the `LTEMIMOChannel` object

---

**Note** `comm.LTEMIMOChannel` has been removed in a future release. Use `comm.MIMOChannel` instead.

---

### Syntax

`reset(H)`

### Description

`reset(H)` resets the states of the `LTEMIMOChannel` object, `H`.

If you set the `RandomStream` property of `H` to `Global` stream, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

## step

**System object:** `comm.LTEMIMOChannel`

**Package:** `comm`

(Removed) Filter input signal through LTE MIMO multipath fading channel

---

**Note** `comm.LTEMIMOChannel` has been removed in a future release. Use `comm.MIMOChannel` instead.

---

### Syntax

`Y = step(H,X)`  
`[Y,PATHGAINS] = step(H,X)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` filters input signal `X` through an LTE MIMO multipath fading channel and returns the result in `Y`. The input `X` can be a double- or single-precision data type scalar, vector, or 2-D matrix with real or complex values. `X` is of size  $N_s$ -by- $N_t$ .  $N_s$  represents the number of samples and  $N_t$  represents the number of transmit antennas that must match the `AntennaConfiguration` property setting of `H`. `Y` is the output signal of size  $N_s$ -by- $N_r$ .  $N_r$  represents the number of receive antennas that is specified by the `AntennaConfiguration` property of `H`. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the LTE MIMO channel path gains of the underlying fading process in `PATHGAINS`. This applies when you set the `PathGainsOutputPort` property to `true`. `PATHGAINS` is of size  $N_s$ -by- $N_p$ -by- $N_t$ -by- $N_r$ .  $N_p$  represents the number of discrete paths of the channel implicitly defined by the `Profile` property of `H`. `PATHGAINS` contains complex values with same precision as input signal.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.MemorylessNonlinearity

**Package:** comm

Apply memoryless nonlinearity to complex baseband signal

## Description

The `comm.MemorylessNonlinearity` System object applies memoryless nonlinear impairments to a baseband signal. Use this System object to model memoryless nonlinear impairments caused by signal amplification in a radio frequency (RF) transmitter or receiver. For more information, see “Memoryless Nonlinear Impairments” on page 3-873.

To apply memoryless nonlinear impairments to a complex baseband signal:

- 1 Create the `comm.MemorylessNonlinearity` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mnl = comm.MemorylessNonlinearity  
mnl = comm.MemorylessNonlinearity(Name,Value)
```

### Description

`mnl = comm.MemorylessNonlinearity` creates a memoryless nonlinearity System object that models RF nonlinear impairments.

`mnl = comm.MemorylessNonlinearity(Name,Value)` specifies properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `'Method', 'Saleh model'` sets the modeling method to the Saleh method.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### Method — Nonlinearity modeling method

```
'Cubic polynomial' (default) | 'Hyperbolic tangent' | 'Saleh model' | 'Ghorbani  
model' | 'Modified Rapp model' | 'Lookup table'
```

Nonlinearity modeling method, specified as 'Cubic polynomial', 'Hyperbolic tangent', 'Saleh model', 'Ghorbani model', 'Modified Rapp model', or 'Lookup table'. For more information, see “Memoryless Nonlinear Impairments” on page 3-873.

Data Types: char | string

### **InputScaling — Input signal scaling factor**

0 (default) | scalar

Input signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the input signal.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the Method property to 'Saleh model' or 'Ghorbani model'.

Data Types: double

### **LinearGain — Linear gain**

0 (default) | scalar

Linear gain in decibels, specified as a scalar. This property scales the power gain of the output signal.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the Method property to 'Cubic polynomial', 'Hyperbolic tangent', or 'Modified Rapp model'.

Data Types: double

### **T0ISpecification — Third-order nonlinearity specification for cubic polynomial**

'IIP3' (default) | 'OIP3' | 'IP1dB' | 'OP1dB' | 'IPsat' | 'OPsat'

Third-order nonlinearity specification for cubic polynomial, specified as 'IIP3', 'OIP3', 'IP1dB', 'OP1dB', 'IPsat', or 'OPsat'. For more information, see “Cubic Polynomial Third-Order Coefficient” on page 3-875.

#### **Dependencies**

To enable this property, set the Method property to 'Cubic polynomial'.

Data Types: char | string

### **IIP3 — Third-order input intercept point**

30 (default) | scalar

Third-order input intercept point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

**OIP3 — Third-order output intercept point**

30 (default) | scalar

Third-order output intercept point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'OIP3'.

Data Types: double

**IP1dB — One dB input compression point**

30 (default) | scalar

One dB input compression point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'IP1dB'.

Data Types: double

**OP1dB — One dB output compression point**

30 (default) | scalar

One dB output compression point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'OP1dB'.

Data Types: double

**IPsat — Input saturation point**

30 (default) | scalar

Input saturation point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `Method` property to 'Cubic polynomial' and the `TOISpecification` property to 'IPsat'.

Data Types: double

**OPsat — Output saturation point**

30 (default) | scalar

Output saturation point in dBm, specified as a scalar.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `Method` property to 'Cubic polynomial' and the `TOISpecification` property to 'OPsat'.

Data Types: double

**AMPMConversion — Linear AM/PM conversion factor**

10 (default) | scalar

Linear AM/PM conversion factor in degrees per decibel, specified as a scalar. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-875.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `Method` property to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

**AMAMPParameters — AM/AM parameters**

[2.1587 1.1517] | [8.1081 1.5413 6.5202 -0.0718] | row vector

AM/AM parameters used to compute the amplitude gain for an input signal, specified as a row vector.

- When the `Method` property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [2.1587 1.1517].
- When the `Method` property is set to 'Ghorbani model', this property must be a four-element vector that specifies  $x_1$ ,  $x_2$ ,  $x_3$ , and  $x_4$  values. In this case, the default value is [8.1081 1.5413 6.5202 -0.0718].

For more information, see “Saleh Model Method” on page 3-877 and “Ghorbani Model Method” on page 3-878.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `Method` property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

**AMPMPParameters — AM/PM parameters**

[4.0033 9.1040] | [4.6645 2.0965 10.88 -0.003] | row vector

AM/PM parameters used to compute the phase change for an input signal, specified as a row vector.

- When the Method property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [4.0033 9.1040].
- When the Method property is set to 'Ghorbani model', this property must be a four-element vector that specifies  $y_1$ ,  $y_2$ ,  $y_3$ , and  $y_4$  values. In this case, the default value is [4.6645 2.0965 10.88 -0.003]

For more information, see “Saleh Model Method” on page 3-877 and “Ghorbani Model Method” on page 3-878.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

**PowerLowerLimit — Input power lower limit**

10 (default) | scalar

Input power lower limit in dBm, specified as a scalar less than the PowerUpperLimit property value. The AM/PM conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-875.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

**PowerUpperLimit — Input power upper limit**

inf (default) | scalar

Input power upper limit in dBm, specified as a scalar greater than PowerLowerLimit. The AM/PM conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is above the input power upper limit, the phase shift resulting from AM/PM conversion is constant. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-875.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

**OutputScaling — Output signal scaling factor**

0 (default) | scalar

Output signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the output signal.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

**Smoothness — Amplitude smoothness factor**

0.5 (default) | scalar

Amplitude smoothness factor, specified as a scalar. For more information, see “Modified Rapp Model Method” on page 3-879.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

**PhaseGainRadian — Phase gain for modified Rapp model**

0 (default) | scalar

Phase gain for modified Rapp model in radians, specified as a scalar. A value of -0.45 is typical. For more information, see “Modified Rapp Model Method” on page 3-879.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

**PhaseSaturation — Phase saturation for modified Rapp model**

0.88 (default) | positive scalar

Phase saturation for modified Rapp model in radians, specified as a positive scalar. For more information, see “Modified Rapp Model Method” on page 3-879.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

**PhaseSmoothness — Phase smoothness for modified Rapp model**

3.43 (default) | positive scalar

Phase smoothness for modified Rapp model in radians, specified as a positive scalar. For more information, see “Modified Rapp Model Method” on page 3-879.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

**OutputSaturationLevel — Output saturation level**

1 (default) | positive scalar

Output saturation level, specified as a scalar. For more information, see “Modified Rapp Model Method” on page 3-879.

**Tunable:** Yes

**Dependencies**

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

**Table — Amplifier characteristics lookup table**

$N$ -by- $[P_{in}, P_{out}, \Delta\Phi]$  matrix

Amplifier characteristics lookup table, specified as an  $N$ -by-3 matrix of measured power amplifier (PA) characteristics. Each row is of the form  $[P_{in}, P_{out}, \Delta\Phi]$ .  $P_{in}$  specifies the input signal in dBm,  $P_{out}$  specifies the output signal in dBm, and  $\Delta\Phi$  specifies the output phase shift in degrees. The default value is  $[-25, 5.16, -0.25; -20, 10.11, -0.47; -15, 15.11, -0.68; -10, 20.05, -0.89; -5, 24.79, -1.22; 0, 27.64, 5.59; 5, 28.49, 12.03]$ .

The measured PA characteristics defined by this property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics.

---

**Note** To determine appropriate  $P_{out}$  and  $\Delta\Phi$  values for any  $P_{in}$  values outside the range of values specified in the Table property, the System object applies linear extrapolation from the first two or last two  $[P_{in}, P_{out}, \Delta\Phi]$  rows of Table.

---

**Tunable:** Yes

## Dependencies

To enable this property, set the Method property to 'Lookup table'.

Data Types: double

## ReferenceImpedance — Reference impedance

1 (default) | positive scalar

Reference impedance in ohms, specified as a positive scalar. This value is used to convert voltage values to power values.

**Tunable:** Yes

Data Types: double

## Usage

### Syntax

```
outsig = mnl(insig)
```

### Description

`outsig = mnl(insig)` applies memoryless nonlinear impairments to the input RF baseband signal.

### Input Arguments

#### **insig** — Input RF baseband signal

scalar | column vector | matrix

Input RF baseband signal, specified as a scalar, column vector, or matrix.

Data Types: double

### Output Arguments

#### **outsig** — Output RF baseband signal

scalar | column vector | matrix

Output RF baseband signal, returned as a scalar, column vector, or matrix. The output is of the same data type as the input.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.MemorylessNonlinearity

`release` Release resources and allow changes to System object property values and input characteristics

clone	Create duplicate System object
isLocked	Determine if System object is in use
plot (memorylessnonlinearity)	Plot nonlinearity AM/AM and AM/PM characteristics

### Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

## Examples

### Show Amplification of Signal at Linear and Nonlinear Input Power Levels

Apply cubic polynomial nonlinearity to two 16-QAM signals. The first input signal power level is in the linear region of the amplifier power characteristic curve. The second input signal power level is in the nonlinear region of the amplifier power characteristic curve. Show the amplifier power characteristic curve and the constellation diagram for the amplified 16-QAM signals.

#### Initialize Simulation

Initialize variables for simulation and create System objects for a memoryless nonlinearity amplifier impairment and a constellation diagram. So that the constellation shows power compression only (and no phase rotation), configure the memoryless nonlinearity amplifier impairment with AM-PM distortion set to zero.

```
M = 16;           % Modulation order
sps = 4;         % Samples per symbol
pindBm = [12 25]; % Input power
gain = 10;      % Amplifier gain

amplifier = comm.MemorylessNonlinearity("Method","Cubic polynomial", ...
    "LinearGain",gain,"AMPMConversion",0,"ReferenceImpedance",50);
refConst = qammod([0:M-1],M);
axisLimits = [-gain gain];
constdiag = comm.ConstellationDiagram("NumInputPorts",2, ...
    "ChannelNames",["Linear" "Nonlinear"],"ShowLegend",true, ...
    "ReferenceConstellation",refConst, ...
    "XLimits",axisLimits,"YLimits",axisLimits);
```

#### Amplify and Plot Signal

Apply 16-QAM to an input signal of random data. Amplify the signal and use the plot function of the comm.MemorylessNonlinearity System object to show the output power and phase response curves. The first input signal power level is 12 dBm and is in the linear region of the amplifier power characteristic curve. The second input signal power level is 25 dBm and is in the nonlinear region of the amplifier power characteristic curve.

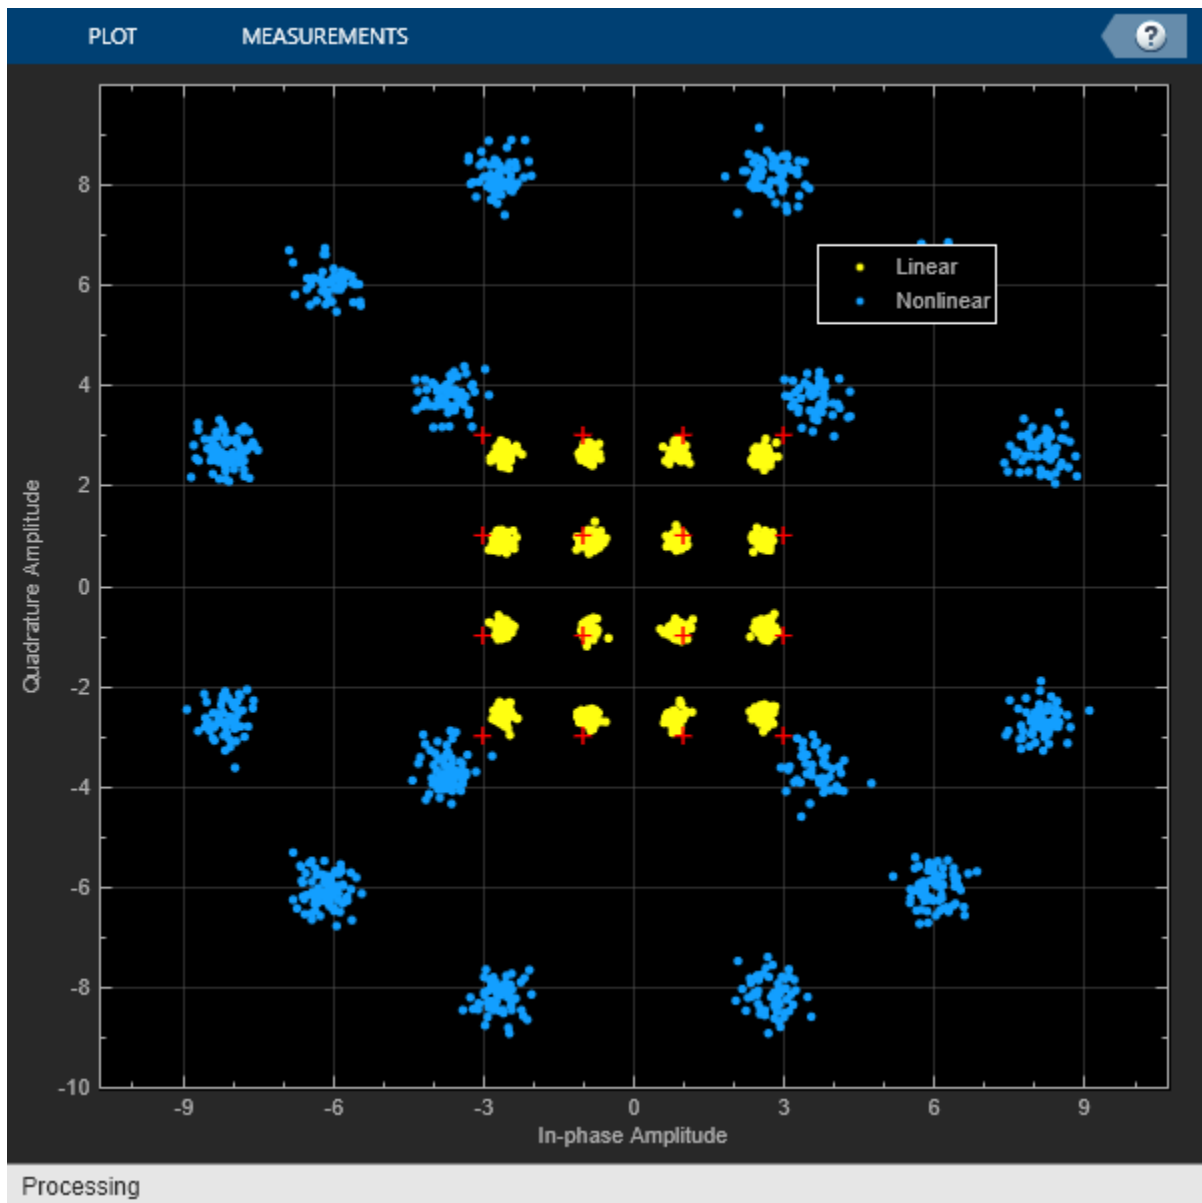

```
pin = 10.^((pindBm-30)/10); % Convert dBm to linear Watts
data = randi([0 M-1],1000,1);
modOut = qammod(data,M,"UnitAveragePower",true)*sqrt(pin*amplifier.ReferenceImpedance);
ampOut = amplifier(modOut);
plot(amplifier);
```

Add AWGN to the two amplified signals and show the constellation diagram for the signals.

```
snr = 25;
noisyLinOut = awgn(ampOut(:,1),snr,"measured");
noisyNonLinOut = awgn(ampOut(:,2),snr,"measured");
constdiag(noisyLinOut,noisyNonLinOut);
```

### Apply Saleh Model of Power Amplifier Nonlinearity to 16-QAM Signal

Generate 16-QAM data with an average power of 10 mW and a reference impedance of 1 ohm. Pass the data through a nonlinear power amplifier (PA).

```
M = 16;
data = randi([0 (M - 1)]', 1000, 1);
avgPow = 1e-2;
minD = avgPow2MinD(avgPow, M);
```

Create a memoryless nonlinearity System object, specifying the Saleh model method.

```
saleh = comm.MemorylessNonlinearity('Method', 'Saleh model');
```

Generate modulated symbols and pass them through the PA nonlinearity model.

```
modData = (minD/2).*qammod(data,M);
y = saleh(modData);
```

Generate a scatter plot of the results.

```
scatterplot(y)
```

Average power normalization of input signal.

```
function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
% Square QAM
sf = (M - 1)/6;
else
% Cross QAM
if (nBits>4)
sf = ((31*M/32) - 1)/6;
else
sf = ((5*M/4) - 1)/6;
end
end
minD = sqrt(avgPow/sf);
end
```

### Nonlinear Amplifier Gain Compression

Plot the gain compression of a nonlinear amplifier for a 16-QAM signal.

Specify the modulation order and samples per symbol parameters.

```
M = 16;  
sps = 4;
```

Model a nonlinear amplifier, by creating a memoryless nonlinearity System object with a 30 dB third-order input intercept point. Create a raised cosine transmit filter System object.

```
amplifier = comm.MemorylessNonlinearity('IIP3',30);  
txfilter = comm.RaisedCosineTransmitFilter( ...  
    'RolloffFactor',0.3,'FilterSpanInSymbols',6, ...  
    'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
```

Specify the input power in dBm and a reference impedance of 1 ohm. Convert the input power to W and initialize the gain vector.

```
pindBm = -5:25;  
pin = 10.^((pindBm-30)/10);  
gain = zeros(length(pindBm),1);
```

Execute the main processing loop, which includes these steps.

- Generate random data symbols.
- Modulate the data symbols and adjust the average power of the signal.
- Filter the modulated signal.
- Amplify the signal.
- Measure the gain.

```
for k = 1:length(pin)  
    data = randi([0 (M - 1)],1000,1);  
    modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin(k));  
    filtSig = txfilter(modSig);  
    ampSig = amplifier(filtSig);  
    gain(k) = 10*log10(mean(abs(ampSig).^2) / mean(abs(filtSig).^2));  
end
```

Plot the amplifier gain as a function of the input signal power. The 1 dB gain compression point occurs for an input power of 18.5 dBm. To increase the point at which a 1 dB compression is observed, increase the third-order intercept point, `amplifier.IIP3`.

```
arrayplot = dsp.ArrayPlot('PlotType','Line','XLabel','Power In (dBm)', ...  
    'XOffset',-5,'YLimits',[-5 5]);  
arrayplot(gain)
```

### Distort 16-QAM Signal with Measured Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics with  $50\ \Omega$  impedance to a 16-QAM signal. Load PA characteristics by setting the `Method` property to `'Lookup table'`. The `pa_performance_characteristics` helper function outputs the amplifier performance characteristics lookup table.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -8; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
paChar = pa_performance_characteristics();
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```

amplifier = comm.MemorylessNonlinearity('Method','Lookup table','Table',paChar,'ReferenceImpedance',100);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4, ...
    'Title','Amplified/Distorted Signal','NumInputPorts',2, ...
    'ReferenceConstellation',refconst,'ShowLegend',true, ...
    'ChannelNames',{'Filtered signal','Amplified signal'});

```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```

modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin * amplifier.ReferenceImpedance);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);

```

Compute input and output signal levels and the phase shift.

```

pSig = abs(ampSig).^2 / amplifier.ReferenceImpedance;
poutdBm = 10 * log10(pSig) + 30;
pfiltSig = abs(filtSig).^2 / amplifier.ReferenceImpedance;
simulated_pindBm = 10 * log10(pfiltSig) + 30;
phase = rad2deg(angle(ampSig.*conj(filtSig)));

```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

```

figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2), '.', 'Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabel = {'Simulated results','Measurement'};
legend(leglabel,'Location','south');

subplot(1,2,2)
plot(simulated_pindBm,phase, '.');

plot(amplifier.Table(:,1),amplifier.Table(:,3), '.', 'Markersize',15);
legend(leglabel,'Location','south');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on;
title('AM/PM Characteristics');

```

For the purpose of constellation comparison, normalize the amplified signal and the filtered signal. Generate a constellation diagram of the filtered signal and amplified signal. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the filtered constellation.

```
filtSig = filtSig/mean(abs(filtSig)); % Normalized filtered signal
ampSig = ampSig/mean(abs(ampSig)); % Normalized amplified signal
constellation(filtSig,ampSig)
```

### Helper Function

```
function paChar = pa_performance_characteristics()
```

The operating specification for the LDMOS-based Doherty amplifier are:

- A frequency of 2110 MHz
- A peak power of 300 W
- A small signal gain of 61 dB

Each row in `HAV08_Table` specifies  $P_{in}$  (dBm), gain (dB), phase shift (degrees) as derived from figure 4 of Hammi, Oualid, et al. "Power amplifiers' model assessment and memory effects intensity quantification using memoryless post-compensation technique." IEEE Transactions on Microwave Theory and Techniques 56.12 (2008): 3170-3179.

```

```

Convert the second column of the HAV08\_Table from gain to Pout for use by the memoryless nonlinearity System object.

```

paChar = HAV08_Table;
paChar(:,2) = paChar(:,1) + paChar(:,2);
end

```

## More About

### Memoryless Nonlinear Impairments

Memoryless nonlinear impairments distort the amplitude and phase of the input signal. The amplitude distortion is amplitude-to-amplitude modulation (AM/AM) and the phase distortion is amplitude-to-phase modulation (AM/PM). These model methods are available for simulating the memoryless nonlinear impairment models.

Model Method	Memoryless Nonlinear Impairment
Cubic polynomial	Applies AM/AM and AM/PM
Hyperbolic tangent	
Saleh model	
Ghorbani model	

Model Method	Memoryless Nonlinear Impairment
Modified Rapp model	
Lookup table	Applies impairment according to $[P_{in}, P_{out}, \Delta\Phi]$ amplifier characteristics specified by the <code>Table</code> property

The modeled impairments apply the AM/AM and AM/PM distortions differently according to the model method you specify. The models apply the memoryless nonlinear impairment to the input signal by following these steps.

- 1 Multiply the signal by an input gain factor.

---

**Note** You can normalize the signal to 1 by setting the input scaling gain to the inverse of the input signal amplitude.

---

- 2 Split the complex signal into its magnitude and angle components. For real-valued input signals, the imaginary component is set to zero.
- 3 Apply an AM/AM distortion to the magnitude of the signal, according to the selected model method, to produce the magnitude of the output signal.
- 4 Apply an AM/PM distortion to the phase of the signal, according to the selected model method, to produce the angle of the output signal.
- 5 Combine the new magnitude and angle components into a complex signal. Then, multiply the result by an output gain factor.

The model methods apply AM/AM and AM/PM impairments as shown in this figure.

The lookup table method uses the power amplifier (PA) characteristics lookup table, specified as an  $N$ -by-3 matrix of measured PA characteristics. Each row is of the form  $[P_{in}, P_{out}, \Delta\Phi]$ .  $P_{in}$  specifies the PA input signal in dBm,  $P_{out}$  specifies the PA output signal in dBm, and  $\Delta\Phi$  specifies the output phase shift in degrees. The measured PA characteristics defined by the `Table` property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) values.

---

**Note** To determine appropriate  $P_{out}$  and  $\Delta\Phi$  values for any  $P_{in}$  values outside the range of values specified in the `Table` property, the System object applies linear extrapolation from the first two or last two  $[P_{in}, P_{out}, \Delta\Phi]$  rows of `Table`.

---

### Cubic Polynomial and Hyperbolic Tangent Model Methods

This figure shows the AM/PM conversion behavior for the cubic polynomial and hyperbolic tangent model methods.

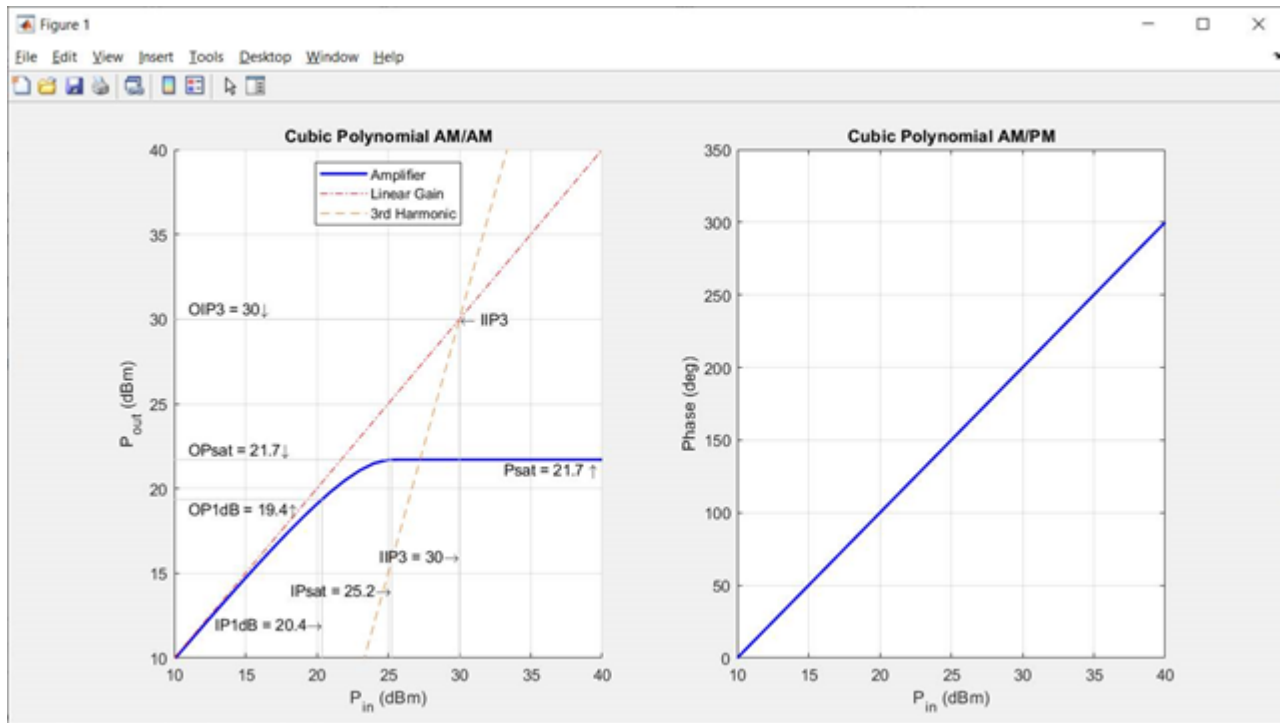

The AM/PM conversion scales linearly with an input power value between the lower and upper limits of the input power level. Outside this range, the AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and  $(AM/PM \text{ conversion}) \times (\text{upper input power limit} - \text{lower input power limit})$ , respectively.

### Cubic Polynomial Third-Order Coefficient

The cubic polynomial model method uses linear power gain to determine the linear coefficient of a third order polynomial. The cubic polynomial model method then uses either the third order intercept point (IP3), the one dB compression point (P1dB), or the saturation power (Psat) to determine the third order coefficient of the polynomial.

This figure shows an example of the plot generated when you set the Method property to 'Cubic polynomial'.

The general form of cubic nonlinearity models the AM/AM characteristics as

$$F_{AM/AM}(|u|) = c_1 \times |u| + \frac{3}{4} c_3 \times |u|^3$$

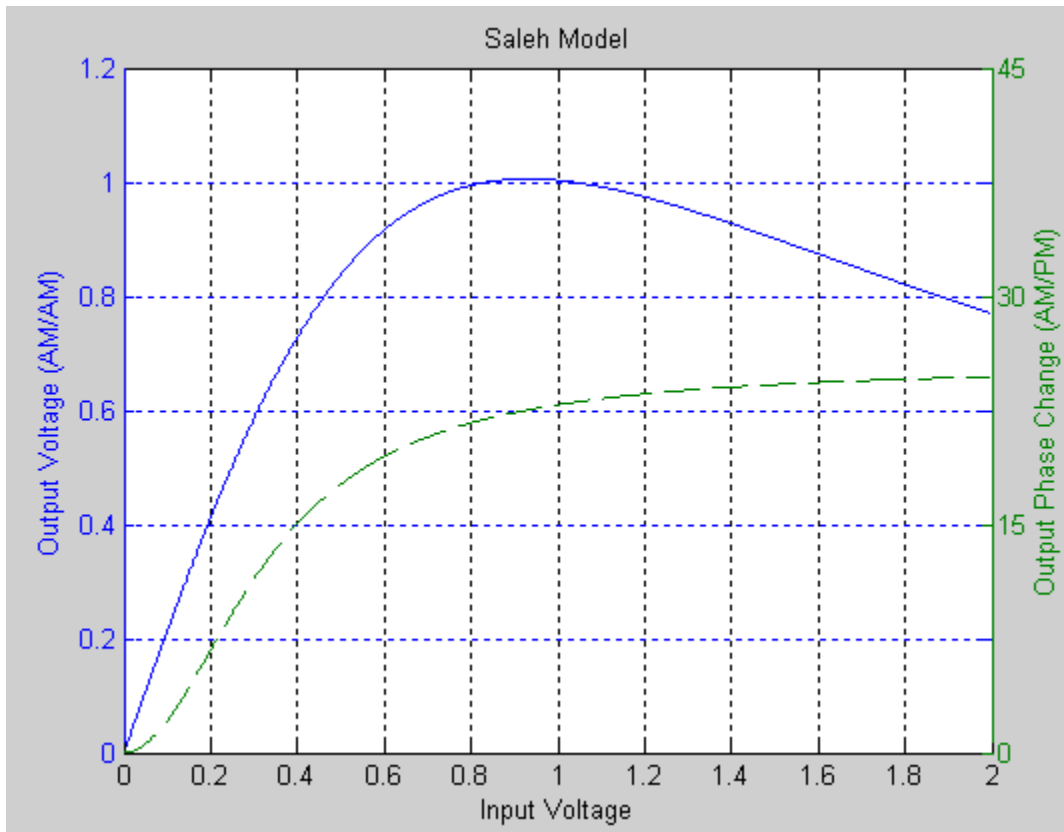

where  $F_{AM/AM}(|u|)$  is the magnitude of the output signal,  $|u|$  is the magnitude of the input signal,  $c_1$  is the coefficient of the linear gain term, and  $c_3$  is the coefficient of the cubic gain term. The results for IIP3, OIP3, IP1dB, OP1dB, IPsat, and OPSat are taken from [6]. The coefficient  $c_3$  values are given in this table.

Nonlinearity Type	Description	Equation
IIP3	Input power level at which the power from linear gain is equal to the power from a third-order nonlinearity	$c_3 = - \frac{4c_1}{3 \times 10^{[(IIP3 - 30)/10]}}$ where $IIP3$ is given in dBm.
OIP3	Output power level at which the power from linear gain is equal to the power from a third-order nonlinearity	$c_3 = - \frac{4c_1^3}{3 \times 10^{[(OIP3 - 30)/10]}}$ where $OIP3$ is given in dBm.
IP1dB	Input power level at which the output power is one dB less than the power from linear gain	$c_3 = - \frac{2c_1(10^{19/20} - 10)}{15 \times 10^{[(IP1dB - 30)/10]}}$ where $IP1dB$ is given in dBm.

Nonlinearity Type	Description	Equation
OP1dB	Output power level one dB less than the power from linear gain	$c_3 = -\frac{2c_1^3(10^{19/20} - 10)}{15 \times 10^{[(OP1dB - 30 - LGdB + 1)/10]}}$ <p>where <i>OP1dB</i> is given in dBm, and <i>LGdB</i> is the linear gain in dB</p>
IPsat	Input power at which the output power saturates	$c_3 = -\frac{4c_1}{9 \times 10^{[(IPsat - 30)/10]}}$ <p>where <i>IPsat</i> is given in dBm.</p>
OPsat	Output saturation power	$c_3 = -\frac{16c_1^3}{81 \times 10^{[(OPsat - 30)/10]}}$ <p>where <i>OPsat</i> is given in dBm.</p>

### Saleh Model Method

This figure shows the AM/AM behavior (output voltage versus input voltage for the AM/AM distortion) and the AM/PM behavior (output phase versus input voltage for the AM/PM distortion) for the Saleh model method.

The AM/AM parameters,  $\alpha_{AMAM}$  and  $\beta_{AMAM}$ , are used to compute the amplitude distortion of the input signal by using

$$F_{AMAM}(u) = \frac{\alpha_{AMAM} \times u}{1 + \beta_{AMAM} \times u^2},$$

where  $u$  is the magnitude of the scaled signal.

The AM/PM parameters,  $\alpha_{AMPM}$  and  $\beta_{AMPM}$ , are used to compute the phase distortion of the input signal by using

$$F_{AMPM}(u) = \frac{\alpha_{AMPM} \times u^2}{1 + \beta_{AMPM} \times u^2},$$

where  $u$  is the magnitude of the scaled signal. The  $\alpha$  and  $\beta$  parameters for AM/AM and AM/PM are similarly named but distinct.

### Ghorbani Model Method

The Ghorbani model method applies AM/AM and AM/PM distortion as described in this section.

The AM/AM parameters ( $x_1$ ,  $x_2$ ,  $x_3$ , and  $x_4$ ) are used to compute the amplitude distortion of the input signal by using

$$F_{AMAM}(u) = \frac{x_1 u^{x_2}}{1 + x_3 u^{x_2}} + x_4 u,$$

where  $u$  is the magnitude of the scaled signal.

The AM/PM parameters ( $y_1$ ,  $y_2$ ,  $y_3$ , and  $y_4$ ) are used to compute the phase distortion of the input signal by using

$$F_{\text{AMPM}}(u) = \frac{y_1 u^{y_2}}{1 + y_3 u^{y_2}} + y_4 u,$$

where  $u$  is the magnitude of the scaled signal.

### Modified Rapp Model Method

The modified Rapp model method applies AM/AM and AM/PM distortion as described in this section.

The amplitude and phase distortion of the input signal are given by

$$F_{\text{AMAM}}(u) = \frac{g_{\text{lin}} \times u}{\left(1 + \left(\frac{g_{\text{lin}} \times u}{O_{\text{sat}}}\right)^{2S}\right)^{1/2S}},$$

$$F_{\text{AMPM}}(u) = \frac{A u^q}{\left(1 + \left(\frac{u}{B}\right)^q\right)},$$

where:

- $g_{\text{lin}}$  is  $10^{(\text{LinearGain}/20)}$  and is the amplitude gain of the amplifier.
- $u$  is the magnitude of the signal.
- $S$  is the smoothness factor, specified by the Smoothness property.
- $O_{\text{sat}}$  is the output saturation level, specified by the OutputSaturationLevel property.
- $A$  is the phase gain in radians, specified by the PhaseGainRadian property.
- $B$  is the phase saturation, specified by the PhaseSaturation property.
- $q$  is the phase smoothness, specified by the PhaseSmoothness property.

# comm.MER

**Package:** comm

Measure modulation error ratio of received signal

## Description

The `comm.MER` System object computes a form of signal-to-noise ratio (SNR) measurement that you can use to assess the ability of a receiver to accurately demodulate a signal. Specifically, it returns the modulation error ratio (MER), minimum MER, and percentile MER for a received signal. You use the MER measurements to determine system performance in communications applications. For example, to determine compliance with applicable DVB-T system radio transmission standards conformance testing requires accurate MER measurements.

To measure the MER of a received signal:

- 1 Create the `comm.MER` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mer1 = comm.MER
mer1 = comm.MER(Name=Value)
```

### Description

`mer1 = comm.MER` creates an MER System object with default property values.

`mer1 = comm.MER(Name=Value)` sets properties using one or more name-value arguments. For example, `comm.MER(ReferenceSignalSource="Estimated from reference constellation")` configures the object to measure the MER of a received signal relative to a reference constellation.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### ReferenceSignalSource — Reference signal source

'Input port' (default) | 'Estimated from reference constellation'

Reference signal source, specified as 'Input port' or 'Estimated from reference constellation'.

- To specify the reference signal with the refSym input, set this property to 'Input port'.
- To specify the reference signal with the ReferenceConstellation property, set this property to 'Estimated from reference constellation'.

**ReferenceConstellation — Reference Constellation**

[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]  
(default) | vector

Reference constellation, specified as a vector. The default value corresponds to a quadrature phase-shift keying (QPSK) constellation with unit average power. You can derive constellation points by using modulation functions or objects.

Example: To define the reference constellation as a 16-QAM signal scaled so that the QAM constellation points are separated by a minimum distance of two, set this property to `qammod(0:15,16)`

**Dependencies**

To enable this property, set the ReferenceSignalSource property to 'Estimated from reference constellation'.

Data Types: double

**MeasurementIntervalSource — Measurement interval source**

'Input length' (default) | 'Entire history' | 'Custom' | 'Custom with periodic reset'

Measurement interval source for MER and minimum MER measurements, specified as one of these values.

- 'Input length' — Measure MER using only the current samples.
- 'Entire history' — Measure MER for all samples.
- 'Custom' — Measure the MER by using a sliding window over an interval that you specify.
- 'Custom with periodic reset' — Measure the MER over an interval that you specify and reset the block after measuring over each interval.

This property affects only the MER and minimum MER outputs.

**MeasurementInterval — Measurement interval**

100 (default) | positive integer

Measurement interval, specified as a positive integer.

**Dependencies**

To enable this property, set the MeasurementIntervalSource property to 'Custom' or 'Custom with periodic reset'.

Data Types: double

**AveragingDimensions — Averaging dimensions**

1 (default) | vector of integers in the range [1, 3]

Averaging dimensions over which the object averages the MER measurements, specified as a vector of integers in the range [1, 3]. For example, to average across the columns, set this property to 2.

This object supports variable-size inputs of the dimensions across which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between calls to the object. For example, if the input has size [1000 3 2] and you set this property to [1 3], the output size is [1 3 1], and the number of elements in the second dimension must remain fixed at 3.

Data Types: double

**MinimumMEROutputPort — Option to return minimum MER measurements**

false or 0 (default) | true or 1

Option to return minimum MER measurements, specified as a logical 1 (true) or 0 (false).

Data Types: logical

**XPercentileMEROutputPort — Option to return X-percentile MER measurements**

false or 0 (default) | true or 1

Option to return X-percentile MER measurements, specified as a logical 1 (true) or 0 (false). Specify the value of X in the XPercentileValue property. When you set this property to 1 (true), X-percentile MER measurements persist until you reset the object. The object performs these measurements by using all of the input frames since the last reset.

Data Types: logical

**XPercentileValue — Value below which X% of MER measurements fall**

95 (default) | scalar in the range [0, 100]

Value below which X% of MER measurements fall, specified as a scalar in the range [0, 100].

**Dependencies**

To enable this property, set the XPercentileMEROutputPort property to true.

Data Types: double

**SymbolCountOutputPort — Option to return number of accumulated symbols**

false or 0 (default) | true or 1

Option to return the number of accumulated symbols that the object uses to measure the X-percentile MER since the last reset, specified as a logical 1 (true) or 0 (false).

**Dependencies**

To enable this property, set the XPercentileMEROutputPort property to true.

Data Types: logical

## Usage

### Syntax

```
merdb = mer1(refSym,rxSym)
[merdb,minMER] = mer1(refSym,rxSym)
[ ___,pMER] = mer1(refSym,rxSym)
[ ___,pMER,numSym] = mer1(refSym,rxSym)
[ ___] = mer1(rxSym)
```

### Description

`merdb = mer1(refSym,rxSym)` returns the MER of received signal `rxSym` relative to reference signal `refSym` over the measurement interval specified in the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`[merdb,minMER] = mer1(refSym,rxSym)` also returns the minimum percentage MER over the configured measurement interval.

To use this syntax, set the `MinimumMEROutputPort` property to `true`.

`[ ___,pMER] = mer1(refSym,rxSym)` also returns the value below which  $X\%$  of MER measurements fall using all input frames since the last reset, regardless of measurement interval configuration. Set the value of  $X$  in the `XPercentileValue` property. For example, if you set the `XPercentileValue` to 95, then 95% of all MER measurements since the last reset fall below the value of `pMER`.

To use this syntax, set the `XPercentileMEROutputPort` property to `true`.

`[ ___,pMER,numSym] = mer1(refSym,rxSym)` also returns the number of symbols used to measure MER. To use this syntax, set the `XPercentileMEROutputPort` and `SymbolCountOutputPort` to `true`.

`[ ___] = mer1(rxSym)` measures the MER of the received signal relative to the reference signal specified in the `ReferenceConstellation` property. You can use this syntax with any previous output argument combination.

To use this syntax, set the `ReferenceSignalSource` property to "Estimated from reference constellation".

### Input Arguments

#### **refSym — Reference signal**

scalar | vector | matrix | 3-D array

Reference signal, specified as a scalar, vector, matrix, or 3-D array. If you specify this input, the object measures the MER of the `rxSym` input by using this input as a reference constellation. The dimensions of this input must match those of the `rxSym` input. The object uses each element of this input as the reference symbol for the corresponding element of the `rxSym` input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

#### **rxSym — Received signal**

scalar | vector | matrix | 3-D array

Received signal, specified as a scalar, vector, matrix, or 3-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

### Output Arguments

#### **merdb — Percentage MER of received signal**

scalar

Percentage MER of the received signal over the configured measurement interval, returned as a scalar in units of decibels.

Data Types: `double`

#### **minMER — Minimum percentage MER**

scalar

Minimum percentage MER over the configured measurement interval, returned as a scalar in units of decibels.

Data Types: `double`

#### **pMER — Value below which X% of MER measurements fall**

scalar

Value below which X% of MER measurements fall since the last reset, returned as a scalar in units of decibels. Set the value of X in the `XPercentileValue` property.

Data Types: `double`

#### **numSym — Number of symbols**

positive integer

Number of symbols that the object uses to measure the pMER output, returned as a positive integer.

Data Types: `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Measure MER Using Reference Constellation

Generate random data symbols and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);  
refSym = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSym = awgn(refSym,30);
```

Create an MER object with default property values.

```
mer = comm.MER;
```

Measure the MER using the transmitted signal as the reference.

```
rmsMER1 = mer(refSym,rxSym);
```

Release the MER object.

```
release(mer)
```

Configure the object to use a reference constellation for making MER measurements.

```
mer.ReferenceSignalSource = "Estimated from reference constellation";  
mer.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the MER using only the received signal as an input. Verify that the two MER measurements match.

```
rmsMER2 = mer(rxSym);  
[rmsMER1 rmsMER2]
```

```
ans = 1×2
```

```
30.0271 30.0271
```

### Measure MER Across Different Dimensions

Specify the FFT length, number of subcarriers, number of symbols, and cyclic prefix length.

```
nfft = 32; % Number of subcarriers  
nSym = 4; % Number of OFDM symbols  
cplen = 16; % Cyclic prefix length
```

Generate a random signal and apply QPSK modulation.

```
msg = randi([0 3],nfft,nSym);  
refSym = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK symbols. Pass the signal through an AWGN channel. OFDM demodulate the noisy signal.

```
txSig = ofdmmod(refSym,nfft,cplen);
rxSig = awgn(txSig,10,"measured");
rxSym = ofdmdemod(rxSig,nfft,cplen);
```

Configure an MER object to measure the average MER across the subcarriers. Averaging across the rows returns MER measurements corresponding to each of the OFDM symbols.

```
mer = comm.MER(AveragingDimensions=1);
merdB = mer(refSym,rxSym)

merdB = 1×4

    9.1136    11.7584    9.1921    9.8452
```

Configure the MER object to measure the MER over the OFDM symbols. Averaging across the columns returns MER measurements corresponding to each of the subcarriers.

```
mer = comm.MER(AveragingDimensions=2);
merdB = mer(refSym,rxSym)

merdB = 32×1

    8.7805
    7.6542
    7.6455
    6.5291
   10.5659
    8.5554
   10.1859
   15.5139
    9.7574
    8.4784
    ⋮
```

Averaging across the rows and columns returns one MER measurement for all the subcarriers and OFDM symbols.

```
mer = comm.MER(AveragingDimensions=[1 2]);
merdB = mer(refSym,rxSym)

merdB = 9.8566
```

### Measure MER of Noisy 16-QAM Signal

Create an MER object to measure MER, minimum MER, 90-percentile MER, and the number of symbols.

```
mer = comm.MER(MinimumMEROutputPort=true, ...
    XPercentileMEROutputPort=true,XPercentileValue=90, ...
    SymbolCountOutputPort=true);
```

Generate random data, apply 16-QAM with unit average power, and pass the signal through an AWGN channel.

```
data = randi([0 15],1000,1);
refsym = qammod(data,16,UnitAveragePower=true);
rxsym = awgn(refsym,20);
```

Determine the MER, minimum MER, and 90th percentile MER values.

```
[MERdB,MinMER,pMER,nSym] = mer(refsym,rxsym)
```

```
MERdB = 20.1071
```

```
MinMER = 11.4248
```

```
pMER = 16.5850
```

```
nSym = 1000
```

### Measure MER Using Custom Measurement Interval

Measure the MER of a noisy 8-PSK signal using two types of custom measurement interval and display the results.

Define variables for the simulation.

```
nframe = 2;           % Number of frames
nsubframe = 5;        % Number of subframes per frame
spsf = 100;           % Number of symbols per subframe
frmLen = nsubframe*spsf; % Frame length
```

Configure an MER object to use a custom measurement interval equal to the frame length and measure MER using an 8-PSK reference constellation.

```
mer1 = comm.MER( ...
    MeasurementIntervalSource="Custom", ...
    MeasurementInterval=frmLen, ...
    ReferenceSignalSource="Estimated from reference constellation", ...
    ReferenceConstellation=pskmod(0:7,8,pi/8));
```

Configure another MER object that uses a 500-symbol measurement interval with a periodic reset and measures MER using the same 8-PSK reference constellation.

```
mer2 = comm.MER( ...
    MeasurementIntervalSource="Custom with periodic reset", ...
    MeasurementInterval=frmLen, ...
    ReferenceSignalSource="Estimated from reference constellation", ...
    ReferenceConstellation=pskmod(0:7,8,pi/8));
```

Initialize the MER and signal-to-noise arrays.

```
merNoReset = zeros(nsubframe,nframe);
merReset = zeros(nsubframe,nframe);
snrdB = zeros(nsubframe,nframe);
```

Measure the MER for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. The `merNoReset` object uses the 500 most recent symbols to compute the estimate. This object uses a sliding window so that an entire data frame is the basis for the estimate. The `merReset` object clears the symbols each time it encounters a new frame.

```

for m = 1:nframe
    for k = 1:nsubframe
        data = randi([0 7],spsf,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*nsubframe+7;
        rxSig = awgn(txSig,snrdB(k,m));
        merNoReset(k,m) = mer1(rxSig);
        merReset(k,m) = mer2(rxSig);
    end
end

```

Display the MER measured using both approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the MER object resets after the first frame so that the calculated MER values more accurately reflect the current SNR.

```

stairs(snrdB(:),[merNoReset(:) merReset(:)])
xlabel("SNR (dB)")
ylabel("MER (%)")
legend("No reset","Periodic reset")

```

## Algorithms

*MER* is a measure of the SNR in a modulated signal calculated in dB. The *MER* over a burst containing  $N$  symbols is

$$MER = 10 \times \log_{10} \left( \frac{\sum_{k=1}^N (I_k^2 + Q_k^2)}{\sum_{k=1}^N (e_k)} \right) \text{dB},$$

where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$ .
- $I_k$  represents the in-phase component of the  $k$ th symbol in the burst.
- $Q_k$  represents the quadrature phase component of the  $k$ th symbol in the burst.
- $I_k$  and  $Q_k$  represent ideal reference values.
- $\tilde{I}_k$  and  $\tilde{Q}_k$  represent received symbols.
- $N$  represents the number of symbols in the burst.

The  $MER$  for the  $k$ th symbol is

$$MER_k = 10 \times \log_{10} \left( \frac{\frac{1}{N} \sum_{k=1}^N (I_k^2 + Q_k^2)}{e_k} \right) \text{dB}.$$

The minimum  $MER$  represents the minimum  $MER$  value in a burst, or

$$MER_{\min} = \min_{k \in [1, \dots, N]} \{MER_k\},$$

The algorithm computes the  $X$ -percentile  $MER$  by creating a histogram of all the incoming  $MER_k$  values. The output provides the  $MER$  value above which  $X\%$  of the  $MER$  values fall.

**Package:** comm

Filter input signal through MIMO multipath fading channel

## Description

The `comm.MIMOChannel` System object filters an input signal through a multiple-input/multiple-output (MIMO) multipath fading channel. This object models Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 3-919 section.

To filter an input signal through a MIMO multipath fading channel:

- 1 Create the `comm.MIMOChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mimochannel = comm.MIMOChannel  
mimochannel = comm.MIMOChannel(Name, Value)
```

### Description

`mimochannel = comm.MIMOChannel` creates a MIMO frequency-selective or frequency-flat fading channel System object.

`mimochannel = comm.MIMOChannel(Name, Value)` sets properties using one or more name-value arguments. For example, `'SampleRate', 2` sets the input signal sample rate to 2.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **SampleRate** — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: `double`

### **PathDelays — Discrete path delay**

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the MIMO channel is frequency flat.
- When you set `PathDelays` to a vector, the MIMO channel is frequency selective.

The `PathDelays` and `AveragePathGains` properties must be the same length.

Data Types: `double`

### **AveragePathGains — Average path gains**

0 (default) | scalar | row vector

Average path gains in decibels, specified as a scalar or row vector. The `AveragePathGains` and `PathDelays` properties must be the same length.

Data Types: `double`

### **NormalizePathGains — Normalize path gains**

`true` or 1 (default) | `false` or 0

Normalize path gains, specified as one of these logical values:

- 1 (`true`) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (`false`) — The total power of the path gains is not normalized.

The `AveragePathGains` property specifies the average powers of the path gains.

Data Types: `logical`

### **FadingDistribution — Fading distribution**

'Rayleigh' (default) | 'Rician'

Fading distribution to use for the channel, specified as 'Rayleigh' or 'Rician'.

Data Types: `char` | `string`

### **KFactor — K-factor of Rician fading channel**

3 (default) | positive scalar | 1-by- $N_P$  vector of nonnegative values

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- $N_P$  vector of nonnegative values.  $N_P$  is the number of discrete path delays specified by the `PathDelays` property.

- When you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- When you set `KFactor` to a vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the `KFactor` vector are Rayleigh fading processes. At least one element must be nonzero.

**Dependencies**

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

**DirectPathDopplerShift — Doppler shifts for line-of-sight components**

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in hertz. This property must be the same size as the `KFactor` property.

- When you set `DirectPathDopplerShift` to a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathDopplerShift` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathDopplerShift` specifies the line-of-sight component for the Doppler shift of that discrete path.

**Dependencies**

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

**DirectPathInitialPhase — Initial phases for line-of-sight components**

0 (default) | scalar | row vector

Initial phases for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in radians. This property must be the same size as the `KFactor` property value.

- When you set `DirectPathInitialPhase` to a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathInitialPhase` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathInitialPhase` specifies the line-of-sight component for the initial phase of that discrete path.

**Dependencies**

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

**MaximumDopplerShift — Maximum Doppler shift for all channel paths**

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than  $\text{SampleRate}/10/f_c$  for each path, where  $f_c$  is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of  $f_c$  is 1. For Gaussian and bi-Gaussian Doppler spectrum types,  $f_c$  is dependent on the Doppler spectrum structure fields. For more details about how  $f_c$  is defined, see the Cutoff Frequency Factor on page 3-920 section.

Data Types: double

### DopplerSpectrum — Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | Doppler spectrum structure | 1-by- $N_p$  cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- $N_p$  cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the `doppler` function.  $N_p$  is the number of discrete path delays specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum.

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `spectype` input to the `doppler` function. If you set the `FadingTechnique` property to 'Sum of sinusoids', you must set `DopplerSpectrum` to `doppler('Jakes')`.

#### Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: struct | cell

### SpatialCorrelationSpecification — Spatial correlation specification

'Separate Tx Rx' (default) | 'None' | 'Combined'

Spatial correlation specification, specified as 'Separate Tx Rx', 'None', or 'Combined'.

- Choose 'Spatial Tx Rx' to separately specify the transmit and receive spatial correlation matrices from which the number of transmit antennas ( $N_T$ ) and number of receive antennas ( $N_R$ ) are derived.
- Choose 'None' to specify the number of transmit and receive antennas.
- Choose 'Combined' to specify a single correlation matrix for the whole channel from which the product of  $N_T$  and  $N_R$  is derived.

Data Types: char | string

### NumTransmitAntennas — Number of transmit antennas

2 (default) | positive integer

Number of transmit antennas, specified as a positive integer.

#### Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to 'None' or 'Combined'.

Data Types: double

### NumReceiveAntennas — Number of receive antennas

2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

**Dependencies**

To enable this property, set the `SpatialCorrelationSpecification` property to 'None' or 'Combined'.

Data Types: double

**TransmitCorrelationMatrix — Spatial correlation of transmitter**

[1 0; 0 1] (default) |  $N_T$ -by- $N_T$  matrix |  $N_T$ -by- $N_T$ -by- $N_P$  array

Spatial correlation of the transmitter, specified as an  $N_T$ -by- $N_T$  matrix or  $N_T$ -by- $N_T$ -by- $N_P$  array.  $N_T$  is the number of transmit antennas.  $N_P$  is the number of discrete path delays specified by the `PathDelays` property.

- If you set `PathDelays` to a scalar, the channel is frequency flat and `TransmitCorrelationMatrix` must be an  $N_T$ -by- $N_T$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `TransmitCorrelationMatrix` as one of these options:
  - An  $N_T$ -by- $N_T$  matrix. In this case, each path has the same transmit spatial correlation matrix.
  - An  $N_T$ -by- $N_T$ -by- $N_P$  array. In this case, each path has its own specified transmit spatial correlation matrix.

**Dependencies**

To enable this property, set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

**ReceiveCorrelationMatrix — Spatial correlation of receiver**

[1 0; 0 1] (default) |  $N_R$ -by- $N_R$  matrix |  $N_R$ -by- $N_R$ -by- $N_P$  array

Spatial correlation of the receiver, specified as an  $N_R$ -by- $N_R$  matrix or  $N_R$ -by- $N_R$ -by- $N_P$  array.  $N_R$  is the number of receive antennas.  $N_P$  is the number of discrete path delays specified by the `PathDelays` property.

- If you set `PathDelays` to a scalar, the channel is frequency flat, and `ReceiveCorrelationMatrix` must be an  $N_R$ -by- $N_R$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `ReceiveCorrelationMatrix` as one of these options:
  - An  $N_R$ -by- $N_R$  matrix. In this case, each path has the same receive spatial correlation matrix.
  - An  $N_R$ -by- $N_R$ -by- $N_P$  array. In this case, each path has its own specified receive spatial correlation matrix.

**Dependencies**

To enable this property, set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

**SpatialCorrelationMatrix — Combined spatial correlation matrix**

[1 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1] (default) |  $N_{TR}$ -by- $N_{TR}$  matrix |  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array

Combined spatial correlation matrix, specified as an  $N_{TR}$ -by- $N_{TR}$  matrix or  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array.  $N_{TR} = (N_T \times N_R)$ , and  $N_P$  is the number of discrete delay paths (the length of the `PathDelays` property).

- If `PathDelays` is a scalar, the channel is frequency flat, and `SpatialCorrelationMatrix` must be an  $N_{TR}$ -by- $N_{TR}$  Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `SpatialCorrelationMatrix` as one of these options:
  - An  $N_{TR}$ -by- $N_{TR}$  matrix. In this case, each path has the same combined spatial correlation matrix.
  - An  $N_{TR}$ -by- $N_{TR}$ -by- $N_P$  array. In this case, each path has its own specified combined spatial correlation matrix.

**Dependencies**

To enable this property, set the `SpatialCorrelationSpecification` property to 'Combined'.

Data Types: double

**AntennaSelection — Antenna selection scheme**

'Off' (default) | 'Tx' | 'Rx' | 'Tx and Rx'

Antenna selection scheme, specified as 'Off', 'Tx', 'Rx', or 'Tx and Rx'.

Tx represents transmit antennas, and Rx represents receive antennas. When you configure any antenna selection other than the default setting, the object requires one or more inputs to specify which antennas are selected for signal transmission. For more information, see [Antenna Selection](#) on page 3-920.

Data Types: char | string

**NormalizeChannelOutputs — Normalize channel outputs**

true or 1 (default) | false or 0

Normalize channel outputs, specified as one of these logical values:

- 1 (true) — The channel outputs are normalized by the number of receive antennas.
- 0 (false) — The channel outputs are not normalized.

Data Types: logical

**ChannelFiltering — Channel filtering**

true or 1 (default) | false or 0

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

### **PathGainsOutputPort — Output channel path gains**

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

#### **Dependencies**

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

### **NumSamples — Number of samples**

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

### **OutputDataType — Path gain output data type**

`'double'` (default) | `'single'`

Path gain output data type, specified as `'double'` or `'single'`.

#### **Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

### **FadingTechnique — Channel model fading technique**

`'Filtered Gaussian noise'` (default) | `'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char` | `string`

### **NumSinusoids — Number of sinusoids**

`48` (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `double`

**InitialTimeSource — Source to control start time of fading process**

`'Property'` (default) | `'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- When you set `InitialTimeSource` to `'Property'`, set the initial time offset by using the `InitialTime` property.
- When you set `InitialTimeSource` to `'Input port'`, specify the start time of the fading process by using the `inittime` input argument. The input value can change in consecutive calls to the object.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `char` | `string`

**InitialTime — Initial time offset**

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

`InitialTime` must be greater than the end time of the last frame. When `mod(InitialTime/SampleRate)` is nonzero, the object rounds the initial time offset up to the nearest sample position.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Property'`.

Data Types: `double`

**RandomStream — Source of random number stream**

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- When you specify `'Global stream'`, the object uses the current global random number stream for random number generation. In this case, the `reset` object function resets only the filters.
- When you specify `'mt19937ar with seed'`, the object uses the `mt19937ar` algorithm for random number generation. In this case, the `reset` object function resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

**Seed — Initial seed of mt19937ar random number stream**

73 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. When you call the `reset` object function, it reinitializes the mt19937ar random number stream to the `Seed` value.

**Dependencies**

To enable this property, set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

**Visualization — Channel visualization**

`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. When you set the channel visualization to a value other than `'Off'`, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see [Channel Visualization](#).

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Filtered Gaussian noise'`.

Data Types: `char` | `string`

**AntennaPairsToDisplay — Transmit-receive antenna pair to display**

`[1 1]` (default) | two-element row vector

Transmit-receive antenna pair to display, specified as a two element row vector. The first element corresponds to the desired transmit antenna, and the second element corresponds to the desired receive antenna. Only a single pair can be displayed.

**Dependencies**

To enable this property, set the `Visualization` property to `'Impulse response'`, `'Frequency response'`, `'Doppler spectrum'`, or `'Impulse and frequency responses'`.

Data Types: `double`

**PathsForDopplerDisplay — Path for which Doppler spectrum is displayed**

`1` (default) | positive integer in the range  $[1, N_p]$

Path for which the Doppler spectrum is displayed, specified as an integer in the range  $[1, N_p]$ .  $N_p$  is the number of discrete path delays specified by the `PathDelays` property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

**Dependencies**

To enable this property, set the `Visualization` property to `'Doppler spectrum'`.

Data Types: `double`

**SamplesToDisplay — Percentage of samples to display**

`'25%'` (default) | `'10%'` | `'50%'` | `'100%'`

Percentage of samples to display, specified as `'25%'`, `'10%'`, `'50%'`, or `'100%'`. Increasing the percentage improves display accuracy at the expense of simulation speed.

## Dependencies

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: char | string

## Usage

## Syntax

```

y = mimochannel(x)
y = mimochannel(x,seltx)
y = mimochannel(x,selrx)
y = mimochannel(x,seltx,selrx)
y = mimochannel( __ ,inittime)
[y,pathgains] = mimochannel( __ )

pathgains = mimochannel()
pathgains = mimochannel(seltx)
pathgains = mimochannel(selrx)
pathgains = mimochannel(seltx,selrx)
pathgains = mimochannel( __ ,inittime)

```

## Description

`y = mimochannel(x)` filters the input signal `x` through the MIMO fading channel and returns the result in `y`.

To enable this syntax, set the ChannelFiltering property to true.

`y = mimochannel(x,seltx)` filters the input signal through the MIMO fading channel by using the transmit antennas specified by `seltx`.

To enable this syntax set the AntennaSelection property to 'Tx'.

For example, this code shows how to select the first and third transmit antenna index as active.

```

mimochannel = comm.MIMOChannel('AntennaSelection','Tx');
seltx = [1 0 1];
...
y = mimochannel(x,seltx);

```

`y = mimochannel(x,selrx)` filters the input signal through the MIMO fading channel by using the receive antennas selected by `selrx`.

To enable this syntax set the AntennaSelection property to 'Rx'.

For example, this code shows how to select the second receive antenna index as active.

```

mimochannel = comm.MIMOChannel('AntennaSelection','Rx');
selrx = [0 1];
...
y = mimochannel(x,selrx);

```

`y = mimochannel(x,seltx,selrx)` filters the input signal through the MIMO fading channel by using the transmit and receive antennas selected by `seltx` and `selrx`.

To enable this syntax set the `AntennaSelection` property to `'Tx and Rx'`.

For example, this code shows how to select the first and second transmit antenna and the second receive antenna as active.

```
mimochannel = comm.MIMOChannel( ...  
    'AntennaSelection','Tx and Rx');  
seltx = [1 1];  
selrx = [0 1];  
...  
y = mimochannel(x,selrx);
```

`y = mimochannel( ____, inittime)` specifies a start time for the fading process in addition to an input argument combination from any of the previous syntaxes.

To enable this syntax, also set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

`[y,pathgains] = mimochannel( ____ )` also returns the MIMO channel path gains for antenna selection schemes using any of the input argument combinations in the previous syntaxes.

`pathgains = mimochannel()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `ChannelFiltering` property to `false`.

`pathgains = mimochannel(seltx)` returns the channel path gains of the underlying fading process by using the transmit antennas specified by `seltx`.

To enable this syntax set `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Tx'`.

`pathgains = mimochannel(selrx)` returns the channel path gains of the underlying fading process by using the transmit antennas specified by `selrx`.

To enable this syntax set the `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Rx'`.

`pathgains = mimochannel(seltx,selrx)` returns the channel path gains of the underlying fading process by using the transmit and receive antennas selected by `seltx` and `selrx`.

To enable this syntax set the `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Tx and Rx'`.

`pathgains = mimochannel( ____, inittime)` specifies a start time for the fading process in addition to an input argument combination from any of the previous syntaxes.

To enable this syntax, also set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

## Input Arguments

### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an  $N_S$ -element column vector, or an  $N_S$ -by- $N_T$  or  $N_S$ -by- $N_{ST}$  matrix.

- $N_S$  is the number of samples.
- $N_T$  is the number of transmit antennas and is determined by the `TransmitCorrelationMatrix` or `NumTransmitAntennas` property values.
- $N_{ST}$  is the number of selected transmit antennas and is determined by the number of elements that are set to 1 in the vector provided by the `selTx` input.

Data Types: single | double

Complex Number Support: Yes

### **selTx** — Select active transmit antennas

1-by- $N_T$  binary-valued vector

Select active transmit antennas, specified as a 1-by- $N_T$  binary-valued vector.  $N_T$  is the number of transmit antennas. Elements set to 1 identify selected antenna indices, and the elements set to 0 identify nonselected antenna indices.

Data Types: single | double

### **selRx** — Select active receive antennas

1-by- $N_R$  binary-valued vector

Select active receive antennas, specified as a 1-by- $N_R$  binary-valued vector.  $N_R$  is the number of receive antennas. Elements set to 1 identify selected antenna indices, and the elements set to 0 identify nonselected antenna indices.

Data Types: single | double

### **inittime** — Initial time offset

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: single | double

## Output Arguments

### **y** — Output signal

matrix

Output signal, returned as an  $N_S$ -by- $N_R$  or  $N_S$ -by- $N_{SR}$  matrix.

- $N_S$  is the number of samples.
- $N_R$  is the number of receive antennas and is determined by the `ReceiveCorrelationMatrix` or `NumReceiveAntennas` property values.
- $N_{SR}$  is the number of selected receive antennas and is determined by the number of elements that are set to 1 in the vector provided by the `selRx` input.

**pathgains — Output path gains** $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array

Output path gains, returned as an  $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array with NaN values for the unselected transmit-receive antenna pairs. `pathgains` contains complex values.

- $N_S$  is the number of samples.
- $N_P$  is the number of discrete path delays specified by the `PathDelays` property.
- $N_T$  is the number of transmit antennas.
- $N_R$  is the number of receive antennas.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Specific to comm.MIMOChannel**

info Characteristic information about fading channel object

**Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

---

**Note**

- If you set the `RandomStream` property of the object to `'Global stream'`, the `reset` object function resets the filters only.
  - If you set `RandomStream` to `'mt19937ar with seed'`, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the `Seed` property.
- 

**Examples****Pass QPSK Data Through 4-by-2 MIMO Channel**

Create a 4-by-2 MIMO channel by using the MIMO channel System object. Modulate and spatially encode data, and then pass the data through the channel.

Generate QPSK-modulated data.

```
data = randi([0 3],1000,1);
modData = pskmod(data,4,pi/4);
```

Create an orthogonal space-time block encoder System object to encode the modulated data into four spatially separated streams. Then, encode the data.

```
ostbc = comm.OSTBCEncoder( ...
    'NumTransmitAntennas',4, ...
    'SymbolRate',1/2);
txSig = ostbc(modData);
```

Create a MIMO channel System object, using name-value pairs to set the properties. The channel consists of two paths, each with a maximum Doppler shift of 5 Hz. Set the `SpatialCorrelationSpecification` property to 'None', which requires that you specify the number of transmit and receive antennas. Specify four transmit antennas and two receive antennas.

```
mimochannel = comm.MIMOChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 2e-3], ...
    'AveragePathGains',[0 -5], ...
    'MaximumDopplerShift',5, ...
    'SpatialCorrelationSpecification','None', ...
    'NumTransmitAntennas',4, ...
    'NumReceiveAntennas',2);
```

Pass the modulated and encoded signal through the MIMO channel.

```
rxSig = mimochannel(txSig);
```

Create a time vector, `t`, to use for plotting the power of the received signal.

```
ts = 1/mimochannel.SampleRate;
t = (0:ts:(size(txSig,1)-1)*ts)';
```

Calculate and plot the power of the signal received by antenna 1.

```
pwrdB = 20*log10(abs(rxSig(:,1)));
plot(t,pwrdB)
title('Channel Response Power (dBW)')
xlabel('Time (s)')
ylabel('Power (dBW)')
```

### Examine Spatial Correlation Characteristics of 2-by-2 Rayleigh Fading Channel

Generate path gains for a 2-by-2 Rayleigh fading channel and examine the spatial correlation characteristics of the channel realization. Use the `release` object function to unlock the object to set the `AntennaSelection` property to 'Tx and Rx' and then confirm the unselected transmit-receive antenna pairs.

Create a 2-by-2 MIMO channel System object with two discrete paths and channel filtering disabled. Each path has different transmit and receive correlation matrices, specified by the `TransmitCorrelationMatrix` and `ReceiveCorrelationMatrix` properties.

```
mimoChan = comm.MIMOChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1e-3], ...
    'AveragePathGains',[3 5], ...
    'NormalizePathGains',false, ...
    'MaximumDopplerShift',5, ...
    'TransmitCorrelationMatrix',cat(3,eye(2),[1 0.1;0.1 1]), ...
    'ReceiveCorrelationMatrix',cat(3,[1 0.2;0.2 1],eye(2)), ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',33, ...
    'ChannelFiltering',false);
```

Generate channel response path gains using the MIMO channel object.

```
pathGains = mimoChan();
```

The transmit spatial correlation for the first discrete path at the first receive antenna is specified as an identity matrix in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the transmit spatial correlation for the first discrete path and the first receive antenna.

```
corrcoef(squeeze(pathGains(:,1,:,1)))
```

```
ans = 2x2 complex
```

```
    1.0000 + 0.0000i   -0.3391 + 0.4285i
   -0.3391 - 0.4285i    1.0000 + 0.0000i
```

The transmit spatial correlation for the second discrete path at the second receive antenna is specified as `[1 0.1;0.1 1]` in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the transmit spatial correlation for the second discrete path and the second receive antenna.

```
corrcoef(squeeze(pathGains(:,2,:,2)))
```

```
ans = 2x2 complex
```

```
    1.0000 + 0.0000i   -0.8989 - 0.2663i
   -0.8989 + 0.2663i    1.0000 + 0.0000i
```

The receive spatial correlation for the first discrete path at the second transmit antenna is specified as `[1 0.2;0.2 1]` in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the receive spatial correlation for the first discrete path and the second transmit antenna.

```
corrcoef(squeeze(pathGains(:,1,2,:)))
```

```
ans = 2x2 complex
```

```
    1.0000 + 0.0000i    0.9170 + 0.3141i
    0.9170 - 0.3141i    1.0000 + 0.0000i
```

The receive spatial correlation for the second discrete path at the first transmit antenna is specified as an identity matrix in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the receive spatial correlation for the second discrete path and the first transmit antenna.

```
corrcoef(squeeze(pathGains(:,2,1,:)))
```

```
ans = 2x2 complex
```

```
    1.0000 + 0.0000i    0.9227 - 0.3435i
    0.9227 + 0.3435i    1.0000 + 0.0000i
```

### Display Impulse and Frequency Responses of Frequency-Selective Channel

Create a frequency-selective MIMO channel, and then display its impulse and frequency responses.

Set the sample rate to 10 MHz. Specify path delays and gains using the extended vehicular A (EVA) channel parameters. Set the maximum Doppler shift to 70 Hz.

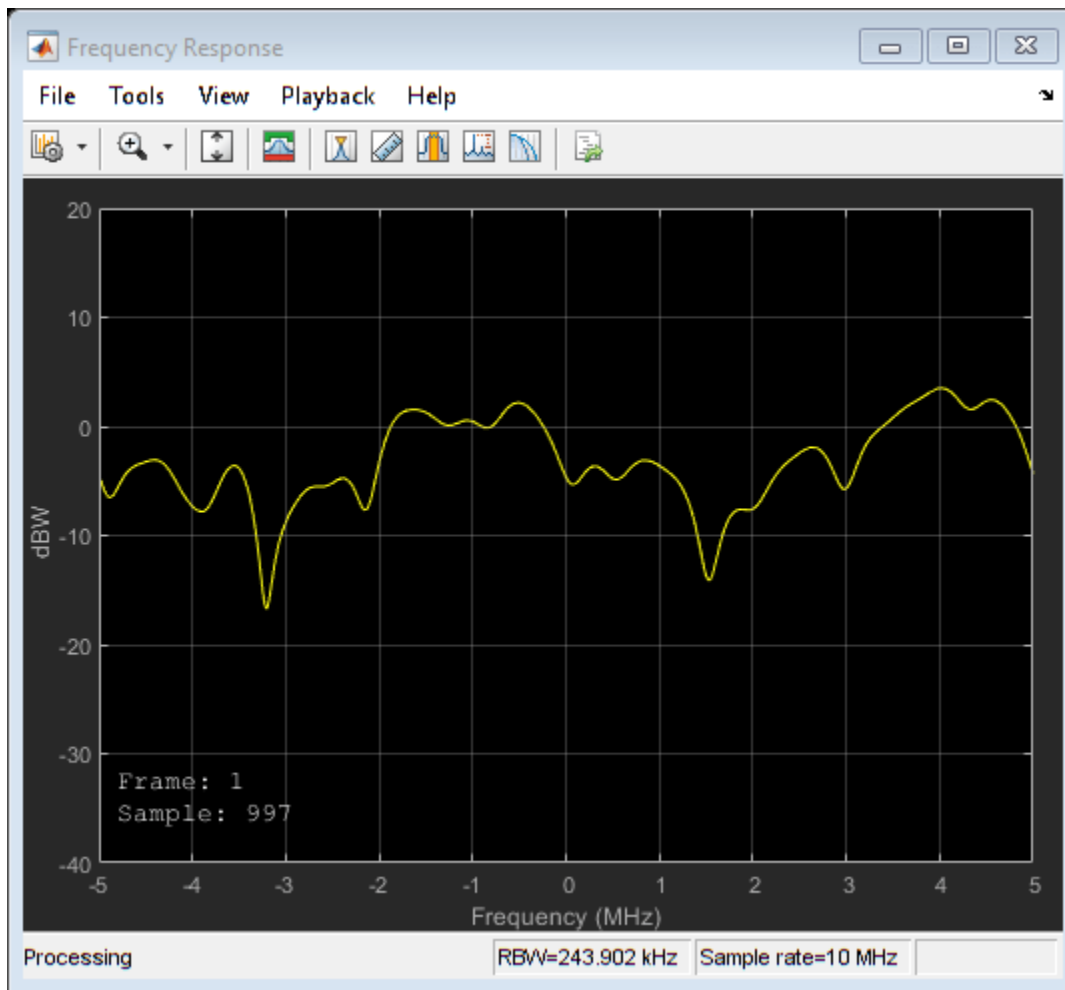

```
fs = 10e6; % Hz
pathDelays = [0 30 150 310 370 710 1090 1730 2510]*1e-9; % Seconds
avgPathGains = [0 -1.5 -1.4 -3.6 -0.6 -9.1 -7 -12 -16.9]; % dB
fD = 70; % Hz
```

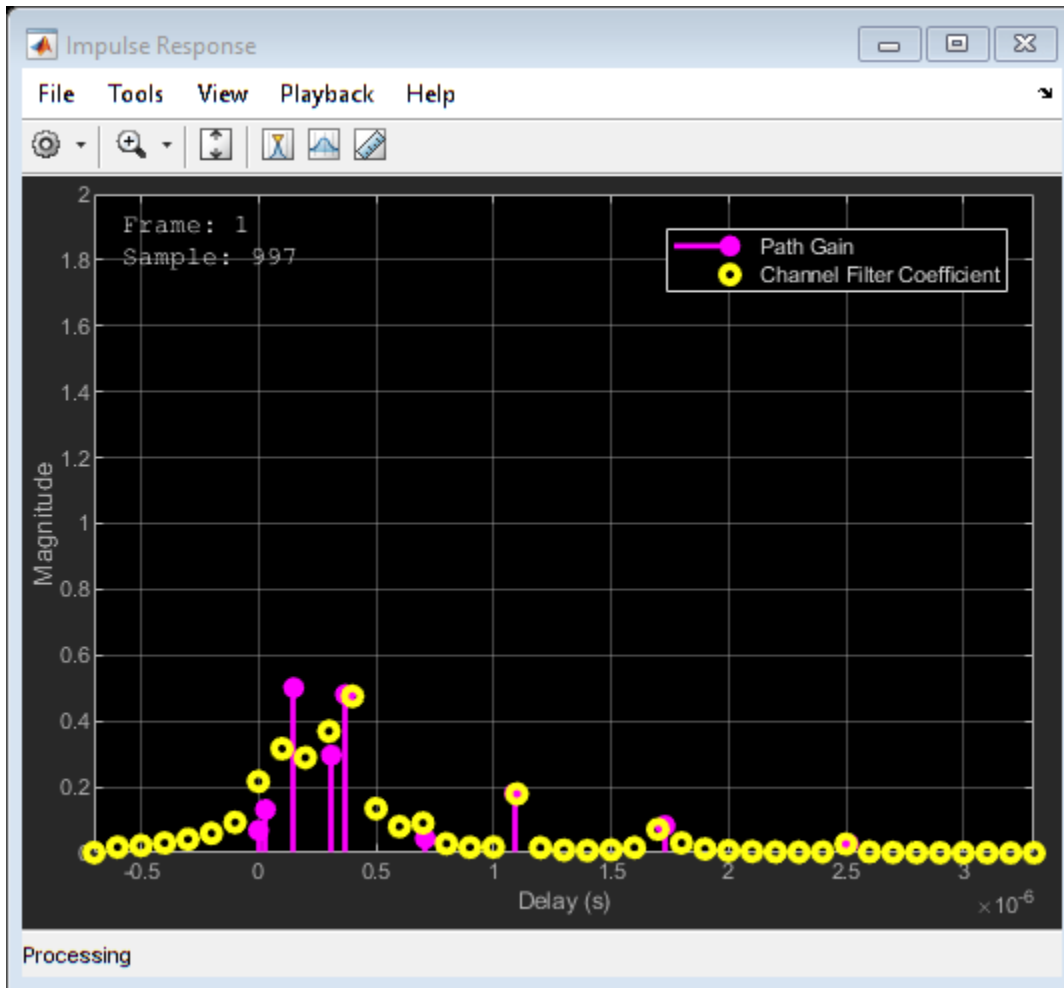

Create a 2-by-2 MIMO channel System object, specifying the previously defined parameters and setting channel visualization to plot the impulse and frequency responses. By default, the plot displays the antenna pair corresponding to first transmit and receive antennas.

```
mimoChan = comm.MIMOChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data, and then pass it through the MIMO channel. The impulse response plot enables you to easily identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the EVA channel.

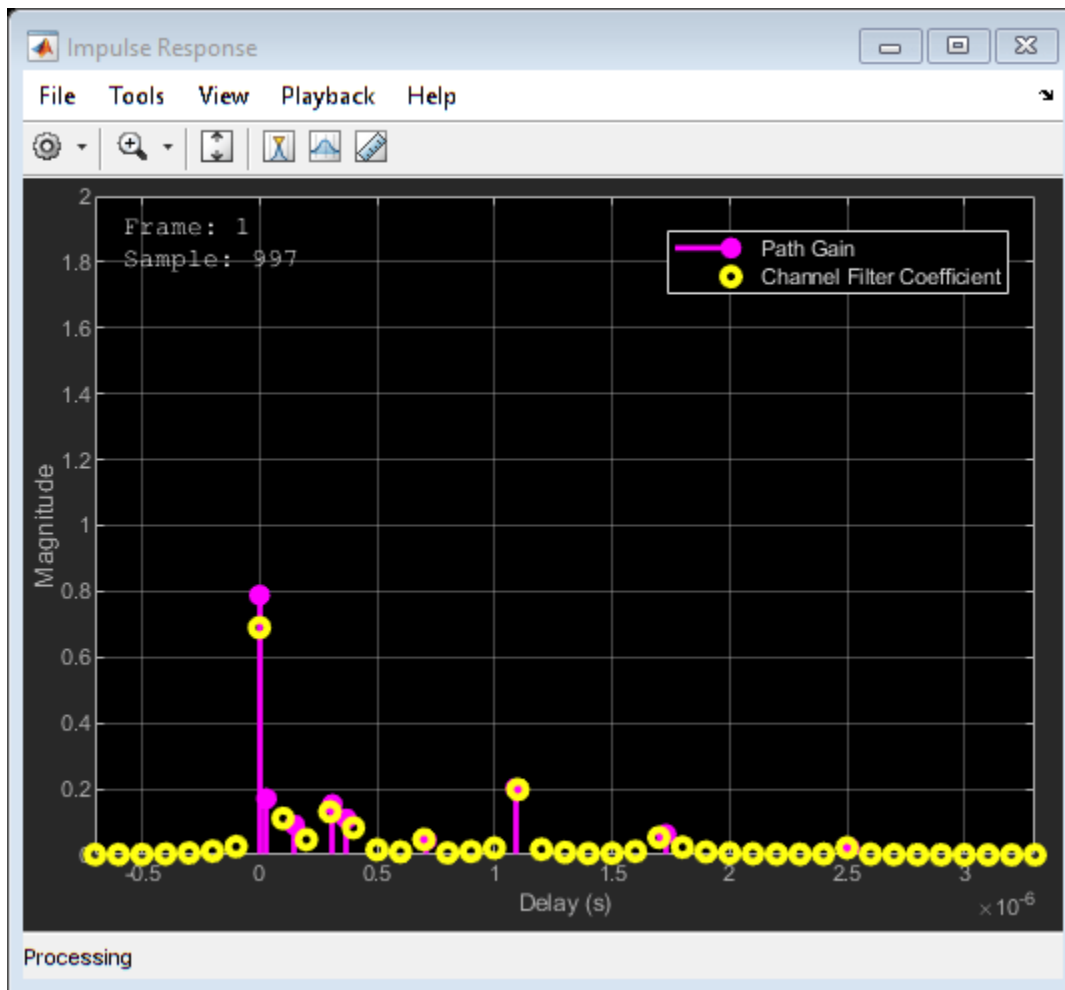

```
x = randi([0 1],1000,2);
y = mimoChan(x);
```

To view the antenna pair corresponding to the second transmit and first receive antennas, release the MIMO channel System object, and then set its `AntennaPairsToDisplay` property to `[2 1]`. Because the `AntennaPairsToDisplay` property is nontunable, to change its value, you must release the System object.

```
release(mimoChan)
mimoChan.AntennaPairsToDisplay = [2 1];
y = mimoChan(x);
```

### Display Doppler for 2-by-2 MIMO Channel

Create and visualize the Doppler spectra of a MIMO channel that has two paths.

Construct a cell array of Doppler structures to be used in creating the channel. Set the Doppler spectrum of the first path to be bell shaped and the second path to be flat.

```
dp{1} = doppler('Bell');
dp{2} = doppler('Flat');
```

Create a 2-by-2 MIMO channel System object, specifying two paths and a maximum Doppler shift of 100 Hz, disabling the channel filtering, and enabling the visualization of the Doppler spectrum for the first Doppler path.

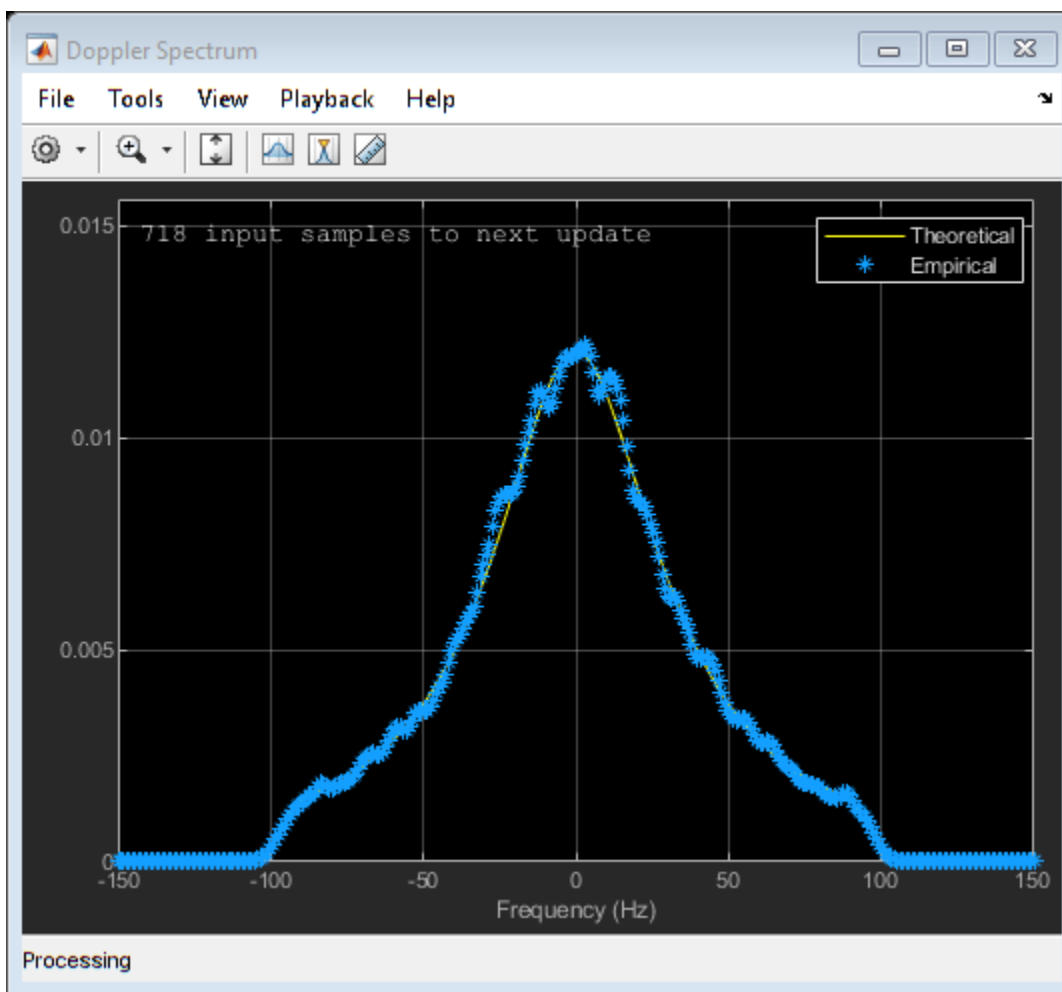

```
mimoChan = comm.MIMOChannel('SampleRate',1000, ...
    'PathDelays',[0 0.002], ...
    'AveragePathGains',[0 -3], ...
    'MaximumDopplerShift',100, ...
    'DopplerSpectrum',dp, ...
```

```
'ChannelFiltering',false, ...
'NumSamples',10000, ...
'Visualization','Doppler spectrum', ...
'PathsForDopplerDisplay',1);
```

Use the MIMO channel to generate the Doppler spectrum of the first path. Because the Doppler spectrum plot does not update until its buffer is filled, call the MIMO channel object multiple times to help improve the accuracy of the estimate. Observe that the spectrum has a bell shape and that its minimum and maximum frequencies fall within the limits set by the `MaximumDopplerShift` property.

```
for k = 1:25
    mimoChan();
end
```

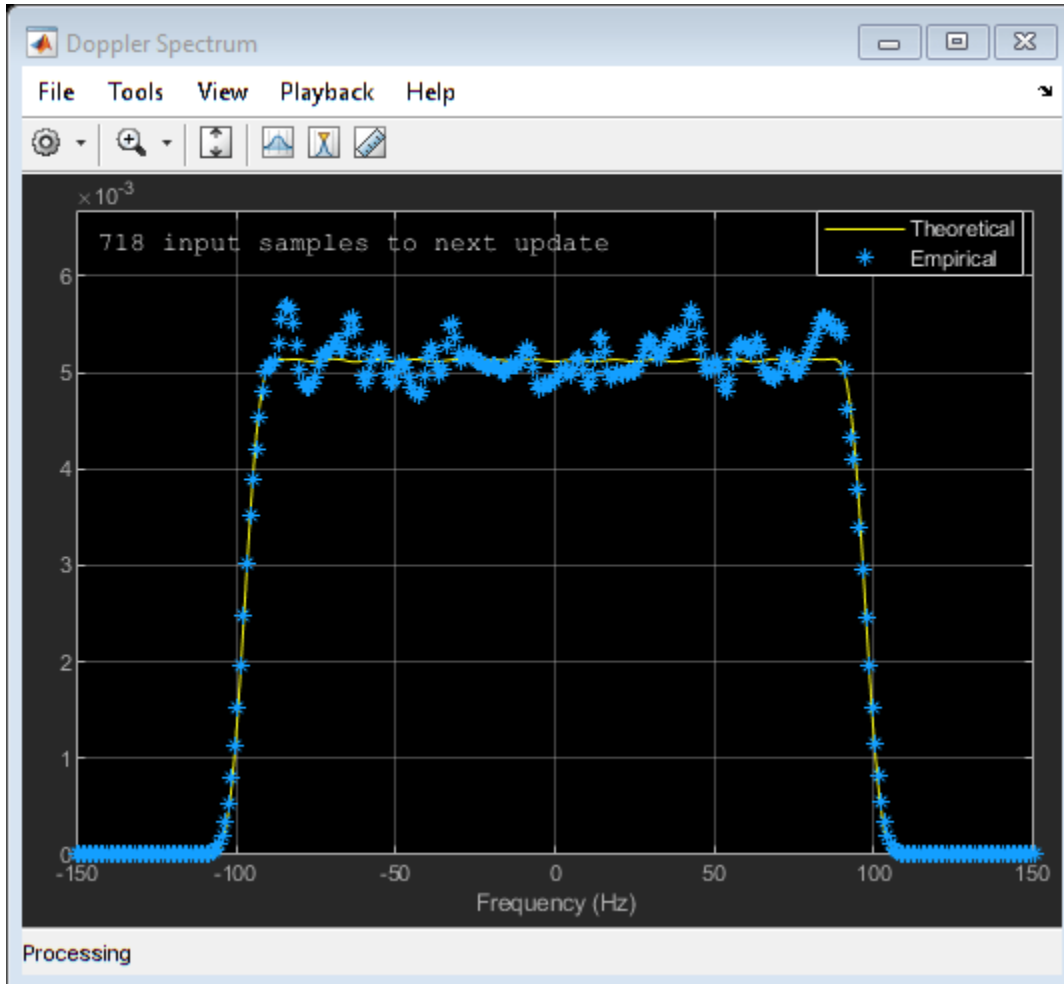

Release the MIMO channel object, and set its `PathsForDopplerDisplay` property to display the second path. Because the `PathsForDopplerDisplay` property is nontunable, to change its value, you must release the System object. Call the object multiple times to display the Doppler spectrum of the second path. The results show that the spectrum is flat.

```
release(mimoChan)
mimoChan.PathsForDopplerDisplay = 2;
```

```

for k = 1:25
    y = mimoChan();
end

```

### Model MIMO Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using MIMO channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```

fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5;             % Maximum Doppler shift (Hz)
ns = 1000;         % Number of samples
nsdel = 100;       % Number of samples for delayed paths

```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response starting at time 0 and three 100-sample channel responses starting at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs;      % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a flat-fading 2-by-2 MIMO channel System object, disabling channel filtering and specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
mimoChan1 = comm.MIMOChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the MIMO channel System object. Change the number of samples for the delayed paths and the source for the initial time so that you can specify the fading channel offset time as an input argument when calling the System object.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
mimoChan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `mimoChan1` object and for the discontinuous delayed channel responses by using the `mimoChan2` object with initial time offsets provided as input arguments.

```
pg0 = mimoChan1();
pg1 = mimoChan2(to1);
pg2 = mimoChan2(to2);
pg3 = mimoChan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` method. The results show that `mimoChan1` processed 1000 samples and that `mimoChan2` processed only 300 samples.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1x2
      1000      300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```

pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));

```

Plot the path gains for the continuous and discontinuous cases. The results show that the gains for the three segments match the gain for the continuous case. The alignment of the two shows that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data because the channel characteristics are maintained even when data is not transmitted.

```

plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
title('Continuous and Discontinuous Channel Response')
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')

```

### Calculate Execution Time Advantage Using Sum-of-Sinusoids Technique

Demonstrate the advantage of using the sum-of-sinusoids fading technique when simulating a channel with burst data.

Set the simulation parameters such that the sampling rate is 100 kHz, the total simulation time is 100 seconds, and the duty cycle for the burst data is 25%.

```
fs = 1e5; % Hz
tsim = 100; % seconds
dutyCycle = 0.25;
```

Create a flat-fading 2-by-2 MIMO channel System object, specifying the sample rate and using the default filtered Gaussian noise technique.

```
fgn = comm.MIMOChannel('SampleRate',fs);
```

Create a similar MIMO channel System object, specifying the same sample rate as the previous MIMO channel object but using the sum-of-sinusoids technique. Additionally specify 48 sinusoids and for the fading process start times to be given as an input argument.

```
sos = comm.MIMOChannel('SampleRate',fs, ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',48, ...
    'InitialTimeSource','Input port');
```

Run a continuous sequence of random bits through the filtered Gaussian noise MIMO channel object. Use the `tic` and `toc` stopwatch timer functions to measure the execution time of the System object call.

```
tic
y = fgn(randi([0 1],fs*tsim,2));
tFGN = toc;
```

To transmit a data burst each second, pass random bits through the sum-of-sinusoids MIMO channel object by calling it inside of a `for` loop. Use the `tic` and `toc` stopwatch timer functions to measure the execution time.

```
tic
for k = 1:tsim
    z = sos(randi([0 1],fs*dutyCycle,2),0.5+(k-1));
end
tSOS = toc;
```

Compare the ratio of the sum-of-sinusoids execution time to the filtered Gaussian noise execution time. The ratio is less than one, which indicates that the sum-of-sinusoids technique is faster than the filtered Gaussian noise technique.

```
tSOS/tFGN
ans = 0.3384
```

### Reciprocal Downlink and Uplink Transmissions in MIMO Channel

Using one MIMO channel System object™ and two identically configured channel filter System objects, switch a link-level simulation between 3-by-2 downlink and reciprocal 2-by-3 uplink signal transmissions.

Define system parameters.

```

modOrder = 256;           % Modulation order
Nant1 = 3;                % Number of 'transmit' antennas
Nant2 = 2;                % Number of 'receive' antennas
Rs = 1e6;                 % Sample rate
pd = [0 1.5 2.3]*1e-6;   % Path delays
frmLen = 1e3;            % Frame length

```

Create a MIMO channel System object™, configuring it for path gain generation by disabling channel filtering.

```

chan = comm.MIMOChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',pd, ...
    'AveragePathGains',[1.5 1.2 0.2], ...
    'MaximumDopplerShift',300, ...
    'SpatialCorrelationSpecification','none', ...
    'NumTransmitAntennas',Nant1, ...
    'NumReceiveAntennas',Nant2, ...
    'ChannelFiltering',false, ...
    'NumSamples',frmLen);

```

Create identical channel filter System objects for both transmission directions: one channel filter for the Nant1-by-Nant2 downlink channel (3 transmit antennas to 2 receive antennas) and a reciprocal channel filter for the Nant2-by-Nant1 uplink channel (2 transmit antennas to 3 receive antennas).

```

chanFiltDownlink = comm.ChannelFilter( ...
    'SampleRate',Rs, ...
    'PathDelays',pd);
chanFiltUplink = clone(chanFiltDownlink);

```

### Downlink Transmission

Generate random path gains for one frame of the downlink 3-by-2 channel. Pass randomly generated 256-QAM signals through the 3-by-2 downlink channel.

```

pgDownlink = chan();
x = qammod(randi([0 modOrder-1],frmLen,Nant1),modOrder);
yDL = chanFiltDownlink(x,pgDownlink);

```

### Uplink Transmission

Switch the link direction. Run the channel object to generate another frame of path gains, permuting its 3rd (Tx) and 4th (Rx) dimensions for the reciprocal uplink 2-by-3 channel. Pass randomly generated 256-QAM signals through the 2-by-3 reciprocal uplink channel.

```

pgUplink = permute(chan(),[1 2 4 3]);
x = qammod(randi([0 modOrder-1],frmLen,Nant2),modOrder);
yUL = chanFiltUplink(x,pgUplink);

```

### Downlink and Uplink Array Dimensions

Show the sizes of the downlink and uplink path gain arrays returned by the MIMO channel object as an  $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array.

- $N_S$  is the number of samples.
- $N_P$  is the number of path delays.

- $N_T$  is the number of transmit antennas. Nant1 for downlink and Nant2 for uplink.
- $N_R$  is the number of receive antennas. Nant2 for downlink and Nant1 for uplink.

```
size(pgDownlink)
```

```
ans = 1×4
```

```
    1000         3         3         2
```

```
size(pgUplink)
```

```
ans = 1×4
```

```
    1000         3         2         3
```

Show the size of the channel output matrices returned by the MIMO channel object as an  $N_S$ -by- $N_R$  matrix.  $N_S$  is the number of samples.  $N_R$  is the number of receive antennas.

```
size(yDL)
```

```
ans = 1×2
```

```
    1000         2
```

```
size(yUL)
```

```
ans = 1×2
```

```
    1000         3
```

## Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all ( $N_T \times N_R$ ) links of the MIMO channel. Each link comprises all multipaths for that link.

### The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$R_H = E[R_t \otimes R_r]$$

- The  $\otimes$  symbol represents the Kronecker product.
- $R_t$  is the correlation matrix at the transmit side,  $R_t = E[H^H H]$ , and is of size  $N_T$ -by- $N_T$ .
- $R_r$  is the correlation matrix at the receive side,  $R_r = E[H H^H]$ , and is of size  $N_R$ -by- $N_R$ .

You can obtain a realization of the MIMO channel matrix as:

$$H = R_r^2 A R_t^2$$

$A$  is an  $N_R$ -by- $N_T$  matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

### Cutoff Frequency Factor

The cutoff frequency factor,  $f_c$ , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian,  $f_c$  equals 1.
- For a `doppler('Gaussian')` spectrum type,  $f_c$  equals `NormalizedStandardDeviation`  $\times \sqrt{2\log 2}$ .
- For a `doppler('BiGaussian')` spectrum type:
  - If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both 0, then  $f_c$  equals `NormalizedStandardDeviation(1)`  $\times \sqrt{2\log 2}$ .
  - If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both 0, then  $f_c$  equals `NormalizedStandardDeviation(2)`  $\times \sqrt{2\log 2}$ .
  - If the `NormalizedCenterFrequencies` field value is `[0,0]` and the `NormalizedStandardDeviation` field has two identical elements, then  $f_c$  equals `NormalizedStandardDeviation(1)`  $\times \sqrt{2\log 2}$ .
  - In all other cases,  $f_c$  equals 1.

### Antenna Selection

When the object is in antenna-selection mode, it uses these algorithms to process an input signal.

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the nonselected links are populated with NaN.
- The spatial correlation applies to only the selected transmit and receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. That is, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths that are associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

## Version History

### Introduced in R2012a

### R2022b: Updates to channel visualization display

The channel visualization feature now presents:

- Configuration settings in the bottom toolbar on the plot window.

- Plots side-by-side in one window when you select the Impulse and frequency response channel visualization option.

## comm.MLSEEqualizer

**Package:** comm

Equalize using maximum likelihood sequence estimation

### Description

The `MLSEEqualizer` object uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The object processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal. This processing uses an estimate of the channel modeled as a finite impulse response (FIR) filter.

To equalize a linearly modulated signal and output the maximum likelihood sequence estimate:

- 1 Define and set up your maximum likelihood sequence estimate equalizer object. See “Construction” on page 3-922.
- 2 Call `step` to equalize a linearly modulated signal and output the maximum likelihood sequence estimate according to the properties of `comm.MLSEEqualizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.MLSEEqualizer` creates a maximum likelihood sequence estimation equalizer (MLSEE) System object, `H`. This object uses the Viterbi algorithm and a channel estimate to equalize a linearly modulated signal that has been transmitted through a dispersive channel.

`H = comm.MLSEEqualizer(Name,Value)` creates an MLSEE object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.MLSEEqualizer(CHANNEL,Name,Value)` creates an MLSEE object, `H`. This object has the `Channel` property set to `CHANNEL`, and the other specified properties set to the specified values.

### Properties

#### ChannelSource

Source of channel coefficients

Specify the source of the channel coefficients as one of `Input port | Property`. The default is `Property`.

#### Channel

## Channel coefficients

Specify the channel as a numeric, column vector containing the coefficients of an FIR filter. The default is  $[1; 0.7; 0.5; 0.3]$ . The length of this vector determines the memory length of the channel. This must be an integer multiple of the samples per symbol, that you specify in the `SamplesPerSymbol` on page 3-0 property. This property applies when you set the `ChannelSource` on page 3-0 property to `Property`.

## Constellation

### Input signal constellation

Specify the constellation of the input modulated signal as a complex vector. The default is  $[1+1i \ -1+1i \ -1-1i \ 1-1i]$ .

## TracebackDepth

### Traceback depth of Viterbi algorithm

Specify the number of trellis branches (the number of symbols), the Viterbi algorithm uses to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay represents the number of zero symbols that precede the first decoded symbol in the output. When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay equals the number of zero symbols of this property. When you set the `TerminationMethod` property to `Truncated`, there is no output delay.

## TerminationMethod

### Termination method of Viterbi algorithm

Specify the termination method of the Viterbi algorithm as one of `Continuous` | `Truncated`. The default is `Truncated`. When you set this property to `Continuous`, the object initializes the Viterbi algorithm metrics of all the states to 0 in the first call to the `step` method. Then, the object saves its internal state metric at the end of each frame, for use with the next frame. When you set this property to `Truncated`, the object resets at every frame. The Viterbi algorithm processes each frame of data independently, resetting the state metric at the end of each frame. The traceback path always starts at the state with the minimum metric. The initialization of the state metrics depends on whether you specify a preamble or postamble. If you set the `PreambleSource` on page 3-0 property to `None`, the object initializes the metrics of all the states to 0 at the beginning of each data frame. If you set the `PreambleSource` property to `Property`, the object uses the preamble that you specify at the `Preamble` on page 3-0 property, to initialize the state metrics at the beginning of each data frame. When you specify a preamble, the traceback path ends at one of the states represented by that preamble. If you set the `PostambleSource` on page 3-0 property to `None`, the traceback path starts at the state with the smallest metric. If you set the `PostambleSource` property to `Property`, the traceback path begins at the state represented by the postamble that you specify at the `Postamble` on page 3-0 property. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble. The decoder then begins traceback decoding at that state. When you set this property to `Truncated`, the `step` method input data signal must contain at least `TracebackDepth` on page 3-0 symbols, not including an optional preamble.

### **ResetInputPort**

Enable equalizer reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this input is a nonzero, double-precision or logical scalar value, the object resets the states of the equalizer. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

### **PreambleSource**

Source of preamble

Specify the source of the preamble that is expected to precede the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a preamble using the `Preamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

### **Preamble**

Preamble that precedes input signals

Specify a preamble that is expected to precede the data in the input signal as an integer, row vector. The default is `[0 3 2 1]`. The values of the preamble should be between 0 and  $M-1$ , where  $M$  is the length of the signal constellation that you specify in the `Constellation` on page 3-0 property. An integer value of  $k-1$  in the vector corresponds to the  $k$ -th entry in the vector stored in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PreambleSource` on page 3-0 property to `Property`.

### **PostambleSource**

Source of postamble

Specify the source of the postamble that is expected to follow the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a postamble in the `Postamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

### **Postamble**

Postamble that follows input signals

Specify a postamble that is expected to follow the data in the input signal as an integer row vector. The default is `[0 2 3 1]`. The values of the postamble should be between 0 and  $M-1$ . In this case,  $M$  indicates the length of the `Constellation` on page 3-0 property. An integer value of  $k-1$  in the vector corresponds to the  $k$ -th entry in the vector specified in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PostambleSource` on page 3-0 property to `Property`. The default is `[0 2 3 1]`.

## SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol in the input signal as an integer scalar value. The default is 1.

## Methods

step Equalize using maximum likelihood sequence estimation

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

## Examples

### MLSE Equalize QPSK Signal Through Dispersive Channel

This example shows how to use an MLSE equalizer to remove the effects of a frequency-selective channel.

Specify static channel coefficients.

```
chCoeffs = [.986; .845; .237; .12345+.31i];
```

Create an MLSE equalizer object. Create an error rate calculator object.

```
mlse = comm.MLSEEqualizer('TracebackDepth',10,...
    'Channel',chCoeffs,'Constellation',pskmod(0:3,4,pi/4));
errorRate = comm.ErrorRate;
```

The main processing loop includes these steps:

- Data generation
- QPSK modulation
- Channel filtering
- Signal equalization
- QPSK demodulation
- Error computation

```
for n = 1:50
    data= randi([0 3],100,1);
    modSignal = pskmod(data,4,pi/4,'gray');

    % Introduce channel distortion.
    chanOutput = filter(chCoeffs,1,modSignal);

    % Equalize the channel output and demodulate.
    eqSignal = mlse(chanOutput);
```

```
demodData = pskdemod(eqSignal,4,pi/4,'gray');  
% Compute BER.  
errorStats = errorRate(data,demodData);  
end
```

Display the bit error rate and the number of errors.

```
ber = errorStats(1)  
numErrors = errorStats(2)
```

```
ber =  
0
```

```
numErrors =  
0
```

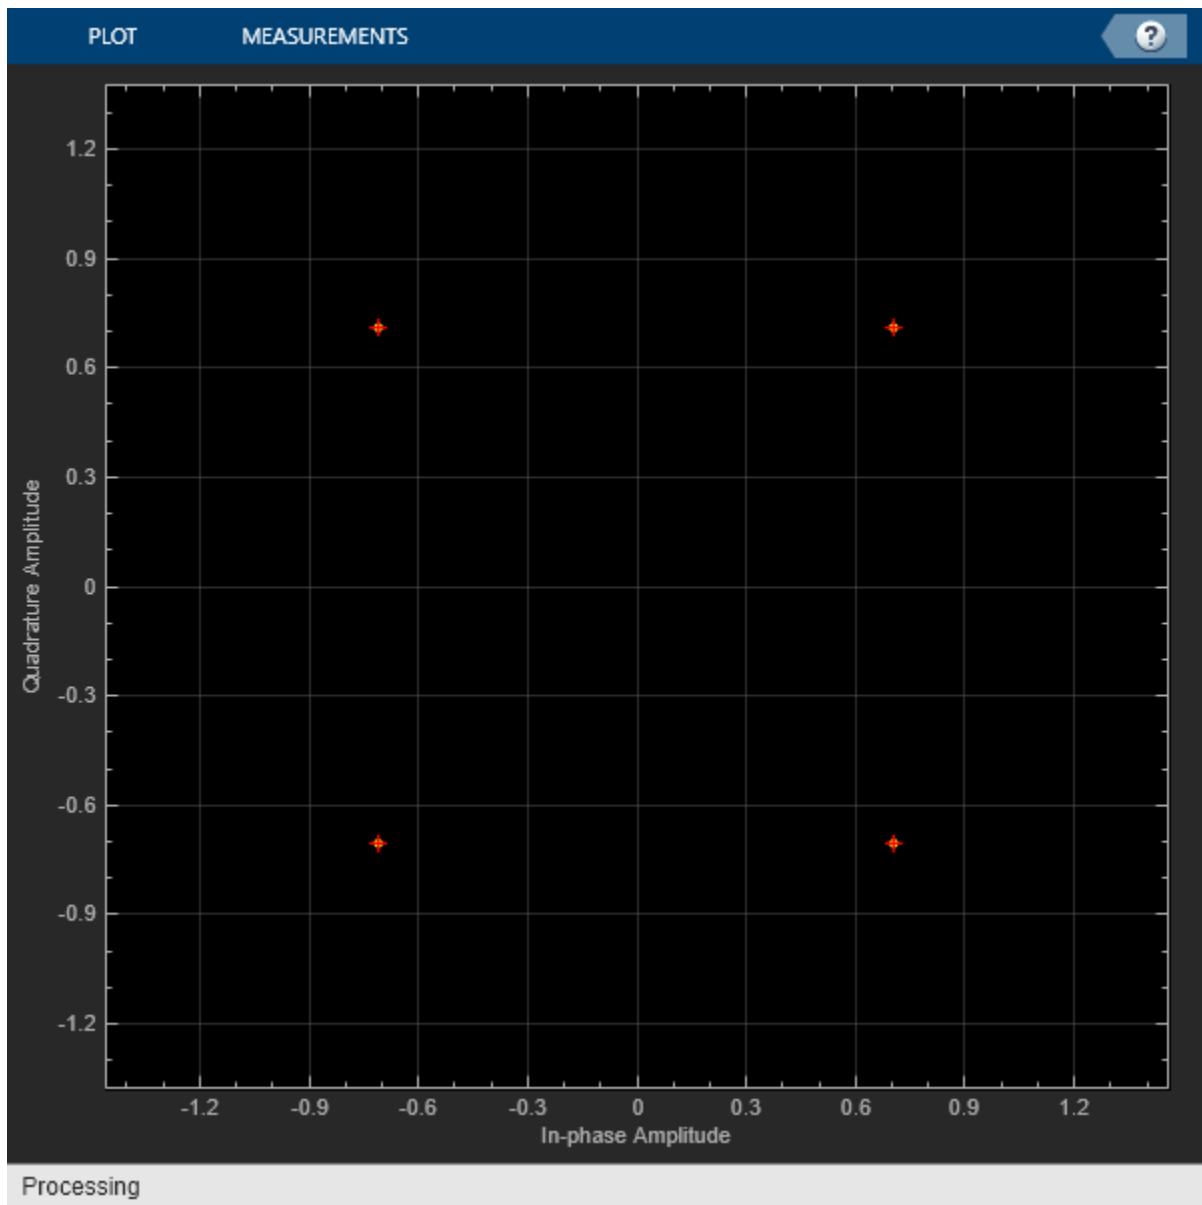

Plot the signal constellation prior to equalization.

```
constDiagram = comm.ConstellationDiagram;  
constDiagram(chanOutput)
```

Plot the signal constellation after equalization.

```
constDiagram(eqSignal)
```

The equalized symbols align perfectly with the QPSK reference constellation.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MLSE Equalizer block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

**System object:** comm.MLSEEqualizer

**Package:** comm

Equalize using maximum likelihood sequence estimation

### Syntax

`Y = step(H,X)`

`Y = step(H,X,CHANNEL)`

`Y = step(H,X,RESET)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` equalizes the linearly modulated data input, `X`, using the Viterbi algorithm. The `step` method outputs `Y`, the maximum likelihood sequence estimate of the signal. Input `X` must be a column vector of data type double or single.

`Y = step(H,X,CHANNEL)` uses `CHANNEL` as the channel coefficients when you set the `ChannelSource` property to 'Input port'. The channel coefficients input, `CHANNEL`, must be a numeric, column vector containing the coefficients of an FIR filter in descending order of powers of `z`. The length of this vector is the channel memory, which must be an integer multiple of the samples per input symbol specified in the `SamplesPerSymbol` property.

`Y = step(H,X,RESET)` uses `RESET` as the reset signal when you set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to true. The object resets when `RESET` has a non-zero value. `RESET` must be a double precision or logical scalar. You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, `Y = step(H,X,CHANNEL,RESET)`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

# comm.MSKDemodulator

**Package:** comm

Demodulate using MSK method and Viterbi algorithm

## Description

The `comm.MSKDemodulator` System object demodulates a signal that was modulated using the differentially encoded minimum shift keying method. The object expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. For more information, see “Algorithms” on page 3-934.

To demodulate a signal that was modulated using minimum shift keying:

- 1 Create the `comm.MSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mskdemod = comm.MSKDemodulator
mskdemod = comm.MSKDemodulator(Name=Value)
```

### Description

`mskdemod = comm.MSKDemodulator` creates a demodulator System object, `mskdemod`. This object demodulates the input minimum shift keying (MSK) modulated data using the Viterbi algorithm.

`mskdemod = comm.MSKDemodulator(Name=Value)` sets “Properties” on page 3-931 using one or more name-value arguments. For example, `InitialPhaseOffset=pi/2` specifies an initial phase of  $\pi/2$  radians for the input modulated waveform.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **BitOutput — Output data as bits**

0 or false (default) | 1 or true

Option to provide output in bits, specified as a numeric or logical 0 (false) or 1 (true).

- When you set this property to `false`, the object method outputs a column vector with a length equal to  $N/\text{SamplesPerSymbol}$  on page 3-0 .  $N$  represents the length of the input signal, which is the number of input baseband modulated symbols. The vector elements are -1 or 1.
- When you set this property to `true`, the object method outputs a binary column vector with a length equal to  $N/\text{SamplesPerSymbol}$ . The vector elements are bit values of 0 or 1.

Data Types: `logical`

### **InitialPhaseOffset — Initial phase offset**

0 (default) | numeric scalar

Initial phase offset of the input modulated waveform in radians, specified as a numeric scalar.

### **SamplesPerSymbol — Number of samples per input symbol**

8 (default) | positive integer

Number of samples per input symbol, specified as a positive integer.

Data Types: `double`

### **TracebackDepth — Traceback depth for Viterbi algorithm**

16 (default) | positive integer

Number of trellis branches that the Viterbi algorithm uses to construct each traceback path, specified as a positive integer. The value of this property is also the output delay. This value indicates the number of zero symbols that precede the first meaningful demodulated symbol in the output.

Data Types: `double`

### **OutputDataType — Data type of output**

"double" (default) | "int8" | "int16" | "int32" | "logical"

Data type of output, specified as:

- `int8`, `int16`, `int32`, or `double` when you set the `BitOutput` on page 3-0 property to `false`.
- `double` or `logical` when you set the `BitOutput` property to `true`.

## **Usage**

### **Syntax**

`y = msksdemod(x)`

### **Description**

`y = msksdemod(x)` applies MSK demodulation to the input signal and returns the demodulated signal.

## Input Arguments

### **x** — MSK-modulated signal

scalar | column vector

MSK-modulated signal, specified as a scalar or column vector.

Data Types: `single` | `double`

## Output Arguments

### **y** — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. The output data type is determined by the `OutputDataType` property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Demodulate MSK Signals with Bit Inputs and Phase Offset

Create an MSK modulator and an MSK demodulator. Use a phase offset of  $\pi/4$ .

```
mskmod = comm.MSKModulator(BitInput=true, ...
    InitialPhaseOffset=pi/4);
mskdemod = comm.MSKDemodulator(BitOutput=true, ...
    InitialPhaseOffset=pi/4);
```

Create an error rate calculator. Account for the delay caused by the Viterbi algorithm.

```
ber = comm.ErrorRate('ReceiveDelay',mskdemod.TracebackDepth);
for counter = 1:100
```

Transmit 100 3-bit words through an AWGN channel, using a signal-to-noise ratio of 0.

```
data = randi([0 1],300,1);
modSignal = mskmod(data);
noisySignal = awgn(modSignal,0);
receivedData = mskdemod(noisySignal);
errorStats = ber(data, receivedData);
```

```

end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

```

```

Error rate = 0.000000
Number of errors = 0

```

## Algorithms

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response obtained from the frequency pulse,  $g(t)$ , through this relation:  $q(t) = \int_{-\infty}^t g(t)dt$ .

The specified frequency pulse shape corresponds to this rectangular pulse shape expression for  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$

- $L$  is the main lobe pulse duration in symbol intervals.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals.

MSK Demodulator Baseband

# comm.MSKModulator

**Package:** comm

Modulate using MSK method

## Description

The `comm.MSKModulator` System object modulates using the minimum shift keying method. The output is a baseband representation of the modulated signal. For more information, see “Algorithms” on page 3-934.

To modulate a signal using minimum shift keying:

- 1 Create the `comm.MSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mskmodulator = comm.MSKModulator
mskmodulator = comm.MSKModulator(Name=Value)
```

### Description

`mskmodulator = comm.MSKModulator` creates a modulator System object that modulates the input signal using the minimum shift keying (MSK) modulation method.

`mskmodulator = comm.MSKModulator(Name=Value)` sets “Properties” on page 3-935 using one or more name-value arguments. For example, `mskmodulator = comm.MSKModulator(InitialPhaseOffset=pi/2)` specifies an initial phase of  $\pi/2$  radians for the modulated waveform.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **BitInput — Assume bit inputs**

false or 0 (default) | true or 1

Option to provide input in bits, specified as a numeric or logical 0 (`false`) or 1 (`true`).

- When you set this property to `false`, the input to the System object call requires a double-precision or signed integer data type column vector with values of -1 or 1.
- When you set this property to `true`, the input to the System object call requires a double-precision or logical data type column vector of 0s and 1s.

Data Types: `logical`

**InitialPhaseOffset — Initial phase offset**

0 (default) | numeric scalar

Initial phase offset of the modulated waveform in radians, specified as a numeric scalar.

**SamplesPerSymbol — Number of samples per output symbol**

8 (default) | positive integer

Number of samples per output symbol, specified as a positive integer. The number of samples per symbol represents the upsampling factor from input samples to output samples.

Data Types: `double`

**OutputDataType — Data type of output**

"double" (default) | "single"

Output data type, specified as either "double" or "single".

## Usage

## Syntax

```
y = mskmodulator(x)
```

## Description

`y = mskmodulator(x)` applies MSK modulation to the input data and returns the modulated MSK baseband signal.

## Input Arguments

**x — Input data**

`integer` | `column vector`

Input data, specified as an integer or column vector of integers or bits.

The setting of the `BitInput` on page 3-0 property determines the interpretation of the input data. If the property is set to `false`, the input must take values of 1 or -1.

Data Types: `double` | `logical`

## Output Arguments

### **y** — MSK-modulated baseband signal

column vector

MSK-modulated baseband signal, returned as a column vector.

The length of the vector is equal to the number of input samples times the `SamplesPerSymbol` on page 3-0 property. For more information about the output data type, see the `OutputDataType` on page 3-0 property.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

- `step`     Run System object algorithm
- `release`   Release resources and allow changes to System object property values and input characteristics
- `reset`     Reset internal states of System object

## Examples

### Modulate MSK Signals with Bit Inputs and Phase Offset

Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a phase offset of  $\pi/4$ .

```
mksmodulator = comm.MSKModulator( ...
    BitInput=true, ...
    InitialPhaseOffset=pi/4);
awgn = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (SNR)', ...
    SNR=0);
mskdemodulator = comm.MSKDemodulator( ...
    BitOutput=true, ...
    InitialPhaseOffset=pi/4);
```

Create an error rate calculator. Account for the delay caused by the Viterbi algorithm.

```
ber = comm.ErrorRate(ReceiveDelay=mskdemodulator.TracebackDepth);
```

Transmit 100 3-bit words.

```
for counter = 1:100
    data = randi([0 1],300,1);
    modSignal = mksmodulator(data);
    noisySignal = awgn(modSignal);
    receivedData = mskdemodulator(noisySignal);
    errorStats = ber(data, receivedData);
```

```
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

### Map Binary Data to MSK Signal

Map binary sequences of zeros and ones to the output of an MSK modulator. This mapping also applies for GMSK modulation.

Create an MSK modulator that accepts binary inputs and has a samples per symbol value of 1.

```
mskmodulator = comm.MSKModulator(BitInput=true, SamplesPerSymbol=1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);
y = mskmodulator(x)
```

```
y = 5×1 complex
```

```
1.0000 + 0.0000i
0.0000 - 1.0000i
-1.0000 - 0.0000i
-0.0000 + 1.0000i
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1
```

```
0
-1.5708
-3.1416
-4.7124
-6.2832
```

A sequence of zeros causes the phase to shift by  $-\pi/2$  between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(mskmodulator)
x = ones(5,1);
y = mskmodulator(x)
```

```
y = 5×1 complex
```

```
1.0000 + 0.0000i
0.0000 + 1.0000i
-1.0000 + 0.0000i
```

```
-0.0000 - 1.0000i
 1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

```
theta = 5×1
```

```
    0
 1.5708
 3.1416
 4.7124
 6.2832
```

A sequence of ones causes the phase to shift by  $+\pi/2$  between samples.

### Compare GMSK and MSK Modulation

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to 1.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
    'SamplesPerSymbol',sps);
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of 30 dB.

```
rxSigGMSK = awgn(modSigGMSK,30);
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to 1, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

```
eyediagram(rxSigMSK,sps,1,sps/2)
```

Set the `PulseLength` property for the GMSK modulator object to 3. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GMSK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to  $\pi/4$  and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “View CPM Phase Tree Using Simulink” example.

## Algorithms

Differentially encoded minimum shift keying modulation uses pulse shaping to smooth the phase transitions of the modulated signal. The function  $q(t)$  is the phase response obtained from the frequency pulse,  $g(t)$ , through this relation:  $q(t) = \int_{-\infty}^t g(t)dt$ .

The specified frequency pulse shape corresponds to this rectangular pulse shape expression for  $g(t)$ .

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$

- $L$  is the main lobe pulse duration in symbol intervals.
- The duration of the pulse,  $LT$ , is the pulse length in symbol intervals.

Recover symbol timing phase using fourth-order nonlinearity method

## Description

The `MSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This object implements a general non-data-aided feedback method that is independent of carrier phase recovery. This method requires prior compensation for the carrier frequency offset. This object is suitable for systems that use baseband minimum shift keying (MSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your MSK timing synchronizer object. See “Construction” on page 3-944.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.MSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.MSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method.

`H = comm.MSKTimingSynchronizer(Name,Value)` creates an MSK timing synchronizer object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

### SamplesPerSymbol

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar greater than 1. The default is 4.

### ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive, real scalar value. The default is 0.05. Typically, this number is less than  $1/\text{SamplesPerSymbol}$  on page 3-0, which corresponds to a slowly varying timing phase. This property is tunable.

### ResetInputPort

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When the reset input is a nonzero value, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

### ResetCondition

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every` frame. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every` frame, the timing phase recovery restarts at the start of each frame of data. Thus, each time the object calls the `step` method. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

## Methods

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Recover Timing Phase of MSK Signal

Create MSK modulator, variable fractional delay, and MSK timing synchronizer System objects.

```
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
mskTimingSync = comm.MSKTimingSynchronizer('SamplesPerSymbol',14,'ErrorUpdateGain',0.05);
```

Main processing loop.

```

phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = mskMod(data); % Modulate data

    % Apply timing offset error.
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery.
    [~,phase] = mskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end

```

Plot the results.

```

plot(1:50,[0.2*ones(50,1) phEst]);
legend('Original','Estimated')
title('Original and Estimated timing phases');

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to MSK.

- The **Reset** parameter corresponds to the `ResetInputPort` on page 3-0 and `ResetCondition` on page 3-0 properties.

## step

**System object:** comm.MSKTimingSynchronizer

**Package:** comm

Recover symbol timing phase using fourth-order nonlinearity method

### Syntax

`[Y,PHASE] = step(H,X)`

`[Y,PHASE] = step(H,X,R)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[Y,PHASE] = step(H,X)` recovers the timing phase and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.MultibandCombiner

**Package:** comm

Frequency-shift and combine signals

## Description

The `comm.MultibandCombiner` System object interpolates, shifts input signals to the specified frequency bands, and then combines them into a single signal. For more information, see the “Algorithms” on page 3-954 section.

To frequency-shift and combine signals:

- 1 Create the `comm.MultibandCombiner` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
multibandcombiner = comm.MultibandCombiner  
multibandcombiner = comm.MultibandCombiner(Name,Value)
```

### Description

`multibandcombiner = comm.MultibandCombiner` creates a multiband combiner System object to frequency-shift and combine input signals.

`multibandcombiner = comm.MultibandCombiner(Name,Value)` sets properties using one or more name-value arguments. For example, `'InputSampleRate',2e6` specifies an input signal sample rate of 2 MHz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **InputSampleRate** — Input signal sample rate

1e6 (default) | positive scalar

Input signal sample rate in Hz, specified as a positive scalar.

Data Types: double

**FrequencyOffsets — Frequency offsets**

[0 1e6] (default) | scalar | 1-by- $N_{\text{chan}}$  vector

Frequency offsets in Hz, specified as one of these options.

- Scalar — Each channel of the input signal is frequency-shifted by this scalar value.
- 1-by- $N_{\text{chan}}$  vector — Each channel of the input signal is frequency-shifted by the corresponding value in this vector.  $N_{\text{chan}}$  is the number of channels in the input signal  $x$ .

Data Types: double

**OutputSampleRateSource — Source of output sample rate**

'Auto' (default) | 'Property'

Source of the output sample rate, specified as one of these values.

- 'Auto' — The object interpolates the input signals to ensure that the resulting sample rate of the signals is sufficient to avoid distorting the frequency content of the original signals after they are frequency-shifted to produce the output signal.
- 'Property' — Specify the output sample rate by using the OutputSampleRate property.

Data Types: char | string

**OutputSampleRate — Output signal sample rate**

3e6 (default) | positive scalar

Output signal sample rate in Hz, specified as a positive scalar.

**Tips**

To avoid distortion, specify this value to be greater than or equal to the automatically computed output sample rate. To determine the automatically computed output sample rate, first run the object with the OutputSampleRateSource property set to 'Auto'.

**Dependencies**

To enable this property, set the OutputSampleRateSource property to 'Property'.

Data Types: double

**Usage****Syntax**

$y = \text{multibandcombiner}(x)$

**Description**

$y = \text{multibandcombiner}(x)$  interpolates, frequency-shifts, and combines the input signal into one output signal.

## Input Arguments

### **x** — Input signals

$N_{\text{samp}}$ -by- $N_{\text{chan}}$  matrix

Input signals, specified as an  $N_{\text{samp}}$ -by- $N_{\text{chan}}$  matrix.  $N_{\text{samp}}$  is the number of input samples per channel, and  $N_{\text{chan}}$  is the number of channels.

Data Types: double | single

## Output Arguments

### **y** — Output signal

$N_{\text{out}}$ -by-1 vector

Output signal, returned as an  $N_{\text{out}}$ -by-1 vector of the same data type as input signal **x**.  $N_{\text{out}}$  is the number of output samples. For more information, see “Algorithms” on page 3-954.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.MultibandCombiner

info Characteristic information about multiband combining

## Common to All System Objects

step Run System object algorithm  
 release Release resources and allow changes to System object property values and input characteristics  
 reset Reset internal states of System object

## Examples

### Combine QPSK and GMSK Signals

Combine two 60 KHz frequency bands that are adjacent to each other.

Set simulation parameters.

```
M = 4;           % QPSK modulation
N = 2000;       % Frame length
Fs1 = 60e3;    % Input sample rate
```

Generate QPSK and GMSK signals.

```
data = randi([0,M-1],N,1);
modSig = pskmod(data,M,pi/4,"gray");
qpskTxFilter = comm.RaisedCosineTransmitFilter( ...
    OutputSamplesPerSymbol=2);
qpsksig = qpskTxFilter(modSig);
```

```
data = randi([0 1],N,1);
gmskMod = comm.GMSKModulator( ...
    BitInput=true, ...
    SamplesPerSymbol=2);
gmsksig = gmskMod(data);
```

Create a multiband combiner and two spectrum analyzer System objects. Use the `info` object function to determine the output sample rate for the combined signal. Use this output sample rate when configuring the spectrum analyzer objects.

```
mbc = comm.MultibandCombiner( ...
    InputSampleRate=Fs1, ...
    FrequencyOffsets=[-30e3 30e3], ...
    OutputSampleRateSource="Auto");
mbcInfo = info(mbc);
Fs2 = mbcInfo.OutputSampleRate

Fs2 = 120000

sa = spectrumAnalyzer( ...
    SampleRate=Fs2, ...
    ShowLegend=true, ...
    ChannelNames=["qpsk", "gmsk"]);
sacombined = spectrumAnalyzer( ...
    SampleRate=Fs2, ...
    ShowLegend=true, ...
    ChannelNames="combined");
```

Use the multiband combiner object to interpolate, frequency-shift, and combine the two signals.

```
combinedsig = mbc([qpsksig,gmsksig]);
```

Use the spectrum analyzer objects to view the individual signals at 60 kHz and the combined signal at 120 kHz.

```
sa(qpsksig,gmsksig);
release(sa);
```

```
sacombined(combinedsig)
```

## Algorithms

### Multiband Combiner

This figure shows how the multiband combiner algorithm processes input signal data.

When the output sample rate is greater than the input sample rate, the input signal is interpolated to avoid distortion in the frequency-shifted signal. Each column of the input signal is frequency-shifted by the corresponding value specified in the `FrequencyOffsets` property. The frequency-shifted signals are then added together into a single channel output signal. Each channel in the input must have the same number of samples.

Setting the `OutputSampleRateSource` to 'Auto' automatically configures the algorithm to compute the output sample rate as  $R_O = R_I \times L$ , where:

- $R_O$  is the output sample rate `OutputSampleRate`.
- $R_I$  is the input sample rate `InputSampleRate`.
- $L$  is the interpolation factor and is computed as  $L = \text{ceil}(2 \times B_{\text{max}}/R_I)$ .

- $B_{\max}$  is the maximum bandwidth and is computed as  $B_{\max} = \max(\text{abs}(\text{FrequencyOffsets})) + (R_f/2)$ .

### **Multiband Combining Delay**

Multiband combining introduces a delay computed as  $\text{delay} = \text{round}(\text{length}(\text{num})/2)$ . The numerator coefficients,  $\text{num}$ , are computed as  $\text{num} = \text{designMultirateFIR}(L,1)$ , where  $L$  is the interpolation factor.

## comm.MultimultiplexedDeinterleaver

**Package:** comm

Deinterleave symbols using set of shift registers with specified delays

### Description

The `comm.MultimultiplexedDeinterleaver` System object deinterleaves the symbols in the input sequence by using a set of shift registers, each with its own specified delay. The deinterleaver uses  $N$  shift registers, where  $N$  is the number of elements in the vector specified by the `Delay` property. When a new input symbol enters the deinterleaver, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the  $N$ th register, upon the next new input, the System object returns to the first register. The multiplexed deinterleaver that is associated with the `comm.MultimultiplexedInterleaver` System object has the same number of registers as the interleaver. The delay in a particular deinterleaver register depends on the difference between the largest interleaver delay and the interleaver delay for the given register. For more information, see “Interleaving”.

To deinterleave the symbols in the input sequence:

- 1 Create the `comm.MultimultiplexedDeinterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
muxdeinterleaver = comm.MultimultiplexedDeinterleaver  
muxdeinterleaver = comm.MultimultiplexedDeinterleaver(Name,Value)
```

#### Description

`muxdeinterleaver = comm.MultimultiplexedDeinterleaver` creates a default multiplexed deinterleaver System object.

`muxdeinterleaver = comm.MultimultiplexedDeinterleaver(Name,Value)` sets the “Properties” on page 3-956 by using one or more name-value arguments. For example, `'InitialConditions',1` sets the initial conditions of shift registers to 1.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **Delay — Interleaver delay**

[2; 0; 1; 3; 10] (default) | column vector of integers

Interleaver delay, specified as a column vector of integers. The values in this vector specify the lengths of the shift registers.

Data Types: double

### **InitialConditions — Initial conditions of shift registers**

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Numeric scalar — The default value is 0. The specified scalar applies to all shift registers.
- Column vector — The length of this vector must be equal to the length of the Delay property value. The *i*th initial condition applies to the *i*th shift register.

Data Types: double

## **Usage**

### **Syntax**

```
deintrlvseq = muxdeinterleaver(intrlvseq)
```

### **Description**

`deintrlvseq = muxdeinterleaver(intrlvseq)` deinterleaves the input sequence of symbols, `deintrlvseq`, by using a set of shift registers with delays specified by the Delay property. The System object returns the deinterleaved sequence, `deintrlvseq`.

### **Input Arguments**

#### **intrlvseq — Interleaved sequence of symbols**

column vector

Interleaved sequence of symbols, specified as a column vector. This sequence must be one that was interleaved using the `comm.MultplexedInterleaver` System object.

Data Types: double | logical | fi

### **Output Arguments**

#### **deintrlvseq — Deinterleaved sequence of symbols**

column vector

Deinterleaved sequence of symbols, returned as a column vector with the same data type and size as the `intrlvseq` argument.

Data Types: double | logical | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Interleave and Deinterleave Sequence

Create a multiplexed interleaver System object, specifying the interleaver delay.

```
interleaver = comm.MultiplexedInterleaver('Delay',[1; 0; 2; 1]);
```

Create a multiplexed deinterleaver System object, specifying the interleaver delay.

```
deinterleaver = comm.MultiplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
[dataIn,dataOut] = deal([]); % Initialize data arrays
```

```
for index = 1:50
    data = randi([0 7],20,1);
    intrlvSequence = interleaver(data);
    deintrlvSequence = deinterleaver(intrlvSequence);
    % Save original data and deinterleaved data
    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deintrlvSequence);
end
```

Determine the delay through the interleaver and deinterleaver.

```
delay = finddelay(dataIn,dataOut)
```

```
delay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-delay),dataOut(delay+1:end))
```

```
ans = logical
     1
```

Permute symbols using set of shift registers with specified delays

### Description

The `comm.MultplexedInterleaver` System object permutes the symbols in the input sequence by using a set of shift registers, each with its own delay value. For more information, see “Interleaving”.

To permute the symbols in the input sequence:

- 1 Create the `comm.MultplexedInterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
muxinterleaver = comm.MultplexedInterleaver  
muxinterleaver = comm.MultplexedInterleaver(Name,Value)
```

#### Description

`muxinterleaver = comm.MultplexedInterleaver` creates a default multiplexed interleaver System object. This System object permutes the symbols in the input sequence by using a set of shift registers with specified delays. The `muxinterleaver` System object consists of  $N$  registers, each with a specified delay. With each new input symbol, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the  $N$ th register, upon the next new input, the commutator returns to the first register.

`muxinterleaver = comm.MultplexedInterleaver(Name,Value)` sets the “Properties” on page 3-960 by using one or more name-value arguments. For example, ‘InitialConditions’,1 sets the initial conditions of the shift registers to 1.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Delay — Interleaver delay**

[2; 0; 1; 3; 10] (default) | column vector of integers

Interleaver delay, specified as a column vector of integers. The values in this vector specify the lengths of the shift registers.

Data Types: double

**InitialConditions — Initial conditions of shift registers**

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Numeric scalar — The default value is 0. The specified scalar applies to all shift registers.
- Column vector — The length of this vector must be equal to the length of the Delay property value. The *i*th initial condition applies to the *i*th shift register.

Data Types: double

**Usage****Syntax**

intrlvseq = muxinterleaver(inputseq)

**Description**

intrlvseq = muxinterleaver(inputseq) permutes the input sequence of symbols, inputseq, by using a set of shift registers with delays specified by the Delay property. The System object returns the interleaved sequence, intrlvseq.

**Input Arguments****inputseq — Sequence of symbols**

column vector

Sequence of symbols, specified as a column vector.

Data Types: double | logical | fi

**Output Arguments****intrlvseq — Interleaved sequence of symbols**

column vector

Interleaved sequence of symbols, returned as a column vector with the same data type and size as the inputseq input.

Data Types: double | logical | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Interleave and Deinterleave Sequence

Create a multiplexed interleaver System object, specifying the interleaver delay.

```
interleaver = comm.MultplexedInterleaver('Delay',[1; 0; 2; 1]);
```

Create a multiplexed deinterleaver System object, specifying the interleaver delay.

```
deinterleaver = comm.MultplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
[dataIn,dataOut] = deal([]); % Initialize data arrays
```

```
for index = 1:50
    data = randi([0 7],20,1);
    intrlvSequence = interleaver(data);
    deintrlvSequence = deinterleaver(intrlvSequence);
    % Save original data and deinterleaved data
    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deintrlvSequence);
end
```

Determine the delay through the interleaver and deinterleaver.

```
delay = finddelay(dataIn,dataOut)
```

```
delay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-delay),dataOut(delay+1:end))
```

```
ans = logical
     1
```

## comm.OQPSKDemodulator

**Package:** comm

Demodulation using OQPSK method

### Description

The `comm.OQPSKDemodulator` object applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see “Pulse Shaping Filter” on page 3-971. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-970.

To demodulate a signal that is OQPSK modulated:

- 1 Create the `comm.OQPSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
oqpskdemod = comm.OQPSKDemodulator
oqpskdemod = comm.OQPSKDemodulator(mod)
oqpskdemod = comm.OQPSKDemodulator(Name,Value)
oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)
```

#### Description

`oqpskdemod = comm.OQPSKDemodulator` creates a demodulator System object. This object can jointly match-filter and decimate a waveform, and demodulate it using the offset quadrature phase shift keying (OQPSK) method.

`oqpskdemod = comm.OQPSKDemodulator(mod)` creates a demodulator System object with symmetric configuration to the OQPSK modulator object, `mod`.

`oqpskdemod = comm.OQPSKDemodulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKDemodulator('BitOutput',true)`

`oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKDemodulator(0.5*pi, 'SamplesPerSymbol', 2)`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### PhaseOffset — Phase of zeroth point of signal constellation

0 (default) | scalar

Phase offset from  $\pi/4$ , specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay the signal is normalized with unity power.

Example: 'PhaseOffset',  $\pi/4$  aligns the zeroth point of the QPSK signal constellation point on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

### BitOutput — Option to output data as bits

false (default) | true

Option to output data as bits, specified as `false` or `true`.

- When you set this property to `false`, the object outputs a column vector of integer values with a length equal to the number of demodulated symbols. The output values are integer representations of two bits and range from 0 to 3.
- When you set this property to `true`, the object outputs a binary column vector of bit values. The output vector length is twice as long as the number of input symbols.

Data Types: logical

### SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as 'Gray', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.
1	0

Data Types: char | double

**PulseShape — Filtering pulse shape**

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine' | 'Root raised cosine', or 'Custom'.

Data Types: char

**RolloffFactor — Raised cosine filter rolloff factor**

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

**Dependencies**

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

**FilterSpanInSymbols — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

**Dependencies**

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

**FilterNumerator — FIR filter numerator**

[0.7071 0.7071] (default) | row vector

FIR filter numerator, specified as a row vector.

**Dependencies**

This property is enabled when PulseShape is 'Custom'.

Data Types: double

**SamplesPerSymbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

**OutputDataType — Data type assigned to output**

'double' (default) | 'single' | 'uint8'

Data type assigned to output, specified as 'double', 'single', or 'uint8'.

Data Types: char

**Usage****Syntax**

```
outsignal = oqpskdemod(waveform)
```

**Description**

`outsignal = oqpskdemod(waveform)` returns the demodulated output signal. The object produces one output symbol for each input pulse.

**Input Arguments****waveform — Received waveform**

scalar | column vector

Received waveform, specified as a complex scalar or column vector.

Data Types: double

Complex Number Support: Yes

**Output Arguments****outsignal — Demodulated signal**

integer vector | bit vector

Demodulated signal, returned as an  $N_S$ -element integer vector or bit vector, where  $N_S$  is the number of samples.

The received waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol. The setting of the BitOutput property determines the interpretation of the received waveform.

Data Types: double

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.OQPSKDemodulator`

`constellation` Calculate or plot ideal signal constellation

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);  
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);  
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300  
    txData = randi([0 1],100,1);  
    modSig = oqpskmod(txData);  
    rxSig = channel(modSig);  
    rxData = oqpskdemod(rxSig);  
    errorStats = errorRate(txData,rxData);  
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```

ber = 3.3336e-05
numErrors = errorStats(2)
numErrors = 1
numBits = errorStats(3)
numBits = 29998

```

### OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

#### System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```

sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator( ...
    'BitInput',true, ...
    'SamplesPerSymbol',sps, ...
    'PulseShape','Root raised cosine');
demodulator = comm.OQPSKDemodulator(modulator);

```

#### Waveform transmission and reception

Use the modulator object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform,snr);
```

Use the demodulator object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```

delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
ber = 0

```

### Soft-Decision OQPSK Modulation-Demodulation

Use the qamdemod function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

### Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex( ...
    real(impairedSig(1+sps/2:end-sps/2)), ...
    imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, ...
    'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdmod` function. Align symbol mapping of `qamdmod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdmod(filteredQPSK,4,oqpskModSymbolMapping, ...
    'OutputType','llr');
```

## More About

### Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by an OQPSK Modulator-Demodulator Object Pair (in samples)
'Half sine' or 'Custom'	Integer	1
	Bit	2
'Normal raised cosine' or 'Root raised cosine'	Integer	FilterSpanInSymbols
	Bit	2*FilterSpanInSymbols
(*) Set the data type property (BitInput for modulation or BitOutput for demodulation) to false for integer data and true for bit data.		

### **Pulse Shaping Filter**

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

Phase Modulation

## comm.OQPSKModulator

**Package:** comm

Modulation using OQPSK method

### Description

The `comm.OQPSKModulator` object modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the output waveform. For more information, see “Pulse Shaping Filter” on page 3-979. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-979.

To modulate a signal using offset quadrature phase shift keying:

- 1 Create the `comm.OQPSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

### Creation

#### Syntax

```
oqpskmod = comm.OQPSKModulator
oqpskmod = comm.OQPSKModulator(demod)
oqpskmod = comm.OQPSKModulator(Name,Value)
oqpskmod = comm.OQPSKModulator(phase,Name,Value)
```

#### Description

`oqpskmod = comm.OQPSKModulator` creates a modulator System object. This object applies offset quadrature phase shift keying (OQPSK) modulation and pulse shape filtering to the input signal.

`oqpskmod = comm.OQPSKModulator(demod)` creates a modulator System object with symmetric configuration to the OQPSK demodulator object, `demod`.

`oqpskmod = comm.OQPSKModulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKModulator('BitInput',true)`

`oqpskmod = comm.OQPSKModulator(phase,Name,Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKModulator(0.5*pi,'SymbolMapping','Binary')`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### PhaseOffset — Phase of zeroth point of signal constellation

0 (default) | scalar

Phase offset from  $\pi/4$ , specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay, the signal is normalized with unity power.

Example: 'PhaseOffset',  $\pi/4$  aligns the zeroth point of the QPSK signal constellation point on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

### BitInput — Option to provide input in bits

false (default) | true

Option to provide input in bits, specified as `false` or `true`.

- When this property is set to `false`, the input values must be integer representations of two-bit input segments and range from 0 to 3.
- When this property is set to `true`, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: logical

### SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as 'Gray', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

Data Types: char | double

**PulseShape — Filtering pulse shape**

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine', 'Root raised cosine', or 'Custom'.

Data Types: char

**RolloffFactor — Raised cosine filter rolloff factor**

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

**Dependencies**

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

**FilterSpanInSymbols — Filter length**

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

**Dependencies**

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

**FilterNumerator — FIR filter numerator**

[0.7071 0.7071] (default) | row vector

FIR filter numerator, specified as a row vector.

**Dependencies**

This property is enabled when PulseShape is 'Custom'.

Data Types: double

**SamplesPerSymbol — Number of samples per symbol**

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

**OutputDataType — Data type assigned to output**

'double' (default) | 'single'

Data type assigned to output, specified as 'double' or 'single'.

Data Types: char

**Usage****Syntax**

```
waveform = oqpskmod(insignal)
```

**Description**

`waveform = oqpskmod(insignal)` returns baseband-modulated output. The output waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol.

**Input Arguments****insignal — Input signal**

integer column vector | bit column vector

Input signal, specified as an  $N_S$ -element column vector of integers or bits, where  $N_S$  is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: double

**Output Arguments****waveform — Output waveform**

vector

Output waveform, returned as a vector. The output waveform is pulse-shaped according to the configuration properties PulseShape and SamplesPerSymbol.

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to comm.OQPSKModulator

constellation Calculate or plot ideal signal constellation

### Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

## Examples

### OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);  
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);  
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300  
    txData = randi([0 1],100,1);  
    modSig = oqpskmod(txData);  
    rxSig = channel(modSig);  
    rxData = oqpskdemod(rxSig);  
    errorStats = errorRate(txData,rxData);  
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 3.3336e-05
```

```
numErrors = errorStats(2)
```

```
numErrors = 1
```

```
numBits = errorStats(3)
```

```
numBits = 29998
```

### Create OQPSK Modulator Using Demodulator

Use an OQPSK demodulator object to initialize an OQPSK modulator object while creating it.

Create an OQPSK demodulator, assigning it a phase offset of  $\frac{1}{2}\pi$ .

```
phase = 0.5*pi;
oqpskdemod = comm.OQPSKDemodulator(phase)
```

```
oqpskdemod =
  comm.OQPSKDemodulator with properties:
```

```
  Modulation
    PhaseOffset: 1.5708
    SymbolMapping: 'Gray'
    BitOutput: false

  Filtering
    PulseShape: 'Half sine'
    SamplesPerSymbol: 4

    OutputDataType: 'double'
```

Use the demodulator object to initialize an OQPSK modulator while creating it.

```
oqpskmod = comm.OQPSKModulator(oqpskdemod)
```

```
oqpskmod =
  comm.OQPSKModulator with properties:
```

```
  Modulation
    PhaseOffset: 1.5708
    SymbolMapping: 'Gray'
    BitInput: false

  Filtering
    PulseShape: 'Half sine'
    SamplesPerSymbol: 4

    OutputDataType: 'double'
```

### OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

### System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator( ...
    'BitInput',true, ...
    'SamplesPerSymbol',sps, ...
    'PulseShape','Root raised cosine');
demodulator = comm.OQPSKDemodulator(modulator);
```

### Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform,snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))

ber = 0
```

### Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

### Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex( ...
    real(impairedSig(1+sps/2:end-sps/2)), ...
    imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, ...
    'DecimationOffset', sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK, 4, oqpskModSymbolMapping, ...
    'OutputType', 'llr');
```

## More About

### Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by an OQPSK Modulator-Demodulator Object Pair (in samples)
'Half sine' or 'Custom'	Integer	1
	Bit	2
'Normal raised cosine' or 'Root raised cosine'	Integer	FilterSpanInSymbols
	Bit	2*FilterSpanInSymbols
(*) Set the data type property ( <code>BitInput</code> for modulation or <code>BitOutput</code> for demodulation) to <code>false</code> for integer data and <code>true</code> for bit data.		

### Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

# comm.OSTBCCombiner

**Package:** comm

Combine inputs using orthogonal space-time block code

## Description

The `OSTBCCombiner` object combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC. The input channel estimate does not need to be constant and can vary at each call to the `step` method. The combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner object in a MIMO communications system.

To combine input signals and extract the soft information of the symbols encoded by an OSTBC:

- 1 Define and set up your OSTBC combiner object. See “Construction” on page 3-981.
- 2 Call `step` to Combine inputs using an orthogonal space-time block code according to the properties of `comm.OSTBCCombiner`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.OSTBCCombiner` creates an orthogonal space-time block code (OSTBC) combiner System object, `H`. This object combines the input signal (from all of the receive antennas) with the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC.

`H = comm.OSTBCCombiner(Name,Value)` creates an OSTBC Combiner object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.OSTBCCombiner(N,M,Name,Value)` creates an OSTBC Combiner object, `H`. This object has the `NumTransmitAntennas` property set to `N`, the `NumReceiveAntennas` property set to `N`, and the other specified properties set to the specified values.

## Properties

### NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

**SymbolRate**

Symbol rate of code

Specify the symbol rate of the code as  $3/4$  |  $1/2$ . The default is  $3/4$ . This property applies when the `NumTransmitAntennas` on page 3-0 property is greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

**NumReceiveAntennas**

Number of receive antennas

Specify the number of antennas at the receiver as a double-precision, real, scalar integer value from 1 to 8. The default is 1.

**Fixed-Point Properties****RoundingMethod**

Rounding of fixed-point numeric values

Specify the rounding method as `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`.

**OverflowAction**

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property specifies the action to be taken in case of overflow. Such overflow occurs if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

**ProductDataType**

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`.

**CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `ProductDataType` property to `Custom`.

**AccumulatorDataType**

Data type of accumulator

Specify the accumulator data type as `Full precision` | `Same as product` | `Custom`. The default is `Full precision`.

### **CustomAccumulatorDataType**

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

### **EnergyProductDataType**

Data type of energy product

Specify the complex energy product data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. This property sets the data type of the complex product in the denominator to calculate the total energy in the MIMO channel.

### **CustomEnergyProductDataType**

Fixed-point data type of energy product

Specify the energy product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyProductDataType` property to `Custom`.

### **EnergyAccumulatorDataType**

Data type of energy accumulator

Specify the energy accumulator data type as one of `Full precision` | `Same as energy product` | `Same as accumulator` | `Custom`. The default is `Full precision`. This property sets the data type of the summation in the denominator to calculate the total energy in the MIMO channel.

### **CustomEnergyAccumulatorDataType**

Fixed-point data type of energy accumulator

Specify the energy accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyAccumulatorDataType` property to `Custom`.

### **DivisionDataType**

Data type of division

Specify the division data type as one of `Same as accumulator` | `Custom`. The default is `Same as accumulator`. This property sets the data type at the output of the division operation. The setting normalizes diversity combining by the total energy in the MIMO channel.

### CustomDivisionDataType

Fixed-point data type of division

Specify the division fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `DivisionDataType` property to `Custom`.

## Examples

### Encode with OSTBC and Calculate Errors

Determine the bit error rate for a QPSK signal employing OSTBC encoding when transmitted through a 4x2 MIMO channel. Perfect channel estimation is assumed to be used by the OSTBC combiner.

Define the system parameters.

```
numTx = 4;           % Number of transmit antennas
numRx = 2;           % Number of receive antennas
Rs = 1e6;            % Sampling rate (Hz)
tau = [0 2e-6];      % Path delays (sec)
pdb = [0 -10];       % Average path gains (dB)
maxDopp = 30;        % Maximum Doppler shift (Hz)
numBits = 12000;     % Number of bits
SNR = 6;             % Signal-to-noise ratio (dB)
```

Set the random number generator to its default state to ensure repeatable results.

```
rng default
```

Create an OSTBC encoder and combiner pair, where the number of antennas is specified in the system parameters.

```
hOSTBCEnc = comm.OSTBCEncoder(...
    NumTransmitAntennas=numTx);

hOSTBCComb = comm.OSTBCCombiner(...
    NumTransmitAntennas=numTx,...
    NumReceiveAntennas=numRx);
```

Create a flat 4x2 MIMO Channel System object, where the channel characteristics are set using name-value pairs. The path gains are made available to serve as a perfect channel estimate for the OSTBC combiner.

```
mimochan = comm.MIMOChannel(...
    SampleRate=Rs,...
    PathDelays=tau,...
    AveragePathGains=pdb,...
    MaximumDopplerShift=maxDopp,...
    SpatialCorrelationSpecification='None',...
    NumTransmitAntennas=numTx,...
    NumReceiveAntennas=numRx,...
    PathGainsOutputPort=true);
```

Create an AWGN channel System object in which the noise method is specified as a signal-to-noise ratio.

```
awgnchan = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (SNR)',...
    SNR=SNR,...
    SignalPower=1);
```

Generate a random sequence of bits.

```
data = randi([0 1],numBits,1);
```

Apply QPSK modulation.

```
modData = pskmod(data,4,InputType='bit');
```

Encode the modulated data using the OSTBC encoder object.

```
encData = hOSTBCEnc(modData);
```

Transmit the encoded data through the MIMO channel and add white noise by using the MIMO and AWGN channel objects, respectively.

```
[chanOut,pathGains] = mimochan(encData);
rxSignal = awgnchan(chanOut);
```

Sum the pathGains array along the number of paths (2nd dimension) to form the channel estimate. Apply the squeeze function to make its dimensions conform with those of rxSignal.

```
chEst = squeeze(sum(pathGains,2));
```

Combine the received MIMO signal and its channel estimate using the OSTBC combiner object. Demodulate the combined signal.

```
combinedData = hOSTBCComb(rxSignal,chEst);
receivedData = pskdemod(combinedData,4,OutputType='bit');
```

Compute the number of bit errors and the bit error rate.

```
[numErrors,ber] = biterr(data,receivedData)
```

```
numErrors = 6
```

```
ber = 5.0000e-04
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Combiner block reference page. The object properties correspond to the block parameters.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

`comm.OSTBCEncoder`

## step

**System object:** comm.OSTBCCCombiner

**Package:** comm

Combine inputs using orthogonal space-time block code

### Syntax

$Y = \text{step}(H, X, \text{CEST})$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, X, \text{CEST})$  combines the received data,  $X$ , and the channel estimate,  $\text{CEST}$ , to extract the symbols encoded by an OSTBC. Both  $X$  and  $\text{CEST}$  are complex-valued and of the same data type, which can be double, single, or signed fixed point with power-of-two slope and zero bias. When the `step` method input  $X$  has double or single precision, the output,  $Y$ , has the same data type as the input. The input channel estimate can remain constant or can vary during each codeword block transmission. The combining algorithm uses the estimate only for the first symbol period per codeword block.

The time domain length,  $T/\text{SymbolRate}$ , must be a multiple of the codeword block length.  $T$  is the output symbol sequence length in the time domain. Specifically, when you set the `NumTransmitAntennas` property to 2,  $T/\text{SymbolRate}$  must be a multiple of two. When you set the `NumTransmitAntennas` property greater than 2,  $T/\text{SymbolRate}$  must be a multiple of four. For an input of  $T/\text{SymbolRate}$  rows by `NumReceiveAntennas` columns, the input channel estimate,  $\text{CEST}$ , must be a matrix of size  $T/\text{SymbolRate}$  by `NumTransmitAntennas` by `NumReceiveAntennas`. In this case, the extracted symbol data,  $Y$ , is a column vector with  $T$  elements. Input matrix size can be  $F$  by  $T/\text{SymbolRate}$  by `NumReceiveAntennas`, where  $F$  is an optional dimension (typically frequency domain) over which the combining calculation is independent. In this case, the input channel estimate,  $\text{CEST}$ , must be a matrix of size  $F$  by  $T/\text{SymbolRate}$  by `NumTransmitAntennas` by `NumReceiveAntennas`. The extracted symbol data,  $Y$ , is an  $F$  rows by  $T$  columns matrix.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.OSTBCEncoder

**Package:** comm

Encode input using orthogonal space-time block code

### Description

The OSTBCEncoder object encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

To encode an input symbol sequence using an orthogonal space-time block code:

- 1 Define and set up your OSTBC encoder object. See “Construction” on page 3-988.
- 2 Call `step` to encode an input symbol sequence according to the properties of `comm.OSTBCEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.OSTBCEncoder` creates an orthogonal space-time block code (OSTBC) encoder System object, `H`. This object maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

`H = comm.OSTBCEncoder(Name, Value)` creates an OSTBC encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.OSTBCEncoder(N, Name, Value)` creates an OSTBC encoder object, `H`. This object has the `NumTransmitAntennas` property set to `N`, and the other specified properties set to the specified values.

### Properties

#### NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

#### SymbolRate

Symbol rate of code

Specify the symbol rate of the code as one of  $3/4$  |  $1/2$ . The default is  $3/4$ . This property applies when you set the NumTransmitAntennas on page 3-0 property to greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

## Fixed-Point Properties

### OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of Wrap | Saturate. The default is Wrap. This property specifies the action to be taken in the case of an overflow. Such overflow occurs when the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

## Examples

### Encode BPSK Modulated Data with OSTBC

Generate random binary data, modulate using the BPSK modulation scheme, and encode the modulated data using OSTBC.

Generate an 8-by-1 vector of random binary data.

```
data = randi([0 1],8,1);
```

Create BPSK Modulator System object and modulated the data using the step function.

```
bpskMod = comm.BPSKModulator;
modData = bpskMod(data);
```

Create an OSTBC Encoder and encode the modulated signal. As the default number of transmit antennas is 2, you can see that encData is an 8-by-2 vector.

```
ostbcEnc = comm.OSTBCEncoder;
encData = ostbcEnc(modData)
```

```
encData = 8×2 complex
```

```
-1.0000 + 0.0000i -1.0000 + 0.0000i
 1.0000 + 0.0000i -1.0000 - 0.0000i
 1.0000 + 0.0000i -1.0000 + 0.0000i
 1.0000 + 0.0000i  1.0000 + 0.0000i
-1.0000 + 0.0000i  1.0000 + 0.0000i
-1.0000 + 0.0000i -1.0000 - 0.0000i
 1.0000 + 0.0000i -1.0000 + 0.0000i
```

1.0000 + 0.0000i 1.0000 + 0.0000i

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Encoder block reference page. The object properties correspond to the block parameters.

When this object processes variable-size signals:

- If the input signal is a column vector, the first dimension can change, but the second dimension must remain fixed at 1.
- If the input signal is a matrix, both dimensions can change.

## Version History

**System object:** comm.OSTBCEncoder

**Package:** comm

Encode input using orthogonal space-time block code

### Syntax

$Y = \text{step}(H,X)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  encodes the input data,  $X$ , using OSTBC encoder object,  $H$ . The input is a complex-valued column vector or matrix of data type `double`, `single`, or signed fixed-point with power-of-two slope and zero bias. The `step` method output,  $Y$ , is the same data type as the input data. The time domain length,  $T$ , of  $X$  must be a multiple of the number of symbols in each codeword matrix. Specifically, when you set the `NumTransmitAntennas` property is 2 or the `SymbolRate` property is  $1/2$ ,  $T$  must be a multiple of two and when the `SymbolRate` property to  $3/4$ ,  $T$  must be a multiple of three. For a time or spatial domain input of  $T$  rows by one column, the encoded output data,  $Y$ , is a  $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix. The input matrix size can be  $F$  rows by  $T$  columns, where  $F$  is the additional dimension (typically the frequency domain) over which the encoding calculation is independent. In this case, the output is an  $F$ -by- $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.OVSFCode

**Package:** comm

Generate OVSF code

### Description

The `OVSFCode` object generates an orthogonal variable spreading factor (OVSF) code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. They are primarily used to preserve orthogonality between different channels in a communication system.

To generate an OVSF code:

- 1 Define and set up your OVSF code object. See “Construction” on page 3-992.
- 2 Call `step` to generate an OVSF code according to the properties of `comm.OVSFCode`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.OVSFCode` creates an orthogonal variable spreading factor (OVSF) code generator System object, `H`. This object generates an OVSF code.

`H = comm.OVSFCode(Name, Value)` creates an OVSF code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

### Properties

#### SpreadingFactor

Length of generated code

Specify the length of the generated code as an integer scalar value with a power of two. The default is 64.

#### Index

Index of code of interest

Specify the index of the desired code from the available set of codes that have the spreading factor specified in the `SpreadingFactor` on page 3-0 property. This property must be an integer scalar in the range 0 to `SpreadingFactor-1`. The default is 60.

OVSF codes are defined as the rows of an  $n$ -by- $n$  matrix,  $C_n$ , where  $n$  is the value specified in the `SpreadingFactor` property.

You can define the matrix  $C_n$  recursively as follows:

First, define  $C_1 = [1]$ .

Next, assume that  $C_n$  is defined and let  $C_n(k)$  denote the  $k$ -th row of  $C_n$ .

Then,  $C_{2n} = [C_n(0) \ C_n(0); C_n(0) \ -C_n(0); \dots; C_n(n-1) \ C_n(n-1); C_n(n-1) \ -C_n(n-1)]$ .

$C_n$  is only defined for values of  $n$  that are a power of 2. Set this property to a value of  $k$  to choose the  $k$ -th row of the  $C$  matrix as the code of interest.

### SamplesPerFrame

Number of output samples per frame

Specify the number of OVSF code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1. If you set this property to a value of  $M$ , then the `step` method outputs  $M$  samples of an OVSF code of length  $N$ .  $N$  is the length of the OVSF code that you specify in the `SpreadingFactor` on page 3-0 property.

### OutputDataType

Data type of output

Specify output data type as one of `double` | `int8`. The default is `double`.

## Methods

`step`                      Generate OVSF code

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

Generate 10 samples of an OVSF code with a spreading factor of 64.

```
hOVSF = comm.OVSFCode('SamplesPerFrame', 10, 'SpreadingFactor', 64);
seq = step(hOVSF)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the OVSF Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

## **Version History**

**System object:** comm.OVSFCode

**Package:** comm

Generate OVSF code

### Syntax

$Y = \text{step}(H)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H)$  outputs a frame of the OVSF code in column vector  $Y$ . Specify the frame length with the `SamplesPerFrame` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.PAMDemodulator

**Package:** comm

(Not recommended) Demodulate using M-ary PAM method

---

**Note** comm.PAMDemodulator is not recommended. Use pamdemod instead.

---

### Description

The PAMDemodulator object demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM demodulator object. See “Construction” on page 3-996.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMDemodulator(Name, Value)` creates an M-PAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PAMDemodulator(M, Name, Value)` creates an M-PAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

### Properties

#### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitOutput` on page 3-0 property to `false`, this value must be even. When you set the `BitOutput` property to `true`, this value requires an integer power of two.

#### BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to  $\log_2(\text{ModulationOrder on page 3-0})$  times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector, with length equal to the input data vector. This value contains integer symbol values between 0 and  $\text{ModulationOrder}-1$ .

### **SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 3-0})$  bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the integer  $m$ , between  $0 \leq m \leq (\text{ModulationOrder}-1)$  maps to the complex value  $2^{m-\text{ModulationOrder}+1}$ .

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Average power`.

### **PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak` power.

### **OutputDataType**

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

When you set this property to `Full precision`, and the input data type is `single` or `double` precision, the output data has the same data type that of the input.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` on page 3-0 property to `Smallest unsigned integer`.

When you set the `BitOutput` on page 3-0 property to `true`, then `logical` data type becomes a valid option.

### **Fixed-Point Properties**

#### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-1001.

#### **DenormalizationFactorDataType**

Data type of denormalization factor

Specify the denormalization factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`.

#### **CustomDenormalizationFactorDataType**

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an `unscalenumtype` object with a signedness of `Auto`. The default is `numerictype([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 3-0 property to `Custom`.

**ProductDataType**

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object calculates the full-precision product word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false.

**CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as an `unscaled numerictype` object with a signedness of `Auto`. The default is `numerictype([], 32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `ProductDataType` on page 3-0 property to `Custom`.

**ProductRoundingMethod**

Rounding of fixed-point numeric value of product

Specify the product rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration

**ProductOverflowAction**

Action when fixed-point numeric value of product overflows

Specify the product overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration.

**SumDataType**

Data type of sum

Specify the sum data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. When you set this property to `Full precision`, the object calculates the full-precision sum word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false

**CustomSumDataType**

Fixed-point data type of sum

Specify the sum fixed-point type as an `unscaled numerictype` object with a signedness of `Auto`. The default is `numerictype([], 32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false and the `SumDataType` on page 3-0 property to `Custom`.

## Methods

constellation (Not recommended) Calculate or plot ideal signal constellation  
 step (Not recommended) Demodulate using M-ary PAM method

Common to All System Objects	
release	Allow System object property value changes

## Examples

Modulate and demodulate a signal using 16-PAM modulation.

```
hMod = comm.PAMModulator(16);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',20, 'SignalPower', 85);
hDemod = comm.PAMDemodulator(16);
%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 hMod.ModulationOrder-1],50,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

## Compatibility Considerations

### **comm.PAMDemodulator is not recommended**

comm.PAMDemodulator is not recommended. Use pamdemod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## step

**System object:** comm.PAMDemodulator

**Package:** comm

(Not recommended) Demodulate using M-ary PAM method

---

**Note** comm.PAMDemodulator is not recommended. Use pamdemod instead.

---

### Syntax

$Y = \text{step}(H,X)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates data,  $X$ , with the M-PAM demodulator System object,  $H$ , and returns  $Y$ . Input  $X$  must be a scalar or column vector. The data type of the input can be double or single precision, signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output  $Y$  can be integer or bit valued.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

# comm.PAMModulator

**Package:** comm

(Not recommended) Modulate using M-ary PAM method

---

**Note** comm.PAMModulator is not recommended. Use pammod instead.

---

## Description

The PAMModulator object modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The M-ary number parameter, M, represents the number of points in the signal constellation and requires an even integer.

To modulate a signal using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM modulator object. See “Construction” on page 3-1005.
- 2 Call `step` to modulate the signal according to the properties of `comm.PAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.PAMModulator` creates a modulator System object, H. This object modulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMModulator(Name, Value)` creates an M-PAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PAMModulator(M, Name, Value)` creates an M-PAM modulator object, H. This object has the `ModulationOrder` property set to M and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitInput` on page 3-0 property to `false`, `ModulationOrder` must be even. When you set the `BitInput` property to `true`, `ModulationOrder` must be an integer power of two.

**BitInput**

Assume bit inputs

Specify whether the input is in bits or integers. The default is `false`.

When you set this property to `true`, the `step` method input requires a column vector of bit values whose length is an integer multiple of  $\log_2(\text{ModulationOrder on page 3-0})$ . This vector contains bit representations of integers between 0 and `ModulationOrder-1`.

When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and `ModulationOrder-1`.

**SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 3-0})$  input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the input integer  $m$ , between  $0 \leq m \leq \text{ModulationOrder}-1$  maps to the complex value  $2^{m - \text{ModulationOrder} + 1}$ .

**NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

**MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

**AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Average power`.

**PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

## Methods

`constellation` (Not recommended) Calculate or plot ideal signal constellation  
`step` (Not recommended) Modulate using M-ary PAM method

### Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

## Examples

Modulate data using 16-PAM modulation, and visualize the data in a scatter plot.

```
% Create binary data for 100, 4-bit symbols
data = randi([0 1],400,1);
% Create a 16-PAM modulator System object with bits as inputs and
% Gray-coded signal constellation
hModulator = comm.PAMModulator(16,'BitInput',true);
% Modulate and plot the data
modData = step(hModulator, data);
constellation(hModulator)
```

## Compatibility Considerations

### comm.PAMModulator is not recommended

`comm.PAMModulator` is not recommended. Use `pammod` instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
```

```
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pandemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pandemodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pandemod(y,M); % Demodulate.
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

(Not recommended) Modulate using M-ary PAM method

---

**Note** comm.PAMModulator is not recommended. Use pammod instead.

---

## Syntax

$Y = \text{step}(H,X)$

## Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  modulates input data,  $X$ , with the M-PAM modulator System object,  $H$ . It returns the baseband modulated output,  $Y$ . Depending on the value of the `BitInput` property, input  $X$  can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

# comm.PhaseFrequencyOffset

**Package:** comm

Apply phase and frequency offsets to input signal

## Description

The `PhaseFrequencyOffset` object applies phase and frequency offsets to an incoming signal.

To apply phase and frequency offsets to the input signal:

- 1 Create the `comm.PhaseFrequencyOffset` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
pfo = comm.PhaseFrequencyOffset  
pfo = comm.PhaseFrequencyOffset(Name=Value)
```

### Description

`pfo = comm.PhaseFrequencyOffset` creates a phase and frequency offset System object. This object applies phase and frequency offsets to an input signal.

`pfo = comm.PhaseFrequencyOffset(Name=Value)` creates a phase and frequency offset object with each specified property set to the specified value. For example, `SampleRate=20` sets a sample rate of 20 Hz. You can specify additional name-value pair arguments in any order as `(Name1=Value1,...,NameN=ValueN)`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### PhaseOffset — Phase offset

0 (default) | scalar | row or column vector | matrix

Phase offset in degrees, specified as numeric scalar, an  $M$ -by-1 or 1-by- $N$  numeric vector, or an  $M$ -by- $N$  numeric matrix. For more information, see “Interdependent Property-Input Dimensions” on page 3-1016.

**Tunable:** Yes

Data Types: double

### FrequencyOffsetSource — Frequency offset source

"Property" (default) | "Input port"

Frequency offset source, specified as one of these values

- "Property" — Specify the frequency offset using the FrequencyOffset property.
- "Input port" — Specify the frequency offset in the fOffset input argument.

### FrequencyOffset — Frequency offset

0 (default) | scalar | row or column vector | matrix

Frequency offset in Hz, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix.

For more information, see “Interdependent Property-Input Dimensions” on page 3-1016.

**Tunable:** Yes

#### Dependency

To enable this property, set the FrequencyOffsetSource property to "Property".

Data Types: double

### SampleRate — Sample rate

1 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar.

Data Types: double

## Usage

### Syntax

```
y = pfo(x)
y = pfo(x, fOffset)
```

### Description

$y = \text{pfo}(x)$  applies phase and frequency offsets to input signal  $x$ . To use this syntax, set the FrequencyOffsetSource to "Property".

$y = \text{pfo}(x, f\text{Offset})$  specifies the frequency offset to apply to  $x$ . To use this syntax, set the FrequencyOffsetSource to "Input port".

### Input Arguments

#### **x — Input signal**

scalar | row or column vector | matrix

Input signal, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix. For more information, see “Interdependent Property-Input Dimensions” on page 3-1016.

Data Types: single | double

#### **f0ffset — Frequency offset**

scalar | row or column vector | matrix

Frequency offset in Hz, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix. For more information, see the description of the `FrequencyOffset` property and “Interdependent Property-Input Dimensions” on page 3-1016.

#### Dependency

To enable this input, set the `FrequencyOffsetSource` property to “Input port”.

Data Types: single | double

### Output Arguments

#### **y — Output signal**

scalar | row or column vector | matrix

Output signal, returned with the same dimensions and data type as `x`.

Data Types: single | double

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

### Examples

#### Introduce Phase Offset to 16-QAM Signal

Introduce a phase offset to a 16-QAM signal and view its effect on the constellation.

Create a phase frequency offset System object™, setting the phase offset to 30 degrees.

```
pfo = comm.PhaseFrequencyOffset(PhaseOffset=30);
```

Generate random symbols and apply 16-QAM modulation.

```
M = 16;  
data = (0:M-1)';  
x = qammod(data,M);
```

Plot the 16-QAM constellation.

```
scatterplot(x);  
title("Original Constellation")  
xlim([-5 5])  
ylim([-5 5])
```

Introduce a phase offset and plot the offset constellation.

```
y = pfo(x);  
scatterplot(y);  
title("Constellation After Phase Offset")  
xlim([-5 5])  
ylim([-5 5])
```

## More About

### Interdependent Property-Input Dimensions

This table outlines the interdependency of property-to-input argument dimensions.

Number of Dimensions	Data I/O Dimension	Frame Size	Number of Channels	Frequency/Phase Offset Property Dimension	Frequency Offset Input Argument Dimension
Any	Scalar	1	1	Scalar	Scalar
2	$M$ -by-1	$M$	1	$M$ -by-1 1-by- $M$ 1-by-1	$M$ $M$ -by-1 1 1-by-1

Number of Dimensions	Data I/O Dimension	Frame Size	Number of Channels	Frequency/Phase Offset Property Dimension	Frequency Offset Input Argument Dimension
2	1-by- $N$	1	$N$	$N$ -by-1 1-by- $N$ 1-by-1	$N$ 1-by- $N$ 1 1-by-1
2	$M$ -by- $N$	$M$	$N$	$M$ -by- $N$ $N$ -by-1 1-by- $N$ $M$ -by-1 1-by- $M$ 1-by-1	$M$ -by- $N$ $N$ 1-by- $N$ 1 1-by-1 $M$ $M$ -by-1

For example:

- When you specify a scalar offset property, the object applies the same offset to all elements of the input signal
- When you specify a 2-by-1 offset property for a 2-by-3 input signal (one offset value per sample), the object applies the same sample offset across the three channels.
- When you specify a 1-by-3 offset property for a 2-by-3 input signal (one offset value per channel), the same channel offset is applied across the two samples of a channel.
- When you specify a 2-by-3 offset property for a 2-by-3 input signal (one offset value per sample for each channel), the offsets are applied element-wise to the input signal.

## Algorithms

If the input signal is  $u(t)$ , then the output signal is

$$y(t) = u(t) \cdot \left( \cos\left(2\pi \int_0^t f(\tau) d\tau + \varphi(t)\right) + j \sin\left(2\pi \int_0^t f(\tau) d\tau + \varphi(t)\right) \right),$$

where  $f(t)$  is the frequency offset, and  $\varphi(t)$  is the phase offset.

The discrete-time output is given by

$$y(0) = u(0)(\cos(\varphi(0)) + j \sin(\varphi(0))) \text{ and}$$

$$y(i) = u(i) \left( \cos\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) + j \sin\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) \right),$$

where  $i > 0$ , and  $\Delta t$  is the sample time.

# comm.PhaseNoise

**Package:** comm

Apply phase noise to baseband signal

## Description

The `comm.PhaseNoise` System object adds phase noise to a complex signal. This object emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The object generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see “Algorithms” on page 3-1025.

To add phase noise using a `comm.PhaseNoise` object:

- 1 Create the `comm.PhaseNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
phznnoise = comm.PhaseNoise
phznnoise = comm.PhaseNoise(Name,Value)
phznnoise = comm.PhaseNoise(level,offset,samplerate)
```

### Description

`phznnoise = comm.PhaseNoise` creates a phase noise System object with default property values.

`phznnoise = comm.PhaseNoise(Name,Value)` creates a phase noise object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`phznnoise = comm.PhaseNoise(level,offset,samplerate)` creates a phase noise object with the phase noise level, frequency offset, and sample rate properties specified as value-only arguments. When specifying a value-only argument, you must specify all preceding value-only arguments.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Level — Phase noise level**

[-80 -100] (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz (dBc/Hz), specified as a vector of negative scalars. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: double

**FrequencyOffset — Frequency offset**

[2000 20000] (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The maximum frequency offset value must be less than  $F_s/2$ , where  $F_s$  represents the `SampleRate` property value.

The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: double

**SampleRate — Sample rate**

1e6 (default) | positive scalar

Sample rate in Hz, specified as a positive scalar greater than two times the maximum value specified by the `FrequencyOffset` property.

Data Types: double

**RandomStream — Source of random stream**

'Global stream' (default) | 'mt19937ar with seed'

Source of the random stream, specified as 'Global stream' or 'mt19937ar with seed'. If `RandomStream` is set to 'mt19937ar with seed', the mt19937ar algorithm is used for normally distributed random number generation, in which case the `reset` method reinitializes the random number stream to the value of the `Seed` property.

Data Types: char | string

**Seed — Initial seed**2137 (default) | positive scalar less than  $2^{32}$ 

Initial seed for `RandomStream`, specified as a positive scalar less than  $2^{32}$ .

**Dependencies**

To enable this property, set `RandomStream` to 'mt19937ar with seed'.

Data Types: double

**Usage****Syntax**

```
out = phznoise(in)
```

**Description**

`out = phznoise(in)` adds phase noise, specified by the `phznoise` System object, to the input signal. The result is returned in `out`.

## Input Arguments

### **in** — Input signal

vector | matrix

Input signal, specified as an  $N_S$ -by-1 numeric vector or  $N_S$ -by- $M$  numeric matrix.  $N_S$  is the number of samples and  $M$  is the number of channels.

Data Types: double | single

Complex Number Support: Yes

## Output Arguments

### **out** — Output signal

vector | matrix

Output signal, returned as a complex-valued signal with the same data type and size as the input signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.PhaseNoise

visualize Visualize spectrum mask of phase noise

## Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

## Examples

### Phase Noise Effects on 16-QAM Signal

Add a phase noise vector and frequency offset vector to a 16-QAM signal. Then plot the signal.

Create a phase noise System object.

```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20);
```

Generate modulated symbols.

```
M = 16; % From 16-QAM
data = randi([0 M-1],1000,1);
modData = qammod(data,M);
```

Use `pnoise` to apply phase noise. Plot the impaired data.

```
y = pnoise(modData);
scatterplot(y)
```

### View Phase Noise Effects on Signal Spectrum

View the effects of phase noise on a 10 MHz sine wave by using a spectrum analyzer. Adjust the resolution bandwidth of the spectrum analyzer to see its impact on the visualized spectral noise.

Initialize variables for the simulation.

```
fc = 1e6; % Carrier frequency in Hz
fs = 4e6; % Sample rate in Hz.
phNzLevel = [-85 -118 -125 -145]; % in dBc/Hz
phNzFreqOff = [1e3 9.5e3 19.5e3 195e3]; % in Hz
Nspf = 6e6; % Number of Samples per frame
freqSpan = 400e3; % in Hz, for spectrum computation
```

Create sine wave, phase noise, and spectrum analyzer objects.

```
sinewave = dsp.SineWave( ...
    Amplitude=1, ...
    Frequency=fc, ...
    SampleRate=fs, ...
    SamplesPerFrame=Nspf, ...
    ComplexOutput=true);
```

```

pnoise = comm.PhaseNoise( ...
    Level=phNzLevel, ...
    FrequencyOffset=phNzFreqOff, ...
    SampleRate=fs);
sascopeRBW100 = spectrumAnalyzer( ...
    SampleRate=fs, ...
    Method="welch", ...
    FrequencySpan="Span and center frequency", ...
    CenterFrequency=fc, ...

    Position=[685 146 605 376]);

```

To analyze the spectrum and phase noise, the example includes two spectrum analyzer objects, with 100 Hz and 1 kHz resolution bandwidths, respectively. The spectrum analyzer objects use the default Hann windowing setting, the spectrum units are set to dBW, and the number of spectral averages is set to 10.

```

x = sinewave();
y = pnoise(x);

```

When the resolution bandwidth is 100 Hz, the dBW/Hz view for the spectrum analyzer shows the tone at -20 dBW/Hz. The spectrum analyzer object corrects for the power spreading effect of the Hann windowing. Results show the visual average of the phase noise match the specified phase noise spectrum.

```

sascopeRBW100(x,y)

```

When the resolution bandwidth is 1 kHz, the dBW/Hz view for the spectrum analyzer shows the tone at -30 dBW/Hz. The tone energy of the sine wave is now spread across 1 kHz instead of 100 Hz, so the sine wave PSD level reduces by 10 dB. With the resolution bandwidth at 1 kHz, the visual average of the phase noise still achieves the phase noise defined by the phase noise object.

With the resolution bandwidth increased from 100 Hz to 1 kHz, the spectrum analyzer object still corrects for the power spreading effect of the Hann window, and it achieves better spectral averaging with the wider resolution bandwidth. For more information, see “Why Use Windows?”

`sascopeRBW1k(x,y)`

Calculate the RMS phase noise in degrees between the pure and noisy sine waves. In the general case, the pure signal must be time aligned with the noisy signal to accurately determine the phase error. However, in this case, the periodicity of the sine wave makes this step unnecessary.

```
ph_err = unwrap(angle(y) - angle(x));
rms_ph_nz_deg = rms(ph_err)*180/pi();
sprintf('The computed RMS phase noise is %3.2f degrees.', ...
        rms_ph_nz_deg)
```

```
ans =
'The computed RMS phase noise is 0.37 degrees.'
```

## Algorithms

The output signal,  $y_k$ , is related to input sequence  $x_k$  by  $y_k = x_k e^{j\varphi_k}$ , where  $\varphi_k$  is the phase noise. The phase noise is filtered Gaussian noise such that  $\varphi_k = f(n_k)$ , where  $n_k$  is the noise sequence and  $f$  represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a  $1/f$  characteristic that passes through the specified point. For more information, see “IIR Digital Filter” on page 3-1026.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across  $\log_{10}(f)$ . For more information, see “FIR Filter” on page 3-1026.

### IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$\lambda = \sqrt{2\pi f_{\text{offset}} 10^{L/10}},$$

where  $f_{\text{offset}}$  is the frequency offset in Hz and  $L$  is the phase noise level in dBc/Hz. The denominator coefficients,  $\gamma_i$ , are recursively determined as

$$\gamma_i = (i - 2.5) \frac{\gamma_{i-1}}{i - 1},$$

where  $\gamma_1 = 1$ ,  $i = \{1, 2, \dots, N_t\}$ , and  $N_t$  is the number of filter coefficients.  $N_t$  is a power of 2 in the range  $[2^7, 2^{19}]$ . The value of  $N_t$  grows as the phase noise offset decreases towards 0 Hz.

### FIR Filter

For the FIR filter, the phase noise level is determined through  $\log_{10}(f)$  interpolation for frequency offsets over the range  $[df, f_s / 2]$ , where  $df$  is the frequency resolution and  $f_s$  is the sample rate. The phase noise is flat over the range  $[0, df]$  in Hz, and from the largest frequency offset to  $f_s / 2$ . The phase noise has  $1/f^3$  characteristic from  $df$  to the smallest frequency offset. The phase noise is linearly interpolated between the smallest and the largest frequency offset. The frequency resolution is equal to  $(f_s / 2)(1 / N_t)$ , where  $N_t$  is the number of coefficients, and is a power of 2 less than or equal to  $2^{16}$ . If  $N_t < 2^8$ , a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases  $N_t$  until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.

- The maximum number of FIR filter taps is  $2^{16}$ .

## comm.PNSequence

**Package:** comm

Generate a pseudonoise (PN) sequence

### Description

The `comm.PNSequence` System object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). This object implements LFSR using a simple shift register generator (SSRG, or Fibonacci) configuration. Pseudonoise sequences are typically used for pseudorandom scrambling and in direct-sequence spread-spectrum systems.

To generate a PN sequence:

- 1 Create the `comm.PNSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
pnSequence = comm.PNSequence  
pnSequence = comm.PNSequence(Name, Value)
```

#### Description

`pnSequence = comm.PNSequence` creates a pseudonoise (PN) sequence generator System object. This object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR).

`pnSequence = comm.PNSequence(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `'Mask', 1` specifies a one sample offset of the output sequence from the starting point.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### Polynomial — Generator polynomial

'z^6 + z + 1' (default) | character vector | string scalar | binary row vector | integer vector

Generator polynomial that determines the feedback connections of the shift register, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be  $N + 1$ , where  $N$  is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree  $N$  and a constant term of 1.
- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

For more information, see “Simple Shift Register Generator” on page 3-1041.

Example: 'z^8 + z^2 + 1', [1 0 0 0 0 0 1 0 1], and [8 2 0] represent the same polynomial,  $p(z) = z^8 + z^2 + 1$ .

Data Types: double | char

### **InitialConditionsSource — Source of initial conditions**

'Property' (default) | 'Input port'

Source of the initial conditions used for the shift register of the PN sequence, specified as one of these values:

- 'Property' — Specify PN sequence generator initial conditions by using the InitialConditions property.
- 'Input port' — Specify PN sequence generator initial conditions by using the initcond input argument.

Data Types: char

### **InitialConditions — Initial conditions of shift register**

[0 0 0 0 0 1] (default) | binary scalar | binary vector

Initial conditions used for the shift register of the PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the Polynomial property.

For more information, see “Simple Shift Register Generator” on page 3-1041.

---

**Note** For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

**Dependencies**

To enable this property, set `InitialConditionsSource` to `'Property'`.

Data Types: `double`

**MaskSource — Source of mask to shift PN sequence**

`'Property'` (default) | `'Input port'`

Source of the mask that determines the shift of the PN sequence, specified as one of these:

- `'Property'` — Specify the mask by using the `Mask` property.
- `'Input port'` — Specify the mask by using the `maskvec` input argument.

Data Types: `char`

**Mask — Mask to shift PN sequence**

`0` (default) | integer scalar | binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as an integer scalar or a binary vector.

- When you set this property to an integer scalar, the value is the length of the shift. The object wraps shift values that are negative or greater than the length of the PN sequence.
- When you set this property to a binary vector, its length must equal the degree of the generator polynomial specified by the `Polynomial` property.

For more information, see “Shifting PN Sequence Starting Point” on page 3-1042. The mask vector can be calculated using the `shift2mask` function.

**Dependencies**

To enable this property, set `MaskSource` to `'Property'`.

**VariableSizeOutput — Enable variable-size outputs**

`false` (default) | `true`

Enable variable-size outputs, specified as a numeric or logical `0` (`false`) or `1` (`true`). To enable variable-size outputs by using the `outputsize` input argument, set this property to `true`. The enabled input specifies the output size of the PN sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to `false`, the `SamplesPerFrame` property specifies the number of output samples.

**MaximumOutputSize — Maximum output size**

`[10 1]` (default) | vector of the form `[m 1]`

Maximum output frame size, specified as a vector of the form `[m 1]`, where `m` is a positive integer. The first element of the vector indicates the maximum length of the output frame and the second element of the vector must be `1`.

Example: `[20 1]` specifies a maximum frame output size of 20-by-1.

**Dependencies**

To enable this property, set `VariableSizeOutput` to `true`.

**SamplesPerFrame — Number of samples output per frame**

1 (default) | positive integer

Number of samples output per frame, specified as a positive integer. If you set this property to a value of  $M$ , then the object outputs  $M$  samples of a PN sequence that has a period of  $N = 2^n - 1$ , where  $n$  represents the degree of the generator polynomial that the `Polynomial` specifies.

If you set the `BitPackedOutput` property to `false`, the samples are bits from the PN sequence. If you set the `BitPackedOutput` property to `true`, then the output corresponds to `SamplesPerFrame` groups of bit-packed samples.

**ResetInputPort — Enable generator reset input**`false` (default) | `true`

Enable the generator reset input, specified as a numeric or logical 0 (`false`) or 1 (`true`). To enable the ability to reset the sequence generator using the `resetseq` input argument, set this property to `true`. This input resets the states of the PN sequence generator to the initial conditions specified in the `InitialConditions` property. For more information, see “Resetting a Signal” on page 3-1042.

**Dependencies**

To enable this property, set `InitialConditionsSource` to 'Property'.

**BitPackedOutput — Output bit-packed words**`false` (default) | `true`

Option to output bit-packed words, specified as `false` or `true`. Set this property to `true` to enable bit-packed outputs.

When `BitPackedOutput` is `true`, the object outputs a column vector of length  $M$ , which contains most-significant-bit (MSB) first integer representations of bit words of length  $P$ .  $M$  is the number of samples per frame specified in the `SamplesPerFrame` property.  $P$  is the size of the bit-packed words specified in the `NumPackedBits` property.

---

**Note** The first bit from the left in the bit-packed word contains the most significant bit for the integer representation.

---

**NumPackedBits — Number of bits per bit-packed word**

8 (default) | integer in the range [1, 32]

Number of bits packed into each output data word, specified as an integer in the range [1, 32].

**Dependencies**

To enable this property, set `BitPackedOutput` to `true`.

**SignedOutput — Output signed bit-packed words**`false` (default) | `true`

Set this property to `true` to obtain signed, bit-packed, output words. In this case, a 1 in the most significant bit (sign bit) indicates a negative value. The property indicates negative numbers in a two's complement format.

**Dependencies**

To enable this property, set `BitPackedOutput` to `true`.

**OutputDataType — Data type of output**

'double' (default) | 'logical' | 'Smallest unsigned integer' | 'Smallest integer'

Output data type, specified as one of these values:

- When `BitPackedOutput` is set to `false`, `OutputDataType` can be 'double', 'logical', or 'Smallest unsigned integer'.
- When `BitPackedOutput` is set to `true`, `OutputDataType` can be 'double' or 'Smallest integer'.

---

**Note** You must have a Fixed-Point Designer user license to use this property in 'Smallest unsigned integer' or 'Smallest integer' mode.

---

**Dependencies**

The valid settings for this property depend on the setting of the `BitPackedOutput` property.

**Usage****Syntax**

```
outSequence = pnSequence()  
outSequence = pnSequence(initcond)  
outSequence = pnSequence(maskvec)  
outSequence = pnSequence(outputsize)  
outSequence = pnSequence(resetseq)  
outSequence = pnSequence(initcond,maskvec,outputsize)  
outSequence = pnSequence(maskvec,outputsize,resetseq)
```

**Description**

`outSequence = pnSequence()` outputs a frame of the PN sequence in a column vector based on the configured object.

`outSequence = pnSequence(initcond)` uses `initcond` as the initial conditions for the PN sequence of the linear-feedback shift register.

To enable this syntax, set the `InitialConditionsSource` property to 'Input port'.

`outSequence = pnSequence(maskvec)` uses the `maskvec` input to specify the mask vector that determines how the PN sequence is shifted from its starting point.

To enable this syntax, set the `MaskSource` property to 'Input port'.

`outSequence = pnSequence(outputsize)` uses `outputsize` as the output size.

To enable this syntax, set the `VariableSizeOutput` property to `true`.

`outSequence = pnSequence(resetseq)` uses `resetseq` as the reset signal.

To enable this syntax, set the `InitialConditionsSource` property to 'Property' and the `ResetInputPort` property to true.

`outSequence = pnSequence(initcond,maskvec,outputsize)`

To enable this syntax, set the `InitialConditionsSource` property to 'Input port', the `ResetInputPort` property to false, the `MaskSource` property to 'Input port', and the `VariableSizeOutput` property to true.

`outSequence = pnSequence(maskvec,outputsize,resetseq)`

To enable this syntax, set the `InitialConditionsSource` property to 'Property', the `MaskSource` property to 'Input port', the `VariableSizeOutput` property to true, the `ResetInputPort` property to true.

## Input Arguments

### **initcond** — Initial register conditions used for shift register

binary-valued scalar | binary-valued vector

Initial conditions used for the shift register when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this input to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `Polynomial` property.

---

**Note** For the object to generate a nonzero sequence, at least one element of the initial condition for the PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

---

Example: `outSequence = pnSequence([1 1 0])` corresponds to possible initial register states for a PN sequence generator specified by a generator polynomial of degree 3.

Data Types: double

### **maskvec** — Mask vector

binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as a binary vector. The length of the vector must equal the degree of the `Polynomial` property.

### **outputsize** — Length of output sequence

nonnegative integer | vector of the form  $[n \ 1]$

Length of output sequence, specified as a nonnegative integer,  $n$ , or a vector of the form  $[n \ 1]$ , where  $n$  is a positive integer. The first element of the vector indicates the length of the output frame and the second element of the vector must be 1.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

### **resetseq — Reset PN sequence generator**

scalar | column vector

Reset sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the object resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a column vector, the object resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in the reset vector.

For more information, see “Resetting a Signal” on page 3-1042.

### **Output Arguments**

#### **outSequence — PN Sequence**

column vector

PN sequence generated by the object, returned as a column vector.

### **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

### **Examples**

#### **Configuring a PN Sequence Generator**

When configuring a PN sequence generator System object™, you have options regarding how to express the polynomial and the mask. This figure defines a PN sequence generator with a generator polynomial  $p(z) = z^6 + z + 1$  and a mask  $m(z) = z^5 + z^4 + z^2 + 1$ . The example shows a few of the formatting options available to define the generator polynomial and the mask when you configure the PN sequence generator in this figure.

You can input the polynomial exponents of  $z$  for the nonzero terms of the polynomial in descending order of powers and the mask as a binary vector.

```
pnseq1 = comm.PNSequence('Polynomial',[6 1 0], ...
    'Mask',[1 1 0 1 0 1], 'SamplesPerFrame',20)
```

```
pnseq1 =
    comm.PNSequence with properties:
        Polynomial: [6 1 0]
        InitialConditionsSource: 'Property'
        InitialConditions: [0 0 0 0 0 1]
        MaskSource: 'Property'
        Mask: [1 1 0 1 0 1]
        VariableSizeOutput: false
        SamplesPerFrame: 20
        ResetInputPort: false
        BitPackedOutput: false
        OutputDataType: 'double'
```

You can input the polynomial exponents as a binary-valued row vector that represents the coefficients of the polynomial in order of descending powers.

```
pnseq2 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ...
    'Mask',[1 1 0 1 0 1], 'SamplesPerFrame',20)
```

```
pnseq2 =
    comm.PNSequence with properties:
        Polynomial: [1 0 0 0 0 1 1]
        InitialConditionsSource: 'Property'
        InitialConditions: [0 0 0 0 0 1]
        MaskSource: 'Property'
        Mask: [1 1 0 1 0 1]
        VariableSizeOutput: false
        SamplesPerFrame: 20
        ResetInputPort: false
        BitPackedOutput: false
```

```
OutputDataType: 'double'
```

You can also define the mask as a scalar value using the `mask2shift` function.

```
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
ans = 22
pnseq3 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ...
    'Mask',22,'SamplesPerFrame',20)
pnseq3 =
    comm.PNSequence with properties:
        Polynomial: [1 0 0 0 0 1 1]
    InitialConditionsSource: 'Property'
    InitialConditions: [0 0 0 0 0 1]
    MaskSource: 'Property'
    Mask: 22
    VariableSizeOutput: false
    SamplesPerFrame: 20
    ResetInputPort: false
    BitPackedOutput: false
    OutputDataType: 'double'
```

Use each PN sequence object to generate a frame of 20 samples and compare the generated sequences.

```
out_1 = pnseq1();
out_2 = pnseq2();
out_3 = pnseq3();
isequal(out_1,out_2)

ans = logical
     1

isequal(out_1,out_3)

ans = logical
     1
```

### Generate Maximal Length PN Sequences

Generate a 14-sample frame of a maximal length PN sequence given generator polynomial,  $x^3 + x^2 + 1$ .

Generate PN sequence data by using the `comm.PNSequence` object. The sequence repeats itself as it contains 14 samples while the maximal sequence length is only 7 samples ( $2^3 - 1$ ).

```
pnSequence = comm.PNSequence('Polynomial',[3 2 0], ...
    'SamplesPerFrame',14,'InitialConditions',[0 0 1]);
```

```
x1 = pnSequence();
[x1(1:7) x1(8:14)]
```

```
ans = 7×2
```

```
1    1
0    0
0    0
1    1
1    1
1    1
0    0
```

Create another maximal length sequence based on the generator polynomial,  $x^4 + x + 1$ . As it is a fourth order polynomial, the sequence repeats itself after 15 samples ( $2^4 - 1$ ).

```
pnSequence2 = comm.PNSequence('Polynomial','x^4+x+1', ...
    'InitialConditions',[0 0 0 1], 'SamplesPerFrame',30);
```

```
x2 = pnSequence2();
[x2(1:15) x2(16:30)]
```

```
ans = 15×2
```

```
1    1
0    0
0    0
0    0
1    1
0    0
0    0
1    1
1    1
0    0
⋮
```

### Generate Galois Linear-Feedback Shift Register Output

The `comm.PNSequence` System object implements a linear-feedback shift register (LFSR) using a simple shift register generator (SSRG, or Fibonacci configuration). This configuration differs from the modular shift register generator (MSRG, or Galois configuration) by a phase difference, that can be determined empirically from the System object.

This phase difference can be specified as the `Mask` parameter for the `comm.PNSequence` System object to generate the equivalent MSRG configuration output. The block diagram represents the implementation of a 5-bit LFSR in the Galois (MSRG) configuration.

Load the file `GaloisLFSR`. The file contains the following variables that define the properties and output PN sequence of the 5-bit Galois LFSR:

- `polyVec`: Generator polynomial
- `polySize`: Degree of the generator polynomial
- `initStates`: Initial conditions of the shift register
- `maskVar`: Mask to shift the PN sequence
- `pn_msrg`: Output PN sequence of maximal length, from the 5-bit Galois LFSR

load `GaloisLFSR`

Generate PN sequence data by using the `comm.PNSequence` object with the same set of properties used to implement the 5-bit Galois LFSR. Compare this PN sequence with the output of the 5-bit Galois LFSR. The two sequences differ by a phase shift.

```
pnSequence = comm.PNSequence( ...
    'Polynomial',polyVec, ...
    'InitialConditions',initStates,...
    'Mask',maskVar, ...
    'SamplesPerFrame',2^polySize-1);
pn = pnSequence();
isequal(pn,pn_msrg)

ans = logical
     0
```

Compute the phase shift between the two configurations. Set the value of the `Mask` property based on this phase shift.

```
for i = 1:length(pn)
    exp_pn = [pn(i:end);pn(1:(i-1))];
    if isequal(exp_pn,pn_msrg)
        break
    end
end
maskVar = i-1;
```

Generate PN sequence data by using the `comm.PNSequence` System object with the modified `Mask` property value. Compare this sequence with the output of the 5-bit Galois LFSR. The two sequences are now equal.

```
pnSequence_mod = comm.PNSequence( ...
    'Polynomial',polyVec, ...
```

```

    'InitialConditions',initStates,...
    'Mask',maskVar, ...
    'SamplesPerFrame',2^polySize-1);
pn_mod = pnSequence_mod();
isequal(pn_mod,pn_msrg)

ans = logical
     1

```

### Additive Scrambling of Input Data

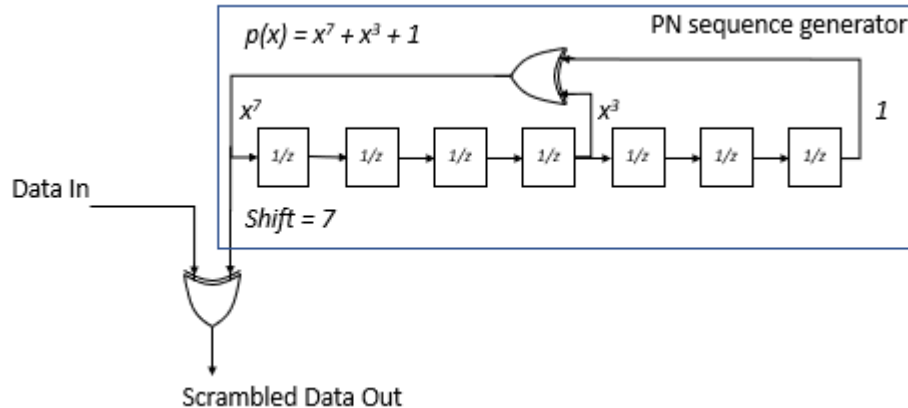

Digital communications systems commonly use additive scrambling to randomize input data to aid in timing synchronization and power spectral requirements. The `comm.Scrambler` System object™ implements multiplicative scrambling but does not support additive scrambling. To perform additive scrambling you can use the `comm.PNSequence` System object. This example implements the additive scrambling specified in IEEE 802.11™ by scrambling input data with an output sequence generated by the `comm.PNSequence` System object. For a Simulink® model that implements a similar workflow, see the “Additive Scrambling of Input Data in Simulink” example.

This figure shows an additive scrambler, that uses the generator polynomial  $x^7 + x^4 + 1$ , as specified in figure 17-7 of IEEE 802.11 Section 17.3.5.5 [1] on page 3-1041.

IEEE 802.11™ section 17.3.5.5 PHY DATA scrambler and descrambler (Figure 17-7 Data Scrambler)

Comparing the shift register specified in 802.11 with the shift register implemented using a `comm.PNSequence` System object, note that the two shift register schematics are mirror images of each other. Therefore, when configuring the `comm.PNSequence` System object to implement an additive scrambler, you must reverse values for the generator polynomial, the initial states, and the mask output. To take the output of the register from the leading end, specify a shift value of 7.

For more information about the 802.11 scrambler, see [1] on page 3-1041 and the `wlanScramble` (WLAN Toolbox) reference page.

Define variables for the generator polynomial, shift value for the output, an initial shift register state, a frame of input data, and a variable containing the 127-bit scrambler sequence specified in section 17.3.5.5 of the IEEE 802.11 standard. Create a PN sequence object that initializes the registers by using an input argument.

```
genPoly = 'x^7 + x^3 + 1'; % Generator polynomial
shift = 7; % Shift value for output
spf = 127; % Samples per frame
initState = [1 1 1 1 1 1 1]; % Initial shift register state
dataIn = randi([0 1],spf,1);
ieee802_11_scram_seq = logical([ ...
    0 0 0 0 1 1 1 0 1 1 1 1 0 0 1 0 1 1 0 0 1 ...

## More About

### Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation.

The Polynomial property determines the feedback connections of the shift register. It is a primitive binary polynomial in  $z$ ,  $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + \dots + g_0$ . For the coefficient,  $g_{k=0}$  to  $r$ , the coefficient  $g_k$  is 1 if there is a connection from the  $k$ th register to the adder. The leading term,  $g_r$ , and the constant term,  $g_0$ , of the Polynomial property must be 1 because the polynomial must be primitive. The InitialConditions property specifies the initial values of the registers. For example, the following

table indicates two sets of parameter values that correspond to a generator polynomial of  $p(z) = z^8 + z^2 + 1$ .

Quantity	Example 1	Example 2
<b>Polynomial</b>	$g1 = [1\ 0\ 0\ 0\ 0\ 0\ 1\ 0\ 1]$	$g2 = [8\ 2\ 0]$
Degree of generator polynomial	8, which is $\text{length}(g1) - 1$	8
<b>InitialConditions</b>	$[1\ 0\ 0\ 0\ 0\ 0\ 1\ 0]$	$[1\ 0\ 0\ 0\ 0\ 0\ 1\ 0]$

Each time you call the object, all  $r$  registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the  $m$  mask vector.

The **Mask** property,  $m$ , determines the shift of the PN sequence starting point. For more information, see “Shifting PN Sequence Starting Point” on page 3-1042.

### Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the **Mask** property as:

- An integer representing the length of the shift.

The default **Mask** setting of 0 corresponds to no shift. As illustrated in the LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1041, there is no shift when the only connection is along the arrow labeled  $m_0$ .

This table shows the shift that occurs when you set **Mask** to 0 versus a positive integer  $d$ .

	<b>T = 0</b>	<b>T = 1</b>	<b>T = 2</b>	...	<b>T = d</b>	<b>T = d+1</b>
<b>Shift = 0</b>	$x_0$	$x_1$	$x_2$	...	$x_d$	$x_{d+1}$
<b>Shift = d</b>	$x_d$	$x_{d+1}$	$x_{d+2}$	...	$x_{2d}$	$x_{2d+1}$

- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1041 shows **Mask** specified as a mask vector,  $m$ . The binary vector must have  $N$  elements, where  $N$  is the degree of the generator polynomial. To calculate the mask vector, use the `shift2mask` function.

The binary vector corresponds to a polynomial in  $z$ ,  $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + \dots + m_1z + m_0$ , of degree at most  $r - 1$ . The mask vector that corresponds to a shift of  $d$  is the vector that represents  $m(z) = z^d$  modulo  $g(z)$ , where  $g(z)$  is the generator polynomial.

For example, if the degree of the generator polynomial is 4, then the mask vector that corresponds to  $d = 2$  is  $[0\ 1\ 0\ 0]$ , which represents the polynomial  $m(z) = z^2$ .

### Resetting a Signal

To reset the PN generator sequence, you must first set the **ResetInputPort** property to `true`. Suppose that the system object generates a PN sequence of  $[1\ 0\ 0\ 1\ 1\ 0\ 1\ 1]$  when there is no reset. When the reset signal  $[0\ 0\ 0\ 1]$  is passed as an input argument to the object, the PN sequence is reset at the fourth bit, because the fourth bit of the reset signal is a 1.

## Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree  $r$ , set `Polynomial` to a value from the following table. The maximum sequence length is  $2^r - 1$ .

r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial
2	[2 1 0]	15	[15 14 0]	28	[28 25 0]	41	[41 3 0]
3	[3 2 0]	16	[16 15 13 4 0]	29	[29 27 0]	42	[42 23 22 1 0]
4	[4 3 0]	17	[17 14 0]	30	[30 29 28 7 0]	43	[43 6 4 3 0]
5	[5 3 0]	18	[18 11 0]	31	[31 28 0]	44	[44 6 5 2 0]
6	[6 5 0]	19	[19 18 17 14 0]	32	[32 31 30 10 0]	45	[45 4 3 1 0]
7	[7 6 0]	20	[20 17 0]	33	[33 20 0]	46	[46 21 10 1 0]
8	[8 6 5 4 0]	21	[21 19 0]	34	[34 15 14 1 0]	47	[47 14 0]
9	[9 5 0]	22	[22 21 0]	35	[35 2 0]	48	[48 28 27 1 0]
10	[10 7 0]	23	[23 18 0]	36	[36 11 0]	49	[49 9 0]
11	[11 9 0]	24	[24 23 22 17 0]	37	[37 12 10 2 0]	50	[50 4 3 2 0]
12	[12 11 8 6 0]	25	[25 22 0]	38	[38 6 5 1 0]	51	[51 6 3 1 0]
13	[13 12 10 9 0]	26	[26 25 24 20 0]	39	[39 8 0]	52	[52 3 0]
14	[14 13 8 4 0]	27	[27 26 25 22 0]	40	[40 5 4 3 0]	53	[53 6 2 1 0]

For more information about the shift register configurations that these polynomials represent, see *Digital Communications* by John Proakis.[1].

PN Sequence Generator

# comm.PreambleDetector

**Package:** comm

Detect preamble in data

## Description

The `comm.PreambleDetector` System object detects a preamble in an input data sequence. A preamble is a set of symbols or bits used in packet-based communication systems to indicate the start of a packet. The preamble detector object finds the location corresponding to the end of the preamble.

To detect a preamble in an input data sequence:

- 1 Create the `comm.PreambleDetector` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
prbdet = comm.PreambleDetector
prbdet = comm.PreambleDetector(Name=Value)
prbdet = comm.PreambleDetector(prb,Name=Value)
```

### Description

`prbdet = comm.PreambleDetector` creates a preamble detector object using the default properties.

`prbdet = comm.PreambleDetector(Name=Value)` specifies additional properties using name-value arguments. For example, `prbdet = comm.PreambleDetector(Input="Bit",Detections="First");` creates a preamble detector that expects a binary input signal and selects the first preamble detected.

`prbdet = comm.PreambleDetector(prb,Name=Value)` creates the object setting the `Preamble` property to `prb` in addition to those properties that you specify using name-value arguments.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Input — Type of input data**`'Symbol' (default) | 'Bit'`

Type of input data, specified as `'Symbol'` or `'Bit'`.

- For binary inputs, set this property to `'Bit'`. Binary data can be of data type `double`, `single`, `Boolean`, `int8`, or `uint8` data types.
- For all other inputs, set this property to `'Symbol'`. Symbol data can be of data type `double` or `single`.

**Preamble — Preamble sequence**`[1+1i; 1-1i] (default) | column vector`

Preamble sequence, specified as a column vector. The object uses this sequence to detect the presence of the preamble in the input data.

- If you set the `Input` property to `'Bit'`, the preamble must be a binary sequence.
- If you set the `Input` property to `'Symbol'`, the preamble can be any real or complex sequence.

Data Types: `double` | `single` | `logical` | `int8` | `uint8`

Complex Number Support: Yes

**Threshold — Detection threshold**`3 (default) | nonnegative scalar`

Detection threshold, specified as a nonnegative scalar. When the computed detection metric is greater than or equal to `Threshold`, the preamble is detected.

**Tunable:** Yes

**Dependencies**

This property is available when you set the `Input` property to `'Symbol'`.

**Detections — Number of preambles to detect**`'All' (default) | 'First'`

Number of preambles to detect, specified as `'All'` or `'First'`.

- `'All'` — Detects all the preambles in the input data sequence.
- `'First'` — Detects only the first preamble in the input data sequence.

**Usage****Syntax**

```
idx = prbdet(X)
[idx,detmet] = prbdet(X)
```

## Description

`idx = prbdet(X)` returns the location of the end of the preamble in data sequence `x`.

`[idx, detmet] = prbdet(X)` also returns the detection metric, `detmet`. This syntax is available when you set the Input property to 'Symbol'.

## Input Arguments

### X — Data sequence

scalar (default) | row vector

Data sequence, specified as a scalar or row vector.

Data Types: `double` | `single` | `logical` | `int8` | `uint8`

Complex Number Support: Yes

## Output Arguments

### idx — Index of preamble end

scalar (default) | column vector

Index of the end of the preamble, returned as a scalar or column vector. When you set the `Detections` property to:

- "All" — The index of all preambles in the input data sequence are returned.
- "First" — The index of the first preamble in the input data sequence is returned.

### detmet — Detection metric

scalar (default) | row vector

Detection metric, returned as a scalar or row vector with the same dimensions and data type as `X`.

The output, `detmet`, is determined by one of these algorithms:

- If either the preamble or the input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input signal.
- If both the preamble and the input data are real, the detection metric is the cross-correlation of the preamble and the input signal.

## Dependencies

This output can be returned when you set the Input property to 'Symbol'.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step`      Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### Detect Preamble from Binary Data Sequence

Specify a six-bit preamble.

```
prb = [1 0 0 1 0 1]';
```

Create a preamble detector object that uses preamble `prb` and takes bit inputs.

```
prbdet = comm.PreambleDetector(prb,Input='Bit');
```

Generate a binary data sequence that contains two preambles and uses random bits to represent the data fields.

```
pkt = [prb; randi([0 1],10,1); prb; randi([0 1],10,1)];
```

Locate the indices of the two preambles. The indices correspond to the end of the preambles. The detector correctly identifies indices 6 and 22 as the end of the two preambles inserted in the sequence. If the random sequence generated for the data field duplicates the preamble pattern, an additional preamble detection would be reported. A longer preamble would reduce the frequency of such false alarms.

```
idx = prbdet(pkt)
```

```
idx = 2×1
```

```
    6  
   22
```

### Detect Preamble in Noisy QPSK Signal

Create a preamble and apply QPSK modulation.

```
p1 = [0 1 2 3 3 2 1 0]';  
p = [p1; p1];  
prb = pskmod(p,4,pi/4,'gray');
```

Create a `comm.PreambleDetector` object using preamble `prb`.

```
prbdet = comm.PreambleDetector(prb)
```

```
prbdet =  
comm.PreambleDetector with properties:
```

```
    Input: 'Symbol'  
  Preamble: [16x1 double]  
  Threshold: 3
```

```
Detections: 'All'
```

Generate a sequence of random symbols. The first sequence represents the last 20 symbols from a previous packet. The second sequence represents the symbols from the current packet.

```
d1 = randi([0 3],20,1);
d2 = randi([0 3],100,1);
```

Modulate the two sequences.

```
x1 = pskmod(d1,4,pi/4,'gray');
x2 = pskmod(d2,4,pi/4,'gray');
```

Create a sequence of modulated symbols consisting of the remnant of the previous packet, the preamble, and the current packet.

```
y = [x1; prb; x2];
```

Add white Gaussian noise.

```
z = awgn(y,10);
```

Determine the preamble index and the detection metric.

```
[idx,detmet] = prbdet(z);
```

Calculate the number of elements in `idx`. Because the number of elements is greater than one, the detection threshold is too low.

```
numel(idx)
```

```
ans = 80
```

Display the five largest detection metrics.

```
detmetSort = sort(detmet,'descend');
detmetSort(1:5)
```

```
ans = 5×1
```

```
16.3115
13.6900
10.5698
 9.1920
 8.9706
```

Increase the threshold and determine the preamble index. The result of 36 corresponds to the sum of the preamble length (16) and the remaining samples in the previous packet (20). This result indicates that the preamble has been successfully detected.

```
prbdet.Threshold = 15;
idx = prbdet(z)
```

```
idx = 36
```

### Find Preamble for Fractional Sample Delay

Using a preamble sequence with good correlation properties, find the last sample of the preamble for a transmitted data frame in a stream of delayed received data.

Define the preamble with a length of 17 by using the ninth root of the Zadoff-Chu sequence. Generate a transmission signal by concatenating several samples from a random signal, the preamble, and a random signal of 100 samples.

```
M = 16; % 16-QAM modulation
preamble = zadoffChuSeq(9,17);
x = randi([0 M-1],100,1);
xmod = qammod(x,M,UnitAverage=true);
txsig = [xmod(23:30); preamble; xmod];
```

Create a variable fractional delay System object. Introduce a variable fractional delay of 82.3 samples. To return the full frame when executing the variable fractional delay object, add zero padding at the end of the transmitted signal. Add AWGN to the transmitted signal.

```
vfd = dsp.VariableFractionalDelay;
samplesToDelay = 82.3;
txsigdelayed = ...
    vfd([txsig; zeros(ceil(samplesToDelay),1)],samplesToDelay);
SNR = 40;
rxsig = awgn(txsigdelayed,SNR);
```

Create a preamble detector System object, specifying the preamble, the threshold level, and output of the index for the first detection. For the conditions in the example, setting the threshold to 60% of the total magnitude of the preamble samples finds the correct index for the preamble. Run the preamble detection object, returning the preamble index and detection metric.

```
thr = 0.6*sum(abs(preamble).^2);
preambleDet = comm.PreambleDetector( ...
    Preamble=preamble, ...
    Threshold=thr, ...
    Detections='First');
[idx,detmet] = preambleDet(rxsig);
idx

idx = 107
```

The detection metric is the absolute value of the cross-correlation of the preamble and the input signal. The cross-correlation peak should align with the returned preamble index. To confirm that the returned index has identified the preamble, plot the returned cross-correlation values and compare the returned index value to the peak in the cross-correlation values.

```
plot(detmet)
```

## Algorithms

### Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

### Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples matches the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. For more information about the FIR filter algorithm, see Discrete FIR Filter.

The cross-correlation values that are greater than or equal to the specified detection threshold are reported as peaks.

- If the detection threshold is too low, the algorithm detects false peaks, or, in the extreme case, as many peaks as there are input samples.
- If the detection threshold is too high, the algorithm misses detecting peaks, or, in the extreme case, it detects no peaks at all.

Consequently, the selection of the detection threshold is critical.

# comm.PSKDemodulator

**Package:** comm

(To be removed) Demodulate using M-ary PSK method

---

**Note** will be removed in a future release. Use `pskdemod` instead. For information on updating your code, see "Version History".

---

## Description

The `comm.PSKDemodulator` object demodulates a signal that was modulated using the M-ary phase shift keying (M-PSK) method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the M-PSK method:

- 1 Create the `comm.PSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mpskdemod = comm.PSKDemodulator
mpskdemod = comm.PSKDemodulator(Name=Value)
mpskdemod = comm.PSKDemodulator(M,Name=Value)
mpskdemod = comm.PSKDemodulator(M,phase,Name=Value)
```

### Description

`mpskdemod = comm.PSKDemodulator` creates a System object to demodulate input M-PSK signals.

`mpskdemod = comm.PSKDemodulator(Name=Value)` sets properties using one or more name-value arguments. For example, `DecisionMethod="Hard decision"` specifies demodulation using the hard-decision method.

`mpskdemod = comm.PSKDemodulator(M,Name=Value)` sets the `ModulationOrder` property to M and optional name-value arguments.

`mpskdemod = comm.PSKDemodulator(M,phase,Name=Value)` sets the `ModulationOrder` property to M, the `PhaseOffset` property to phase, and optional name-value arguments. Specify phase in radians.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **ModulationOrder — Number of points in signal constellation**

8 (default) | positive integer

Number of points in signal constellation, specified as a positive integer.

Data Types: `double`

### **PhaseOffset — Phase of zeroth point in constellation**

$\pi/8$  (default) | scalar

Phase of the zeroth point in the constellation in radians, specified as a scalar.

Example: `PhaseOffset=0` aligns the QPSK signal constellation points on the axes  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: `double`

### **BitOutput — Option to output data as bits**

0 or false (default) | 1 or true

Option to output data as bits, specified as a logical 0 (false) or 1 (true).

- Set this property to `false` to output symbols as integer values in the range  $[0, (M - 1)]$  with length equal to the input data vector.  $M$  represents the value of the `ModulationOrder`.
- Set this property to `true` to output a column vector of bit values with length equal to  $\log_2(M)$  times the number of demodulated symbols. Groups of  $\log_2(M)$  bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: `logical`

### **SymbolMapping — Symbol encoding mapping**

'Gray' (default) | 'Binary' | 'Custom'

Symbol encoding mapping of constellation bits, specified as 'Gray', 'Binary', or 'Custom'. Each integer or group of  $\log_2(\text{ModulationOrder})$  bits corresponds to one symbol.

- When you set this property to 'Gray', the object map symbols to a Gray-encoded signal constellation.
- When you set this property to 'Binary', the object map symbols to a natural binary-encoded signal constellation. Specifically, the complex value  $e^{j(\text{PhaseOffset} + (2mm/\text{ModulationOrder}))}$ , where  $m$  is an integer in the range  $[0, (\text{ModulationOrder} - 1)]$ .

- When you set this property to 'Custom', the object maps symbols to the signal constellation defined in the CustomSymbolMapping property.

### CustomSymbolMapping — Custom symbol encoding

0:7 (default) | integer vector

Custom symbol encoding, specified as an integer vector with length equal to the value of ModulationOrder and unique values in the range [0, (ModulationOrder - 1)]. The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$ .

#### Dependencies

To enable this property, set the SymbolMapping property to 'Custom'.

Data Types: double

### DecisionMethod — Demodulation decision method

'Hard decision' (default) | 'Log-likelihood ratio' | 'Approximate log-likelihood ratio'

Demodulation decision method, specified as 'Hard decision', 'Log-likelihood ratio', or 'Approximate log-likelihood ratio'. When you set the BitOutput property to false, the object always performs hard-decision demodulation.

#### Dependencies

To enable this property, set the BitOutput property to true.

### VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

#### Dependencies

To enable this property, set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio'.

### Variance — Noise variance

1 (default) | positive scalar

Noise variance, specified as a positive scalar.

**Tunable:** Yes

#### Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value

- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

**Dependencies**

To enable this property, set the BitOutput property to true, the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', and the VarianceSource property to 'Property'.

Data Types: double

**OutputDataType — Data type of output**

'Full precision' (default) | 'Smallest unsigned integer' | 'double' | ...

Data type of the output, specified as 'Full precision', 'Smallest unsigned integer', 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', or 'uint32', 'logical'.

- When the input data type is single or double precision and you set the BitOutput property to true, the DecisionMethod property to 'Hard decision', and the OutputDataType property to 'Full precision', the output has the same data type as that of the input.
- When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to 'Smallest unsigned integer'.
- When you set BitOutput to true and the DecisionMethod property to 'Hard Decision', then 'logical' data type is a valid option.
- When you set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', the output data type is the same as that of the input and the input data type must be single or double precision.

**Dependencies**

To enable this property, set the BitOutput property to false or set the BitOutput property to true and the DecisionMethod property to 'Hard decision'.

**Fixed-Point Properties****DerotateFactorDataType — Data type of derotate factor**

'Same word length as input' (default) | 'Custom'

Data type of the derotate factor, specified as 'Same word length as input' or 'Custom'. The object uses the derotate factor in the computations only when the ModulationOrder property is 2, 4, or 8, the input signal is a fixed-point type, and the PhaseOffset property has a nontrivial value.

- For ModulationOrder = 2, the phase offset is trivial if it is a multiple of  $\pi/2$ .
- For ModulationOrder = 4, the phase offset is trivial if it is an even multiple of  $\pi/4$ .
- For ModulationOrder = 8, there are no trivial phase offsets.

**Dependencies**

To enable this property, set the BitOutput property to false or set the BitOutput property to true and the DecisionMethod property to 'Hard decision'.

**CustomDerotateFactorDataType — Fixed-point data type of derotate factor**

numericitytype([],16) (default) | unscaled numericitytype object

Fixed-point data type of the derotate factor, specified as an unscaled numericitytype object with a Signedness of Auto. The word length must be a value in the range [2, 128].

**Dependencies**

To enable this property, set the DerotateFactorDataType property to 'Custom'.

Data Types: numericitytype object

**Usage****Syntax**

```
y = mpskdemod(x)
y = mpskdemod(x,var)
```

**Description**

`y = mpskdemod(x)` applies M-PSK demodulation to the input signal and returns the demodulated signal.

`y = mpskdemod(x,var)` uses soft decision demodulation and noise variance `var`. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio', and the VarianceSource property to 'Input port'.

**Input Arguments****x — M-PSK-modulated signal**

scalar | column vector

M-PSK-modulated signal, specified as a scalar or column vector.

**Dependencies**

The object accepts inputs with a signed integer data type or signed fixed point (sfi) objects when you set the ModulationOrder property to a value less than or equal to 8 and you set the BitOutput property to false or you set the DecisionMethod property to 'Hard decision' and the BitOutput property to true.

Data Types: double | single | int | fi

**var — Noise variance**

scalar

Noise variance, specified as a scalar.

**Dependencies**

To enable this argument, set the VarianceSource property to 'Input port', the BitOutput property to true, and the DecisionMethod property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio'.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Output signal

`scalar` | `column vector`

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. To specify the output data type, use the `OutputDataType` property.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.PSKDemodulator`

`constellation` Calculate or plot ideal signal constellation

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

### Examples

#### 16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects that use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values in the range [0, 15].

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...  
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);  
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...  
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol',log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. Vary  $E_b/N_0$  from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for n = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(n);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end

    % Save the BER data
    ber(n) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec,'psk',16,'nondiff');
```

Use this code to plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

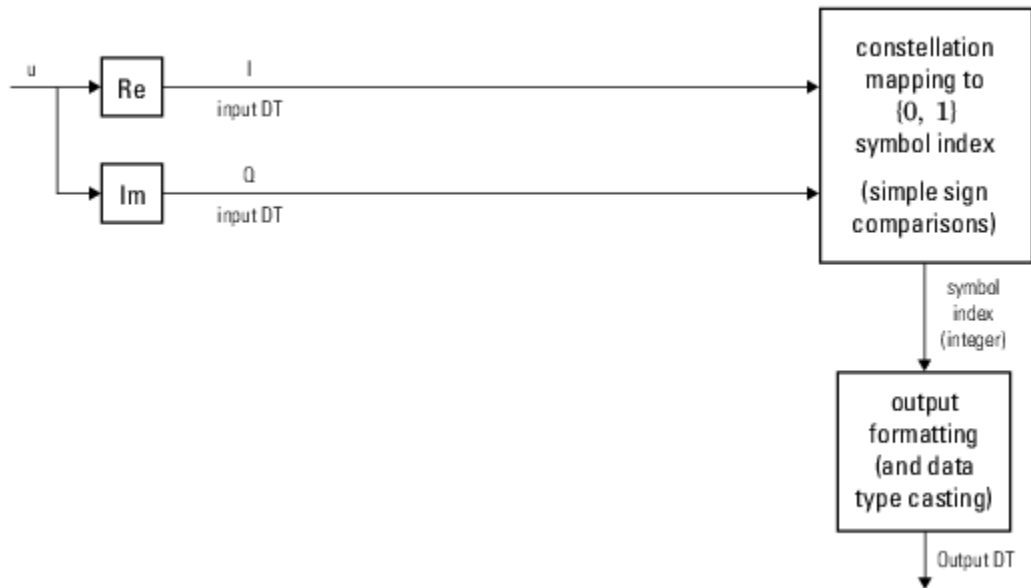

```
figure
semilogy(ebnoVec,[ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')
```

## More About

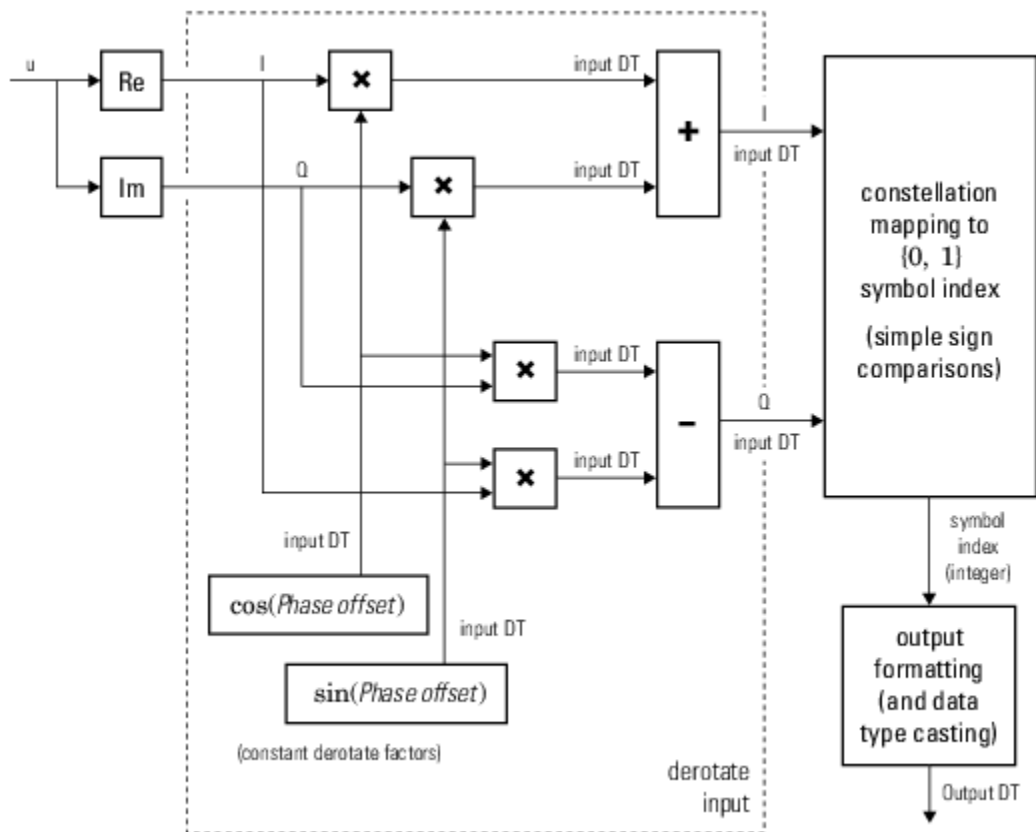

### Hard-Decision BPSK Demodulation

The signal preprocessing required for BPSK demodulation depends on the configuration.

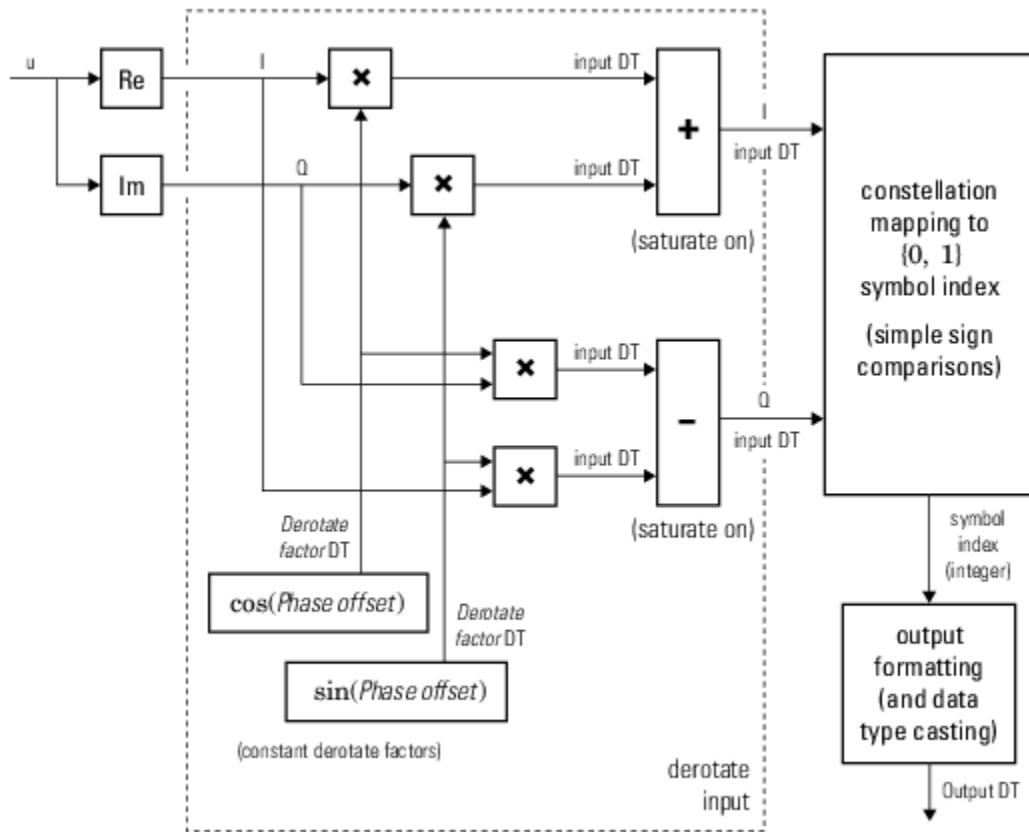

This figure shows the hard-decision BPSK demodulation signal diagram for the trivial phase offset (multiple of  $\pi/2$ ) configuration.

This figure shows the hard-decision BPSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

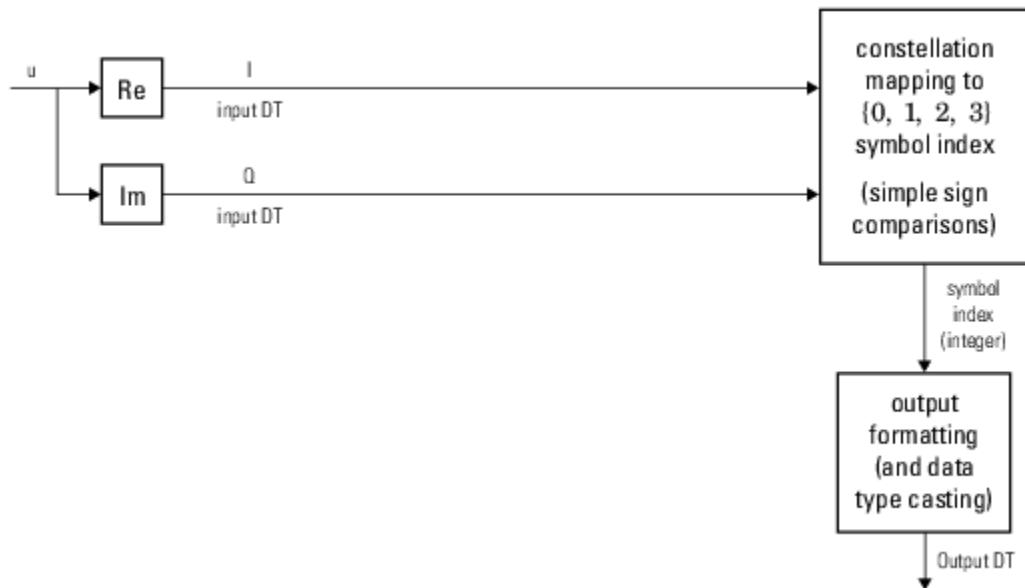

This figure shows the hard-decision BPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

### Hard-Decision QPSK Demodulation

The signal preprocessing required for QPSK demodulation depends on the configuration.

This figure shows the hard-decision QPSK demodulation signal diagram for the trivial phase offset (odd multiple of  $\pi/4$ ) configuration.

This figure shows the hard-decision QPSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision QPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

### Hard-Decision Higher-Order PSK

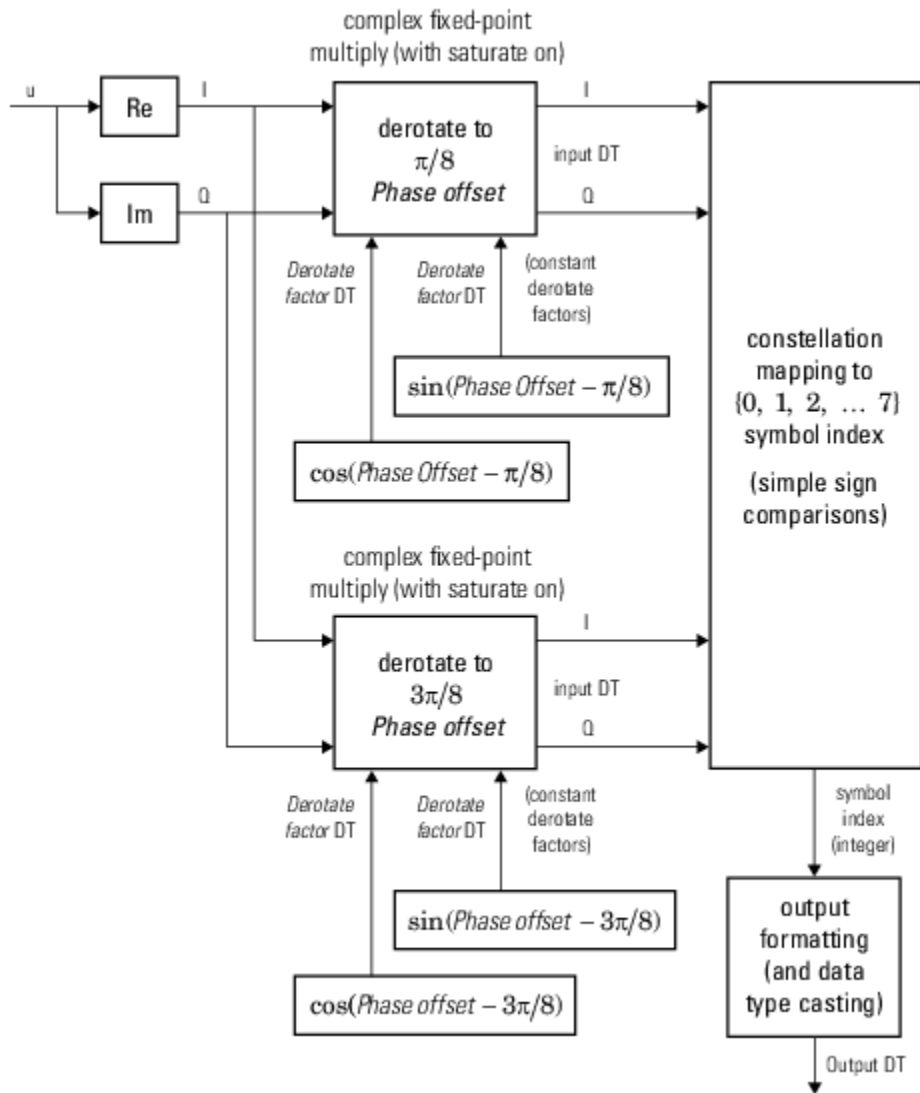

The signal preprocessing required for higher order PSK demodulation depends on the configuration.

This figure shows the hard-decision 8-PSK demodulation signal diagram for the trivial phase offset (odd multiple of  $\pi/8$ ) configuration.

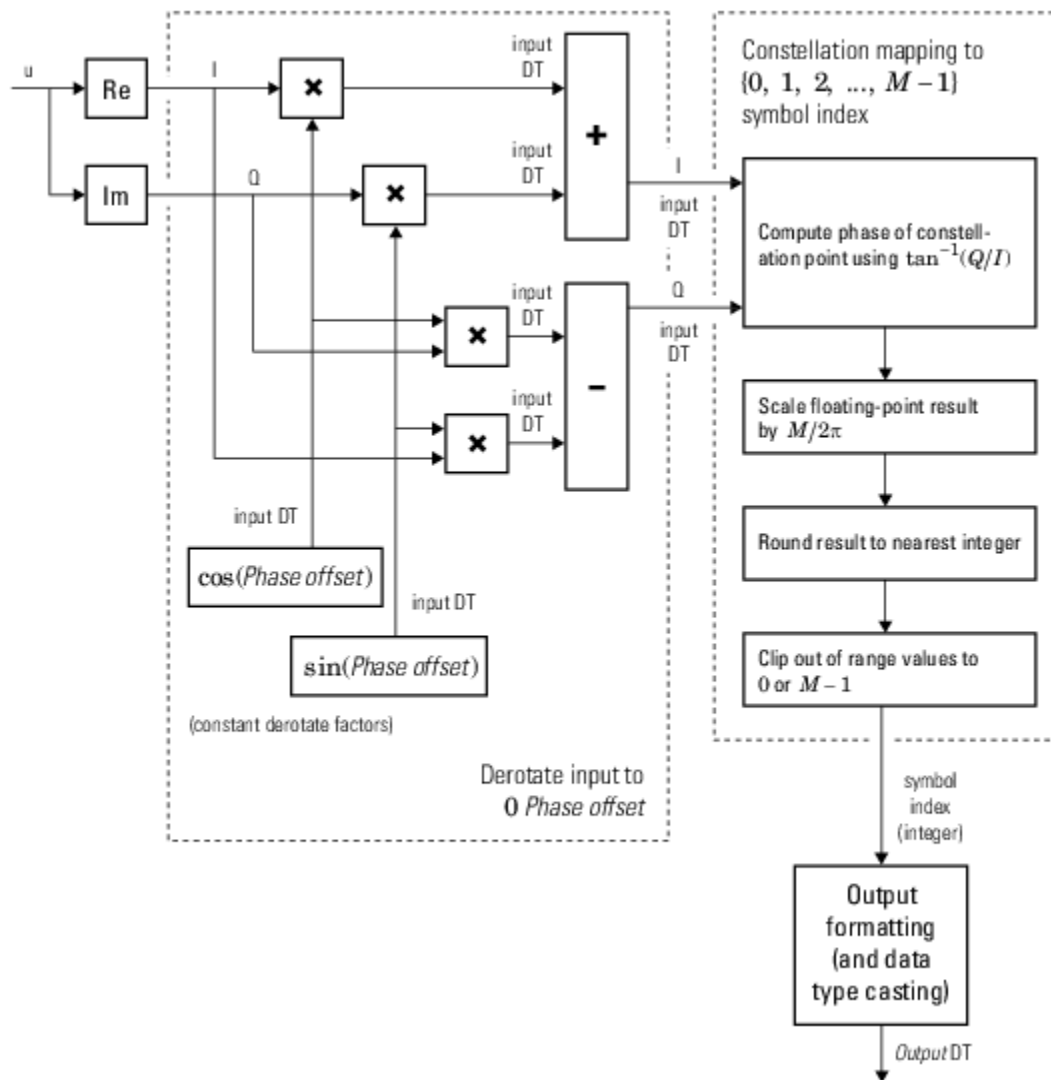

This figure shows the hard-decision 8-PSK demodulation fixed-point signal diagram for trivial phase offset (odd multiple of  $\pi/8$ ) configuration.

This figure shows the hard-decision M-PSK demodulation floating-point signal diagram for the nontrivial phase offset configuration.

For  $M > 8$ , to improve speed and implementation costs, no derotation arithmetic is performed for trivial case (specifically, when phase offset is  $0$ ,  $\pi/2$ ,  $\pi$ , or  $3\pi/2$ ).

Also, for  $M > 8$ , only double and single input types are supported.

### Soft-Decision M-PSK Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the "Hard- vs. Soft-Decision Demodulation" topic.

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- $\text{Inf}$  or  $-\text{Inf}$  if the noise variance is a very large value

- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

(To be removed) Modulate signal using M-PSK method

---

**Note** will be removed in a future release. Use `pskmod` instead. For information on updating your code, see “Version History”.

---

## Description

The `PSKModulator` System object modulates using the M-ary phase shift keying (M-PSK) method. The output is a baseband representation of the modulated signal.

To modulate a signal by using the M-PSK method:

- 1 Create the `comm.PSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mpskmod = comm.PSKModulator
mpskmod = comm.PSKModulator(Name=Value)
mpskmod = comm.PSKModulator(M,phase,Name=Value)
mpskmod = comm.PSKModulator(M,phase,Name=Value)
```

### Description

`mpskmod = comm.PSKModulator` creates a modulator System object, that modulates the input signal using the M-ary phase shift keying (M-PSK) method.

`mpskmod = comm.PSKModulator(Name=Value)` sets properties using one or more name-value arguments. For example, `BitInput=true` specifies input values must be binary.

`mpskmod = comm.PSKModulator(M,phase,Name=Value)` sets the `ModulationOrder` property to `M`, and optional name-value arguments.

`mpskmod = comm.PSKModulator(M,phase,Name=Value)` sets the `ModulationOrder` property to `M`, the `PhaseOffset` property to `phase`, and optional name-value arguments. Specify `phase` in radians.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **ModulationOrder — Number of points in signal constellation**

8 (default) | positive integer

Number of points in the signal constellation, specified as a positive integer.

Data Types: double

### **PhaseOffset — Phase of zeroth point of constellation**

$\pi/8$  (default) | scalar

Phase of the zeroth point of the constellation in radians, specified as a scalar.

Example: `PhaseOffset=0` aligns the QPSK signal constellation points on the axes  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

### **BitInput — Option to provide input in bits**

0 or false (default) | 1 or true

Option to provide input in bits, specified as a numeric or logical 0 (false) or 1 (true).

- If you set this property to `false`, the input values must be integers in the range  $[0, M-1]$ , where  $M$  is the `ModulationOrder`.
- If you set this property to `true`, the input values must be binary and the input vector length must be an integer multiple of the number of bits per symbol,  $\log_2(M)$ . Groups of  $\log_2(M)$  bits are mapped onto a symbol, with the first bit representing the MSB and the last bit representing the LSB.

Data Types: logical

### **SymbolMapping — Symbol encoding mapping of constellation bits**

'Gray' (default) | 'Binary' | 'Custom'

Symbol encoding mapping of constellation bits, specified as 'Gray', 'Binary', or 'Custom'. Each integer or group of  $\log_2(\text{ModulationOrder})$  bits corresponds to one symbol.

- When you set this property to 'Gray', the object maps symbols to a Gray-encoded signal constellation.

- When you set this property to 'Binary', the object map symbols to a natural binary-encoded signal constellation. Specifically, the complex value  $e^{j(\text{PhaseOffset} + (2\pi m/\text{ModulationOrder}))}$ , where  $m$  is an integer in the range  $[0, (\text{ModulationOrder} - 1)]$ .
- When you set this property to 'Custom', the object map symbols to the signal constellation defined in the CustomSymbolMapping property.

### CustomSymbolMapping — Custom constellation encoding

$\theta:7$  (default) | integer vector

Custom symbol encoding, specified as an integer vector with length equal to the value of ModulationOrder and unique values in the range  $[0, (\text{ModulationOrder} - 1)]$ . The first element of this vector corresponds to the constellation point at an angle of  $\theta + \text{PhaseOffset}$ , with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of  $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$ .

#### Dependencies

To enable this property, set the SymbolMapping property to 'Custom'.

Data Types: double

### OutputDataType — Output datatype

'double' (default) | 'single' | 'Custom'

Output data type, specified as either 'double', 'single' or 'Custom'.

#### Fixed-Point Properties

### CustomOutputDataType — Fixed-point data type of output

numericType([],16) (default) | numericType object

Fixed-point data type of the output signal, specified as a numericType object with its Signedness property set to Auto. To create this type of object, use the numericType function.

#### Dependencies

To enable this property, set the OutputDataType property to 'Custom'.

## Usage

### Syntax

```
mpsksignal = mpskmod(insignal)
```

### Description

mpksignal = mpskmod(insignal) modulates the input signal by using the M-PSK method. The output is the modulated M-PSK baseband signal.

## Input Arguments

### **insignal** — Input signal

column vector

Input signal, specified as a column vector of integers or bits. The `BitInput` property specifies the expected input values and vector length.

Data Types: `double`

## Output Arguments

### **mpsksignal** — M-PSK modulated baseband signal

scalar | vector

M-PSK modulated baseband signal, returned as a scalar or vector of complex-valued constellation symbols. The `OutputDataType` property specifies the data type of the output.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `comm.PSKModulator`

`constellation` Calculate or plot ideal signal constellation

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### 16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects that use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values in the range [0, 15].

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...  
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

```
pskDemodulator = comm.PSKDemodulator(16, 'BitOutput', true, ...
    'SymbolMapping', 'Custom', 'CustomSymbolMapping', custMap);
```

Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol', log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. Vary  $E_b/N_0$  from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for n = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(n);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1], 4000, 1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data, rxData);
    end

    % Save the BER data
    ber(n) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec, 'psk', 16, 'nondiff');
```

Use this code to plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

```
figure
semilogy(ebnoVec, [ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
```

```
grid  
legend('Simulation','Theory','location','ne')
```

## Algorithms

For binary-encoding, the output baseband signal maps input bits or integers to complex symbols according to:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \{0, 1, \dots, M-1\}.$$

When the input is configured for bits, groups of  $\log_2(M)$  bits represent the complex symbols for the configured symbol mapping. The mapping can be binary encoded, Gray encoded, or custom encoded.

Gray coding has the advantage that only one bit changes between adjacent constellation points, which results in better bit error rate performance. This table shows the mapping between the input and output symbols for 8-PSK modulation with Gray coding.

Input	Output
0	0 (000)
1	1 (001)
2	3 (011)
3	2 (010)
4	6 (110)
5	7 (111)
6	5 (101)
7	4 (100)

This constellation diagram shows the corresponding symbols and their binary values.

M-PSK Modulator Baseband

# comm.PSKTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to M-ary PSK signal constellation

## Description

The `PSKTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

To demodulate a signal that was modulated using trellis-coded modulation:

- 1 Define and set up your PSK TCM demodulator object. See “Construction” on page 3-1077.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PSKTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.PSKTCMDemodulator` creates a trellis-coded, M-ary phase shift, keying (PSK TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an M-PSK constellation.

`H = comm.PSKTCMDemodulator(Name, Value)` creates a PSK TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PSKTCMDemodulator(TRELLIS, Name, Value)` creates a PSK TCM demodulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether the trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

### **TracebackDepth**

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`× $K$  zero bits for a rate  $K/N$  convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

### **ResetInputPort**

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

### **ModulationOrder**

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, or 16. The default is 8. The `ModulationOrder` on page 3-0 property value must equal the number of possible input symbols to the convolutional decoder of the PSK TCM demodulator object. The `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### **OutputDataType**

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

## Methods

`step` Demodulate convolutionally encoded data mapped to M-ary PSK constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Demodulate Noisy PSK TCM Data

Modulate and demodulate data using 8-PSK TCM modulation in an AWGN channel. Estimate the resulting error rate.

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create 8-PSK TCM modulator and demodulator System objects using trellis, `t`.

```
M = 8;
psktcmmod = comm.PSKTCModulator(t,ModulationOrder=M);
psktcmdemod = comm.PSKTCMDemodulator(t, ...
    ModulationOrder=M, ...
    TracebackDepth=16);
```

Create an AWGN channel object.

```
awgnchan = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (SNR)', ...
    SNR=7);
```

Create an error rate calculator with delay in bits equal to `TracebackDepth` times the number of bits per symbol.

```
errRate = comm.ErrorRate( ...
    ReceiveDelay=psktcmdemod.TracebackDepth*log2(t.numInputSymbols));
```

Generate random binary data and modulate with 8-PSK TCM. Pass the modulated signal through the AWGN channel and demodulate. Calculate the error statistics.

```
for counter = 1:10
    % Transmit frames of 250 2-bit symbols
    data = randi([0 1],500,1);
    % Modulate
    modSignal = psktcmmod(data);
    % Pass through AWGN channel
    noisySignal = awgnchan(modSignal);
    % Demodulate
    receivedData = psktcmdemod(noisySignal);
```

```
    % Calculate error statistics
    errorStats = errRate(data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
        errorStats(1),errorStats(2))
```

```
Error rate = 2.17e-02
Number of errors = 108
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

$Y = \text{step}(H,X)$   
 $Y = \text{step}(H,X,R)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  demodulates the PSK modulated input data,  $X$ , and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits.  $X$  must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector,  $Y$ . When the convolutional encoder represents a rate  $K/N$  code, the length of the output vector is  $K \times L$ , where  $L$  is the length of the input vector,  $X$ .

$Y = \text{step}(H,X,R)$  resets the decoder to the all-zeros state when you input a reset signal,  $R$  that is non-zero.  $R$  must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

---

## comm.PSKTCMModulator

**Package:** comm

Convolutionally encode binary data and map using M-ary PSK signal constellation

### Description

The `PSKTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and then mapping the result to a PSK signal constellation.

To modulate a signal using trellis-coded modulation:

- 1 Define and set up your PSK TCM modulator object. See “Construction” on page 3-1082.
- 2 Call `step` to modulate the signal according to the properties of `comm.PSKTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.PSKTCMModulator` creates a trellis-coded M-ary phase shift keying (PSK TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result to an M-PSK constellation.

`H = comm.PSKTCMModulator(Name, Value)` creates a PSK TCM encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PSKTCMModulator(TRELLIS, Name, Value)` creates a PSK TCM encoder object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

### Properties

#### TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

#### TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. However, for each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with a length given by  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ ).  $L$  indicates the length of the input to the `step` method.

### ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, or 16. The default is 8. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the PSK TCM modulator. Thus, the value for the `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

## Methods

`step` Convolutionally encode binary data and map using M-ary PSK constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Modulate Data Using 8-PSK TCM Modulation

Modulate random data using 8-PSK TCM modulation and display the constellation diagram.

Create binary data.

```
data = randi([0 1],1000,1);
```

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create an 8-PSK TCM modulator object using the trellis structure variable, `t`.

```
hMod = comm.PSKTCModulator(t,'ModulationOrder',8);
```

Modulate and plot the data.

```
modData = step(hMod,data);  
scatterplot(modData);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

## step

**System object:** `comm.PSKTCMModulator`

**Package:** `comm`

Convolutionally encode binary data and map using M-ary PSK constellation

### Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` convolutionally encodes and modulates the input binary data column vector, `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector, `X`, must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector, `Y`, of length  $L$ .

`Y = step(H,X,R)` resets the encoder of the PSK TCM modulator object to the all-zeros state when you input a reset signal, `R`, that is non-zero. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.QPSKDemodulator

**Package:** comm

(To be removed) Demodulate using QPSK method

---

**Note** will be removed in a future release. Use `pskdemod` instead. For information on updating your code, see "Version History".

---

## Description

The `comm.QPSKDemodulator` object demodulates a signal that was modulated using the quadrature phase shift keying (QPSK) method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the QPSK method:

- 1 Create the `comm.QPSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
pskdemod = comm.QPSKDemodulator
pskdemod = comm.QPSKDemodulator(Name=Value)
pskdemod = comm.QPSKDemodulator(phase=Name,Value)
```

### Description

`pskdemod = comm.QPSKDemodulator` creates a System object to demodulate input QPSK signals.

`pskdemod = comm.QPSKDemodulator(Name=Value)` sets properties using one or more name-value arguments. For example, `DecisionMethod="Hard decision"` specifies demodulation using the hard-decision method.

`pskdemod = comm.QPSKDemodulator(phase=Name,Value)` sets the `PhaseOffset` property to `phase`, and optional name-value arguments. Specify `phase` in radians.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**PhaseOffset — Phase of zeroth point in constellation**

pi/4 (default) | scalar

Phase of the zeroth point in the constellation in radians, specified as a scalar.

Example: PhaseOffset=0 aligns the QPSK signal constellation points on the axes {(1,0), (0,j), (-1,0), (0,-j)}.

Data Types: double

**BitOutput — Option to output data as bits**

0 or false (default) | 1 or true

Option to output data as bits, specified as a logical 0 (false) or 1 (true).

- Set this property to false to output symbols as integer values in the range [0, 3] with length equal to the input data vector length.
- Set this property to true to output a column vector of bit values with length equal to twice the input data vector length.

Data Types: logical

**SymbolMapping — Symbol encoding**

'Gray' (default) | 'Binary'

Symbol encoding mapping of constellation bits, specified as 'Gray' or 'Binary'.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment												
Gray	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="padding: 5px;">1</td> <td style="padding: 5px;">0</td> </tr> <tr> <td colspan="2" style="border-top: 1px dashed black;"></td> </tr> <tr> <td style="padding: 5px;">3</td> <td style="padding: 5px;">2</td> </tr> </table>	1	0			3	2	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="padding: 5px;">01</td> <td style="padding: 5px;">00</td> </tr> <tr> <td colspan="2" style="border-top: 1px dashed black;"></td> </tr> <tr> <td style="padding: 5px;">11</td> <td style="padding: 5px;">10</td> </tr> </table>	01	00			11	10	Map symbols using Gray-coded ordering.

2	3														
01	00														
10	11														

**DecisionMethod — Demodulation decision method**

'Hard decision' (default) | 'Log-likelihood ratio' | 'Approximate log-likelihood ratio'

Demodulation decision method, specified as 'Hard decision', 'Log-likelihood ratio', or 'Approximate log-likelihood ratio'. When you set the BitOutput property to false, the object always performs hard-decision demodulation.

#### Dependencies

To enable this property, set the BitOutput property to true.

#### VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

#### Dependencies

To enable this property, set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio'.

#### Variance — Noise variance

1 (default) | positive scalar

Noise variance, specified as a positive scalar.

**Tunable:** Yes

#### Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

#### Dependencies

To enable this property, set the BitOutput property to true, the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', and the VarianceSource property to 'Property'.

Data Types: double

#### OutputDataType — Data type of output

'Full precision' (default) | 'Smallest unsigned integer' | 'double' | ...

Data type of the output, specified as 'Full precision', 'Smallest unsigned integer', 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', or 'uint32', 'logical'.

- When the input data type is single or double precision and you set the BitOutput property to true, the DecisionMethod property to 'Hard decision', and the OutputDataType property to 'Full precision', the output has the same data type as that of the input.

- When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to 'Smallest unsigned integer'.
- When you set `BitOutput` to `true` and the `DecisionMethod` property to 'Hard Decision', then 'logical' data type is a valid option.
- When you set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', the output data type is the same as that of the input and the input data type must be single or double precision.

**Dependencies**

To enable this property, set the `BitOutput` property to `false` or set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Hard decision'.

**Fixed-Point Properties****DerotateFactorDataType — Data type of derotate factor**

'Same word length as input' (default) | 'Custom'

Data type of the derotate factor, specified as 'Same word length as input' or 'Custom'. The object uses the derotate factor in the computations only when the input signal is a fixed-point type and the `PhaseOffset` property has a value that is not an even multiple of  $\pi/4$ .

**Dependencies**

To enable this property, set the `BitOutput` property to `false` or set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Hard decision'.

**CustomDerotateFactorDataType — Fixed-point data type of derotate factor**

`numerictype([],16)` (default) | unscaled `numerictype` object

Fixed-point data type of the derotate factor, specified as an unscaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

To enable this property, set the `DerotateFactorDataType` property to 'Custom'.

Data Types: `numerictype` object

**Usage****Syntax**

```
y = qpskdemod(x)
y = qpskdemod(x,var)
```

**Description**

`y = qpskdemod(x)` applies QPSK demodulation to the input signal and returns the demodulated signal.

`y = qpskdemod(x,var)` uses soft decision demodulation and noise variance `var`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to

'Approximate log-likelihood ratio' or 'Log-likelihood ratio', and the VarianceSource property to 'Input port'.

### Input Arguments

#### **x — QPSK-modulated signal**

scalar | column vector

QPSK-modulated signal, specified as a scalar or column vector.

#### Dependencies

The object accepts inputs with a signed integer data type or signed fixed point (sfi) objects when you set the BitOutput property to false or you set the DecisionMethod property to 'Hard decision' and the BitOutput property to true.

Data Types: double | single | int | fi

#### **var — Noise variance**

scalar

Noise variance, specified as a scalar.

#### Dependencies

To enable this argument, set the VarianceSource property to 'Input port', the BitOutput property to true, and the DecisionMethod property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio'.

Data Types: single | double

### Output Arguments

#### **y — Output signal**

scalar | column vector

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the BitOutput property. To specify the output data type, use the OutputDataType property.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

### Specific to comm.QPSKDemodulator

constellation Calculate or plot ideal signal constellation

### Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset     Reset internal states of System object

## Examples

### BER Estimate of QPSK Signal

Estimate the bit error rate of a QPSK modulated signal filtered through an AWGN channel.

Create a QPSK modulator and demodulator pair that operate on bits.

```
qpskModulator = comm.QPSKModulator('BitInput',true);  
qpskDemodulator = comm.QPSKDemodulator('BitOutput',true);
```

Create an AWGN channel object and an error rate counter.

```
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);  
errorRate = comm.ErrorRate;
```

Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);  
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);  
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```
errorStats = errorRate(data,rxData);
```

```
errorStats(1)
```

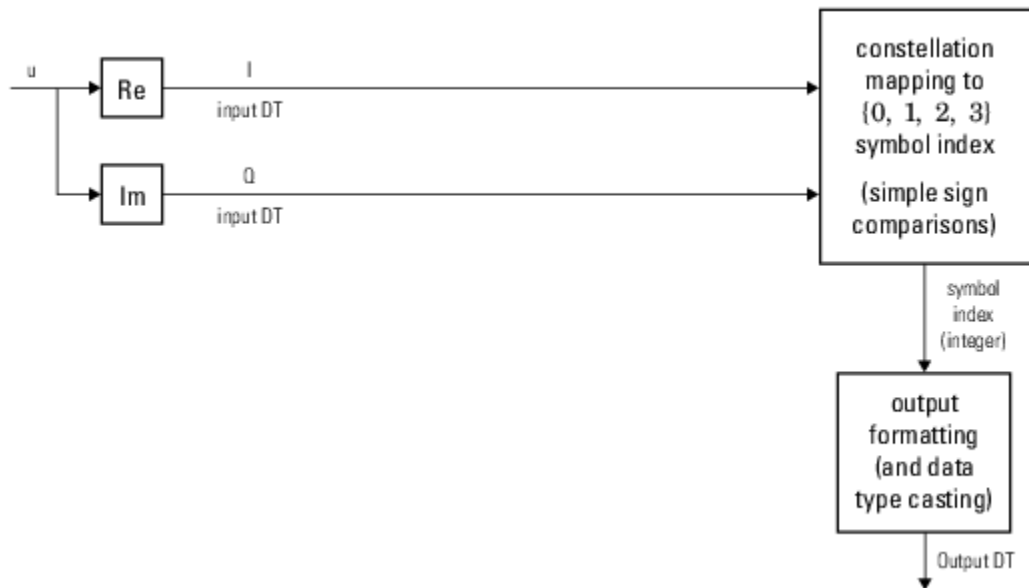

```
ans = 0.0100
```

## More About

### Hard-Decision QPSK Demodulation

The signal preprocessing required for QPSK demodulation depends on the configuration.

This figure shows the hard-decision QPSK demodulation signal diagram for the trivial phase offset (odd multiple of  $\pi/4$ ) configuration.

This figure shows the hard-decision QPSK demodulation floating point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision QPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

### Soft-Decision QPSK Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Hard- vs. Soft-Decision Demodulation” topic.

**Note** The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

## Version History

Introduced in R2012a

**R2023a: To be removed**

*Not recommended starting in R2023a*

comm.QPSKDemodulator will be removed in a future release. Use the pskdemod function with the modulation order set to 4 to QPSK demodulate the input signal.

**Package:** comm

(To be removed) Modulate using QPSK method

---

**Note** will be removed in a future release. Use `pskmod` instead. For information on updating your code, see “Version History”.

---

### Description

The `comm.QPSKModulator` object modulates a signal using the quadrature phase shift keying (QPSK) method. The output is a baseband representation of the modulated signal.

To modulate using the QPSK method:

- 1 Create the `comm.QPSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
qpskmod = comm.QPSKModulator  
qpskmod = comm.QPSKModulator(Name,Value)  
qpskmod = comm.QPSKModulator(phase,Name,Value)
```

#### Description

`qpskmod = comm.QPSKModulator` creates a System object to modulate input signals using the QPSK method.

`qpskmod = comm.QPSKModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'OutputDataType'='single'` specifies output of the modulated signal values in single precision data type.

`qpskmod = comm.QPSKModulator(phase,Name,Value)` sets the `PhaseOffset` property to phase and optional name-value arguments. Specify phase in radians.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### PhaseOffset — Phase offset of zeroth point in constellation

$\pi/4$  (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: 'PhaseOffset',  $\theta$  aligns the QPSK signal constellation points on the axes,  $\{(1,0), (0,j), (-1,0), (0,-j)\}$ .

Data Types: double

### BitInput — Option to provide input in bits

0 or false (default) | 1 or true

Option to provide input in bits, specified as a logical 0 (false) or 1 (true).

- When this property is set to `false`, the input values must be integer representations of two-bit input segments in the range [0, 3].
- When this property is set to `true`, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: logical

### SymbolMapping — Symbol encoding

'Gray' (default) | 'Binary'

Symbol encoding mapping of constellation bits, specified as 'Gray' or 'Binary'.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	Map symbols using Gray-coded ordering.

Binary	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>2</td> <td>3</td> </tr> </table>	1	0	2	3	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>10</td> <td>11</td> </tr> </table>	01	00	10	11	Map symbols using natural binary-coded ordering. The signal constellation maps to the complex value $e^{j(\text{PhaseOffset} + (2\pi m/4))}$ , where $m$ is an integer in the range [0, 3].
1	0										
2	3										
01	00										
10	11										

Data Types: char

### OutputDataType — Data type assigned to output

'double' (default) | 'single' | 'Custom'

Data type assigned to output, specified as 'double', 'single', or 'Custom'.

Data Types: char

### Fixed-Point Properties

#### **CustomOutputDataType** — Fixed-point data type of output

numericType([],16) (default) | numericType object

Fixed-point data type of output, specified as a numericType object with a signedness of Auto.

### Dependencies

This property applies when you set the OutputDataType property to 'Custom'.

## Usage

## Syntax

```
y = qpskmod(x)
```

### Description

`y = qpskmod(x)` returns baseband-modulated output.

### Input Arguments

#### **x** — Input signal

integer column vector | bit column vector

Input signal, specified as an  $N_S$ -element column vector of integers or bits, where  $N_S$  is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: double | int8 | logical | fi

### Output Arguments

#### **y** — Output QPSK-modulated signal

vector

Output QPSK-modulated signal, returned as a complex-valued vector.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.QPSKModulator

constellation Calculate or plot ideal signal constellation

## Common to All System Objects

step Run System object algorithm  
 release Release resources and allow changes to System object property values and input characteristics  
 reset Reset internal states of System object

## Examples

### BER Estimate of QPSK Signal

Estimate the bit error rate of a QPSK modulated signal filtered through an AWGN channel.

Create a QPSK modulator and demodulator pair that operate on bits.

```
qpskModulator = comm.QPSKModulator('BitInput',true);
qpskDemodulator = comm.QPSKDemodulator('BitOutput',true);
```

Create an AWGN channel object and an error rate counter.

```
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
errorRate = comm.ErrorRate;
```

Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```
errorStats = errorRate(data,rxData);
```

```
errorStats(1)
```

```
ans = 0.0100
```

## Version History

# comm.RaisedCosineReceiveFilter

**Package:** comm

Apply pulse shaping by decimating signal using raised-cosine FIR filter

## Description

The `comm.RaisedCosineReceiveFilter` System object applies pulse shaping by decimating an input signal using a raised-cosine finite impulse response (FIR) filter. The FIR filter has  $(\text{FilterSpanInSymbols} \times \text{InputSamplesPerSymbol} + 1)$  tap coefficients.

To apply pulse shaping by decimating an input signal using a raised-cosine FIR filter:

- 1 Create the `comm.RaisedCosineReceiveFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
rxfilter = comm.RaisedCosineReceiveFilter
rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)
```

### Description

`rxfilter = comm.RaisedCosineReceiveFilter` returns a raised-cosine FIR receive filter System object, which decimates the input signal using a raised-cosine FIR filter. The filter uses an efficient polyphase FIR decimation structure and has unit energy.

`rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineReceiveFilter('RolloffFactor',0.3)` configures a raised-cosine receive filter System object with the roll-off factor set to 0.3.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Shape — Filter shape

Square root (default) | Normal

Filter shape, specified as 'Square root' or 'Normal'.

Data Types: char | string

**RolloffFactor — Roll-off factor**

0.2 (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: double

**FilterSpanInSymbols — Filter span in symbols**

10 (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: double

**InputSamplesPerSymbol — Input samples per symbol**

8 (default) | positive integer

Input samples per symbol, specified as a positive integer.

Data Types: double

**DecimationFactor — Decimation factor**

8 (default) | integer

Decimation factor, specified as an integer in the range [1, InputSamplesPerSymbol]. This value must evenly divide into InputSamplesPerSymbol. The sampling rate of the output signal is reduced by the decimation factor such that  $\text{length}(y)/\text{length}(x)$  is equal to DecimationFactor. For a matrix input signal, the number of input rows must be a multiple of the decimation factor.

Data Types: double

**DecimationOffset — Decimation offset**

0 (default) | integer

Decimation offset, specified as an integer in the range [0, (DecimationFactor - 1)]. This property specifies the number of filtered samples the object discards before downsampling.

Data Types: double

**Gain — Linear filter gain**

1 (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: double

## Usage

## Syntax

```
y = rxfilter(x)
```

## Description

`y = rxfilter(x)` applies pulse shaping by decimating an input signal using a raised cosine FIR filter. The output consists of decimated signal values.

## Input Arguments

### x — Input signal

column vector | matrix

Input signal, specified as a column vector or a  $K_i$ -by- $N$  matrix.  $K_i$  is the number of input samples per signal channel, and  $N$  is the number of signal channels.

For a  $K_i$ -by- $N$  matrix input, the object processes columns of the input matrix as  $N$  independent channels.

Data Types: double | single

## Output Arguments

### y — Output signal

column vector | matrix

Output signal, returned as a column vector or a  $K_o$ -by- $N$  matrix.  $K_o$  is equal to  $K_i / \text{DecimationFactor}$ .  $K_i$  is the number of input samples per signal channel, and  $N$  is the number of signal channels.

The System object filters each channel over time and generates a  $K_o$ -by- $N$  output matrix. The output signal is the same data type as the input signal.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.RaisedCosineReceiveFilter

<code>info</code>	Information about filter System object
<code>coeffs</code>	Coefficients for filters
<code>cost</code>	Computational cost of implementing filter System object
<code>freqz</code>	Frequency response of discrete-time filter
<code>fvtool</code>	Plot frequency response of filter
<code>grpdelay</code>	Group delay response of discrete-time filter

impz        Impulse response of discrete-time filter  
order      Order of discrete-time filter System object

## Common to All System Objects

step        Run System object algorithm  
release     Release resources and allow changes to System object property values and input characteristics  
reset       Reset internal states of System object

## Examples

### Filter Signal Using Square-Root-Raised-Cosine Receive Filter

Filter the output of a square-root-raised-cosine (SRRC) transmit filter by using a matched SRRC receive filter. The input signal has eight samples per symbol.

Create an SRRC transmit filter object, setting the number of output samples per symbol to 8.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',8);
```

Create an SRRC receive filter, setting the number of input samples per symbol to 8 and the decimation factor to 8.

```
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',8, ...  
    'DecimationFactor',8);
```

Use the `coeffs` function to determine the filter coefficients for both filters.

```
txCoef = coeffs(txfilter);  
rxCoef = coeffs(rxfilter);
```

Display the magnitude responses of the two filters. The results show that the responses are the same. Here we use the `freqz` and `plot` functions to plot the magnitude responses. The FVTool app can also generate the filter responses.

```
[htx,f] = freqz(txfilter);  
hrx = freqz(rxfilter);  
  
plot(f/pi,mag2db(abs([htx hrx])))  
ylabel("Magnitude (dB)")  
xlabel("Normalized Frequency (\times\pi rad/sample)")  
legend(["Tx" "Rx"]+" Filter")  
grid  
ylim([-65 15])
```

Generate a random bipolar signal. Interpolate the signal by using the SRRC transmit filter object.

```
preTx = 2*randi([0 1],100,1) - 1;
y = txfilter(preTx);
```

Decimate the signal by using the SRRC receive filter object.

```
postRx = rxfilter(y);
```

The filter delay is equal to the filter span. Accounting for the filter delay, adjust the plotted samples to compare the pre-Tx filter signal with the post-Rx filter signal. Because the combined receive and the transmit RRC filters generate a matched filter pair, the two signals overlap one another.

```
delay = txfilter.FilterSpanInSymbols;
x = (1:(length(preTx)-delay));
plot(x,preTx(1:end-delay),x,postRx(delay+1:end))
legend('Pre-Tx filter','Post-Rx filter')
```

### Specify Filter Span of Square-Root-Raised-Cosine Receive Filter

Decimate a bipolar signal using a square-root-raised-cosine (SRRC) filter whose impulse response is truncated to filter a span of six symbol durations.

Create a SRRC transmit FIR filter, setting the filter span to six symbols. The object truncates the impulse response to six symbols.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
```

Generate a random bipolar signal . Filter the signal by using the SRRC transmit FIR filter object.

```
x = 2*randi([0 1],25,1) - 1;
y = txfilter(x);
```

Create a matched SRRC receive filter object.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',6);
```

Launch the filter visualization tool to show the impulse response of the receive filter.

```
fvtool(rxfilter,'Analysis','impulse')
```

Filter the output signal from the transmit filter by using the matched SRRRC receive filter object.

```
r = rxfilter(y);
```

Plot the interpolated signal. The results show a delay equal to the filter span (six symbols) before data passes through the filter.

```
stem(r)
```

### Create Square-Root-Raised-Cosine Receive Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) receive filter object. Use FVTool to plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is more than 0 dB.

```
rxfilter = comm.RaisedCosineReceiveFilter;  
fvtool(rxfilter)
```

Use the `coeffs` object function to obtain the filter coefficients and adjust the filter gain to unit energy.

```
b = coeffs(rxfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
rxfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(rxfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(rxfilter)
```

## Version History

Introduced in R2013b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `comm.RaisedCosineReceiveFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code. For details, see “Generate SIMD Code for MATLAB Functions” (Embedded Coder).

## comm.RaisedCosineTransmitFilter

**Package:** comm

Apply pulse shaping by interpolating signal using raised-cosine FIR filter

### Description

The `comm.RaisedCosineTransmitFilter` System object applies pulse shaping by interpolating an input signal using a raised cosine finite impulse response (FIR) filter. The FIR filter has  $(\text{FilterSpanInSymbols} \times \text{OutputSamplesPerSymbol} + 1)$  tap coefficients.

To apply pulse shaping by interpolating an input signal using a raised cosine FIR filter:

- 1 Create the `comm.RaisedCosineTransmitFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
txfilter = comm.RaisedCosineTransmitFilter  
txfilter = comm.RaisedCosineTransmitFilter(Name,Value)
```

#### Description

`txfilter = comm.RaisedCosineTransmitFilter` returns a raised cosine transmit FIR filter System object, which interpolates an input signal using a raised cosine FIR filter. The filter uses an efficient polyphase FIR interpolation structure and has unit energy.

`txfilter = comm.RaisedCosineTransmitFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',15)` configures a raised cosine transmit filter System object with the filter span set to 15 symbols.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### Shape — Filter shape

'Square root' (default) | 'Normal'

Filter shape, specified as 'Square root' or 'Normal'.

Data Types: char | string

**RolloffFactor — Roll-off factor**

0.2 (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: double

**FilterSpanInSymbols — Filter span in symbols**

10 (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: double

**OutputSamplesPerSymbol — Output samples per symbol**

8 (default) | positive integer

Output samples per symbol, specified as a positive integer.

Data Types: double

**Gain — Linear filter gain**

1 (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: double

## Usage

### Syntax

$y = \text{txfilter}(x)$

### Description

$y = \text{txfilter}(x)$  applies pulse shaping by interpolating an input signal using a raised cosine FIR filter. The output consists of interpolated signal values.

### Input Arguments

**x — Input signal**

column vector | matrix

Input signal, specified as a column vector or a  $K_i$ -by- $N$  matrix.  $K_i$  is the number of input samples per signal channel, and  $N$  is the number of signal channels.

For a  $K_i$ -by- $N$  matrix input, the object processes columns of the input matrix as  $N$  independent channels.

Data Types: `double` | `single`

### Output Arguments

#### **y** — Output signal

column vector | matrix

Output signal, returned as a column vector or a  $K_o$ -by- $N$  matrix.  $K_o$  is equal to  $K_i \times \text{OutputSamplesPerSymbol}$ .  $K_i$  is the number of input samples per signal channel, and  $N$  is the number of signal channels.

The object interpolates and filters each channel over the first dimension and then generates a  $K_o$ -by- $N$  output matrix. The output signal is the same data type as the input signal.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.RaisedCosineTransmitFilter`

<code>info</code>	Information about filter System object
<code>coeffs</code>	Coefficients for filters
<code>cost</code>	Computational cost of implementing filter System object
<code>freqz</code>	Frequency response of discrete-time filter
<code>fvtool</code>	Plot frequency response of filter
<code>grpdelay</code>	Group delay response of discrete-time filter
<code>impz</code>	Impulse response of discrete-time filter
<code>order</code>	Order of discrete-time filter System object

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

### Examples

#### Interpolate Signal Using Square-Root-Raised-Cosine Filter

Interpolate a signal using square-root-raised-cosine (SRRC) transmit filter object and display the spectrum of the filtered signal.

Create random bipolar symbols at a symbol rate of 1e6 symbols per second.

```
data = 2*randi([0 1],1e6,1) - 1;
```

Create a SRRC transmit filter object. The default sets the filter to a square-root shape and the number of samples per symbol to 8.

```
txfilter = comm.RaisedCosineTransmitFilter
```

```
txfilter =  
comm.RaisedCosineTransmitFilter with properties:
```

```
          Shape: 'Square root'  
    RolloffFactor: 0.2000  
  FilterSpanInSymbols: 10  
OutputSamplesPerSymbol: 8  
          Gain: 1
```

Filter the data by using the SRRC filter.

```
filteredData = txfilter(data);
```

Create a spectrum analyzer object with an 8e6 sampling rate. This sampling rate matches the sampling rate of the filtered signal.

```
spectrumAnalyzer = spectrumAnalyzer(SampleRate=8e6);
```

View the spectrum of the filtered signal by using the spectrum analyzer object.

```
spectrumAnalyzer(filteredData)  
release(spectrumAnalyzer)
```

### Examine Effect of Filter Span on Magnitude Response

Create interpolated signals from a square-root-raised-cosine (SRRC) filter with various filter spans. Examine the magnitude response of the various filter designs.

Create SRRC filter objects setting various filter spans. Use the `coeffs` object function to obtain the filter coefficients.

```
txfilt2 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',2);
txfilt4 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',4);
txfilt6 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
txfilt8 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',8);
txfilt16 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',16);
```

```
taps2 = coeffs(txfilt2).Numerator;
taps4 = coeffs(txfilt4).Numerator;
taps6 = coeffs(txfilt6).Numerator;
taps8 = coeffs(txfilt8).Numerator;
taps16 = coeffs(txfilt16).Numerator;
```

Launch the filter visualization tool to show the magnitude response for various filter spans. Specify a sample rate of 1 kHz. Display the two-sided centered response.

```
fvt = fvtool(taps2,1,taps4,1,taps8,1,taps16,1);
fvt.Fs = 1e3;
```

```
fvt.FrequencyRange = '[-Fs/2, Fs/2]';
legend(fvt, 'Span 2 symbols', 'Span 4 symbols', ...
        'Span 8 symbols', 'Span 10 symbols')
```

### Create Square-Root-Raised-Cosine Transmit Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) transmit filter System object™, and then plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is greater than 0 dB.

```
txfilter = comm.RaisedCosineTransmitFilter;
fvtool(txfilter)
```

Obtain the filter coefficients by using the `coeffs` object function and adjust the filter gain to unit energy.

```
b = coeffs(txfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response again. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(txfilter)
```

### Examine Polyphase Matrix of RRC Filter

When you create a multirate filter that uses polyphase decomposition, the `polyphase` function lets you analyze the component filters individually by returning the components as rows in a matrix. Using `polyphase` with an output argument returns a matrix containing the polyphase decomposition with individual rows defining each subfilter.

```
rcfilter = comm.RaisedCosineTransmitFilter;
p = polyphase(rcfilter)
```

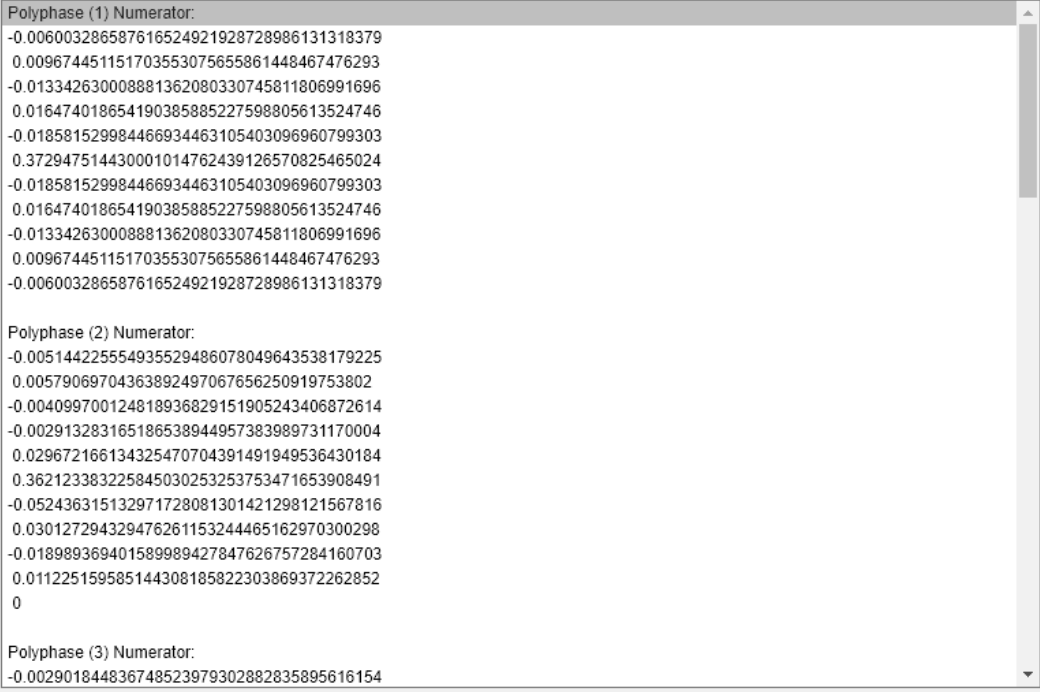

```
p = 8x11
```

Using `polyphase` without an output argument opens the Filter Visualization Tool, ready for you to use the analysis capabilities of the tool to investigate the filter. The “Filter Analysis Using FVTool”

shows the coefficients of the subfilters. To see the magnitude response of the subfilters, click on the **Magnitude Response** button on the “Filter Analysis Using FVTool” toolstrip.

`polyphase(rcfilter)`

The screenshot shows a MATLAB window titled "Polyphase (1) Numerator:" with a scrollable text area containing the following coefficients:

## comm.RayleighChannel

**Package:** comm

Filter input signal through multipath Rayleigh fading channel

### Description

The `comm.RayleighChannel` System object filters an input signal through the multipath Rayleigh fading channel. For more information on fading model processing, see the Methodology for Simulating Multipath Fading Channels section.

To filter an input signal through a multipath Rayleigh fading channel:

- 1 Create the `comm.RayleighChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

### Creation

#### Syntax

```
rayleighchan = comm.RayleighChannel  
rayleighchan = comm.RayleighChannel(Name,Value)
```

#### Description

`rayleighchan = comm.RayleighChannel` creates a frequency-selective or frequency-flat multipath Rayleigh fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain a channel-impaired signal.

`rayleighchan = comm.RayleighChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate', 2` sets the input signal sample rate to 2.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

#### SampleRate — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: double

### **PathDelays — Discrete path delay**

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set PathDelays to a scalar, the channel is frequency flat.
- When you set PathDelays to a vector, the channel is frequency selective.

The PathDelays and AveragePathGains properties must be the same length.

Data Types: double

### **AveragePathGains — Average gains of discrete paths**

0 (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. The AveragePathGains and PathDelays properties must be the same length.

Data Types: double

### **NormalizePathGains — Normalize average path gains**

true or 1 (default) | false or 0

Normalize average path gains, specified as one of these logical values:

- 1 (true) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (false) — The total power of the path gains is not normalized.

The AveragePathGains property specifies the average powers of the path gains.

Data Types: logical

### **MaximumDopplerShift — Maximum Doppler shift for all channel paths**

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the reset object function to generate a new channel realization. The MaximumDopplerShift property value must be smaller than  $\text{SampleRate}/10/f_c$  for each path.  $f_c$  is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of  $f_c$  is 1. For Gaussian and bi-Gaussian Doppler spectrum types,  $f_c$  is dependent on the Doppler spectrum structure fields. For more details about how  $f_c$  is defined, see the “Cutoff Frequency Factor” on page 3-1140 section.

Data Types: double

### **DopplerSpectrum — Doppler spectrum shape for all channel paths**

doppler('Jakes') (default) | Doppler spectrum structure | 1-by- $N_p$  cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- $N_p$  cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the `doppler` function.  $N_p$  is the number of discrete delay paths specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum..

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `specType` input to the `doppler` function. If you set the `FadingTechnique` property to 'Sum of sinusoids', you must set `DopplerSpectrum` to `doppler('Jakes')`.

#### **Dependencies**

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: `struct` | `cell`

#### **ChannelFiltering — Channel filtering**

`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

#### **PathGainsOutputPort — Output channel path gains**

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

#### **Dependencies**

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

#### **NumSamples — Number of samples**

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

**OutputDataType — Path gain output data type**

`'double'` (default) | `'single'`

Path gain output data type, specified as `'double'` or `'single'`.

**Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

**FadingTechnique — Channel model fading technique**

`'Filtered Gaussian noise'` (default) | `'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char` | `string`

**NumSinusoids — Number of sinusoids used**

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `double`

**InitialTimeSource — Source to control start time of fading process**

`'Property'` (default) | `'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- When you set `InitialTimeSource` to `'Property'`, set the initial time offset by using the `InitialTime` property.
- When you set `InitialTimeSource` to `'Input port'`, specify the start time of the fading process by using the `inittime` input argument. The input value can change in consecutive calls to the object.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `char` | `string`

**InitialTime — Initial time offset**

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When `mod(InitialTime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Property'`.

Data Types: `double`

**RandomStream — Source of random number stream**

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- When you specify `'Global stream'`, the object uses the current global random number stream for random number generation. In this case, the `reset` object function resets only the filters.
- When you specify `'mt19937ar with seed'`, the object uses the `mt19937ar` algorithm for random number generation. In this case, the `reset` object function resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

**Seed — Initial seed of mt19937ar random number stream**

73 (default) | nonnegative integer

Initial seed of the `mt19937ar` random number stream generator algorithm, specified as a nonnegative integer. When you call the `reset` object function, it reinitializes the `mt19937ar` random number stream to the `Seed` value.

**Dependencies**

To enable this property, set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

**Visualization — Channel visualization**

`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. For more information, see the [Channel Visualization](#) topic.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Filtered Gaussian noise'`.

Data Types: `char` | `string`

**PathsForDopplerDisplay — Path used for displaying Doppler spectrum**

1 (default) | positive integer

Path used for displaying the Doppler spectrum, specified as a positive integer in the range  $[1, N_p]$ .  $N_p$  is the number of discrete delay paths specified by the `PathDelays` property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

**Dependencies**

To enable this property, set the `Visualization` property to `'Doppler spectrum'`.

Data Types: double

**SamplesToDisplay — Percentage of samples to display**

'25%' (default) | '10%' | '50%' | '100%'

Percentage of samples to display, specified as `'25%'`, `'10%'`, `'50%'`, or `'100%'`. Increasing the percentage improves display accuracy at the expense of simulation speed.

**Dependencies**

To enable this property, set the `Visualization` property to `'Impulse response'`, `'Frequency response'`, or `'Impulse and frequency responses'`.

Data Types: char | string

**Usage****Syntax**

```
y = rayleighchan(x)
y = rayleighchan(x, inittime)
[y, pathgains] = rayleighchan( ___ )

pathgains = rayleighchan()
pathgains = rayleighchan(inittime)
```

**Description**

`y = rayleighchan(x)` filters the input signal `x` through a multipath Rayleigh fading channel and returns the result in `y`.

To enable this syntax, set the `ChannelFiltering` property to `true`.

`y = rayleighchan(x, inittime)` specifies a start time for the fading process.

To enable this syntax, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

`[y, pathgains] = rayleighchan( ___ )` also returns the channel path gains of the underlying multipath Rayleigh fading process in `pathgains` using any of the input argument combinations in the previous syntaxes.

To enable this syntax, set the `PathGainsOutputPort` property set to `true`.

`pathgains = rayleighchan()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `ChannelFiltering` property to `false`.

`pathgains = rayleighchan(inittime)` returns the channel path gains of the underlying fading process beginning at the specified initial time. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `FadingTechnique` property to `'Sum of sinusoids'`, the `InitialTimeSource` property to `'Input port'`, and the `ChannelFiltering` property to `false`.

### Input Arguments

#### **x** — Input signal

$N_S$ -by-1 vector

Input signal, specified as an  $N_S$ -by-1 vector, where  $N_S$  is the number of samples.

Data Types: `single` | `double`

Complex Number Support: Yes

#### **inittime** — Initial time offset

0 | nonnegative scalar

Initial time offset in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Output signal

$N_S$ -by-1 vector

Output signal, returned as an  $N_S$ -by-1 vector of complex values with the same data precision as the input signal `x`.  $N_S$  is the number of samples.

#### **pathgains** — Output path gains

$N_S$ -by- $N_P$  matrix

Output path gains, returned as an  $N_S$ -by- $N_P$  matrix.  $N_S$  is the number of samples.  $N_P$  is the number of discrete delay paths specified by the `PathDelays` property. `pathgains` contains complex values.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to comm.RayleighChannel

info Characteristic information about fading channel object

## Common to All System Objects

step Run System object algorithm  
 release Release resources and allow changes to System object property values and input characteristics  
 reset Reset internal states of System object

## Examples

### Produce Same Rayleigh Channel Outputs Using Two Random Number Generation Methods

Produce the same multipath Rayleigh fading channel response by using two different methods for random number generation. The multipath Rayleigh fading channel System object includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from these two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
insig = randi([0,pskModulator.ModulationOrder-1],1024,1);
channelInput = pskModulator(insig);
```

Create a multipath Rayleigh fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 22.

```
rayleighchan = comm.RayleighChannel( ...
    'SampleRate',10e3, ...
    'PathDelays',[0 1.5e-4], ...
    'AveragePathGains',[2 3], ...
    'NormalizePathGains',true, ...
    'MaximumDopplerShift',30, ...
    'DopplerSpectrum',{doppler('Gaussian',0.6),doppler('Flat')}, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',22, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rayleigh fading channel System object.

```
[chanOut1,pathGains1] = rayleighchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(rayleighchan);
rayleighchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that you specified when creating the multipath Rayleigh fading channel System object.

```
rng(22)
```

Filter the modulated data by using the multipath Rayleigh fading channel System object again.

```
[chanOut2,pathGains2] = rayleighchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(chanOut1,chanOut2)
```

```
ans = logical  
     1
```

```
isequal(pathGains1,pathGains2)
```

```
ans = logical  
     1
```

### Display Impulse and Frequency Responses of Multipath Rayleigh Fading Channel

Display the impulse and frequency responses of a frequency-selective multipath Rayleigh fading channel that is configured to disable channel filtering.

Define simulation variables. Specify path delays and gains by using the ITU pedestrian B channel configuration.

```
fs = 3.84e6; % Sample rate in Hz  
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % in seconds  
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB  
fD = 50; % Max Doppler shift in Hz
```

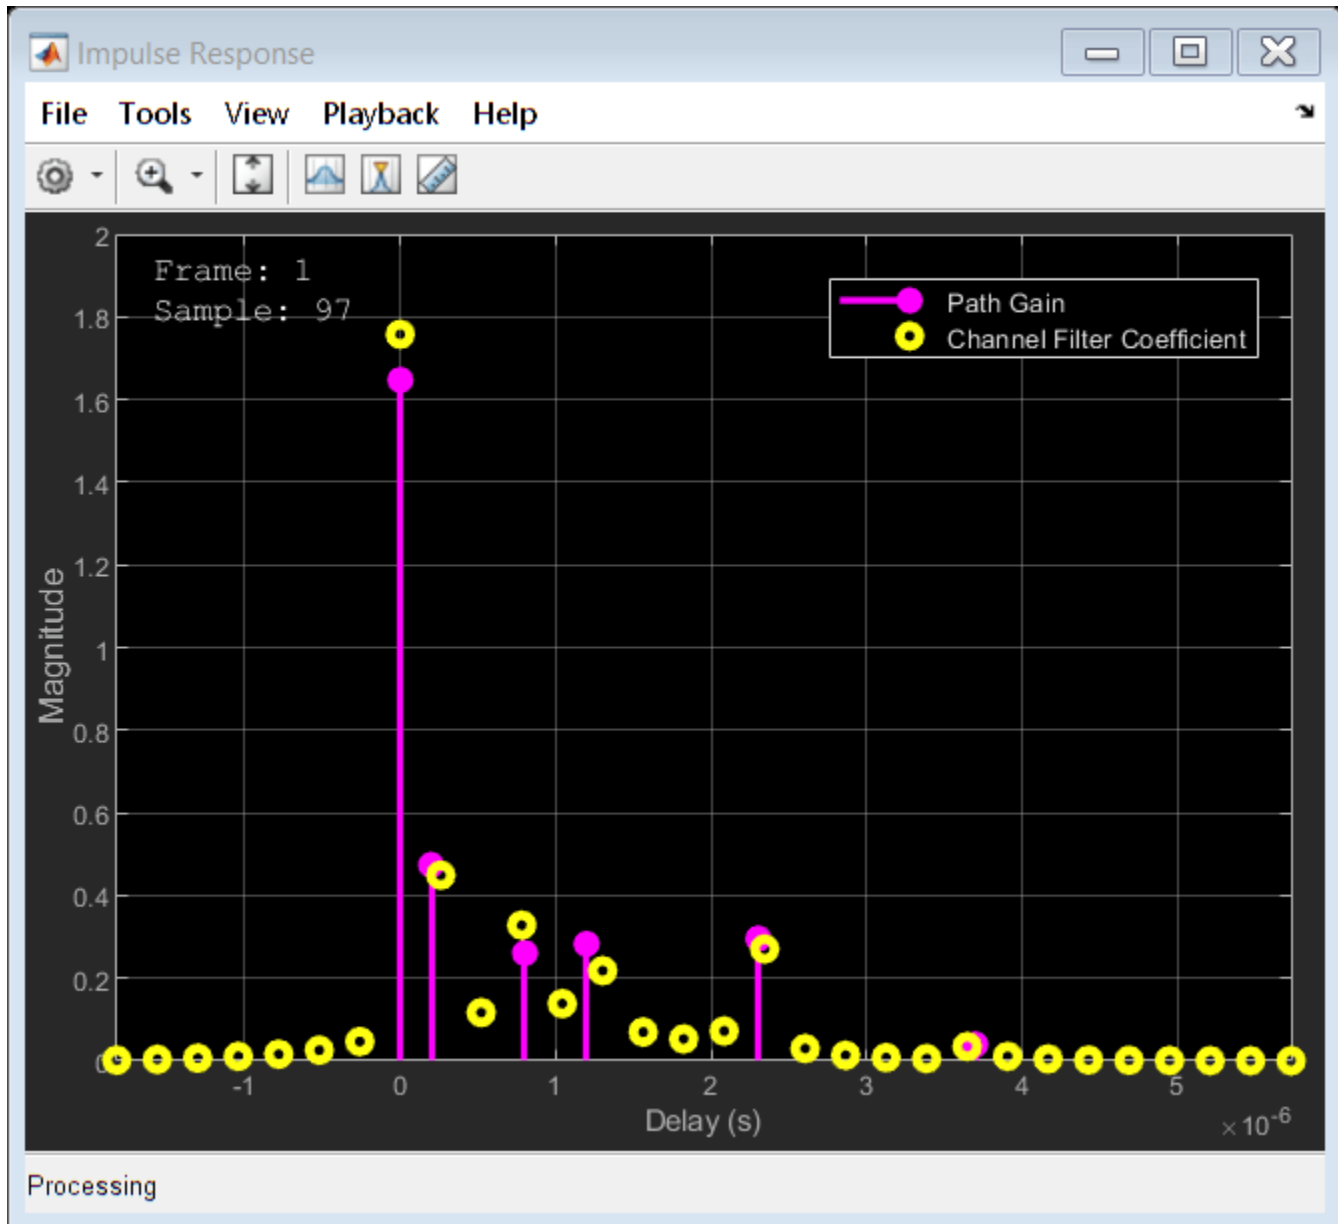

Create a multipath Rayleigh fading channel System object to visualize the impulse response and frequency response plots.

```
rayleighchan = comm.RayleighChannel('SampleRate',fs, ...  
    'PathDelays',pathDelays, ...  
    'AveragePathGains',avgPathGains, ...  
    'MaximumDopplerShift',fD, ...  
    'ChannelFiltering',false, ...  
    'Visualization','Impulse and frequency responses');
```

Visualize the channel response by running the multipath Rayleigh fading channel System object with no input signal. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
rayleighchan();
```

### Model Multipath Rayleigh Fading Channel by Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using multipath Rayleigh fading channel System objects that use the sum-of-sinusoids technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % In seconds
pathPower = [0 -6]; % In dB
```

```

fD = 5;           % Maximum Doppler shift (Hz)
ns = 1000;       % Number of samples
nsdel = 100;     % Number of samples for delayed paths

```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response that starts at time 0 and three 100-sample channel responses that start at times 0.1, 0.4, and 0.7 seconds, respectively.

```

to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs;   % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3

```

Create a frequency-flat multipath Rayleigh fading System object, specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, disabled channel filtering, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```

rayleighchan1 = comm.RayleighChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);

```

Create a clone of the multipath Rayleigh fading channel System object. In the cloned object, set the number of samples to view for the delayed paths. Also configure the initial time source as an input so that you can specify the fading channel offset time as an input argument when using the System object.

```

rayleighchan2 = clone(rayleighchan1);
rayleighchan2.NumSamples = nsdel;
rayleighchan2.InitialTimeSource = 'Input port';

```

Save the path gain output for the continuous channel response by using the `rayleighchan1` object and for the discontinuous delayed channel responses by using the `rayleighchan2` object with initial time offsets are provided as input arguments.

```

pg0 = rayleighchan1();
pg1 = rayleighchan2(to1);
pg2 = rayleighchan2(to2);
pg3 = rayleighchan2(to3);

```

Compare the number of samples processed by the two channels by using the `info` object function. The `rayleighchan1` object processed 1000 samples, while the `rayleighchan2` object processed only 300 samples.

```

G = info(rayleighchan1);
H = info(rayleighchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]

```

```

ans = 1x2

```

1000

300

Convert the path gains into decibels.

```
pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. Because the channel characteristics are maintained even when data is not transmitted, the alignment of the two plots shows that the sum-of-sinusoids technique is suited to the simulation of packetized data.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```

## Reproduce Multipath Rayleigh Fading Channel Response

Reproduce the multipath Rayleigh fading channel output across multiple frames by using the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RayleighChannel` System object.

Create a multipath Rayleigh fading channel System object, defining two paths. Generate data to pass through the channel.

```
rayleighchan = comm.RayleighChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1.5e-3], ...
    'AveragePathGains',[0 -3], ...
    'PathGainsOutputPort',true)
```

```
rayleighchan =
    comm.RayleighChannel with properties:
```

```
        SampleRate: 1000
        PathDelays: [0 0.0015]
    AveragePathGains: [0 -3]
    NormalizePathGains: true
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
    PathGainsOutputPort: true
```

```
Show all properties
```

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the `ChannelFilterCoefficients` property value to the variable `coeff`. Within a `for` loop, calculate the fractional delayed input signal at the path delay locations stored in `coeff`, apply the path gains, and sum the results for all of the paths. Compare the output of the multipath Rayleigh fading channel System object (`chanout1`) to the output reproduced using the path gains and the `ChannelFilterCoefficients` property of the multipath Rayleigh fading channel System object (`chanout2`).

```
chaninfo = info(rayleighchan);
coeff = chaninfo.ChannelFilterCoefficients;
Np = length(rayleighchan.PathDelays);
state = zeros(size(coeff,2)-1,size(coeff,1));
nFrames = 10;
chkChan = zeros(nFrames,1);
for jj = 1 : nFrames
    data = randi([0 1],600,1);
    [chanout1,pg] = rayleighchan(data);
    fracdelaydata = zeros(size(data,1),Np);
    % Calculate the fractional delayed input signal.
    for ii = 1:Np
        [fracdelaydata(:,ii),state(:,ii)] = ...
            filter(coeff(ii,:),1,data,state(:,ii));
    end
    % Apply the path gains and sum the results for all of the paths.
    % Compare the channel outputs.
    chanout2 = sum(pg .* fracdelaydata,2);
    chkChan(jj) = isequal(chanout1,chanout2);
```

```

end
chkChan'

ans = 1×10

     1     1     1     1     1     1     1     1     1     1

```

### Verify Autocorrelation of Rayleigh Channel Path Gains

Verify that the autocorrelation of the path gain output from the Rayleigh channel System object is a Bessel function. The results in [ 1 ] on page 3-1138 and Appendix A of [ 2 ] on page 3-1138, show that when the autocorrelation of the path gain outputs is a Bessel function, the Doppler spectrum is Jakes-shaped.

Initialize simulation parameters.

```

Rsym = 9600;           % Input symbol rate (symbols/s)
sps = 10;             % Number of samples per input symbol
Fs = sps*Rsym;        % Input sampling frequency (samples/s)
Ts = 1/Fs;           % Input sampling period (s)
numsym = 1e6;         % Number of input symbols to simulate
numsamp = numsym*sps; % Number of channel samples to simulate
fd = 100;            % Maximum Doppler frequency shift (Hz)
num_acsamp = 5000;   % Number of samples of autocovariance
                    % of complex fading process calculated
numtx = 1;           % Number of transmit antennas
numrx = 1;           % Number of receive antennas
numsin = 48;         % Number of sinusoids
frmLen = 10000;
numFrames = numsamp/frmLen;

```

Configure a Rayleigh channel System object.

```

chan = comm.RayleighChannel( ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',numsin, ...
    'RandomStream','mt19937ar with seed', ...
    'PathDelays',0, ...
    'AveragePathGains',0, ...
    'SampleRate',Fs, ...
    'MaximumDopplerShift',fd, ...
    'PathGainsOutputPort',true);

```

Apply DPSK modulation to a random bit stream.

```

tx = randi([0 1],numsamp,numtx); % Random bit stream
dpskSig = dpskmod(tx,2);         % DPSK signal

```

Pass the modulated signal through the channel.

```

outsig = zeros(numsamp,numrx);
pg_rx = zeros(numsamp,numrx,numtx);
for frmNum = 1:numFrames
    [outsig((1:frmLen)+(frmNum-1)*frmLen,:),pathGains] = ...
        chan(dpskSig((1:frmLen)+(frmNum-1)*frmLen,:));
end

```

```

    for i = 1:numrx
        pg_rx((1:frmLen)+(frmNum-1)*frmLen,i,:) = ...
            pathGains(:,:,:,i);
    end
end

```

Using the channel path gains received per antenna, compute the autocovariance of the fading process for each transmit-receive path.

```

autocov = zeros(frmLen+1,numrx,numtx);
autocov_normalized_real = zeros(num_acsamp+1,numrx,numtx);
autocov_normalized_imag = zeros(num_acsamp+1,numrx,numtx);
for i = 1:numrx
    % Compute autocovariance of simulated complex fading process
    for j = 1:numtx
        autocov(:,i,j) = xcov(pg_rx(:,i,j),num_acsamp);
        % Real part of normalized autocovariance
        autocov_normalized_real(:,i,j) = ...
            real(autocov(num_acsamp+1:end,i,j) ...
                / autocov(num_acsamp+1,i,j));
        % Imaginary part of normalized autocovariance
        autocov_normalized_imag(:,i,j) = ...
            imag(autocov(num_acsamp+1:end,i,j) ...
                / autocov(num_acsamp+1,i,j));
    end
end

```

Compute the theoretical autocovariance of the complex fading process by using the `besselj` function.

```

Rrr = zeros(1,num_acsamp+1);
for n = 1:1:num_acsamp+1
    Rrr(n) = besselj(0,2*pi*fd*(n-1)*Ts);
end
Rrr_normalized = Rrr/Rrr(1);

```

Display the autocovariance to compare the results from the Rayleigh channel System object and the `besselj` function.

```

subplot(2,1,1)
plot(autocov_normalized_real,'b-')
hold on
plot(Rrr_normalized,'r-')
hold off
legend('comm.RayleighChannel', ...
    'Bessel function of the first kind')
title('Autocovariance of Real Part of Rayleigh Process')
subplot(2,1,2)
plot(autocov_normalized_imag)
legend('comm.RayleighChannel')
title('Autocovariance of Imaginary Part of Rayleigh Process')

```

As computed below, the mean square error comparing the results from the Rayleigh channel object versus the Bessel function is insignificant.

```
act_mse_real = ...
    sum((autocov_normalized_real-repmat(Rrr_normalized.',1,numrx,numtx)).^2,1) ...
    / size(autocov_normalized_real,1)
```

```
act_mse_real = 7.0043e-08
```

```
act_mse_imag = sum((autocov_normalized_imag-0).^2,1) ...
    / size(autocov_normalized_imag,1)
```

```
act_mse_imag = 4.1064e-07
```

## Compare PDF of Empirical and Theoretical Rayleigh Channel

Compute and plot the empirical and theoretical probability density function (PDF) for a Rayleigh channel with one path.

Initialize parameters and create a Rayleigh channel System object that does not apply channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;

chan = comm.RayleighChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical PDF for the Rayleigh channel, by using the `fitdist` (Statistics and Machine Learning Toolbox) and `pdf` (Statistics and Machine Learning Toolbox) functions.

```
figure;
hold on;

% Empirical PDF plot
gain = chan();
pd = fitdist(abs(gain),'Kernel','BandWidth',.01);
r = 0:.1:3;
y = pdf(pd,r);
plot(r,y)

% Theoretical PDF plot
exp_pdf_amplitude = raylpdf(r,0.7);
plot(r,exp_pdf_amplitude)
legend('Empirical','Theoretical')
title('Empirical and Theoretical PDF Curves')
```

## More About

### Cutoff Frequency Factor

The cutoff frequency factor,  $f_c$ , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian,  $f_c$  equals 1.
- For a doppler('Gaussian') spectrum type,  $f_c$  equals  $\text{NormalizedStandardDeviation} \times \sqrt{2\log 2}$ .
- For a doppler('BiGaussian') spectrum type:
  - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$ .
  - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \times \sqrt{2\log 2}$ .
  - If the NormalizedCenterFrequencies field value is [0, 0] and the NormalizedStandardDeviation field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$ .
  - In all other cases,  $f_c$  equals 1.

## Version History

Introduced in R2013b

### R2022b: Updates to channel visualization display

The channel visualization feature now presents:

- Configuration settings in the bottom toolbar on the plot window.
- Plots side-by-side in one window when you select the Impulse and frequency response channel visualization option.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when you set the `Visualization` property to 'Off'.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

**Package:** comm

Filter signal through multipath fading channel defined by propagation rays

## Description

The `comm.RayTracingChannel` System object filters a signal through a multipath fading channel that is defined by propagation rays. For more information, see the “Channel Impulse Response” on page 3-1157 section.

To filter an input signal through a fading channel defined by propagation rays:

- 1 Create the `comm.RayTracingChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
rtchan = comm.RayTracingChannel
rtchan = comm.RayTracingChannel(Name,Value)
rtchan = comm.RayTracingChannel(rays,tx,rx)
```

### Description

`rtchan = comm.RayTracingChannel` creates a ray-tracing fading channel System object, which defines the multipath environment using a set of propagation rays.

`rtchan = comm.RayTracingChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',1e6` sets the sample rate to 1 MHz.

`rtchan = comm.RayTracingChannel(rays,tx,rx)` creates a ray-tracing fading channel System object given inputs `rays`, `tx`, and `rx`.

- `rays`, specified as a set of `comm.Ray` objects, is used to set the `PropagationRays` property.
- `tx`, specified as a `txsite` object, is used to set the `TransmitArray` and `TransmitArrayOrientationAxes` properties.
- `rx`, specified as an `rxsite`, is used to set the `ReceiveArray` and `ReceiveArrayOrientationAxes` properties.

When you use this syntax, to configure other properties set their values after creating the System object. For example, see “Configure Sample Rate for Ray Tracing Channel” on page 3-1155.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **SampleRate — Input signal sample rate**

10000000 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar. The “Configure Sample Rate for Ray Tracing Channel” on page 3-1155 example shows workflows to set the sample rate.

Data Types: `double`

### **PropagationRays — Propagation rays**

`comm.Ray` object (default) | row vector of `comm.Ray` objects | row cell array of `comm.Ray` objects

Propagation rays, specified as a `comm.Ray` object, a row vector of `comm.Ray` objects, or a row cell array of `comm.Ray` objects. This property specifies the propagation rays between the transmit and receive antenna arrays. All of the specified `comm.Ray` objects must have the same `Frequency` property setting. Any of the specified `comm.Ray` objects that have their `PathSpecification` property set to 'Locations' must have the same `CoordinateSystem`, `TransmitterLocation`, and `ReceiverLocation` property settings.

For code generation, the `PropagationRays` property must be a cell array of `comm.Ray` objects.

Data Types: `object` | `cell`

### **MinimizePropagationDelay — Option to force zero minimum propagation delay**

`true` or `1` (default) | `false` or `0`

Option to force zero minimum propagation delay, specified as a logical `1` (`true`) or `0` (`false`). Set this property to `true` to subtract the minimum propagation delay from all of the propagation delays of the rays to force zero minimum delay. For more information, see the “Tips” on page 3-1157 section.

Data Types: `logical` | `double`

### **TransmitArray — Transmit antenna array**

`arrayConfig` object (default) | `phased.IsotropicAntennaElement` System object | phased array antenna System object

Transmit antenna array, specified as one of these options.

- When you set `TransmitArray` to an `arrayConfig` object, you can adjust the `Size` property of the `arrayConfig` object to have the transmit array represent a uniform rectangular array (URA), uniform linear array (ULA), or single `phased.IsotropicAntennaElement` System object. The default configuration for an `arrayConfig` object is a 2-by-2 URA with an element spacing of 0.5 m.
- When you configure the `TransmitArray` to use a phased array antenna System object, you must have the “Phased Array System Toolbox” product. For a list of these additional supported values, see the “Phased Array Antenna Options” on page 3-1157 section.

**TransmitArrayOrientationAxes — Orientation axes of transmit antenna array**

eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the transmit antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the local coordinate system (LCS) to the global coordinate system (GCS). If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the transmitter.

Data Types: double

**ReceiveArray — Receive antenna array**

arrayConfig object | phased.IsotropicAntennaElement System object | phased array antenna System object | ...

Receive antenna array, specified as one of these options.

- When you set `ReceiveArray` to an `arrayConfig` object, you can adjust the `Size` property of the `arrayConfig` object to have the receive array represent a uniform rectangular array (URA), uniform linear array (ULA), or single `phased.IsotropicAntennaElement` System object. The default configuration for an `arrayConfig` object is a 2-by-2 URA with an element spacing of 0.5 m.
- When you set `ReceiveArray` to a phased array antenna System object configuration, you must have the “Phased Array System Toolbox” product. For a list of these additional supported values, see the “Phased Array Antenna Options” on page 3-1157 section.

**ReceiveArrayOrientationAxes — Orientation axes of receive antenna array**

eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the receive antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the LCS to the GCS. If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

**ReceiverVirtualVelocity — Receive antenna array instantaneous velocity**

[1; 1; 0] (default) | three-element column vector

Receive antenna array instantaneous velocity in the GCS in m/s, specified as a three-element column vector of the form  $[x; y; z]$ . The three elements in this vector specify the  $x$ -,  $y$ -, and  $z$ -velocity, respectively. If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

**NormalizeImpulseResponses — Option to normalize channel impulse responses**

true or 1 (default) | false or 0

Option to normalize channel impulse responses, specified as a logical 1 (true) or 0 (false). Set this property to `true` to normalize the gains of CIRs to 0 dB from each transmit array element to each receive array element.

Data Types: logical

**NormalizeChannelOutputs — Option to normalize channel outputs by number of receive elements**`true` or `1` (default) | `false` or `0`

Option to normalize channel outputs by the number of receive elements, specified as a logical `1` (`true`) or `0` (`false`). Set this property to `true` to normalize the channel output by the number of receive array elements.

Data Types: `logical`

**ChannelFiltering — Channel filtering**`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel impulse responses. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical` | `double`

**NumSamples — Number of samples**`100` (default) | nonnegative integer

Number of samples used for the duration of the channel impulse responses, specified as a nonnegative integer.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

**OutputDataType — Channel impulse response output data type**`'double'` (default) | `'single'`

Channel impulse response output data type, specified as `'double'` or `'single'`.

**Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

**Usage****Syntax**

```
y = rtchan(x)
y = rtchan(x,starttime)
[y,cir] = rtchan(____)

cir = rtchan()
```

```
cir = rtchan(starttime)
```

### Description

`y = rtchan(x)` filters the input signal through a multipath fading channel defined by a set of propagation rays and returns the result in `y`.

`y = rtchan(x, starttime)` specifies the start time of the input signal. When the last and current frames are not continuous in time, the System object resets the channel filter states.

`[y, cir] = rtchan( ___ )` also returns the channel impulse response using an input argument combination from either of the prior syntaxes.

`cir = rtchan()` returns the channel impulse response. To enable this syntax, set the `ChannelFiltering` property to `false`.

`cir = rtchan(starttime)` specifies the start time for the channel impulse response generation. To enable this syntax set the `ChannelFiltering` property to `false`.

### Input Arguments

#### **x** — Input signal

$N_S$ -by- $N_T$  matrix

Input signal, specified as an  $N_S$ -by- $N_T$  matrix.

- $N_S$  is the number of samples.
- $N_T$  is the number of transmit array elements.

Data Types: `single` | `double`

Complex Number Support: Yes

#### **starttime** — Start time

0 (default) | nonnegative scalar

Start time of input signal in seconds, specified as a nonnegative scalar.

When `mod(starttime/SampleRate)` is nonzero, the start time is rounded up to the nearest sample position. The start time must be greater than the end time of the last frame processed by the channel. You can use the `info` function to obtain the end time of the last processed frame.

Data Types: `double`

### Output Arguments

#### **y** — Output signal

$N_S$ -by- $N_R$  matrix

Output signal, returned as an  $N_S$ -by- $N_R$  matrix.

- $N_S$  is the number of samples.
- $N_R$  is the number of receive array elements.

`y` is the same data type as input `x`.

**cir** — Channel impulse response $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array

Channel impulse response, returned as an  $N_S$ -by- $N_P$ -by- $N_T$ -by- $N_R$  array.

- $N_S$  is the number of samples. When you set the `ChannelFiltering` property to `true`,  $N_S$  is the length of the input. When you set `ChannelFiltering` to `false`,  $N_S$  is specified by the `NumSamples` property.
- $N_P$  is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property).
- $N_T$  is the number of transmit array elements.
- $N_R$  is the number of receive array elements.

When you set `ChannelFiltering` to `true`, the data type for this output is the same data type as input `x`. When you set `ChannelFiltering` to `false`, the data type for this output is specified by the `OutputDataType` property.

For more information, see the “Channel Impulse Response” on page 3-1157 section.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to comm.RayTracingChannel

<code>info</code>	Characteristic information about ray-tracing channel
<code>showProfile</code>	Plot temporal and spatial profiles of ray-tracing channel
<code>clone</code>	Create duplicate System object
<code>isLocked</code>	Determine if System object is in use

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Remove Minimum Propagation Path Delay from Multipath Ray Trace Channel

Show the impact of not forcing the smallest propagation delay to be zero for a multipath channel model. Filter signals through a multipath ray tracing channel between two sites in Hong Kong, China. Build two multipath channel models by using the result from ray tracing. For the first ray tracing channel model, force the minimum propagation delay to zero. For the second ray tracing channel model, do not force the minimum propagation delay to zero.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the OSM file, see [1] on page 3-1152.

```
sv = siteviewer("Buildings","hongkong.osm");
```

```
tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ...      % Azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ...    % Azimuth angle
    "AntennaHeight",1);
```

Create a ray tracing propagation model, which MATLAB® represents using a RayTracing object. Configure the model to use the image method and to find paths with up to 2 surface reflections. Perform ray tracing to find rays by using the propagation model.

```
pm = propagationModel("raytracing", ...
    "Method","image", ...
    "MaxNumReflections",2);
rays = raytrace(tx,rx,pm);
```

Create a channel model using the calculated rays in between the transmitter and receiver sites. The default configuration forces zero minimum propagation delay. Show the temporal and spatial profiles of the channel.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
rtchan.SampleRate = 50e6;
showProfile(rtchan);
```

Angle of Departure

Angle of Arrival

Create a clone of the ray tracing channel model and reconfigure it to not force zero minimum propagation delay. Show the temporal and spatial profiles of the channel. The angle of departure and arrival plots do not change, but the power delay profile plot shows the updated delay profile result when the minimum delay profile is not forced to zero.

```
rtchandelayed= clone(rtchan);
rtchandelayed.MinimizePropagationDelay = false;
showProfile(rtchandelayed);
```

Filter randomly generated 16-QAM signals through the channel models. Display the leading 15 elements of  $y$  and  $y_{\text{delayed}}$ , which are output by the ray tracing channel objects  $\text{rtchan}$  and  $\text{rtchandelayed}$ , respectively. The leading samples in the delayed signal,  $y_{\text{delayed}}$ , are all zeros. When you model your communications system, you must account for this signal delay to avoid losing trailing signal data.

```
M = 16;           % Modulation order
frmLen = 1e3;    % Frame length
numTx = rtchan.info.NumTransmitElements;

x = qammod(randi([0,M-1],frmLen,numTx),M);
y = rtchan(x);
numTxdelayed = rtchandelayed.info.NumTransmitElements;
x = qammod(randi([0,M-1],frmLen,numTxdelayed),M);
ydelayed = rtchandelayed(x);
y(1:15)
```

*ans = 15x1 complex*

```
-0.0000 - 0.0000i
 0.0000 + 0.0000i
-0.0000 - 0.0000i
 0.0000 + 0.0000i
-0.0000 - 0.0000i
 0.0003 + 0.0011i
-0.0022 - 0.0110i
 1.0137 - 0.0002i
```

```
-1.0413 - 2.0091i
-3.0858 + 0.0390i
:

## Appendix

[1] The OSM file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Show Multipath Ray Trace Channel Modeling in Conference Room

Filter signals through a multipath ray tracing channel model between two sites in a conference room. Build the multipath channel model by using the result from ray tracing.

Define a 3-D map for a conference room with one table and four chairs by using a standard tessellation language (STL) data file. Define a transmitter site close to the wall and a receiver site above the table.

```
mapFileName = "conferenceroom.stl";

tx = txsite("cartesian", ...
    "AntennaPosition", [-1.45; -1.4; 2.3], ...
    "TransmitterFrequency", 2.8e9);
rx = rxsite("cartesian", ...
    "AntennaPosition", [.6; .2; 1.0]);
```

Use the `siteviewer` object and the `show` object function to visualize the 3-D scenario. The transmitter and receiver sites are colored in red and blue, respectively.

```
siteviewer(SceneModel=mapFileName);
show(tx, "ShowAntennaHeight", false)
show(rx, "ShowAntennaHeight", false)
```

Create a ray tracing propagation model, which MATLAB represents using a `RayTracing` object. Configure the model to find paths with up to 3 surface reflections. By default, the model uses the shooting and bouncing rays (SBR) method.

```
pm = propagationModel("raytracing", ...
    "CoordinateSystem","cartesian", ...
    "MaxNumReflections",3);
```

Perform ray tracing to find rays by using the propagation model.

```
rays = raytrace(tx,rx,pm,"Map",mapFileName);
```

Extract the computed rays from the returned cell array, and then plot the rays. Each ray is colored based on its path loss value.

```
rays = rays{1,1};
plot(rays)
```

Create a channel model using the calculated rays in between the transmitter and receiver sites. Show the temporal and spatial profiles of the channel.

```
rtchan = comm.RayTracingChannel(rays,tx,rx);
showProfile(rtchan);
```

Filter randomly generated 16-QAM signals through the channel. With the default sample rate of 10e6, the channel frequency response is flat. Increasing the sample rate to 1e9 results in a frequency selective channel. Show the filtered signal for the flat frequency response channel and the frequency selective channel in a constellation diagram.

```
M = 16;           % Modulation order
frmLen = 1e3;    % Frame length

numTx = rtchan.info.NumTransmitElements;
x = qammod(randi([0,M-1],frmLen,numTx),M);
y_samprate10e6 = rtchan(x);

release(rtchan);
rtchan.SampleRate = 1e9;
y_samprate1e9 = rtchan(x);
constellationdiag = comm.ConstellationDiagram( ...
    NumInputPorts=2, ...
    ChannelNames={ ...
        "Flat frequency response channel","Frequency selective channel"}, ...
    XLimits=[-5 5], ...
    YLimits=[-5 5], ...
    ReferenceConstellation=qammod(0:M-1,M));
constellationdiag(y_samprate10e6(:),y_samprate1e9);
```

### Configure Sample Rate for Ray Tracing Channel

To modify the sample rate of the ray tracing channel, you can set the `SampleRate` property by using a name-value argument when you create the object or you can create a channel model by using the rays and site and set the `SampleRate` property after you create the object.

#### Set Sample Rate when Creating Ray Tracing Channel Object

Create a ray tracing channel model, specifying the sample rate as 20 MHz.

```
rtchan1 = comm.RayTracingChannel(SampleRate=2e7)
```

```

rtchan1 =
  comm.RayTracingChannel with properties:
      SampleRate: 20000000
      PropagationRays: [1x1 comm.Ray]
      MinimizePropagationDelay: true
      TransmitArray: [1x1 arrayConfig]
      TransmitArrayOrientationAxes: [3x3 double]
      ReceiveArray: [1x1 arrayConfig]
      ReceiveArrayOrientationAxes: [3x3 double]
      ReceiverVirtualVelocity: [3x1 double]
      NormalizeImpulseResponses: true
      NormalizeChannelOutputs: true
      ChannelFiltering: true

```

### Set Sample Rate After Creating Ray Tracing Channel Object

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites. After creating the object, set the sample rate to 20 MHz.

```

tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ...           % Azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ...         % Azimuth angle
    "AntennaHeight",1);
pm = propagationModel("raytracing", ...
    "Method","sbr", ...
    "MaxNumReflections",3);
rays = raytrace(tx,rx,pm);

rtchan2 = comm.RayTracingChannel(rays{1},tx,rx);
rtchan2.SampleRate = 2e7

```

```

rtchan2 =
  comm.RayTracingChannel with properties:
      SampleRate: 20000000
      PropagationRays: [1x2 comm.Ray]
      MinimizePropagationDelay: true
      TransmitArray: [1x1 arrayConfig]
      TransmitArrayOrientationAxes: [3x3 double]
      ReceiveArray: [1x1 arrayConfig]
      ReceiveArrayOrientationAxes: [3x3 double]
      ReceiverVirtualVelocity: [3x1 double]
      NormalizeImpulseResponses: true
      NormalizeChannelOutputs: true
      ChannelFiltering: true

```

After configuring the channel object, you would typically filter a modulated signal through the channel. Here a 16-QAM signal is passed through the `rtchan2` ray tracing channel.

```

modOrd = 16;
frmLen = 1e3;
numTx = rtchan2.info.NumTransmitElements;
x = qammod(randi([0,modOrd-1],frmLen,numTx),modOrd);
y = rtchan2(x);

```

## More About

### Channel Impulse Response

The channel impulse response contains the computed Doppler fading over all rays individually. The phases of individual rays change over time, and their combination contributes to the channel fading. The rate of phase change depends on the angle between the receiver velocity and the angle of arrival (AoA) of the individual ray.

### Phased Array Antenna Options

If you have the “Phased Array System Toolbox” product, you can specify any of these phased array antenna System object configurations for the TransmitArray and ReceiveArray properties.

- `phased.IsotropicAntennaElement`
- `phased.NRAntennaElement`
- `phased.CustomAntennaElement`
- `phased.URA` with the `Element` property set to a `phased.IsotropicAntennaElement`, `phased.NRAntennaElement`, or `phased.CustomAntennaElement` System object
- `phased.ULA` with the `Element` property set to a `phased.IsotropicAntennaElement`, `phased.NRAntennaElement`, or `phased.CustomAntennaElement` System object
- `phased.ConformalArray` with the `Element` property set to a `phased.IsotropicAntennaElement`, `phased.NRAntennaElement`, or `phased.CustomAntennaElement` System object
- `phased.NRRectangularPanelArray` with the `ElementSet` property set to a `phased.IsotropicAntennaElement`, `phased.NRAntennaElement`, or `phased.CustomAntennaElement` System object

## Tips

- When you set the `MinimizePropagationDelay` property to `true`, the System object shifts all propagation delay paths to remove the amount of delay that is associated with the minimum propagation delay path. Shifting the paths removes potential leading zeros in the channel output and eliminates the need to account for the delay to receive the trailing signal samples.

## Version History

Introduced in R2020b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- For code generation, the `PropagationRays` property must be a cell array of `comm.Ray` objects.
- For `comm.Ray` objects, when you set the `PathSpecification` property to 'Locations' and the `LineOfSight` property to `false`, the `Type` field setting must be the same (either all 'Reflection' or all 'Diffraction') in the structures specified by the `Interactions` property for each individual `comm.Ray` object.

Generate RDS/RBDS waveform

## Description

The `comm.RBDSWaveformGenerator` System object generates configurable standard-compliant baseband RDS/RBDS waveforms in MATLAB. RDS/RBDS waveforms supplement FM radio stations with additional textual information, such as song title, artist name, and station description. The RDS/RBDS signal lies in the 57-kHz band of the baseband FM radio signal.

Use this object to generate a waveform containing RadioText Plus (RT+) information and register a custom encoding implementation for an Open Data Application (ODA). You can also specify the time, data, and the program type. The object supports short, scrolling 8-character text, and longer 32-character or 64-character text.

To generate baseband RDS/RBDS waveforms:

- 1 Create a `comm.RBDSWaveformGenerator` object and set the properties of the object.
- 2 Call `step` to generate the waveform.

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`rbdsngen = comm.RBDSWaveformGenerator` creates an RDS/RBDS waveform generator object, `rbdsngen`, using the default properties.

`rbdsngen = comm.RBDSWaveformGenerator(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

### Example:

```
rbdsngen = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame',20,'SamplesPerSymbol',10, ...
    'SendRadioTextPlus',true);
```

## Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

### **SamplesPerSymbol** — Number of samples per symbol

10 (default) | positive even integer

Number of samples per symbol (bit), specified as a positive even integer. Half of the samples represent one amplitude level of Manchester coding. The other half of the samples represent the opposite level.

**GroupsPerFrame — Number of groups per output frame**

10 (default) | scalar integer

Number of groups per output frame, specified as a scalar integer. Each group is 104 symbols (bits) long.

**RadioText — Long text conveyed with type 2A groups**

'Long text' (default) | character vector

Radio text conveyed with type 2A groups, specified as a character vector that is up to 64 characters long. The object transmits the specified text four characters at a time, using type 2A groups.

Tunable: Yes

**ProgramServiceName — Label of the program service**

'ShortTxt' (default) | character vector

Label of the program service, specified as a character vector that is up to eight characters long. This information is conveyed as a short text with type 0A groups, two characters at a time.

Tunable: Yes

**ProgramIdentificationCode — Program identification code**

[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0] (default) | 16-bit row vector

Program identification (PI) code, specified as a 16-bit row vector. In North America, the PI code conveys the call letters of the station. Example call letters include 'WABC' and 'KXYZ'.

To generate North American PI codes for a station's call letters, use the `callLettersToPICode` method.

**ProgramType — Program type**

'No program type or undefined' (default) | character vector

Program type, specified as a character vector containing one of the 31 values allowed by the RDS/RBDS standard. For a list of program types that the RDS/RBDS standard allows in North America, see [1].

Tunable: Yes

**ProgramTypeName — Program type name**

' ' (default) | character vector

Program type name, specified as a character vector that is up to eight characters long. This text further characterizes the program type, such as 'Football' for the program type 'Sports'. The object conveys the program type name using type 10A groups. If this property is empty, then no 10A groups are generated.

Tunable: Yes

**SendDateTime — Option to advertise date and time**

false (default) | true

Option to advertise the date and time, specified as either `false` or `true`. When you set this property to `true`, one 4A group is periodically generated every 685 groups (once a minute).

### AlternativeFrequencies — Alternative frequencies

`[]` (default) | row vector

Alternative frequencies, specified as a row vector in MHz. This information is conveyed with type 0A groups. It indicates other transmitters broadcasting the same program in the same or adjacent reception areas. With this information, receivers can switch to a different frequency with better reception.

### SendRadioTextPlus — Option to send RT+ information

`false` (default) | `true`

Option to transmit RadioText Plus (RT+) information, specified as a scalar logical. When you set this property to `true`, the RT+ ODA information is advertised with type 3A groups. In addition, the RT+ content types, specified in `RadioTextType1`, `RadioTextType2`, and the two RT+ substrings indexed by `RadioTextIndices` are conveyed with the open-format type 11A group.

### RadioTextType1 — Content type of first RT+ substring

`'Item.Artist'` (default) | character vector

Content type of the first RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

### RadioTextType2 — Content type of second RT+ substring

`'Item.Title'` (default) | character vector

Content type of the second RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

### RadioTextIndices — Start and end indices of RT+ substrings

`[1 2; 3 4]` (default) | 2-by-2 matrix of positive integers

Start and end indices of RT+ substrings, specified as a 2-by-2 matrix of positive integers. The first column indexes the beginning of each RT+ substring. The second column indexes the end of each substring.

Tunable: Yes

**Examples****Generate a Basic RBDS Waveform**

Generate a basic RBDS waveform, FM modulate the waveform with an audio signal, and then demodulate the waveform.

Each frame of the RBDS waveform contains 19 groups, with a group length of 104 bits (symbols) each. Set the number of samples per RBDS symbol to 10. Therefore, the number of samples in each frame of RBDS waveform is  $104 \times 10 \times 19 = 19,760$ . According to the RBDS standard, the bit rate is 1187.5 Hz. So, the RBDS sample rate =  $1187.5 \times$  samples per RBDS symbol. Set the audio frame rate to  $40 \times 1187.5 = 47,500$ .

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader( ...
    "rbds_capture_47500.wav", ...
    SamplesPerFrame=rbdsFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator( ...
    GroupsPerFrame=groupsPerFrame, ...
    SamplesPerSymbol=sps);

fmMod = comm.FMBroadcastModulator( ...
    AudioSampleRate=afr.SampleRate, ...
    SampleRate=outRate, ...
    Stereo=true, ...
    RBDS=true, ...
    RBDSsamplesPerSymbol=sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    SampleRate=outRate, ...
    Stereo=true, ...
    RBDS=true, ...
    PlaySound=true);
scope = timescope(SampleRate=outRate,YLimits=10^-2*[-1 1]);
```

Get the audio input and generate the RBDS waveform. FM modulate the stereo audio with the RBDS waveform, add noise, and FM demodulate the audio and RBDS waveforms. View the demodulated RBDS waveform in the time scope.

```
for idx = 1:7
    % Get current audio input
    input = afr();
    % Generate RBDS info at the same configured rate
    rbdsWave = rbds();
    % FM modulate stereo audio with RBDS info
```

```

yFM = fmMod( ...
    [input input], ...
    rbdswave);
% Add noise
rcv = awgn(yFM, 40);
% FM demodulate the audio and RBDS waveforms
[audioRcv, rbdswave] = fmDemod(rcv);
scope(rbdswave);
end
release(scope)

```

### Generate RBDS Waveform with RadioText Plus Information

Create a `comm.RBDSWaveformGenerator` System object™ with 20 groups per frame and 10 samples per symbol. Add the Radio Text plus (RT+) information, such as artist name and song, title, to the waveform. Indicate the start and end of the RT+ substrings by using the `RadioTextIndices` property.

```

rbdswave = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
    'SendRadioTextPlus', true);
rbdswave.RadioText = 'MyArtist - MySongTitle';
rbdswave.RadioTextType1 = 'Item.Artist';
rbdswave.RadioTextType2 = 'Item.Title';
rbdswave.RadioTextIndices = [1 8; 12 22];

```

```
for idx = 1:10
    rbds.step();
end
```

### Register a Custom Encoding Implementation

Register a custom encoding implementation for an Open Data Application (ODA) by using the `registerODA` method of the `comm.RBDSWaveformGenerator` System object™. Set the ODA ID to 'CD46', which is the ID for the traffic message channel. The allocated group type is 8A.

```
rbds = comm.RBDSWaveformGenerator();
odaID = 'CD46';
allocatedGroupType = '8A';
```

This example uses the following templates as a starting point for custom encoding implementation.

```
mainProcessingFcn = @CustomODAEncodingMain;
fcn3A             = @CustomODAEncoding3A;
registerODA(rbds,odaID,allocatedGroupType,mainProcessingFcn,fcn3A);
s = info(rbds);
s.ODAMap
```

```
ans=2×1 struct array with fields:
    ID
    GroupType
    FunctionMain
    Function3A
```

### Configure RBDS Waveforms with Date and Time Information

Generate RBDS waveform with date and time information, the program type, and alternative frequencies. The `comm.RBDSWaveformGenerator` object uses type 4A groups for date and time information, type 10A groups for the program type information, and type 0A groups for alternative frequencies. View the waveform in a spectrum analyzer.

```
rbds = comm.RBDSWaveformGenerator( ...
    GroupsPerFrame=1000);
sa = spectrumAnalyzer( ...
    SampleRate=1187.5*rbds.SamplesPerSymbol, ...
    YLimits=[-140 20]);
rbds.SendDateTime = true;           % send type 4A groups
rbds.ProgramType = "Sports";
rbds.ProgramTypeName = "Football"; % send type 10A groups
rbds.AlternativeFrequencies = ... % info sent in type 0A groups
    [99.1 102.5];
wave = rbds();
sa(wave)
release(sa)
```

## Algorithms

`comm.RBDSWaveformGenerator` generates waveforms according to the RDS/RBDS standard [1]. The RDS/RBDS standard consists of three layers: physical layer, data-link layer, and session and application layer.

### Physical Layer

The physical layer (first layer) converts the data-link bits to an analog waveform by conducting differential encoding and biphase symbol encoding (Manchester encoding) and pulse-shaping filtering.

### Data-Link Layer

The data-link layer (second layer) performs (26,16) cyclic encoding shortened from (341,331) encoding [1]. The second layer is responsible for error detection, error correction, and the establishment of group-level synchronization. Each group of RDS/RBDS frames contains four blocks of 26 bits (that is 104 bits) each. Each block contains an information word and a check word. Each information word contains 16 bits, and each check word contains 10 bits.

Here is the baseband coding structure for the RDS/RBDS waveform. For more details, see [1].

For each block, a unique offset word is modulo-2 added to the checkword bits. The added offset word provides a group and block synchronization system in the receiver (decoder). Because the addition of the offset is reversible in the decoder, the normal additive error-correcting and detecting properties of the basic code are unaffected.

### Session and Application Layer

The first block in every group contains a program identification (PI) code. The first four bits of the second block of every group are allocated to a four-bit code. This code specifies the application of the group. Groups are referred to as types 0-15 according to the binary weighting  $A_3 = 8, A_2 = 4, A_1 = 2, A_0 = 1$ . The fifth bit of the second block,  $B_0$ , defines the version of the application. If  $B_0 = 0$ , the version of the group is A. The PI code in this version is inserted into block 1 only. Example group types include 0A, 1A, 2A, 3A, and 4A.

The Program Type code and Traffic Program Identification (PI) occupy fixed locations in block 2 of every group.

### Group Types

Group Type	Group Type Code/Version					Description
	A <sub>3</sub>	A <sub>2</sub>	A <sub>1</sub>	A <sub>0</sub>	B <sub>0</sub>	
0A	0	0	0	0	0	Basic station information. Short, usually scrolling text, up to 8 characters long. Transmitted 2 characters at a time.
2A	0	0	1	0	0	Radio text. Long text, up to 64 characters long. Transmitted 4 characters at a time.
3A	0	0	1	1	0	Specification of used Open Data Applications and their allocation group type. Example: Radio Text Plus information is sent using 11A group.
4A	0	1	0	0	0	Date and time. Optional group that can be transmitted once in every 685 groups (once a minute).
10A	1	0	1	0	0	Program type name. Example: Football for ProgramType = 'Sports'.
11A	1	0	1	1	0	Open Data Applications. Example: RadioText Plus (RT+).

## Version History

Introduced in R2017a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

In addition, the following limitations apply when you generate code that contains this System object or when you use this object in a MATLAB function block.

- The group type 4A cannot be transmitted in the generated code.
- The registerODA method is not supported.
- The ProgramType property is not tunable.

# registerODA

**System object:** comm.RBDSWaveformGenerator

**Package:** comm

Register a custom encoding implementation for an ODA

## Syntax

```
registerODA(rbdsgen,odaID,group,handleMain,handle3A)
```

## Description

`registerODA(rbdsgen,odaID,group,handleMain,handle3A)` associates the Open Data Application (ODA) specified by the hexadecimal ID `odaID`, with the type `group` groups generated by `rbdsgen`. The four 16-bit information words of these groups are generated by the function `handleMain`. The third information word of type 3A groups, which is ODA-specific, is generated by the function `handle3A`.

## step

**System object:** `comm.RBDSWaveformGenerator`

**Package:** `comm`

Generate RDS/RBDS waveform

### Syntax

```
y = step(rbdsgen)
```

### Description

---

**Note** Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

`y = step(rbdsgen)` outputs a frame of the baseband RDS/RBDS waveform in column vector `y`. The waveform contains the number of 104-bit groups, specified in the `GroupsPerFrame` property of the object. Each symbol is oversampled according to the `SamplesPerSymbol` property. Thus, the output length is `SamplesPerSymbol × 104 × GroupsPerFrame` samples. The object uses an internal scheduler to determine the order and frequency of the transmitted group types.

---

**Note** `rbdsgen` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

# comm.RectangularQAMDemodulator

**Package:** comm

(To be removed) Demodulate using rectangular QAM signal constellation

---

**Note** `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `RectangularQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM demodulator object. See “Construction” on page 3-1171.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMDemodulator(Name, Value)` creates a rectangular QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMDemodulator(M, Name, Value)` creates a rectangular QAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value with a positive, integer power of two. The default is 16.

### **PhaseOffset**

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

### **BitOutput**

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to `true` the `step` method outputs a column vector of bit values whose length equals  $\log_2(\text{ModulationOrder on page 3-0})$  times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and `ModulationOrder-1`. The default is `false`.

### **SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of  $\log_2(\text{ModulationOrder on page 3-0})$  bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping on page 3-0` property.

### **CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder on page 3-0` and with unique integer values in the range `[0, ModulationOrder-1]`. The values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping on page 3-0` property to `Custom`.

### **NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

### **MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Minimum distance between symbols`.

### **AveragePower**

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

### **PeakPower**

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

### **DecisionMethod**

Demodulation decision method

Specify the decision method the object uses as `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 3-0 property to `false` the object always performs hard-decision demodulation. This property applies when you set the `BitOutput` property to `true`.

### **VarianceSource**

Source of noise variance

Specify the source of the noise variance as `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 3-0 property to `true` and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

### **Variance**

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `BitOutput` on page 3-0 property to `true`, the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` on page 3-0 property to `Property`. This property is tunable.

## **OutputDataType**

Data type of output

Specify the output data type as `Full precision | Smallest unsigned integer | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32`. The default is `Full precision`.

This property applies only when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`. In this case, when the `OutputDataType` on page 3-0 property is set to `Full precision`, and the input data type is single- or double-precision, the output data has the same data type as the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Hard Decision`, then logical data type becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data type is the same as that of the input. In this case, that data type can only be single- or double-precision.

## **Fixed-Point Properties**

### **FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-1176.

### **DerotateFactorDataType**

Data type of derotate factor

Specify the derotate factor data type as `Same word length as input | Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 3-0 property to `false`, or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`. The object uses the derotate factor in the computations only when the step method input is of a fixed-point type and the `PhaseOffset` on page 3-0 property has a value that is not a multiple of  $\pi/2$ .

### **CustomDerotateFactorDataType**

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `DerotateFactorDataType` on page 3-0 property to `Custom`.

### **DenormalizationFactorDataType**

Data type of denormalization factor

Specify the denormalization factor data type as `Same word length as input | Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`.

### **CustomDenormalizationFactorDataType**

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 3-0 property to `Custom`.

### **ProductDataType**

Data type of product

Specify the product data type as `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`.

### **CustomProductDataType**

Fixed-point data type of product

Specify the product fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32)`. This property applies when you set the `ProductDataType` on page 3-0 property to `Custom`.

### **ProductRoundingMethod**

Rounding of fixed-point numeric value of product

Specify the product rounding method as `Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`.

### ProductOverflowAction

Action when fixed-point numeric value of product overflows

Specify the product overflow action as `Wrap | Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard` decision.

### SumDataType

Data type of sum

Specify the sum data type as `Full precision | Same as product | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false`, when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard` decision.

### CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an `unscaled numerictype` object with a signedness of `Auto`. The default is `numerictype ([ ], 32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false` or when you set the `SumDataType` on page 3-0 property to `Custom`.

## Methods

- `constellation` (To be removed) Calculate or plot ideal signal constellation
- `step` (To be removed) Demodulate using rectangular QAM method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## More About

### Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer

apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

## Version History

### Introduced in R2012a

**R2018b: `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.**

*Not recommended starting in R2018b*

Constellation normalization by `PeakPower` and `AveragePower` (other than unit average power) as supported by `comm.RectangularQAMModulator` and `comm.RectangularQAMDemodulator` is not inherently provided by functions. To perform peak power and average power normalization using `qammod` and `qamdemod` functions, you can use these utility functions to scale symbols from peak or average power normalization to minimum distance normalization.

```
function minD = pkPow2MinD(pkPow,M)
% Peak power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = 0.5*M - sqrt(M) + 0.5;
    else
        % Cross QAM
        mBy32 = M/32;
        if (nBits > 4)
            sf = (13 * mBy32) - (5 * sqrt(mBy32)) + 0.5;
        else
            sf = (20 * mBy32) - (6 * sqrt(mBy32)) + 0.5;
        end
    end
    minD = sqrt(pkPow/sf);
end

function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = (M - 1)/6;
    else
        % Cross QAM
        if (nBits > 4)
            sf = ((31 * M / 32) - 1) / 6;
        else
            sf = ((5 * M / 4) - 1) / 6;
        end
    end
end
```

```

    minD = sqrt(avgPow/sf);
end

```

### Peak Power Normalization for Hard Decision

This example compares computation of peak power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `pkPow2MinD` utility function.

```

% QAM alternative for "Peak power" normalization method for
% hard decision output when using functions.
M = 128;
pkPow = 5;
minD = pkPow2MinD(pkPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]);
constellationFcn = qammod([0:M-1],M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))

maxConstellationErr =
    0

```

```

Check 2 - Modulate and demodulate symbols using the System objects.
x = randi([0,M-1],100,1);
y1 = modObj(x);
z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)

objModDemodOutputIsEqual =
    logical
    1

```

```

% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)

```

```

objModFcnDemodIsEqual =
    logical
    1

```

```

% Check 4 - Demodulate the qammod output using the
% demodulator System object.
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)

```

```

fcnModObjDemodIsEqual =
    logical
    1

```

### Average Power Normalization for Hard Decision

This example compares computation of average power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `avgPow2MinD` utility function..

```

% QAM alternative for "Average power" normalization method for
% hard decision output when using functions.

```

```

M = 64;          % Modulation order
avgPow = 100;   % Average constellation power

minD = avgPow2MinD(avgPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))

maxConstellationErr =
    0

Check 2 - Modulate and demodulate symbols using the System objects.
x = randi([0,M-1],100,1);
y1 = modObj(x);
z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)

objModDemodOutputIsEqual =
    logical
     1

% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)

objModFcnDemodIsEqual =
    logical
     1

% Check 4 - Demodulate the qammod output using the
% demodulator System object.
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)

fcnModObjDemodIsEqual =
    logical
     1

```

### Peak Power Normalization for Approximate LLR

Output shown here compares computation of peak power normalization for approximate LLR by using the qammod and qamdemod functions and the pkPow2MinD utility function.

```

% QAM alternative for "Peak power" normalization method for
% Approximate LLR output when using functions.

```

```

%
% Modulation order must be supported by QAM modulator-demodulator.
M = 256; % Modulation order

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## **See Also**

### **Functions**

qamdemod | genqamdemod

### **Objects**

comm.GeneralQAMDemodulator

# constellation

**System object:** `comm.RectangularQAMDemodulator`

**Package:** `comm`

(To be removed) Calculate or plot ideal signal constellation

---

**Note** `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

---

## Syntax

```
y = constellation(h)  
constellation(h)
```

## Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## step

**System object:** `comm.RectangularQAMDemodulator`

**Package:** `comm`

(To be removed) Demodulate using rectangular QAM method

---

**Note** `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

---

### Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates the input data, `X`, with the rectangular QAM demodulator System object, `H`, and returns, `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When `ModulationOrder` is an even power of two and you set the `BitOutput` property to `false` or, when you set the `DecisionMethod` to `Hard decision` and the `BitOutput` property to `true`, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.RectangularQAMModulator

**Package:** comm

(To be removed) Modulate using rectangular QAM signal constellation

---

**Note** `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `RectangularQAMModulator` object modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM modulator object. See “Construction” on page 3-1187.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMModulator` creates a modulator object, `H`. This object modulates the input using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMModulator(Name, Value)` creates a rectangular QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMModulator(M, Name, Value)` creates a rectangular QAM modulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

## Properties

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value that is a positive integer power of two. The default is 16.

**PhaseOffset**

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

**BitInput**

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input requires a column vector of bit values. The length of this vector must be an integer multiple of `log2(ModulationOrder on page 3-0)`. This vector contains bit representations of integers between 0 and `ModulationOrder-1`. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and `ModulationOrder-1`.

**SymbolMapping**

Constellation encoding

Specify how the object maps an integer or group of `log2(ModulationOrder on page 3-0)` input bits to the corresponding symbol as `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the System object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping on page 3-0` property.

**CustomSymbolMapping**

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder on page 3-0`. This vector has unique integer values in the range `[0, ModulationOrder-1]`. These values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping on page 3-0` property to `Custom`.

**NormalizationMethod**

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

**MinimumDistance**

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Minimum distance between symbols`.

### AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

### PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

### OutputDataType

Data type of output

Specify the output data type as `double` | `single` | `Custom`. The default is `double`.

### Fixed-Point Properties

#### CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

## Methods

`constellation` (To be removed) Calculate or plot ideal signal constellation  
`step` (To be removed) Modulate using rectangular QAM method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

**R2018b: `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.**

*Not recommended starting in R2018b*

Constellation normalization by `PeakPower` and `AveragePower` (other than unit average power) as supported by `comm.RectangularQAMModulator` and `comm.RectangularQAMDemodulator` is not inherently provided by functions. To perform peak power and average power normalization using `qammod` and `qamdemod` functions, you can use these utility functions to scale symbols from peak or average power normalization to minimum distance normalization.

```
function minD = pkPow2MinD(pkPow,M)
% Peak power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
    % Square QAM
    sf = 0.5*M - sqrt(M) + 0.5;
else
    % Cross QAM
    mBy32 = M/32;
    if (nBits > 4)
        sf = (13 * mBy32) - (5 * sqrt(mBy32)) + 0.5;
    else
        sf = (20 * mBy32) - (6 * sqrt(mBy32)) + 0.5;
    end
end
minD = sqrt(pkPow/sf);
end
```

```
function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
    % Square QAM
    sf = (M - 1)/6;
else
    % Cross QAM
    if (nBits > 4)
        sf = ((31 * M / 32) - 1) / 6;
    else
        sf = ((5 * M / 4) - 1) / 6;
    end
end
minD = sqrt(avgPow/sf);
end
```

## Peak Power Normalization for Hard Decision

This example compares computation of peak power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `pkPow2MinD` utility function.

```
% QAM alternative for "Peak power" normalization method for
% hard decision output when using functions.
M = 128;
pkPow = 5;
minD = pkPow2MinD(pkPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))
```

```
maxConstellationErr =
    0
```

```
Check 2 - Modulate and demodulate symbols using the System objects.
x = randi([0,M-1],100,1);
y1 = modObj(x);
z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)
```

```
objModDemodOutputIsEqual =
    logical
     1
```

```
% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)
```

```
objModFcnDemodIsEqual =
    logical
     1
```

```
% Check 4 - Demodulate the qammod output using the
% demodulator System object.
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)
```

```
fcnModObjDemodIsEqual =
    logical
     1
```

## Average Power Normalization for Hard Decision

This example compares computation of average power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `avgPow2MinD` utility function..

```
% QAM alternative for "Average power" normalization method for
% hard decision output when using functions.
M = 64;           % Modulation order
avgPow = 100;    % Average constellation power
```

```

minD = avgPow2MinD(avgPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))

maxConstellationErr =
    0

Check 2 - Modulate and demodulate symbols using the System objects.
x = randi([0,M-1],100,1);
y1 = modObj(x);
z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)

objModDemodOutputIsEqual =
    logical
     1

% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)

objModFcnDemodIsEqual =
    logical
     1

% Check 4 - Demodulate the qammod output using the
% demodulator System object.
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)

fcnModObjDemodIsEqual =
    logical
     1

```

### Peak Power Normalization for Approximate LLR

Output shown here compares computation of peak power normalization for approximate LLR by using the qammod and qamdemod functions and the pkPow2MinD utility function.

```

% QAM alternative for "Peak power" normalization method for
% Approximate LLR output when using functions.
%
% Modulation order must be supported by QAM modulator-demodulator.
M = 256;      % Modulation order

```

```

### Functions

qammod | genqammod

**Objects**

comm.GeneralQAMModulator

## constellation

**System object:** `comm.RectangularQAMModulator`

**Package:** `comm`

(To be removed) Calculate or plot ideal signal constellation

---

**Note** `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

---

### Syntax

```
y = constellation(h)  
constellation(h)
```

### Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

## step

**System object:** `comm.RectangularQAMModulator`

**Package:** `comm`

(To be removed) Modulate using rectangular QAM method

---

**Note** `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

---

### Syntax

`Y = step(H,X)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` modulates input data, `X`, with the rectangular QAM modulator object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

# comm.RectangularQAMTCMDemodulator

**Package:** comm

Demodulate convolutionally encoded data mapped to rectangular QAM signal constellation

## Description

The `RectangularQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a rectangular QAM signal constellation.

To demodulate convolutionally encoded data mapped to a rectangular QAM signal constellation:

- 1 Define and set up your rectangular QAM TCM demodulator object. See “Construction” on page 3-1200.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMTCMDemodulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMDemodulator(Name, Value)` creates a rectangular, QAM TCM, demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMTCMDemodulator(TRELLIS, Name, Value)` creates a rectangular QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [5 2 0 0; 0 0 1 0; 0 0 0 1])`.

## TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, you should use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

## TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`× $K$  zero bits for a rate  $K/N$  convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

## ResetInputPort

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` property to `Continuous`.

## ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, 16, 32, or 64. The default is 16. The `ModulationOrder` property value must equal the number of possible input symbols to the convolutional decoder of the rectangular QAM TCM demodulator object. The `ModulationOrder` must equal  $2^N$  for a rate  $K/N$  convolutional code.

## OutputDataType

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

## Methods

`step` Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

## Examples

### Modulate and Demodulate Using Rectangular 16-QAM TCM

Modulate and demodulate data using 16-QAM TCM in an AWGN channel. Estimate the BER.

Create QAM TCM modulator and demodulator System objects.

```
rqamtcmod = comm.RectangularQAMTCModulator;
rqamtcdemod = comm.RectangularQAMTCMDemodulator(TracebackDepth=16);
```

Create an AWGN channel object.

```
awgnchan = comm.AWGNChannel(EbNo=5);
```

Determine the delay through the QAM TCM demodulator. The demodulator uses the Viterbi algorithm to decode the TCM signal that was modulated using rectangular QAM. The error rate calculation must align the received samples with the transmitted sample to accurately calculate the bit error rate. Calculate the delay in the system with the number of bits per symbol and the decoder traceback depth in the TCM demodulator.

```
bitsPerSymbol = log2(rqamtcdemod.TrellisStructure.numInputSymbols);
delay = rqamtcdemod.TracebackDepth*bitsPerSymbol;
```

Create an error rate calculator object with the `ReceiveDelay` property set to `delay`.

```
errRate = comm.ErrorRate(ReceiveDelay=delay);
```

Generate binary data and modulate with 16-QAM TCM. Pass the signal through an AWGN channel and demodulate. Calculate the error statistics. The loop runs until either 100 bit errors are encountered or  $1e7$  total bits are transmitted.

```
% Initialize the error results vector.
errStats = [0 0 0];

while errStats(2) < 100 && errStats(3) < 1e7
    % Transmit frames of 200 3-bit symbols
    txData = randi([0 1],600,1);
    % Modulate
    txSig = rqamtcmod(txData);
    % Pass through AWGN channel
```

```
rxSig = awgnchan(txSig);  
% Demodulate  
rxData = rqamtcodemod(rxSig);  
% Collect error statistics  
errStats = errRate(txData,rxData);  
end
```

Display the error data.

```
fprintf('Error rate = %4.2e\nNumber of errors = %d\n', ...  
    errStats(1),errStats(2))
```

```
Error rate = 1.94e-03  
Number of errors = 100
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Decoder block reference page. The object properties correspond to the block parameters.

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` demodulates the rectangular QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. `X` must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector, `Y`. When the convolutional encoder represents a rate  $K/N$  code, the length of the output vector is  $K*L$ , where  $L$  is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder to the all-zeros state when you input a reset signal, `R` that is non-zero. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.RectangularQAMTCMModulator

**Package:** comm

Convolutionally encode binary data and map using rectangular QAM signal constellation

## Description

The `RectangularQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a rectangular QAM signal constellation.

To convolutionally encode binary data and map the result using a rectangular QAM constellation:

- 1 Define and set up your rectangular QAM TCM modulator object. See “Construction” on page 3-1205.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`H = comm.RectangularQAMTCMModulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) System object, `H`. This object convolutionally encodes a binary input signal and maps the result to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMModulator(Name,Value)` creates a rectangular QAM TCM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.RectangularQAMTCMModulator(TRELLIS,Name,Value)` creates a rectangular QAM TCM modulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

## Properties

### TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1],[ 5 2 0 0; 0 0 1 0; 0 0 0 1])`.

### TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate  $K/N$  code, the `step` method outputs the vector with a length given by  $y = N \times (L + S)/K$ , where  $S = \text{constraintLength}-1$  (or, in the case of multiple constraint lengths,  $S = \text{sum}(\text{constraintLength}(i)-1)$ ).  $L$  is the length of the input to the `step` method.

### ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When you set the reset input to the `step` method to a nonzero value, the object resets the encoder to the all-zeros state. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

### ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, 16, 32, or 64. The default is 16. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the QAM TCM modulator. Thus, the value for the `ModulationOrder` property must equal  $2^N$  for a rate  $K/N$  convolutional code.

### OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

### Methods

`step` Convolutionally encode binary data and map using rectangular QAM constellation

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

## Examples

### Modulate Data Using Rectangular QAM TCM

Modulate data using rectangular 16-QAM TCM modulation and display the scatter plot.

Generate random binary data. The length of the data vector must be an integer multiple of the number of input streams into the encoder,  $\log_2(8) = 3$ .

```
data = randi([0 1],3000,1);
```

Create a modulator System object™ and use its step function to modulate the data.

```
hMod = comm.RectangularQAMTCMModulator;
modData = step(hMod,data);
```

Plot the modulated data.

```
scatterplot(modData)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Encoder block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**System object:** `comm.RectangularQAMTCMModulator`

**Package:** `comm`

Convolutionally encode binary data and map using rectangular QAM constellation

### Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(H,X)` convolutionally encodes and modulates the input data numeric or logical column vector `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate  $K/N$  code, the length of the input vector, `X`, must be  $K \times L$ , for some positive integer  $L$ . The `step` method outputs a complex column vector, `Y`, of length  $L$ .

`Y = step(H,X,R)` resets the encoder of the rectangular QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.RicianChannel

**Package:** comm

Filter input signal through multipath Rician fading channel

### Description

The `comm.RicianChannel` System object filters an input signal through a multipath Rician fading channel. For more information on fading model processing, see the Methodology for Simulating Multipath Fading Channels section.

To filter an input signal through a multipath Rician fading channel:

- 1 Create the `comm.RicianChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

### Creation

#### Syntax

```
ricianchan = comm.RicianChannel  
ricianchan = comm.RicianChannel(Name,Value)
```

#### Description

`ricianchan = comm.RicianChannel` creates a frequency-selective or frequency-flat multipath Rician fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain a channel-impaired signal.

`ricianchan = comm.RicianChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',2` sets the input signal sample rate to 2.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

#### SampleRate — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: `double`

### **PathDelays — Discrete path delay**

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the channel is frequency flat.
- When you set `PathDelays` to a vector, the channel is frequency selective.

The `PathDelays` and `AveragePathGains` properties must be the same length.

Data Types: `double`

### **AveragePathGains — Average gains of discrete paths**

0 (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. The `AveragePathGains` and `PathDelays` properties must be the same length.

Data Types: `double`

### **NormalizePathGains — Normalize average path gains**

`true` or 1 (default) | `false` or 0

Normalize average path gains, specified as one of these logical values:

- 1 (`true`) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (`false`) — The total power of the path gains is not normalized.

The `AveragePathGains` property specifies the average powers of the path gains.

Data Types: `logical`

### **KFactor — K-factor of Rician fading channel**

3 (default) | positive scalar | 1-by- $N_p$  vector of nonnegative values

K-factor of Rician fading channel, specified as a positive scalar or a 1-by- $N_p$  vector of nonnegative values.  $N_p$  is the number of discrete path delays specified by the `PathDelays` property.

- When you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- When you set `KFactor` to a vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the `KFactor` vector are Rayleigh fading processes. At least one element must be nonzero.

Data Types: `double`

### **DirectPathDopplerShift — Doppler shifts for line-of-sight components**

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in hertz. This property must be the same size as the `KFactor` property.

- When you set `DirectPathDopplerShift` to a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathDopplerShift` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathDopplerShift` specifies the line-of-sight component for the Doppler shift of that discrete path.

Data Types: double

### **DirectPathInitialPhase — Initial phases for line-of-sight components**

0 (default) | scalar | row vector

Initial phase for the line-of-sight components of a multipath Rician fading channel, specified as a scalar or row vector. Units are in radians. This property must be the same size as the `KFactor` property.

- When you set `DirectPathInitialPhase` to a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathInitialPhase` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathInitialPhase` specifies the line-of-sight component initial phase of that discrete path.

Data Types: double

### **MaximumDopplerShift — Maximum Doppler shift for all channel paths**

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than  $\text{SampleRate}/10/f_c$  for each path.  $f_c$  is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of  $f_c$  is 1. For Gaussian and bi-Gaussian Doppler spectrum types, the value of  $f_c$  is dependent on the Doppler spectrum structure fields. For more details about how  $f_c$  is defined, see the “Cutoff Frequency Factor” on page 3-1227 section.

Data Types: double

### **DopplerSpectrum — Doppler spectrum shape for all channel paths**

`doppler('Jakes')` (default) | Doppler spectrum structure | 1-by- $N_p$  cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- $N_p$  cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the

form returned from the `doppler` function.  $N_p$  is the number of discrete delay paths specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum.

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `specType` input to the `doppler` function. If you set the `FadingTechnique` property to 'Sum of sinusoids', you must set `DopplerSpectrum` to `doppler('Jakes')`.

#### Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: `struct` | `cell`

#### ChannelFiltering — Channel filtering

`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

#### PathGainsOutputPort — Output channel path gains

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

#### Dependencies

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

#### NumSamples — Number of samples

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

**Tunable:** Yes

#### Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

**OutputDataType — Path gain output data type**`'double' (default) | 'single'`

Path gain output data type, specified as `'double'` or `'single'`.

**Dependencies**

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

**FadingTechnique — Channel model fading technique**`'Filtered Gaussian noise' (default) | 'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char` | `string`

**NumSinusoids — Number of sinusoids**`48 (default) | positive integer`

Number of sinusoids used to model the fading process, specified as a positive integer.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `double`

**InitialTimeSource — Source to control start time of fading process**`'Property' (default) | 'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- When you set `InitialTimeSource` to `'Property'`, set the initial time offset by using the `InitialTime` property.
- When you set `InitialTimeSource` to `'Input port'`, specify the start time of the fading process by using the `inittime` input argument. The input value can change in consecutive calls to the object.

**Dependencies**

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `char` | `string`

**InitialTime — Initial time offset**`0 (default) | nonnegative scalar`

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When `mod(InitialTime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

**Dependencies**

To enable this property, set the `FadingTechnique` property to 'Sum of sinusoids' and the `InitialTimeSource` property to 'Property'.

Data Types: double

**RandomStream — Source of random number stream**

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- When you specify 'Global stream', the object uses the current global random number stream for random number generation. In this case, the `reset` object function resets only the filters.
- When you specify 'mt19937ar with seed', the object uses the mt19937ar algorithm for random number generation. In this case, the `reset` object function resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: char | string

**Seed — Initial seed of mt19937ar random number stream**

73 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When you call the `reset` object function, it reinitializes the mt19937ar random number stream to the `Seed` value.

**Dependencies**

To enable this property, set the `RandomStream` property to 'mt19937ar with seed'.

Data Types: double

**Visualization — Channel visualization**

'Off' (default) | 'Impulse response' | 'Frequency response' | 'Impulse and frequency responses' | 'Doppler spectrum'

Channel visualization, specified as 'Off', 'Impulse response', 'Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. For more information, see the Channel Visualization topic.

**Dependencies**

To enable this property, set the `FadingTechnique` property to 'Filtered Gaussian noise'.

Data Types: char | string

**PathsForDopplerDisplay — Path used for displaying Doppler spectrum**

1 (default) | positive integer

Path used for displaying the Doppler spectrum, specified as a positive integer in the range  $[1, N_P]$ .  $N_P$  is the number of discrete delay paths specified by the `PathDelays` property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

**Dependencies**

To enable this property, set the `Visualization` property to `'Doppler spectrum'`.

Data Types: `double`

**SamplesToDisplay — Percentage of samples to display**

`'25%'` (default) | `'10%'` | `'50%'` | `'100%'`

Percentage of samples to display, specified as `'25%'`, `'10%'`, `'50%'`, or `'100%'`. Increasing the percentage improves display accuracy at the expense of simulation speed.

**Dependencies**

To enable this property, set the `Visualization` property to `'Impulse response'`, `'Frequency response'`, or `'Impulse and frequency responses'`.

Data Types: `char` | `string`

**Usage****Syntax**

```
y = ricianchan(x)
y = ricianchan(x, inittime)
[y, pathgains] = ricianchan( ___ )
```

```
pathgains = ricianchan()
pathgains = ricianchan(inittime)
```

**Description**

`y = ricianchan(x)` filters input signal `x` through a multipath Rician fading channel and returns the result in `y`.

To enable this syntax, set the `ChannelFiltering` property to `true`.

`y = ricianchan(x, inittime)` specifies a start time for the fading process.

To enable this syntax, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

`[y, pathgains] = ricianchan( ___ )` also returns the channel path gains of the underlying multipath Rician fading process in `pathgains` using any of the input argument combinations in the previous syntaxes.

To enable this syntax, set the `PathGainsOutputPort` property to `true`.

`pathgains = ricianchan()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `ChannelFiltering` property to `false`.

`pathgains = ricianchan(inittime)` returns the channel path gains of the underlying fading process beginning at the specified initial time. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `FadingTechnique` property to `'Sum of sinusoids'`, the `InitialTimeSource` property to `'Input port'`, and the `ChannelFiltering` property to `false`.

## Input Arguments

### **x** — Input signal

$N_S$ -by-1 vector

Input signal, specified as an  $N_S$ -by-1 vector, where  $N_S$  is the number of samples.

Data Types: `single` | `double`

Complex Number Support: Yes

### **inittime** — Initial time offset

0 | nonnegative scalar

Initial time offset in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: `single` | `double`

## Output Arguments

### **y** — Output signal

$N_S$ -by-1 vector

Output signal, returned as an  $N_S$ -by-1 vector of complex values with the same data precision as input signal `x`.  $N_S$  is the number of samples.

### **pathgains** — Output path gains

$N_S$ -by- $N_P$  matrix

Output path gains, returned as an  $N_S$ -by- $N_P$  matrix.  $N_S$  is the number of samples.  $N_P$  is the number of discrete delay paths specified by the `PathDelays` property. `pathgains` contains complex values.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `comm.RicianChannel`

`info` Characteristic information about fading channel object

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Produce Same Rician Channel Outputs Using Two Random Number Generation Methods

Produce the same multipath Rician fading channel response by using two different methods for random number generation. The multipath Rician fading channel System object includes two methods for random number generation. You can use the current global stream or the `mt19937ar` algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from the two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;  
insig = randi([0,pskModulator.ModulationOrder-1],1024,1);  
channelInput = pskModulator(insig);
```

Create a multipath Rician fading channel System object, specifying the random number generation method as the `my19937ar` algorithm and the random number seed as 73.

```
ricianchan = comm.RicianChannel( ...  
    'SampleRate',1e6, ...  
    'PathDelays',[0.0 0.5 1.2]*1e-6, ...  
    'AveragePathGains',[0.1 0.5 0.2], ...  
    'KFactor',2.8, ...  
    'DirectPathDopplerShift',5.0, ...  
    'DirectPathInitialPhase',0.5, ...  
    'MaximumDopplerShift',50, ...  
    'DopplerSpectrum',doppler('Bell', 8), ...  
    'RandomStream','mt19937ar with seed', ...  
    'Seed',73, ...  
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rician fading channel System object.

```
[RicianChanOut1,RicianPathGains1] = ricianchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(ricianchan);  
ricianchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that you specified when creating the multipath Rician fading channel System object.

```
rng(73)
```

Filter the modulated data by using the multipath Rician fading channel System object again.

```
[RicianChanOut2,RicianPathGains2] = ricianchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(RicianChanOut1,RicianChanOut2)
```

```
ans = logical
      1
```

```
isequal(RicianPathGains1,RicianPathGains2)
```

```
ans = logical
      1
```

### Display Impulse and Frequency Responses of Multipath Rician Fading Channel

Display the impulse and frequency responses of a frequency-selective multipath Rician fading channel that is configured to disable channel filtering.

Define simulation variables. Specify path delays and gains by using the ITU pedestrian B channel configuration.

```
fs = 3.84e6; % Sample rate in Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % in seconds
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
kfact = 10; % Rician K-factor
fD = 50; % Max Doppler shift in Hz
```

Create a multipath Rician fading channel System object to visualize the impulse response and frequency response plots.

```
ricianChan = comm.RicianChannel( ...
    SampleRate=fs, ...
    PathDelays=pathDelays, ...
    AveragePathGains=avgPathGains, ...
    KFactor=kfact, ...
    MaximumDopplerShift=fD, ...
    ChannelFiltering=false, ...
    Visualization='Impulse and frequency responses');
```

Visualize the channel response by running the multipath Rician fading channel System object with no input signal. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
ricianChan();
```

### Model Rician Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using multipath Rician fading channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000;           % Sample rate in Hz
pathDelays = [0 2.5e-3]; % In seconds
pathPower = [0 -6]; % In dB
fD = 5;             % Maximum Doppler shift in Hz
ns = 1000;         % Number of samples
nsdel = 100;       % Number of samples for delayed paths
```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response that starts at time 0 and three 100-sample channel responses that start at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.5;
to3 = 0.8;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a frequency-flat multipath Rician fading System object, specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, disabled channel filtering, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
ricianchan1 = comm.RicianChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the multipath Rician fading channel System object. Set the number of samples for the delayed paths. Set the source for the initial time so that you can specify the fading channel offset time as an input argument when using the System object.

```
ricianchan2 = clone(ricianchan1);
ricianchan2.InitialTimeSource = 'Input port';
ricianchan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `ricianchan1` object and for the discontinuous delayed channel responses by using the `ricianchan2` object with the initial time offsets provided as input arguments.

```
pg0 = ricianchan1();
pg1 = ricianchan2(to1);
pg2 = ricianchan2(to2);
pg3 = ricianchan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` object function. The `ricianchan1` object processed 1000 samples, while the `ricianchan2` object processed only 300 samples.

```
G = info(ricianchan1);
H = info(ricianchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
```

```
1000      300
```

Convert the path gains into decibels.

```
pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. Because the channel characteristics are maintained even when data is not transmitted, the alignment of the two plots shows that the sum-of-sinusoids technique is suited to the simulation of packetized data.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (s)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```

### Reproduce Multipath Rician Fading Channel Response

Reproduce the multipath Rician fading channel output by using the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RicianChannel` System object.

Create a multipath Rician fading channel System object, defining two paths. Generate data to pass through the channel.

```
ricianchan = comm.RicianChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1e-3], ...
    'AveragePathGains',[0 -2], ...
    'PathGainsOutputPort',true)

ricianchan =
    comm.RicianChannel with properties:

        SampleRate: 1000
        PathDelays: [0 1.0000e-03]
        AveragePathGains: [0 -2]
        NormalizePathGains: true
        KFactor: 3
        DirectPathDopplerShift: 0
        DirectPathInitialPhase: 0
        MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
        ChannelFiltering: true
        PathGainsOutputPort: true
```

Show all properties

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the `ChannelFilterCoefficients` property value to the variable `coeff`.

```
[chanout1,pg] = ricianchan(data);
chaninfo = info(ricianchan)

chaninfo = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x2 double]
    NumSamplesProcessed: 600
```

```
coeff = chaninfo.ChannelFilterCoefficients;
```

Calculate the fractional delayed input signal at the path delay locations stored in `coeff`.

```
Np = length(ricianchan.PathDelays);
fracdelaydata = zeros(size(data,1),Np);
for ii = 1:Np
    fracdelaydata(:,ii) = filter(coeff(ii,:),1,data);
end
```

Apply the path gains and sum the results for all paths.

```
chanout2 = sum(pg .* fracdelaydata,2);
```

Compare the output of the multipath Rician fading channel System object to the output reproduced using the path gains and the ChannelFilterCoefficients property of the multipath Rician fading channel System object.

```
isequal(chanout1,chanout2)
```

```
ans = logical
     1
```

### Compare PDF of Empirical and Theoretical Rician Channel

Compute and plot the empirical and theoretical probability density function (PDF) for a Rician channel with one path.

Initialize parameters and create a Rician channel System object that does not apply channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;
KFactor = -3; % In dB
KFactorLin = 10.^(KFactor/10); % Linear units
```

```
chan = comm.RicianChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'KFactor',KFactorLin, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical PDF for the Rician channel, by using the `fitdist` (Statistics and Machine Learning Toolbox) and `pdf` (Statistics and Machine Learning Toolbox) functions.

```
figure;
hold on;

% Empirical PDF plot
gain = chan();
pd = fitdist(abs(gain),'Kernel','BandWidth',.01);
r = 0:.1:3;
y = pdf(pd,r);
plot(r,y)

% Theoretical PDF plot
s = sqrt(KFactorLin)/sqrt(KFactorLin+1);
sigma = sqrt(1/2)/sqrt(KFactorLin+1);
exp_pdf_amplitude = pdf('Rician',r,s,sigma);
plot(r,exp_pdf_amplitude)
legend('Empirical','Theoretical')
title('Empirical and Theoretical PDF Curves')
```

### Compare CDF of Empirical and Theoretical Rician Channel

Compute and plot the empirical and theoretical cumulative distribution function (CDF) for a Rician channel with one path.

Initialize parameters and create a Rician channel System object that does not perform channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;
KFactor = -3; % In dB
KFactorLin = 10.^(KFactor/10); % Linear units
```

```
chan = comm.RicianChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'KFactor',KFactorLin, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical CDF for the Rician channel by using the `ecdf` (Statistics and Machine Learning Toolbox) and `cdf` (Statistics and Machine Learning Toolbox) functions. Compute the empirical CDF by using the path gains.

```
% Empirical CDF plot
g = chan();
ecdf(abs(g));
hold on;

% Theoretical CDF plot
r = 0:.1:3;
s = sqrt(KFactorLin)/sqrt(KFactorLin+1);
sigma = sqrt(1/2)/sqrt(KFactorLin+1);
exp_cdf_amplitude = cdf('Rician',r,s,sigma);
plot(r,exp_cdf_amplitude)
legend('Emp','Theor')
title('Empirical and Theoretical CDF Curves')
```

## More About

### Cutoff Frequency Factor

The cutoff frequency factor,  $f_c$ , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian,  $f_c$  equals 1.

- For a doppler('Gaussian') spectrum type,  $f_c$  equals  $\text{NormalizedStandardDeviation} \times \sqrt{2\log 2}$ .
- For a doppler('BiGaussian') spectrum type:
  - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$ .
  - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(2) \times \sqrt{2\log 2}$ .
  - If the NormalizedCenterFrequencies field value is [0, 0] and the NormalizedStandardDeviation field has two identical elements, then  $f_c$  equals  $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$ .
  - In all other cases,  $f_c$  equals 1.

## Version History

Introduced in R2013b

### R2022b: Updates to channel visualization display

The channel visualization feature now presents:

- Configuration settings in the bottom toolbar on the plot window.
- Plots side-by-side in one window when you select the Impulse and frequency response channel visualization option.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when you set the `Visualization` property to 'Off'.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## comm.RSDecoder

**Package:** comm

Decode data using Reed-Solomon decoder

### Description

The `RSDecoder` object recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the property values for this object should match the property values in the corresponding RS Encoder object.

To decode data using a Reed-Solomon decoding scheme:

- 1 Define and set up your Reed-Solomon decoder object. See “Construction” on page 3-1230.
- 2 Call `step` to decode data according to the properties of `comm.RSDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`dec = comm.RSDecoder` creates a block decoder System object, `dec`. This object performs Reed-Solomon (RS) decoding.

`dec = comm.RSDecoder(N,K)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`dec = comm.RSDecoder(N,K,GP)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`dec = comm.RSDecoder(N,K,GP,S)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`dec = comm.RSDecoder(N,K,GP,S,Name,Value)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and each specified property `Name` set to the specified `Value`.

`dec = comm.RSDecoder(Name,Value)` creates an RS decoder object, `dec`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

## Properties

---

**Note** The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-86 on the `comm.BCHDecoder` reference page.

---

### BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

- When you set this property to `false`, the input data value to run the object must be a numeric, column vector of integers. Running the object outputs an encoded data output vector. The output result is a column vector of integers. Each symbol that forms the input message and output codewords is an integer in the range  $[0, 2^M - 1]$ . These integers correspond to an element of the finite Galois field  $\text{gf}(2^M)$ .  $M$  is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties.
- When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

### CodewordLength

Codeword length

Specify the codeword length of the RS code in symbols as a double-precision, positive, integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be  $2^M - 1$ , where  $M$  is an integer such that  $3 \leq M \leq 16$ .

### MessageLength

Message length

Specify the message length in symbols as a double-precision positive integer scalar value. The default is 3.

### ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as `Auto` or `Property`.

- When you set this property to `Auto`, the RS code is defined by the `CodewordLength`, `MessageLength`, `GeneratorPolynomial`, and `PrimitivePolynomial` properties.

When you set this property to `Property`, you must specify the `ShortMessageLength` property, which is used with the other properties to define the RS code. The default is `Auto`.

### **ShortMessageLength**

Shortened message length

Specify the length of the shortened message in symbols as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength`. The default is 3.

When `ShortMessageLength < MessageLength`, the RS code is shortened.

### **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object automatically chooses the generator polynomial. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` property.
- When you set this property to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` property.

### **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois field row vector. The Galois field row vector entries must be in the range  $[0, 2^M - 1]$  and represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field  $\text{gf}(2^M)$ , represented in integer format. The length of the generator polynomial must be `CodewordLength - MessageLength + 1`. The default is the result of `rsgenpoly(7, 3, [], [], 'double')`, which corresponds to `[1 3 1 2 3]`.

When you use this object to generate code, you must set the generator polynomial to a double-precision integer row vector.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

### **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`.

This check verifies that  $X^{\text{CodewordLength} + 1}$  is divisible by the generator polynomial specified in the `GeneratorPolynomial` property. For codes with generator polynomials of high degree, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to `false`.

A valid generator polynomial is given by  $(X - \alpha^B) \times (X - \alpha^{(B+1)}) \times \dots \times (X - \alpha^{(B + \text{CodewordLength} - \text{MessageLength} - 1)})$ , where  $\alpha$  is a root of the primitive polynomial and  $B$  is an integer. If the value of  $B$  is 1, then you

can set this property to `false`. Otherwise, always set this property to `true`. For more information about  $B$ , see the `rsgenpoly` function reference page.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$ .
- When you set this property to `Property`, you must specify a polynomial using `PrimitivePolynomial`.

### **PrimitivePolynomial**

Primitive polynomial

Specify the primitive polynomial that defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords. The default is the result of `int2bit(primpoly(3),4)'`, which is `[1 0 1 1]` or the polynomial  $x^3 + x + 1$ . Specify this property as a double-precision, binary, row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$  in descending order of powers.

This property applies when you set `PrimitivePolynomialSource` to `Property`.

### **PuncturePatternSource**

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

- When you set this property to `None`, the object does not apply puncturing to the code.
- When you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in `PuncturePattern`.

### **PuncturePattern**

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector of length  $(\text{CodewordLength} - \text{MessageLength})$ . The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

This property applies when you set `PuncturePatternSource` to `Property`.

### **ErasuresInputPort**

Enable erasures input

Set this property to `true` to specify a vector of erasures as an input when running the object. The default is `false`. The erasures input must be a double-precision or logical binary column vector that indicates which symbols of the input codewords to erase. The length of the erasures vector is explained in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-86.

When you set this property to `false`, the object assumes no erasures.

### NumCorrectedErrorsOutputPort

Enable number of corrected errors output

Set this property to `true` to obtain the number of corrected errors as an output when running the object. The default is `true`. A nonnegative value in the  $i$ -th element of the error output vector, denotes the number of corrected errors in the  $i$ -th input codeword. A value of `-1` in the  $i$ -th element of the error output vector indicates that a decoding error occurred for that codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the RS code.

### OutputDataType

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`.

This property applies when you set `BitInput` to `true`.

## Methods

`step` Decode data using a Reed-Solomon decoder

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Transmit an RS-Encoded, 8-DPSK-Modulated Symbol Stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hdDecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);
```

```

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

```

```

Error rate = 0.115578
Number of errors = 69

```

### Estimate BER of QPSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using QPSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Compute theoretical bit error rate (BER) for coded and noncoded data. Plot the BER results to compare performance.

Define the example parameters.

```

rng(1993);      % Seed random number generator for repeatable results
M = 4;          % Modulation order
bps = log2(M); % Bits per symbol
N = 7;          % RS codeword length
K = 5;          % RS message length

```

Create AWGN channel and error rate objects.

```

awgnChannel = comm.AWGNChannel( ...
    BitsPerSymbol=bps);
errorRate = comm.ErrorRate;

```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```

rsEncoder = comm.RSEncoder( ...
    BitInput=true, ...
    CodewordLength=N, ...
    MessageLength=K);
rsDecoder = comm.RSDecoder( ...
    BitInput=true, ...
    CodewordLength=N, ...
    MessageLength=K);

```

Set the range of  $E_b/N_0$  values and account for RS coding gain. Initialize the error statistics matrix.

```

ebnoVec = (3:0.5:8)';
ebnoVecCodingGain = ...
    ebnoVec + 10*log10(K/N); % Account for RS coding gain
errorStats = zeros(length(ebnoVec),3);

```

Estimate the bit error rate for each  $E_b/N_0$  value. The simulation runs until either 100 errors or  $10^7$  bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

```
for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVecCodingGain(i);
    reset(errorRate)
    while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
        data = randi([0 1],1500,1);
        encData = rsEncoder(data);
        modData = pskmod(encData,M,InputType='bit');
        rxSig = awgnChannel(modData);
        rxData = pskdemod(rxSig,M,OutputType='bit');
        decData = rsDecoder(rxData);
        errorStats(i,:) = errorRate(data,decData);
    end
end
```

Fit a curve to the BER data using `berfit`. Generate an estimate of QPSK performance with and without coding using the `bercoding` and `berawgn` functions.

```
berCurveFit = berfit(ebnoVecCodingGain,errorStats(:,1));
berwCoding = bercoding(ebnoVec, 'RS', 'hard', N, K, 'psk', M, 'nondiff');
berNoCoding = berawgn(ebnoVec, 'psk', M, 'nondiff');
```

Plot the RS coded BER data, curve fit of the BER data, theoretical performance with RS coding, and theoretical performance without RS coding. The (7,5) RS code improves the  $E_b/N_0$  required to achieve a  $10^{-2}$  bit error rate by approximately 1.2 dB.

```
semilogy(ebnoVecCodingGain,errorStats(:,1), 'b*', ...
    ebnoVecCodingGain,berCurveFit, 'c-', ...
    ebnoVecCodingGain,berwCoding, 'r', ...
    ebnoVec,berNoCoding)
ylabel('BER')
xlabel('Eb/No (dB)')
legend( ...
    'RS coded BER', 'Curve Fit', ...
    'Theory with coding', 'Theory no coding')
grid
```

### Transmit a Shortened RS-Encoded, 256-QAM-Modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where  $N$  is the codeword length,  $K$  is the nominal message length, and  $S$  is the shortened message length. Set the modulation order,  $M$ , and the number of frames,  $L$ .

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
bps = log2(M);
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (Eb/No)', ...
    EbNo=15, ...
    BitsPerSymbol=bps);
errorRate = comm.ErrorRate(ComputationDelay=3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[1],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length,  $S$ , and the DVB-T generator polynomial,  $gp$ .

```
enc = comm.RSEncoder(N,K,gp,S);  
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L  
    data = randi([0 1],S*bps,1);  
    encodedData = enc(bit2int(data,bps));  
    modSignal = qammod(encodedData,M,UnitAveragePower=true);  
    rxSignal = awgnChan(modSignal);  
    demodSignal = qamdemod(rxSignal,M,UnitAveragePower=true);  
    rxBits = dec(demodSignal);  
    dataOut = int2bit(rxBits,bps);  
    errorStats = errorRate(data(:),dataOut(:));  
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02  
Number of errors = 1514
```

### Reed-Solomon Coding with Erasures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system. RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per bit to noise power spectral density ratio ( $E_b/N_0$ ). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

## Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio is set  $E_b/N_0_{\text{Uncoded}} = 15$  dB. Criteria to stop the simulation are defined to stop the simulation if 500 errors occur or a maximum  $5e6$  bits are transmitted.

```
helperRSCodingConfig;
```

## Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct  $(63-53)/2 = 5$  errors, or it can alternatively correct  $(63-53) = 10$  erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of  $(10-6)/2 = 2$  errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K, 'BitInput', false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K, 'BitInput', false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of -1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

## Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has  $K$  symbols in the  $[0 N]$  range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is  $(N - \text{numPunc})$  symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the  $i$ th element of the vector erases the  $i$ th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors + errs;
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...
    chanBERCalc(int2bit(encData,log2(M)),int2bit(demodData,log2(M)));
codedErrorStats(:,1) = ...
    codedBERCalc(int2bit(data,log2(M)),int2bit(estData,log2(M)));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0017

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 0
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 882
```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because  $E_b/N_0$  is reduced by the code rate.

## Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

### Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. Given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

#### Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum  $5 \times 10^6$  bits are transmitted.

```
helperRSCodingConfig;
```

#### Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algorithm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K,BitInput=false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K,BitInput=false);
rsDecoder.ErasuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to 'Property' and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of 1 in the puncture pattern vector indicate nonpunctured symbols, and values of 0 indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
```

```
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

### Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded  $E_b/N_0$  ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is  $(N - \text{numPuncs})$  and the uncoded  $E_b/N_0$  ratio relates to the coded  $E_b/N_0$  as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has  $K$  symbols in the  $[0 N]$  range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is  $(N - \text{numPunc})$  symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the  $i$ th element of the vector erases the  $i$ th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);  
if (errs >= 0)  
    correctedErrors = correctedErrors+errs;  
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...  
    chanBERCalc(int2bit(encData,log2(M)),int2bit(demodData,log2(M)));  
codedErrorStats(:,1) = ...  
    codedBERCalc(int2bit(data,log2(M)),int2bit(estData,log2(M)));  
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)  
chanBitErrorRate = 0.0015  
codedBitErrorRate = codedErrorStats(1)  
codedBitErrorRate = 0  
totalCorrectedErrors = correctedErrors  
totalCorrectedErrors = 632
```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to  $50 \times 10^6$ . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded  $E_b/N_0$  is slightly higher than the channel  $E_b/N_0$ , so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only  $(10 - 6 - 2) / 2 = 1$  error per codeword.

### Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

### Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of

message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input  $E_b/N_0$ .

### Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio is set `EbNoUncoded = 15 dB`. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum  $5 \times 10^6$  bits are transmitted.

```
helperRSCodingConfig;
```

### Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since  $2\lceil\log_2(53 + 1)\rceil - 1 = 63$ ). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field  $GF(2^6)$ . Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since  $2\lceil\log_2(28 + 1)\rceil - 1 = 31$ ).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63; % Codeword length
K = 53; % Message length
S = 18; % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of  $GF(2^6)$  in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to 'Property' and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
```

```
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
```

### Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. The value of the coded  $E_b/N_0$  ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is  $(N - \text{numPuncs} - S)$  and the uncoded  $E_b/N_0$  ratio relates to the coded  $E_b/N_0$  as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has  $K-S$  symbols in the  $[0, 2^{\text{primPolyDegree}}-1]$  range.

```
data = randi([0 2^primPolyDegree-1], S, 1);
```

Encode the shortened message word. The encoded word `encData` is  $(N - \text{numPuncs} - S)$  symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData, M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput, M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the  $i$ th element of the vector erases the  $i$ th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput, numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData, errs] = rsDecoder(demodData, erasuresVec);
if (errs >= 0)
```

```

        correctedErrors = correctedErrors + errs;
    end

```

When computing the channel and coded BERs, convert integers to bits.

```

    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
            reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
            reshape(de2bi(estData,log2(M))',[],1));
end

```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```

chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0036

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 9.6599e-05

totalCorrectedErrors = correctedErrors

totalCorrectedErrors = 1436

```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to  $50 \times 10^6$ . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shortening
- Theoretical BER for 64-QAM

The BER out of the 64-QAM Demodulator is worse with shortening than it is without shortening. This is because the code rate of the shortened code is much lower than the code rate of the non-shortened code and therefore the coded  $E_b/N_0$  into the demodulator is worse with shortening. A shortened code has the same error correcting capability as non-shortened code for the same  $E_b/N_0$ , but the reduction in  $E_b/N_0$  manifests in the form of a higher BER out of the RS Decoder with shortening than without.

The coded  $E_b/N_0$  is slightly higher than the channel  $E_b/N_0$ , so the channel BER is slightly better than the coded BER in the shortened case. The degraded coded  $E_b/N_0$  occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening results in degraded coded BER, most noticeably at lower  $E_b/N_0$  values.

## Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

## Algorithms

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

## Version History

Introduced in R2012a

## step

**System object:** comm.RSDecoder

**Package:** comm

Decode data using a Reed-Solomon decoder

### Syntax

```
[Y,ERR] = step(H,X)
Y = step(H,X)
Y = step(H,X,ERASURES)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[Y,ERR] = step(H,X)` decodes the encoded input data, `X`, into the output vector `Y` and returns the number of corrected symbols in output vector `ERR`. The value of the `BitInput` property determines whether `X` is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the `step` function equal the values listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-86. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `true`. A value of `-1` in the  $i$ -th element of the error output vector indicates that a decoding error occurred for that codeword.

`Y = step(H,X)` decodes the encoded data, `X`, into the output vector `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `false`.

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type `double` or `logical`. Values of `1` in the `ERASURES` vector correspond to erased symbols, and values of `0` correspond to non-erased symbols. This syntax applies when you set the `ErasuresInputPort` property to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

## comm.RSEncoder

**Package:** comm

Encode data using Reed-Solomon encoder

### Description

The RSEncoder object creates a Reed-Solomon code with message and codeword lengths you specify.

To encode data using a Reed-Solomon encoding scheme:

- 1 Define and set up your Reed-Solomon encoder object. See “Construction” on page 3-1252.
- 2 Call `step` to encode data according to the properties of `comm.RSEncoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`enc = comm.RSEncoder` creates a block encoder System object, `enc`. This object performs Reed-Solomon (RS) encoding.

`enc = comm.RSEncoder(N,K)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`enc = comm.RSEncoder(N,K,GP)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`enc = comm.RSEncoder(N,K,GP,S)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`enc = comm.RSEncoder(N,K,GP,S,Name,Value)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, the `ShortMessageLength` property set to `S`, and each specified property `Name` set to the specified `Value`.

`enc = comm.RSEncoder(Name,Value)` creates an RS encoder object, `enc`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

### Properties

---

**Note** The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-86 on the `comm.BCHDecoder` reference page.

---

**BitInput**

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the input data value when running the object must be a numeric, column vector of integers. Each symbol that forms the input message and output codewords is an integer in the range  $[0, 2^M-1]$ . These integers correspond to an element of the finite Galois field  $\text{gf}(2^M)$ , where  $M$  is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

**CodewordLength**

Codeword length

Specify the codeword length of the RS code as a double-precision positive integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be  $2^M-1$ , where  $M$  is an integer in the range  $[3, 16]$ .

**MessageLength**

Message length

Specify the message length as a double-precision positive integer scalar value. The default is 3.

**ShortMessageLengthSource**

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the RS code is defined by the `CodewordLength`, `MessageLength`, `GeneratorPolynomial`, and `PrimitivePolynomial` properties.
- When you set this property to `Property`, you must specify the `ShortMessageLength` property to be used with the other properties to define the RS code.

**ShortMessageLength**

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength`. The default is 3.

When `ShortMessageLength < MessageLength`, the RS code is shortened.

### **GeneratorPolynomialSource**

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` property.
- When you set this property to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` property.

### **GeneratorPolynomial**

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois row vector. The Galois field row vector entries must be in the range  $[0, 2^M-1]$  and represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field  $gf(2^M)$ , represented in integer format. The length of the generator polynomial must be `CodewordLength - MessageLength + 1`. The default is the result of `rsgenpoly(7,3,[],[],'double')`, which corresponds to `[1 3 1 2 3]`.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

### **CheckGeneratorPolynomial**

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`.

This check verifies that  $X^{\text{CodewordLength}} + 1$  is divisible by the generator polynomial specified in the `GeneratorPolynomial` property. For codes with generator polynomials of high degree, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to `false`.

This property applies when `GeneratorPolynomialSource` is set to `Property`.

### **PrimitivePolynomialSource**

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object uses a primitive polynomial of degree  $M = \text{ceil}(\log_2(\text{CodewordLength}+1))$ .
- When you set this property to `Property`, you must specify a polynomial using the `PrimitivePolynomial` property.

### **PrimitivePolynomial**

### Primitive polynomial

Specify the primitive polynomial that defines the finite field  $\text{gf}(2^M)$  corresponding to the integers that form messages and codewords. Specify this property as a double-precision, binary row vector that represents a primitive polynomial over  $\text{gf}(2)$  of degree  $M$  in descending order of powers.

If `CodewordLength` is less than  $2^M-1$ , the object uses a shortened RS code. The default is the result of `int2bit(primpoly(3),4)'`, which is `[1 0 1 1]` or the polynomial  $x^3+x+1$ .

This property applies when you set `PrimitivePolynomialSource` to `Property`.

### PuncturePatternSource

#### Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

- When you set this property to `None`, the object does not apply puncturing to the code.
- When you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` property.

### PuncturePattern

#### Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector with a length of  $(\text{CodewordLength} - \text{MessageLength})$ . The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

This property applies when you set the `PuncturePatternSource` property to `Property`.

### OutputDataType

#### Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`.

This property applies when you set the `BitInput` property to `true`.

## Methods

`step` Encode data using a Reed-Solomon encoder

Common to All System Objects	
<code>release</code>	Allow System object property value changes

## Examples

### Transmit an RS-Encoded, 8-DPSK-Modulated Symbol Stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```

enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))

```

```

Error rate = 0.115578
Number of errors = 69

```

### Estimate BER of QPSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using QPSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Compute theoretical bit error rate (BER) for coded and noncoded data. Plot the BER results to compare performance.

Define the example parameters.

```

rng(1993);      % Seed random number generator for repeatable results
M = 4;          % Modulation order
bps = log2(M); % Bits per symbol
N = 7;          % RS codeword length
K = 5;          % RS message length

```

Create AWGN channel and error rate objects.

```

awgnChannel = comm.AWGNChannel( ...
    BitsPerSymbol=bps);
errorRate = comm.ErrorRate;

```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```

rsEncoder = comm.RSEncoder( ...
    BitInput=true, ...
    CodewordLength=N, ...
    MessageLength=K);

```

```
rsDecoder = comm.RSDecoder( ...
    BitInput=true, ...
    CodewordLength=N, ...
    MessageLength=K);
```

Set the range of  $E_b/N_0$  values and account for RS coding gain. Initialize the error statistics matrix.

```
ebnoVec = (3:0.5:8)';
ebnoVecCodingGain = ...
    ebnoVec + 10*log10(K/N); % Account for RS coding gain
errorStats = zeros(length(ebnoVec),3);
```

Estimate the bit error rate for each  $E_b/N_0$  value. The simulation runs until either 100 errors or  $10^7$  bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

```
for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVecCodingGain(i);
    reset(errorRate)
    while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
        data = randi([0 1],1500,1);
        encData = rsEncoder(data);
        modData = pskmod(encData,M,InputType='bit');
        rxSig = awgnChannel(modData);
        rxData = pskdemod(rxSig,M,OutputType='bit');
        decData = rsDecoder(rxData);
        errorStats(i,:) = errorRate(data,decData);
    end
end
```

Fit a curve to the BER data using `berfit`. Generate an estimate of QPSK performance with and without coding using the `bercoding` and `berawgn` functions.

```
berCurveFit = berfit(ebnoVecCodingGain,errorStats(:,1));
berwCoding = bercoding(ebnoVec,'RS','hard',N,K,'psk',M,'nondiff');
berNoCoding = berawgn(ebnoVec,'psk',M,'nondiff');
```

Plot the RS coded BER data, curve fit of the BER data, theoretical performance with RS coding, and theoretical performance without RS coding. The (7,5) RS code improves the  $E_b/N_0$  required to achieve a  $10^{-2}$  bit error rate by approximately 1.2 dB.

```
semilogy(ebnoVecCodingGain,errorStats(:,1),'b*', ...
    ebnoVecCodingGain,berCurveFit,'c-', ...
    ebnoVecCodingGain,berwCoding,'r', ...
    ebnoVec,berNoCoding)
ylabel('BER')
xlabel('Eb/No (dB)')
legend( ...
    'RS coded BER','Curve Fit', ...
    'Theory with coding','Theory no coding')
grid
```

### Transmit a Shortened RS-Encoded, 256-QAM-Modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where  $N$  is the codeword length,  $K$  is the nominal message length, and  $S$  is the shortened message length. Set the modulation order,  $M$ , and the number of frames,  $L$ .

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
bps = log2(M);
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel( ...
    NoiseMethod='Signal to noise ratio (Eb/No)', ...
    EbNo=15, ...
    BitsPerSymbol=bps);
errorRate = comm.ErrorRate(ComputationDelay=3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[1],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length,  $S$ , and the DVB-T generator polynomial,  $gp$ .

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S*bps,1);
    encodedData = enc(bit2int(data,bps));
    modSignal = qammod(encodedData,M,UnitAveragePower=true);
    rxSignal = awgnChan(modSignal);
    demodSignal = qamdemod(rxSignal,M,UnitAveragePower=true);
    rxBits = dec(demodSignal);
    dataOut = int2bit(rxBits,bps);
    errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02
Number of errors = 1514
```

### Reed-Solomon Coding with Erasures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system. RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per bit to noise power spectral density ratio ( $E_b/N_0$ ). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

### Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio is set `EbNoUncoded = 15` dB. Criteria to stop the simulation are defined to stop the simulation if 500 errors occur or a maximum `5e6` bits are transmitted.

```
helperRSCodingConfig;
```

### Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct  $(63-53)/2 = 5$  errors, or it can alternatively correct  $(63-53) = 10$  erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of  $(10-6)/2 = 2$  errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K, 'BitInput', false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K, 'BitInput', false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of -1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

### Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the [0 N] range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, encData, is (N-numPunc) symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the helperRSCodingGetErasures.m helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the ith element of the vector erases the ith symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors + errs;
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...
    chanBERCalc(int2bit(encData,log2(M)),int2bit(demodData,log2(M)));
codedErrorStats(:,1) = ...
    codedBERCalc(int2bit(data,log2(M)),int2bit(estData,log2(M)));
end
```

The error rate measurement objects, chanBERCalc and codedBERCalc, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0017

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 0
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 882
```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because  $E_b/N_0$  is reduced by the code rate.

### Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

## Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. Given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

### Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum  $5 \times 10^6$  bits are transmitted.

```
helperRSCodingConfig;
```

### Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algorithm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K,BitInput=false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K,BitInput=false);
rsDecoder.ErasuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to 'Property' and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of 1 in the puncture pattern vector indicate nonpunctured symbols, and values of 0 indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
```

```
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

### Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded  $E_b/N_0$  ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is  $(N - \text{numPuncs})$  and the uncoded  $E_b/N_0$  ratio relates to the coded  $E_b/N_0$  as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has  $K$  symbols in the  $[0 N]$  range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is  $(N - \text{numPunc})$  symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the  $i$ th element of the vector erases the  $i$ th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```

[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors+errs;
end

```

When computing the channel and coded BERs, convert integers to bits.

```

chanErrorStats(:,1) = ...
    chanBERCalc(int2bit(encData,log2(M)),int2bit(demodData,log2(M)));
codedErrorStats(:,1) = ...
    codedBERCalc(int2bit(data,log2(M)),int2bit(estData,log2(M)));
end

```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```

chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0015

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 0

totalCorrectedErrors = correctedErrors

totalCorrectedErrors = 632

```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to  $50 \times 10^6$ . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded  $E_b/N_0$  is slightly higher than the channel  $E_b/N_0$ , so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only  $(10 - 6 - 2) / 2 = 1$  error per codeword.

### Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

### Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of

message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input  $E_b/N_0$ .

### Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded  $E_b/N_0$  ratio is set `EbNoUncoded = 15 dB`. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum  $5 \times 10^6$  bits are transmitted.

```
helperRSCodingConfig;
```

### Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since  $2\lceil\log_2(53 + 1)\rceil - 1 = 63$ ). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field  $GF(26)$ . Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since  $2\lceil\log_2(28 + 1)\rceil - 1 = 31$ ).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63; % Codeword length
K = 53; % Message length
S = 18; % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of  $GF(2^6)$  in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to 'Property' and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
```

```
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
```

### Run Stream Processing Loop

Simulate the communications system for an uncoded  $E_b/N_0$  ratio of 15 dB. The uncoded  $E_b/N_0$  is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded  $E_b/N_0$  values so that they correspond to the energy ratio at the encoder output. This ratio is the coded  $E_b/N_0$  ratio. If you input  $K$  symbols to the encoder and obtain  $N$  output symbols, then the energy relation is given by the  $K/N$  rate. The value of the coded  $E_b/N_0$  ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is  $(N - \text{numPuncs} - S)$  and the uncoded  $E_b/N_0$  ratio relates to the coded  $E_b/N_0$  as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded  $E_b/N_0$  value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has  $K-S$  symbols in the  $[0, 2^{\text{primPolyDegree}}-1]$  range.

```
data = randi([0 2^primPolyDegree-1], S, 1);
```

Encode the shortened message word. The encoded word `encData` is  $(N - \text{numPuncs} - S)$  symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData, M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput, M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the  $i$ th element of the vector erases the  $i$ th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput, numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData, errs] = rsDecoder(demodData, erasuresVec);
if (errs >= 0)
```

```

        correctedErrors = correctedErrors + errs;
    end

```

When computing the channel and coded BERs, convert integers to bits.

```

    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
            reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
            reshape(de2bi(estData,log2(M))',[],1));
end

```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```

chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0036

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 9.6599e-05

totalCorrectedErrors = correctedErrors

totalCorrectedErrors = 1436

```

You can add a for loop around the processing loop above to run simulations for a set of  $E_b/N_0$  values. Simulations were run offline for uncoded  $E_b/N_0$  values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to  $50 \times 10^6$ . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shortening
- Theoretical BER for 64-QAM

The BER out of the 64-QAM Demodulator is worse with shortening than it is without shortening. This is because the code rate of the shortened code is much lower than the code rate of the non-shortened code and therefore the coded  $E_b/N_0$  into the demodulator is worse with shortening. A shortened code has the same error correcting capability as non-shortened code for the same  $E_b/N_0$ , but the reduction in  $E_b/N_0$  manifests in the form of a higher BER out of the RS Decoder with shortening than without.

The coded  $E_b/N_0$  is slightly higher than the channel  $E_b/N_0$ , so the channel BER is slightly better than the coded BER in the shortened case. The degraded coded  $E_b/N_0$  occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening results in degraded coded BER, most noticeably at lower  $E_b/N_0$  values.

### Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

### Algorithms

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

### Version History

Introduced in R2012a

## step

**System object:** comm.RSEncoder

**Package:** comm

Encode data using a Reed-Solomon encoder

### Syntax

$Y = \text{step}(H,X)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H,X)$  encodes the numeric column input data vector,  $X$ , and returns the encoded data,  $Y$ . The value of the `BitInput` property determines whether  $X$  is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the `step` function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-86.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.SampleRateOffset

**Package:** comm

Apply sample rate offset to signal

## Description

The `comm.SampleRateOffset` System object applies a sample rate offset to the input signal. Applying a sample rate offset is equivalent to changing the ADC clock rate.

To apply a sample rate offset to a signal:

- 1 Create the `comm.SampleRateOffset` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
sro = comm.SampleRateOffset
sro = comm.SampleRateOffset(offset)
sro = comm.SampleRateOffset(Offset=offset)
```

### Description

`sro = comm.SampleRateOffset` creates a sample rate offset System object.

`sro = comm.SampleRateOffset(offset)` sets the `Offset` property to the value of the `offset` input argument.

`sro = comm.SampleRateOffset(Offset=offset)` sets the `Offset` property to the value specified by `offset`.

## Properties

### Offset — Sample rate offset

10 (default) | scalar

Sample rate offset in parts per million (ppm), specified as a scalar greater than  $-1e6$ .

Data Types: double

## Usage

### Syntax

```
y = sro(x)
```

### Description

`y = sro(x)` applies the sample rate offset configured by `sro` to the input signal and returns the resulting signal.

### Input Arguments

#### **x** — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an  $N_S$  element column vector, or an  $N_S$ -by- $N_C$  matrix.  $N_S$  is the number of time samples.  $N_C$  is the number of channels. For matrix input signals, the sample rate offset is applied independently to each column.

Data Types: double | single

Complex Number Support: Yes

### Output Arguments

#### **y** — Output signal

scalar | vector | matrix

Output signal, returned as a scalar, vector or matrix with the same data type as input signal `x`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Apply Sample Rate Offset to 16-QAM Signal

Set parameters and an input signal.

```
M = 16; % Modulation order  
offset = 50; % Parts per million
```

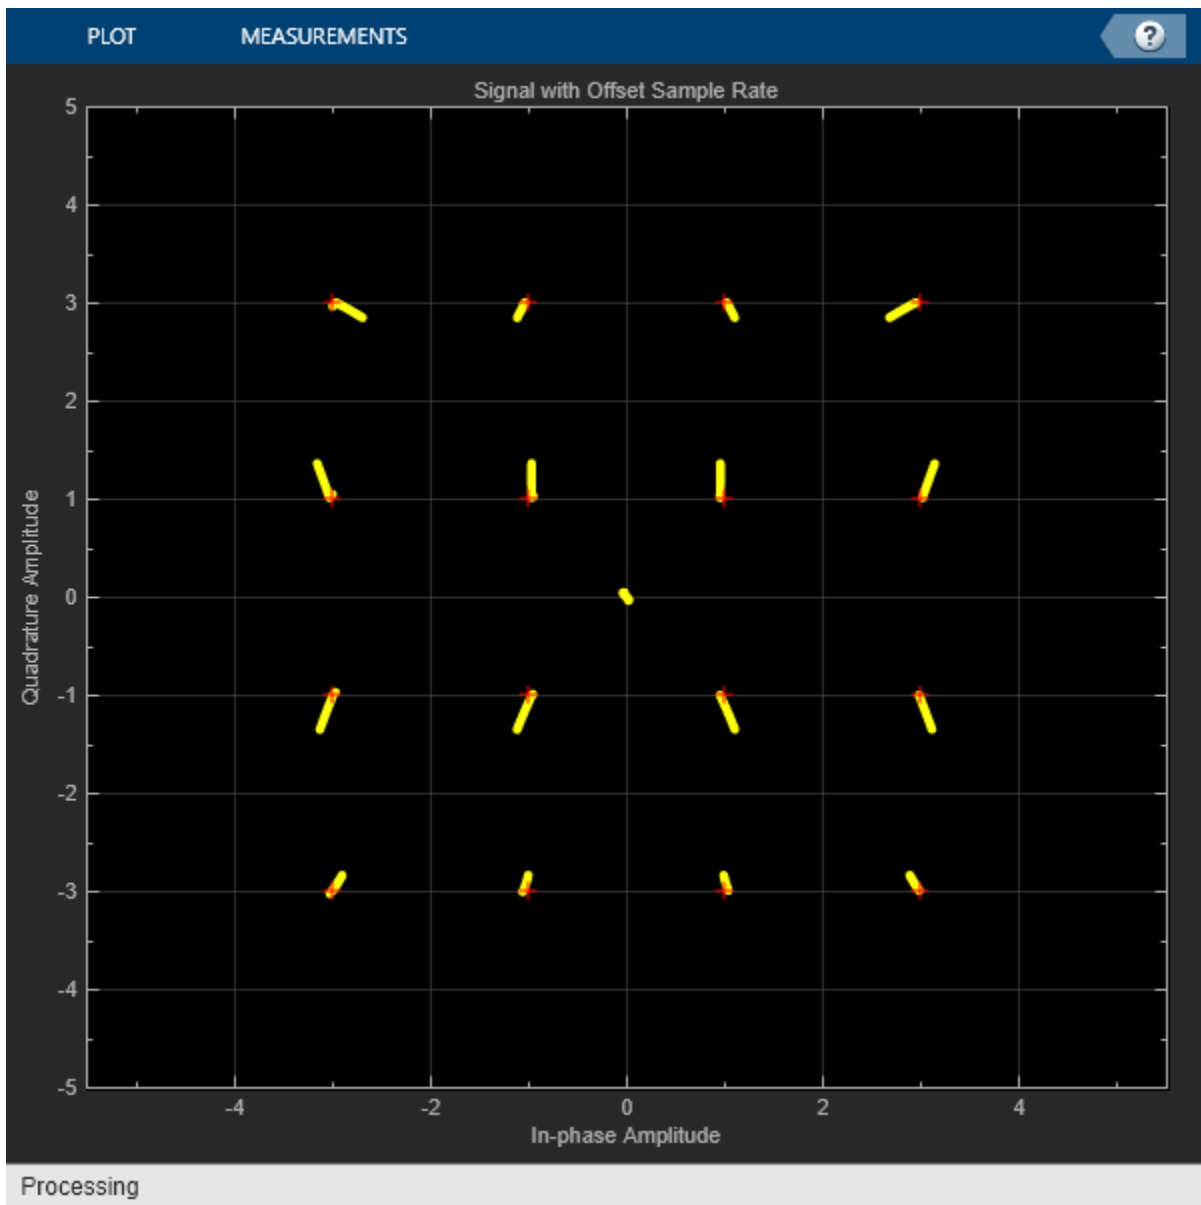

```
data = (0:M-1)';           % Input signal
refconst = qammod(data,M); % Reference constellation points
```

Create sample rate offset and constellation diagram System objects.

```
sro = comm.SampleRateOffset(offset);
constdiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',refconst, ...
    'XLimits',[-5 5], ...
    'YLimits',[-5 5], ...
    'Title','Signal with Offset Sample Rate');
```

Apply 16-QAM modulation to random data, and then apply a sample rate offset to the modulated signal. Plot the reference constellation and the signal with offset sample rate offset.

```
modData = qammod(repmat(data,100,1),M);
impairedData = sro(modData);
constdiagram(impairedData)
```

### Apply Sample Rate Offset to Sine Wave

Apply sample rate offsets to a 30 kHz single tone sine wave. Confirm the offset by computing the frequency difference between the transmitted tone and the received tone after applying positive and negative sample rate offsets.

Generate a single tone at 30 kHz.

```
f = 30e3;
samplerate = 100e3;
src = dsp.SineWave('Frequency',f, ...
    'SampleRate',samplerate, ...
```

```

    'SamplesPerFrame',10000, ...
    'ComplexOutput',true);
txsig = src();

```

Verify the frequency of the tone.

```

freqtx = samplerate * ...
    (mean(angle(txsig(2:end) ./ txsig(1:end-1)))/(2*pi))

freqtx = 3.0000e+04

```

Apply a sample rate offset of 20 ppm to the transmission tone (txsig). Increasing the sample rate offset is equivalent to increasing the ADC clock rate.

```

sro = comm.SampleRateOffset(20);
rxsig = sro(txsig);

```

Find the frequency of the received tone (rxsig) after offsetting the sample rate. To skip samples with transient effects, ignore the first 100 samples.

```

freqrx = samplerate * ...
    (mean(angle(rxsig(101:end) ./ rxsig(100:end-1)))/(2*pi))

freqrx = 2.9999e+04

```

Increasing the ADC clock rate, decreases the frequency of the received tone. To show that the frequency of the received tone decreases by approximately 20 ppm, compare the frequency of the transmitted tone to the frequency of the received tone.

```

freqchangeppm = (freqrx-freqtx)/freqtx*1e6

freqchangeppm = -19.9365

```

Apply a sample rate offset of -30 ppm to the transmission tone (txsig). Decreasing the sample rate offset is equivalent to decreasing the ADC clock rate.

```

sro = comm.SampleRateOffset(-30);
rxsig = sro(txsig);

```

Find the frequency of the received tone (rxsig) after offsetting the sample rate. To skip samples with transient effects, ignore the first 100 samples.

```

freqrx = samplerate * ...
    (mean(angle(rxsig(101:end) ./ rxsig(100:end-1)))/(2*pi))

freqrx = 3.0001e+04

```

Decreasing the ADC clock rate, increases the frequency of the received tone. To show that the frequency of the received tone increases by approximately 30 ppm, compare the frequency of the transmitted tone to the frequency of the received tone.

```

freqchangeppm = (freqrx-freqtx)/freqtx*1e6

freqchangeppm = 30.0736

```

### Display Impact of Sample Rate Offset on Received QPSK Signal

Display the effects of a sample rate offset in the receiver on a QPSK signal.

Transmit frames containing a fixed preamble and random payload. In the receiver, use the preamble to find the beginning of a frame, and then demodulate the payload and measure the EVM. With a constant nonzero sample rate offset, the EVM varies from frame to frame with a consistent periodicity.

Initialize configuration parameters and create pulse-shaping filter objects for the transmitter and receiver.

```
numFrames = 200;
numSymbolsPerFrame = 4096;
preambleLength = 64;
payloadLength = numSymbolsPerFrame - preambleLength;
modulationOrder = 4;

rolloff = 0.2;
filterSpan = 10;
samplesPerSymbol = 8;
txFilter = comm.RaisedCosineTransmitFilter(RolloffFactor=rolloff, ...
    FilterSpanInSymbols=filterSpan, ...
    OutputSamplesPerSymbol=samplesPerSymbol);
rxFilter = comm.RaisedCosineReceiveFilter(RolloffFactor=rolloff, ...
    FilterSpanInSymbols=filterSpan, ...
    InputSamplesPerSymbol=samplesPerSymbol,DecimationFactor=1);
```

Use a Gold sequence for the preamble. Map the Gold sequence to  $0.7071 + 0.7071i$  and  $-0.7071 - 0.7071i$  in the QPSK constellation.

```
goldSeq = comm.GoldSequence(SamplesPerFrame=preambleLength);
preamble = goldSeq();
preamble(preamble==1)=2;
preambleModOut = pskmod(preamble,modulationOrder,pi/modulationOrder);
```

Generate a time-domain reference signal for the preamble.

```
preambleRefDelayed = rxFilter( ...
    txFilter([preambleModOut;zeros(filterSpan,1)]));
preambleRef = preambleRefDelayed( ...
    filterSpan*samplesPerSymbol+(1:samplesPerSymbol*preambleLength));
```

Generate a random payload and transmit signal.

```
txPayload = pskmod( ...
    randi([0 modulationOrder-1],payloadLength,numFrames), ...
    modulationOrder, ...
    pi/modulationOrder);
txFrames = reshape([ repmat(preambleModOut,1,numFrames);txPayload],[],1);
txSig = txFilter([txFrames;zeros(payloadLength,1)]);
```

Apply a 0.8 ppm sample rate offset to the received signal.

```
simulatedSRO = 0.8;
sro = comm.SampleRateOffset(simulatedSRO);
rxSig = rxFilter(sro(txSig));
```

Use a matched filter to find the preamble.

```
matchedFilterResponse = conj(flipud(preambleRef));
matchedFilterOutMag = abs(filter(matchedFilterResponse,1,rxSig));
```

Find the peak locations and plot the first ten peaks.

```
threshold = max(matchedFilterOutMag)*0.7;
[~, peakLocations] = findpeaks(matchedFilterOutMag, ...
    MinPeakHeight=threshold, ...
    MinPeakDistance=preambleLength*samplesPerSymbol);
plot(matchedFilterOutMag)
title('Matched Filter Output (Magnitude)')
xlabel('Sample')
axis([0 numSymbolsPerFrame*samplesPerSymbol*10 ...
    -0.15*max(matchedFilterOutMag) 1.25*max(matchedFilterOutMag)]);
grid on
```

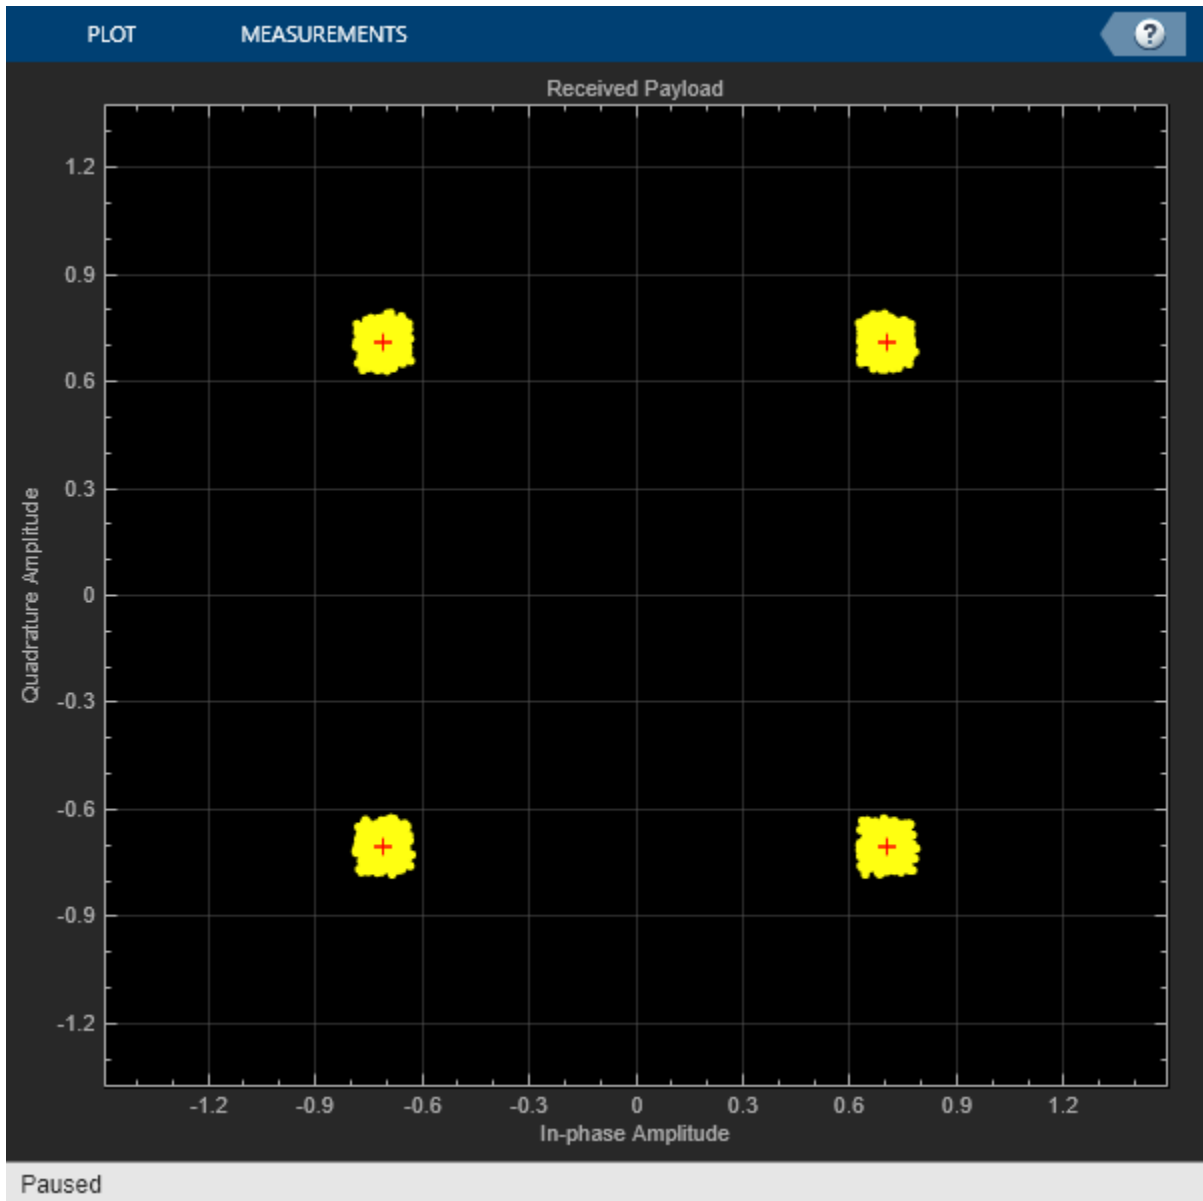

Locate the frames and examine the received data by plotting the computed EVM value and the received signal constellation. Estimate the sample rate offset. For a more accurate estimate, you can increase the number of transmitted frames.

```
frameDelay = peakLocations - length(preambleRef);
constDiag = comm.ConstellationDiagram(Title='Received Payload', ...
    Position=[20 70 600 600]);
evm = comm.EVM;
evmScope = timescope(TimeUnits='none',TimeSpan=length(frameDelay), ...
    YLabel='EVM (%)',YLimits=[0 15],TimeAxisLabels='none', ...
```

```
Position=[650 120 800 500]);  
for i = 1:length(frameDelay)  
    rxFrame = rxSig(frameDelay(i) + ...  
        (1:samplesPerSymbol:numSymbolsPerFrame*samplesPerSymbol));  
    evmScope(evm(txPayload(:,i),rxFrame(preambleLength+1:end)));  
    constDiag(rxFrame(preambleLength+1:end));  
    pause(0.1)  
end
```

```
peakSpacings = diff(peakLocations);  
nominalPeakSpacing = numSymbolsPerFrame*samplesPerSymbol;  
estimatedSRO = (mean(peakSpacings)/nominalPeakSpacing-1)*1e6
```

```
estimatedSRO = 0.7668
```

# comm.Scrambler

**Package:** comm

Scramble input signal

## Description

The comm.Scrambler object applies multiplicative scrambling to input data.

This schematic shows the multiplicative scrambler operation. The adders operate modulo  $N$ , where  $N$  is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the scrambler.

---

**Note** To apply additive scrambling to input data, you can use the comm.PNSequence System object and the xor function. For an example, see “Additive Scrambling of Input Data” on page 3-1039.

---

To scramble an input signal:

- 1 Create the comm.Scrambler object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

## Creation

### Syntax

```
scrambler = comm.Scrambler
scrambler = comm.Scrambler(base,poly,cond)
scrambler = comm.Scrambler( ___,Name,Value)
```

### Description

`scrambler = comm.Scrambler` creates a scrambler System object. This object scrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.

`scrambler = comm.Scrambler(base,poly,cond)` creates the scrambler object with the `CalculationBase` property set to `base`, the `Polynomial` property set to `poly`, and the `InitialConditions` property set to `cond`.

Example: `comm.Scrambler(8,'1 + x^-2 + x^-3 + x^-5 + x^-7',[0 3 2 2 5 1 7])` sets the calculation base to 8, and the scrambler polynomial and initial conditions as specified.

`scrambler = comm.Scrambler(___,Name,Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Scrambler('CalculationBase',2)`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### CalculationBase — Range of input data

4 (default) | nonnegative integer

Range of input data used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to `CalculationBase - 1`.

Data Types: `double`

### Polynomial — Connections for linear feedback shift registers

'1 + x^-1 + x^-2 + x^-4' (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the scrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + x^-6 + x^-8'. For more details on specifying polynomials in this way, see "Representation of Polynomials in Communications Toolbox".
- An integer vector, such as [0 -6 -8], listing the scrambler coefficients in order of descending powers of  $x^{-1}$ , where  $p(x^{-1}) = 1 + p_1x^{-1} + p_2x^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of  $x$  that appear in the polynomial that have a coefficient of 1. In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: '1 + x^-6 + x^-8', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(x^{-1}) = 1 + x^{-6} + x^{-8}$$

Data Types: `double` | `char`

### InitialConditionsSource — Initial conditions source

'Property' (default) | 'Input port'

- 'Property' - Specify scrambler initial conditions by using the InitialConditions property.
- 'Input port' - Specify scrambler initial conditions by using an additional input argument, initcond, when calling the object.

Data Types: char

### InitialConditions — Initial conditions of scrambler registers

[0 1 2 3] (default) | nonnegative integer vector

Initial conditions of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of InitialConditions must equal the order of the Polynomial property. The vector element values must be integers from 0 to CalculationBase - 1.

#### Dependencies

This property is available when InitialConditionsSource is set to 'Property'.

### ResetInputPort — Scrambler state reset port

false (default) | true

Scrambler state reset port, specified as false or true. If ResetInputPort is true, you can reset the scrambler object by using an additional input argument, reset, when calling the object.

#### Dependencies

This property is available when InitialConditionsSource is set to 'Property'.

## Usage

### Syntax

```
scrambledOut = scrambler(signal)
scrambledOut = scrambler(signal,initcond)
scrambledOut = scrambler(signal,reset)
```

#### Description

scrambledOut = scrambler(signal) scrambles the input signal. The output is the same data type and length as the input vector.

scrambledOut = scrambler(signal,initcond) provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the InitialConditionsSource property of the object to 'Input port'.

scrambledOut = scrambler(signal,reset) provides an additional input indicating whether to reset the state of the scrambler.

This syntax applies when you set InitialConditionsSource to 'Property' and ResetInputPort to true.

## Input Arguments

### **signal** — Input signal

column vector

Input signal, specified as a column vector.

Example: `scrambledOut = scrambler([0 1 1 0 1])`

Data Types: `double` | `logical` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### **initcond** — Initial register conditions

nonnegative integer column vector

Initial scrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from 0 to `CalculationBase - 1`.

Example: `scrambledOut = scrambler(signal,[0 1 1 0])` corresponds to possible initial register states for a scrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

### **reset** — Reset initial state of scrambler

scalar

Reset the initial state of the scrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `scrambledOut = scrambler(signal,0)` scrambles the input signal without resetting the scrambler states.

Data Types: `double`

## Output Arguments

### **out** — Scrambled output

column vector

Scrambled output, returned as a column vector with the same data type and length as `signal`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

## Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + x^-2 + x^-3 + x^-5 + x^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3
```

```
    6     7     6
    7     5     7
    1     7     1
    7     0     7
    5     3     5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
     1
```

## Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to 'Input port' so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
descrambler = comm.Descrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

```
errVec
errVec = 10x1
```

### Additive Scrambling of Input Data

Digital communications systems commonly use additive scrambling to randomize input data to aid in timing synchronization and power spectral requirements. The `comm.Scrambler` System object™ implements multiplicative scrambling but does not support additive scrambling. To perform additive scrambling you can use the `comm.PNSequence` System object. This example implements the additive scrambling specified in IEEE 802.11™ by scrambling input data with an output sequence generated by the `comm.PNSequence` System object. For a Simulink® model that implements a similar workflow, see the “Additive Scrambling of Input Data in Simulink” example.

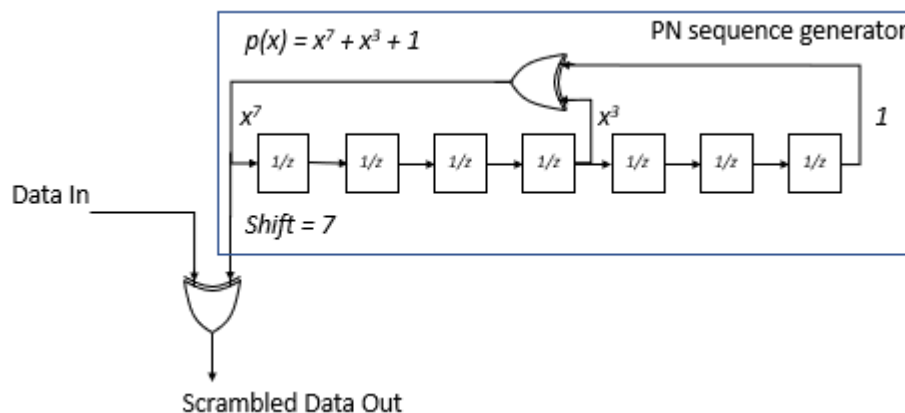

This figure shows an additive scrambler, that uses the generator polynomial  $x^7 + x^4 + 1$ , as specified in figure 17-7 of IEEE 802.11 Section 17.3.5.5 [1] on page 3-1290.

IEEE 802.11™ section 17.3.5.5 PHY DATA scrambler and descrambler (Figure 17-7 Data Scrambler)

Comparing the shift register specified in 802.11 with the shift register implemented using a `comm.PNSequence` System object, note that the two shift register schematics are mirror images of each other. Therefore, when configuring the `comm.PNSequence` System object to implement an additive scrambler, you must reverse values for the generator polynomial, the initial states, and the mask output. To take the output of the register from the leading end, specify a shift value of 7.

For more information about the 802.11 scrambler, see [1] on page 3-1290 and the `wlanScramble` (WLAN Toolbox) reference page.

Define variables for the generator polynomial, shift value for the output, an initial shift register state, a frame of input data, and a variable containing the 127-bit scrambler sequence specified in section 17.3.5.5 of the IEEE 802.11 standard. Create a PN sequence object that initializes the registers by using an input argument.

```
genPoly = 'x^7 + x^3 + 1'; % Generator polynomial
shift = 7; % Shift value for output
spf = 127; % Samples per frame
initState = [1 1 1 1 1 1 1]; % Initial shift register state
dataIn = randi([0 1], spf, 1);
ieee802_11_scram_seq = logical([ ...
    0 0 0 0 1 1 1 0 1 1 1 1 0 0 1 0 1 1 0 0 1 ...
    0 0 1 0 0 0 0 0 0 1 0 0 0 1 0 0 1 1 0 0 0 ...
    1 0 1 1 1 0 1 0 1 1 0 1 1 0 0 0 0 0 1 1 0 ...
    0 1 1 0 1 0 1 0 0 1 1 1 0 0 1 1 1 1 1 0 1 1 ...
    0 1 0 0 0 0 1 0 1 0 1 0 1 1 1 1 1 1 1 0 1 0 ...
    1 0 1 0 0 0 1 1 0 1 1 1 0 0 0 1 1 1 1 1 1 1]);

pnSeq = comm.PNSequence( ...
    Polynomial=genPoly, ...
```

```
InitialConditionsSource="Input Port", ...  
Mask=shift, ...  
SamplesPerFrame=spf, ...  
OutputDataType="logical");  
pnsequence = pnSeq(initState);
```

Compare the PN sequence object output to the IEEE 802.11 127-bit scrambler sequence to confirm the generated PN sequence matches the 802.11 specified sequence.

```
isequal(ieee802_11_scram_seq,pnsequence)
```

```
ans = logical  
     1
```

Scramble input data according to the 802.11 specified additive scrambler by modulo-adding input data with the PN sequence output.

```
scrambledOut = xor(dataIn,pnSeq(initState));
```

Descramble the scrambled data by applying the same scrambler and initial conditions to the scrambled data.

```
descrambledData = xor(scrambledOut,pnSeq(initState));
```

Verify that the descrambled data matches the input data.

```
isequal(dataIn,descrambledData)
```

```
ans = logical  
     1
```

## comm.SphereDecoder

**Package:** comm

Decode input using sphere decoder

### Description

The Sphere Decoder System object decodes the symbols sent over  $N_T$  antennas using the sphere decoding algorithm.

To decode input symbols using a sphere decoder:

- 1 Define and set up your sphere decoder object. See “Construction” on page 3-1292.
- 2 Call `step` to decode input symbols according to the properties of `comm.SphereDecoder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`H = comm.SphereDecoder` creates a System object, `H`. This object uses the sphere decoding algorithm to find the maximum-likelihood solution for a set of received symbols over a MIMO channel with  $N_T$  transmit antennas and  $N_R$  receive antennas.

`H = comm.SphereDecoder(Name, Value)` creates a sphere decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes (''). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`H = comm.SphereDecoder(CONSTELLATION, BITTABLE)` creates a sphere decoder object, `H`, with the `Constellation` property set to `CONSTELLATION`, and the `BitTable` property set to `BITTABLE`.

### Properties

#### Constellation

Signal constellation per transmit antenna

Specify the constellation as a complex column vector containing the constellation points to which the transmitted bits are mapped. The default setting is a QPSK constellation with an average power of 1. The length of the vector must be a power of two. The object assumes that each transmit antenna uses the same constellation.

#### BitTable

Bit mapping used for each constellation point.

Specify the bit mapping for the symbols that the `Constellation` property specifies as a numerical matrix. The default is `[0 0; 0 1; 1 0; 1 1]`, which matches the default `Constellation` property value.

The matrix size must be `[ConstellationLength bitsPerSymbol]`. `ConstellationLength` represents the length of the `Constellation` property. `bitsPerSymbol` represents the number of bits that each symbol encodes.

### InitialRadius

Initial search radius of the decoding algorithm.

Specify the initial search radius for the decoding algorithm as either `Infinity` | `ZF Solution`. The default is `Infinity`.

When you set this property to `Infinity`, the object sets the initial search radius to `Inf`.

When you set this property to `ZF Solution`, the object sets the initial search radius to the zero-forcing solution. This calculation uses the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the `ZF Solution` will not provide a benefit.

### DecisionType

Specify the decoding decision method as either `Soft` | `Hard`. The default is `Soft`.

When you set this property to `Soft`, the decoder outputs log-likelihood ratios (LLRs), or soft bits.

When you set this property to `Hard`, the decoder converts the soft LLRs to bits. The hard-decision output logical array follows the mapping of a zero for a negative LLR and one for all other values.

### Methods

`step` Decode received symbols using sphere decoding algorithm

Common to All System Objects	
<code>release</code>	Allow System object property value changes

### Examples

#### Decode Using a Sphere Decoder

Modulate a set of bits using 16-QAM constellation. Transmit the signal as two parallel streams over a MIMO channel. Decode using a sphere decoder with perfect channel knowledge.

Specify the modulation order, the number of transmitted bits, the Eb/No ratio, and the symbol mapping.

```

bps = 4; % Bits per symbol
M = 2^bps; % Modulation order
nBits = 1e3*bps;
ebno = 10;
symMap = [11 10 14 15 9 8 12 13 1 0 4 5 3 2 6 7];

```

Generate and display the symbol mapping of the 16-QAM modulator by using the `qammod` function and the custom symbol map.

```

sym = qammod(symMap(1:M)',M,symMap, ...
    'UnitAveragePower',true,'PlotConstellation',true);

```

Convert the decimal value of the symbol map to binary bits using the left bit as the most significant bit (msb). The M-by-bps matrix `bitTable` is used by the sphere decoder.

```
bitTable = int2bit(symMap,bps)';
```

Create a 2x2 MIMO Channel System object with `PathGainsOutputPort` set to `true` to use the path gains as a channel estimate. To ensure the repeatability of results, set the object to use the global random number stream.

```

mimo = comm.MIMOChannel( ...
    'PathGainsOutputPort',true, ...
    'RandomStream','Global stream');

```

Create an AWGN Channel System object.

```
awgnChan = comm.AWGNChannel('EbNo',ebno,'BitsPerSymbol',bps);
```

Create a Sphere Decoder System object that processes bits using hard-decision decoding. Configure using the custom bit table and symbol map.

```
sphDec = comm.SphereDecoder('Constellation',sym, ...
    'BitTable',bitTable,'DecisionType','Hard');
```

Create an error rate System object.

```
berRate = comm.ErrorRate;
```

Set the global random number generator seed.

```
rng(37)
```

Generate a random data stream.

```
data = randi([0 1],nBits,1);
```

Modulate the data and reshape it into two streams to be used with the 2x2 MIMO channel.

```
modData = qammod(data,M,symMap, ...
    'InputType','bit','UnitAveragePower',true);
modData = reshape(modData,[],2);
```

Pass the modulated data through the MIMO fading channel and add AWGN.

```
[fadedSig,pathGains] = mimo(modData);
rxSig = awgnChan(fadedSig);
```

Decode the received signal using pathGains as a perfect channel estimate.

```
decodedData = sphDec(rxSig,squeeze(pathGains));
```

Convert the decoded hard-decision data, which is a logical matrix, into a double column vector to enable the calculation of error statistics. Calculate and display the bit error rate and the number of errors.

```
dataOut = double(decodedData(:));
errorStats = berRate(data,dataOut);
errorStats(1:2)
```

```
ans = 2×1
```

```
    0.0380
   152.0000
```

## Algorithm

This object implements a soft-output max-log a posteriori probability (APP) MIMO detector by means of a soft-output Schnorr-Euchner sphere decoder (SESD), implemented as single tree search (STS) tree traversal. The algorithm assumes the same constellation and bit table on all of the transmit antennas. Given as inputs, the received symbol vector and the estimated channel matrix, the algorithm outputs the log-likelihood ratios (LLRs) of the transmitted bits.

The algorithm assumes a MIMO system model with  $N_T$  transmit antennas and  $N_R$  receive antennas where  $N_T$  symbols are simultaneously sent, expressed as:

$$y = Hs + n.$$

where  $y$  is the received symbols,  $H$  is the MIMO channel matrix,  $s$  is the transmitted symbol vector, and  $n$  is the thermal noise.

The MIMO detector seeks the maximum-likelihood (ML) solution,  $\hat{s}_{ML}$ , such that:

$$\hat{s}_{ML} = \underset{s \in O}{\operatorname{argmin}} \|y - Hs\|^2$$

where  $O$  is the complex-valued constellation from which the  $N_T$  elements of  $s$  are chosen.

Soft detection also computes a log-likelihood ratio (LLR) for each bit that serves as a measure of the reliability of the estimate for each bit. The LLR is calculated as using the max-log approximation:

$$L(x_{j,b}) = \min_{s \in x_{j,b}^{(0)}} \|y - Hs\|^2 - \min_{s \in x_{j,b}^{(1)}} \|y - Hs\|^2$$

$\lambda^{ML}$ 
 $\lambda^{\overline{ML}}$

where

- $L(x_{j,b})$  is the LLR estimate for each bit.
- $x_{j,b}$  is each sent bit, the  $b$ th bit of the  $j$ th symbol.
- $x_{j,b}^{(0)}$  and  $x_{j,b}^{(1)}$  are the disjoint sets of vector symbols that have the  $b$ th bit in the label of the  $j$ th scalar symbol equal to 0 and 1, respectively. The two  $\lambda$  symbols denotes the distance calculated as norm squared., specifically:

- $\lambda^{ML}$  is the distance  $\hat{s}_{ML}$ .
- $\lambda^{\overline{ML}}$  is the distance to the counter-hypothesis, which denotes the binary complement of the  $b$ th

bit in the binary label of the  $j$ th entry of  $\hat{s}_{ML}$ , specifically the minimum of the symbol set  $x_{j,b}^{\overline{ML}}$ ,

which contains all of the possible vectors for which the  $b$ th bit of the  $j$ th entry is flipped compared to the same entry of  $\hat{s}_{ML}$ .

Based on whether  $x_{j,b}^{(ML)}$  is 0 or 1, the LLR estimate for bit  $x_{j,b}$  is computed as follows:

$$L(x_{j,b}) = \begin{cases} \lambda^{ML} - \lambda_{j,b}^{\overline{ML}}, & x_{j,b}^{ML} = 0 \\ \lambda_{j,b}^{\overline{ML}} - \lambda^{ML}, & x_{j,b}^{ML} = 1 \end{cases}$$

The design of a decoder strives to efficiently find  $\hat{s}_{ML}$ ,  $\lambda^{ML}$ , and  $\lambda_{j,b}^{\overline{ML}}$ .

This search can be converted into a tree search by means of the sphere decoding algorithms. To this end, the channel matrix is decomposed into  $H = QR$  by means of a QR decomposition. Left-multiplying  $y$  by  $Q^H$ , the problem can be reformulated as:

$$\lambda^{ML} = \arg \min_{s \in \mathcal{O}} \|\bar{y} - Rs\|$$

$$\lambda_{j,b}^{\overline{ML}} = \underset{s \in \mathcal{X}_{j,b} \left( x_{j,b}^{\overline{ML}} \right)}{\operatorname{argmin}} \|\bar{y} - Rs\|^2$$

Using this reformulated problem statement, the triangular structure of  $R$  can be exploited to arrange a tree structure such that each of the leaf nodes corresponds to a possible  $s$  vector and the partial

distances to the nodes in the tree can be calculated cumulatively adding to the partial distance of the parent node.

In the STS algorithm, the  $\lambda^{ML}$  and  $\lambda_{j,b}^{\overline{ML}}$  metrics are searched concurrently. The goal is to have a list containing the metric  $\lambda^{ML}$ , along with the corresponding bit sequence  $x^{ML}$  and the metrics  $x_{j,b}^{(ML)}$  of all counter-hypotheses. The sub-tree originating from a given node is searched only if the result can lead to an update of either  $\lambda^{ML}$  or  $\lambda_{j,b}^{\overline{ML}}$ .

The STS algorithm flow can be summarized as:

- 1** If when reaching a leaf node, a new ML hypothesis is found ( $d(x) < \lambda^{ML}$ ), all  $\lambda_{j,b}^{\overline{ML}}$  for which  $x_{j,b} = x_{j,b}^{\overline{ML}}$  are set to  $\lambda^{ML}$  which now turns into a valued counter-hypothesis. Then,  $\lambda^{ML}$  is set to the current distance,  $d(x)$ .
- 2** If  $d(x) \geq \lambda^{ML}$ , only the counter-hypotheses have to be checked. For all  $j$  and  $b$  for which ( $d(x) < \lambda^{ML}$ ) and  $x_{j,b} = x_{j,b}^{\overline{ML}}$ , the decoder updates  $\lambda_{j,b}^{\overline{ML}}$  to be  $d(x)$ .
- 3** A sub-tree is pruned if the partial distance of the node is bigger than the current  $\lambda_{j,b}^{\overline{ML}}$  which may be affected when traversing the subtree.
- 4** The STS concludes once all of the tree nodes have been visited once or pruned.

## Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

## step

**System object:** comm.SphereDecoder

**Package:** comm

Decode received symbols using sphere decoding algorithm

### Syntax

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$  decodes the received symbols, `RXSYMBOLS`, using the sphere decoding algorithm. The algorithm can be employed to decode  $N_s$  channel realizations in one call, where in each channel realization,  $N_r$  symbols are received.

The inputs are:

`RXSYMBOLS`: a  $[N_s \ N_r]$  complex double matrix containing the received symbols.

`CHAN`: a  $[N_s \ N_t \ N_r]$  or  $[1 \ N_t \ N_r]$  complex double matrix representing the fading channel coefficients of the flat-fading MIMO channel. For the  $[N_s \ N_t \ N_r]$  case, the object applies each channel matrix to each  $N_r$  symbol set. For the block fading case, i.e., when the size of `CHAN` is  $[1 \ N_t \ N_r]$ , the same channel is applied to all of the received symbols.

The output  $Y$ , which depends on the setting of the `DecisionType` property, is a double matrix containing the Log-Likelihood Ratios (LLRs) of the decoded bits or the bits themselves. For both cases, the size of the output is  $[N_s * \text{bitsPerSymbol} \ N_t]$ , where `bitsPerSymbol` represents the number of bits per transmitted symbol, as determined by the `BitTable` property.

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

---

# comm.SymbolSynchronizer

**Package:** comm

Correct symbol timing clock skew

## Description

The `comm.SymbolSynchronizer` System object corrects symbol timing clock skew between a single-carrier transmitter and receiver for PAM, PSK, QAM, and OQPSK modulation schemes. For more information, see “Symbol Synchronization Overview” on page 3-1319.

---

**Note** The input signal operates on a sample-rate basis and the output signal operates on a symbol-rate basis.

---

To correct symbol timing clock skew:

- 1 Create the `comm.SymbolSynchronizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
symbolSync = comm.SymbolSynchronizer
symbolSync = comm.SymbolSynchronizer(Name,Value)
```

### Description

`symbolSync = comm.SymbolSynchronizer` creates a symbol synchronizer System object for correcting the clock skew between a single-carrier transmitter and receiver.

`symbolSync = comm.SymbolSynchronizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.SymbolSynchronizer('Modulation','OQPSK')` configures the symbol synchronizer System object for an OQPSK-modulated input signal. Enclose each property name in quotes.

Tunable `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties enable you to optimize synchronizer performance in your simulation loop without releasing the object.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**Modulation — Modulation type**

'PAM/PSK/QAM' (default) | 'QPSK'

Modulation type, specified as 'PAM/PSK/QAM' or 'QPSK'.

**Tunable:** No

Data Types: char | string

**TimingErrorDetector — Timing error detector method**

Zero-Crossing (decision-directed) (default) | Gardner (non-data-aided) | Early-Late (non-data-aided) | Mueller-Muller (decision-directed)

Timing error detector method, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decision-directed). This property assigns the timing error detection scheme used in the synchronizer. For more information, see “Timing Error Detection (TED)” on page 3-1320.

**Tunable:** No

Data Types: char | string

**SamplesPerSymbol — Samples per symbol**

2 (default) | integer greater than 1

Samples per symbol, specified as an integer greater than 1. For more information, see  $N_{\text{sps}}$  in “Loop Filter” on page 3-1323.

**Tunable:** No

Data Types: double

**DampingFactor — Damping factor of loop filter**

1 (default) | positive scalar

Damping factor of the loop filter, specified as a positive scalar. For more information, see  $\zeta$  in “Loop Filter” on page 3-1323.

**Tunable:** Yes

Data Types: double | single

**NormalizedLoopBandwidth — Normalized bandwidth of loop filter**

0.01 (default) | scalar in the range (0, 1)

Normalized bandwidth of the loop filter, specified as a scalar in the range (0, 1). The loop bandwidth is normalized to the sample rate of the input signal. For more information, see  $B_n T_s$  in “Loop Filter” on page 3-1323.

---

**Note** To ensure the symbol synchronizer locks, set the `NormalizedLoopBandwidth` property to a value less than 0.1.

---

**Tunable:** Yes

Data Types: double | single

### **DetectorGain — Phase detector gain**

2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar. For more information, see  $K_p$  in “Loop Filter” on page 3-1323.

**Tunable:** Yes

Data Types: double | single

## **Usage**

---

**Note** For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## **Syntax**

```
symbols = symbolSync(samples)
```

### **Description**

`symbols = symbolSync(samples)` corrects symbol timing clock skew between a single-carrier transmitter and receiver based on the input samples and outputs synchronized symbols.

- The input operates on a sample-rate basis and the output signal operates on a symbol-rate basis.
- You can tune the `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties to improve the synchronizer performance.

### **Input Arguments**

#### **samples — Input samples**

scalar (default) | column vector

Input samples, specified as a scalar or column vector of a PAM-, PSK-, QAM-, or OQPSK-modulated single-carrier signal.

Data Types: double | single

Complex Number Support: Yes

### **Output Arguments**

#### **symbols — Synchronized symbols**

column vector

Synchronized symbols, returned as a variable-sized column vector. The output symbols inherit the data type from the input samples. For an input with dimensions  $N_{\text{samp}}$ -by-1, this output has dimensions  $N_{\text{sym}}$ -by-1.  $N_{\text{sym}}$  is approximately equal to  $N_{\text{samp}}$  divided by  $N_{\text{sps}}$ , where  $N_{\text{sps}}$  is equal to the `SamplesPerSymbol` property value. The output length is truncated if it exceeds the maximum output size of  $\left\lceil \frac{N_{\text{samp}}}{N_{\text{sps}}} \times 1.1 \right\rceil$ .

#### **timingErr** – Estimated timing error

scalar in the range [0, 1] | column vector of elements in the range [0, 1]

Estimated timing error for each input sample, returned as a scalar in the range [0, 1] or column vector of elements in the range [0, 1]. The estimated timing error is normalized to the input sample rate. `timingErr` has the same data type and size as `input samples`.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `comm.SymbolSynchronizer`

`clone`      Create duplicate System object  
`isLocked`   Determine if System object is in use

### Common to All System Objects

`step`      Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

## Examples

### Correct Symbol Timing Error of QPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy QPSK-modulated signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 4;                    % Modulation order for QPSK
nSym = 5000;            % Number of symbols in a packet
sps = 4;                % Samples per symbol
timingErr = 2;          % Samples of timing error
snr = 15;               % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps,'DecimationFactor',2);
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer;
```

Generate random M-ary symbols and apply QPSK modulation.

```
data = randi([0 M-1],nSym,1);  
modSig = pskmod(data,M,pi/4);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);  
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

```
txSig = txfilter(modSig);  
delaySig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected QPSK reference constellation.

```
rxSample = rxfilter(rxSig);  
scatterplot(rxSample(1001:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected QPSK constellation.

```
rxSync = symbolSync(rxSample);  
scatterplot(rxSync(1001:end),2)
```

Demodulate the QPSK signal.

```
recData = pskdemod(rxSync,M,pi/4);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr,ber] = biterr(sysDelay(data), recData)
```

```
numErr = 10
```

```
ber = 1.0000e-03
```

### Correct Symbol Timing Error of BPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy BPSK transmission signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 2;           % Modulation order for BPSK
nSym = 20000;   % Number of symbols in a packet
sps = 4;        % Samples per symbol
timingErr = 2;  % Samples of timing error
snr = 15;       % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',1);
```

Create a symbol synchronizer System object™ to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'SamplesPerSymbol',sps, ...
    'NormalizedLoopBandwidth',0.01, ...
    'DampingFactor',1.0, ...
    'TimingErrorDetector','Early-Late (non-data-aided)');
```

Generate random data symbols and apply BPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

```
txSig = txfilter(modSig);
delayedSig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel.

```
rxSig = awgn(delayedSig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected BPSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample(10000:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected BPSK constellation.

```
rxSync = symbolSync(rxSample);  
scatterplot(rxSync(10000:end),2)
```

Demodulate the BPSK signal.

```
recData = pskdemod(rxSync,M);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr1,ber1] = biterr(sysDelay(data),recData)
```

```
numErr1 = 8
```

```
ber1 = 4.0000e-04
```

### Correct Symbol Timing and Doppler Offsets

Correct symbol timing and frequency offset errors by using the `comm.SymbolSynchronizer` and `comm.CarrierSynchronizer` System objects.

#### Configuration

Initialize simulation parameters.

```

M = 16;           % Modulation order
nSym = 2000;     % Number of symbols in a packet
sps = 2;         % Samples per symbol
spsFilt = 8;     % Samples per symbol for filters and channel
spsSync = 2;    % Samples per symbol for synchronizers
lenFilt = 10;   % RRC filter length

```

Create a matched pair of root raised cosine (RRC) filter System objects for transmitter and receiver.

```

txfilter = comm.RaisedCosineTransmitFilter( ...
    FilterSpanInSymbols=lenFilt, ...
    OutputSamplesPerSymbol=spsFilt, ...
    Gain=sqrt(spsFilt));
rxfilter = comm.RaisedCosineReceiveFilter( ...
    FilterSpanInSymbols=lenFilt, ...
    InputSamplesPerSymbol=spsFilt, ...
    DecimationFactor=spsFilt/2, ...
    Gain=sqrt(1/spsFilt));

```

Create a phase-frequency offset System object to introduce a 100 Hz Doppler shift.

```

doppler = comm.PhaseFrequencyOffset( ...
    FrequencyOffset=100, ...
    PhaseOffset=45, ...
    SampleRate=1e6);

```

Create a variable delay System object to introduce timing offsets.

```

varDelay = dsp.VariableFractionalDelay;

```

Create carrier and symbol synchronizer System objects to correct for Doppler shift and timing offset, respectively.

```

carrierSync = comm.CarrierSynchronizer( ...
    SamplesPerSymbol=spsSync);
symbolSync = comm.SymbolSynchronizer( ...
    TimingErrorDetector='Early-Late (non-data-aided)', ...
    SamplesPerSymbol=spsSync);

```

Create constellation diagram System objects to view the results.

```

refConst = qammod(0:M-1,M,UnitAveragePower=true);
cdReceive = comm.ConstellationDiagram( ...
    ReferenceConstellation=refConst, ...
    SamplesPerSymbol=spsFilt,Title='Received Signal');
cdDoppler = comm.ConstellationDiagram( ...
    ReferenceConstellation=refConst, ...
    SamplesPerSymbol=spsSync, ...
    Title='Frequency Corrected Signal');
cdTiming = comm.ConstellationDiagram( ...
    ReferenceConstellation=refConst, ...
    SamplesPerSymbol=spsSync, ...
    Title='Frequency and Timing Synchronized Signal');

```

### Main Processing Loop

The main processing loop:

- Generates random symbols and applies QAM modulation.
- Filters the modulated signal.
- Applies frequency and timing offsets.
- Passes the transmitted signal through an AWGN channel.
- Filters the received signal.
- Corrects the Doppler shift.
- Corrects the timing offset.

```
for k = 1:15
    data = randi([0 M-1],nSym,1);
    modSig = qammod(data,M,UnitAveragePower=true);
    txSig = txfilter(modSig);

    txDoppler = doppler(txSig);
    txDelay = varDelay(txDoppler,k/15);

    rxSig = awgn(txDelay,25);

    rxFiltSig = rxfilter(rxSig);
    rxCorr = carrierSync(rxFiltSig);
    rxData = symbolSync(rxCorr);
end
```

### Visualization

Plot the constellation diagrams of the received signal, frequency corrected signal, and frequency and timing synchronized signal. Specific constellation points cannot be identified in the received signal and can be only partially identified in the frequency corrected signal. However, the timing and frequency synchronized signal aligns with the expected QAM constellation points.

```
cdReceive(rxSig)
```

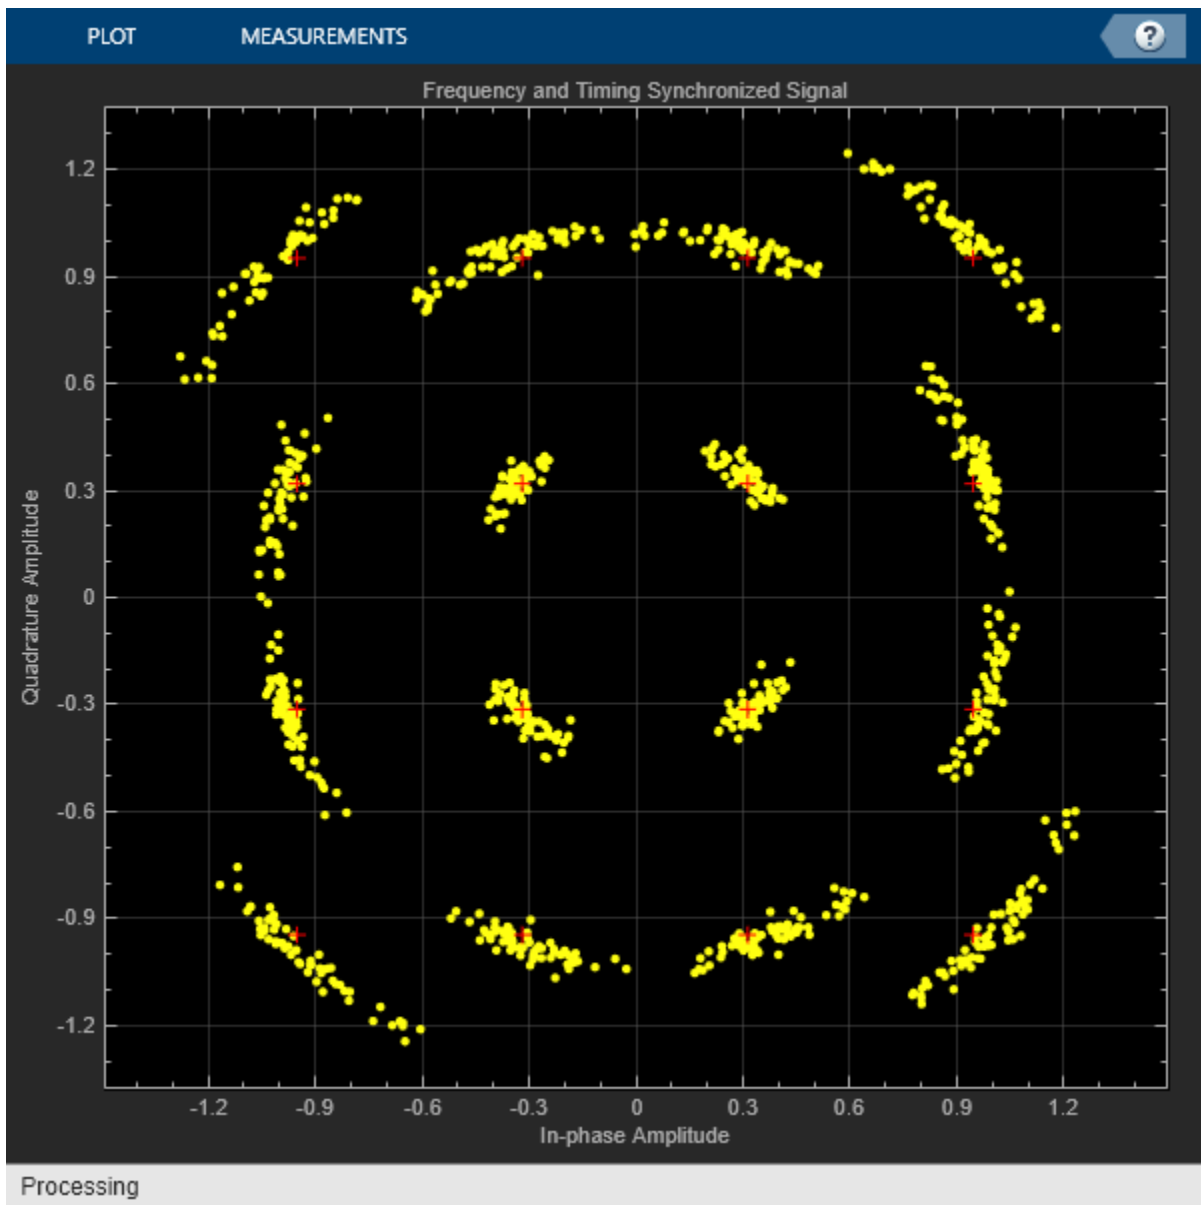

```
cdDoppler(rxCorr)
```

`cdTiming(rxData)`

### Timing Error for Noisy 8-PSK Signal

Correct a monotonically increasing symbol timing error on a noisy 8-PSK signal. Display the normalized timing error.

Initialize simulation parameters.

```
M = 8;           % Modulation order
nSym = 5000;    % Number of symbol in a packet
sps = 2;       % Samples per symbol
nSamp = sps*nSym; % Number of samples in a packet
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...  
    'OutputSamplesPerSymbol',sps);  
rxfilter = comm.RaisedCosineReceiveFilter( ...  
    'InputSamplesPerSymbol',sps, ...  
    'DecimationFactor',1);
```

Create a variable fractional delay System object™ to introduce a monotonically increasing timing error.

```
varDelay = dsp.VariableFractionalDelay;
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...  
    'TimingErrorDetector','Mueller-Muller (decision-directed)', ...  
    'SamplesPerSymbol',sps);
```

Generate random 8-ary symbols and apply 8-PSK modulation.

```
data = randi([0 M-1],nSym,1);  
modSig = pskmod(data,M,pi/8);
```

Filter the modulated signal through a raised cosine transmit filter and apply a monotonically increasing timing delay.

```
vdelay = (0:1/nSamp:1-1/nSamp)';  
txSig = txfilter(modSig);  
delaySig = varDelay(txSig,vdelay);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,15,'measured');
```

Filter the modulated signal through a receive RRC filter. Display the scatter plot. Due to the timing error, the received signal does not align with the expected 8-PSK reference constellation.

```
rxSample = rxfilter(rxSig);  
scatterplot(rxSample,sps)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected 8-PSK constellation.

```
[rxSym,tError] = symbolSync(rxSample);  
scatterplot(rxSym(1001:end))
```

Plot the timing error estimate. Over time, the normalized timing error increases to 1 sample.

```
figure
plot(vdelay,tError)
xlabel('Time (s)')
ylabel('Timing Error (samples)')
```

## More About

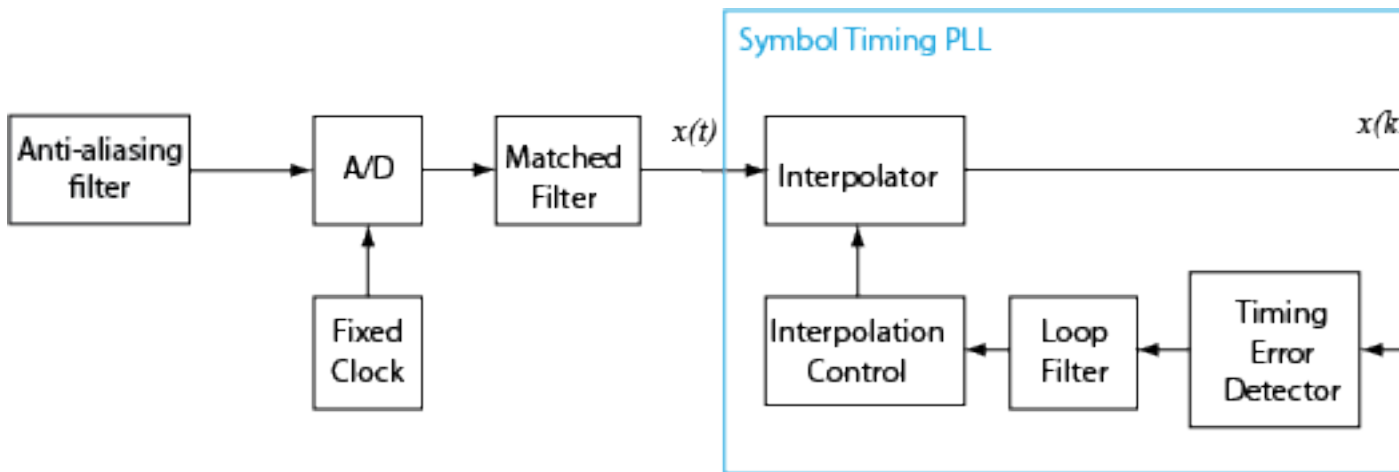

### Symbol Synchronization Overview

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- Timing error detector (TED)
- Interpolator
- Interpolation controller
- Loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on  $x(t)$ , the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal,  $x(kT_s + \hat{\tau})$ , after correcting for the clock skew between the transmitter and receiver.

### Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

TED Method	Expression
Zero-crossing (decision-directed)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[\hat{a}_0(k - 1) - \hat{a}_0(k)] + y((k - 1/2)T_s + \hat{\tau})[\hat{a}_1(k - 1) - \hat{a}_1(k)]$
Gardner (non-data-aided)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[x((k - 1)T_s + \hat{\tau}) - x(kT_s + \hat{\tau})] + y((k - 1/2)T_s + \hat{\tau})[y((k - 1)T_s + \hat{\tau}) - y(kT_s + \hat{\tau})]$
Early-late (non-data-aided)	$e(k) = x(kT_s + \hat{\tau})[x((k + 1/2)T_s + \hat{\tau}) - x((k - 1/2)T_s + \hat{\tau})] + y(kT_s + \hat{\tau})[y((k + 1/2)T_s + \hat{\tau}) - y((k - 1/2)T_s + \hat{\tau})]$
Mueller-Muller (decision-directed)	$e(k) = \hat{a}_0(k - 1)x(kT_s + \hat{\tau}) - \hat{a}_0(k)x((k - 1)T_s + \hat{\tau}) + \hat{a}_1(k - 1)y(kT_s + \hat{\tau}) - \hat{a}_1(k)y((k - 1)T_s + \hat{\tau})$

The non-data-aided TED (Gardner and early-late) methods use received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at  $\{1+0i, 0+1i, -1+0i, 0-1i\}$  and BPSK-modulated signals with a zero phase offset.

The early-late method is similar to the Gardner method but the Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

- Gardner method** — The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately 40% and 100%. Examples

include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.

- **Early-late method** — The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

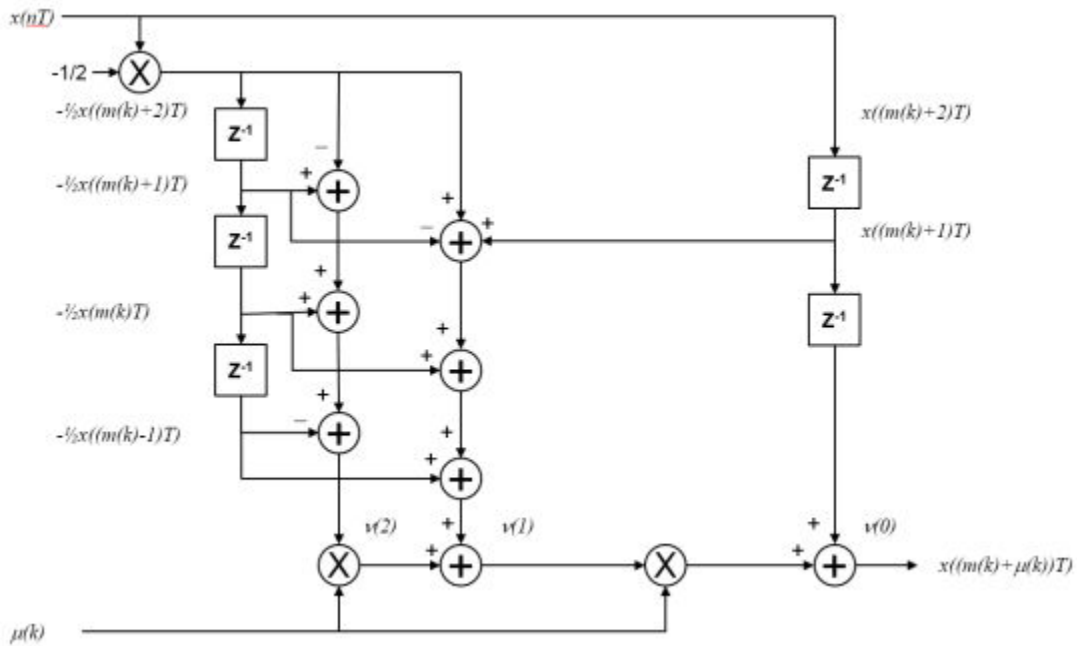

The decision-directed TED (zero-crossing and Mueller-Muller) methods use the `sign` function to estimate the in-phase and quadrature components of received samples, which results in lower computational complexity than the non-data-aided TED methods.

- **Zero-crossing method** — The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- **Mueller-Muller method** — The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component.  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$  are the in-phase and quadrature components of the input signals to the timing error detector, where  $\hat{\tau}$  is the estimated timing error. The Mueller-Muller method coefficients  $\hat{a}_0(k)$  and  $\hat{a}_1(k)$  are the estimates of  $x(kT_s + \hat{\tau})$  and  $y(kT_s + \hat{\tau})$ . The timing estimates are made by applying the `sign` function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

### Interpolator

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient  $\alpha$  set to  $1/2$  (see Rice, Michael, *Digital Communications: A Discrete-Time Approach*).

### Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

### Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain,  $K_1$ , and the integrator gain,  $K_2$ , are calculated by

$$K_1 = \frac{-4\zeta\theta}{(1 + 2\zeta\theta + \theta^2)K_p}$$

and

$$K_2 = \frac{-4\theta^2}{(1 + 2\zeta\theta + \theta^2)K_p}.$$

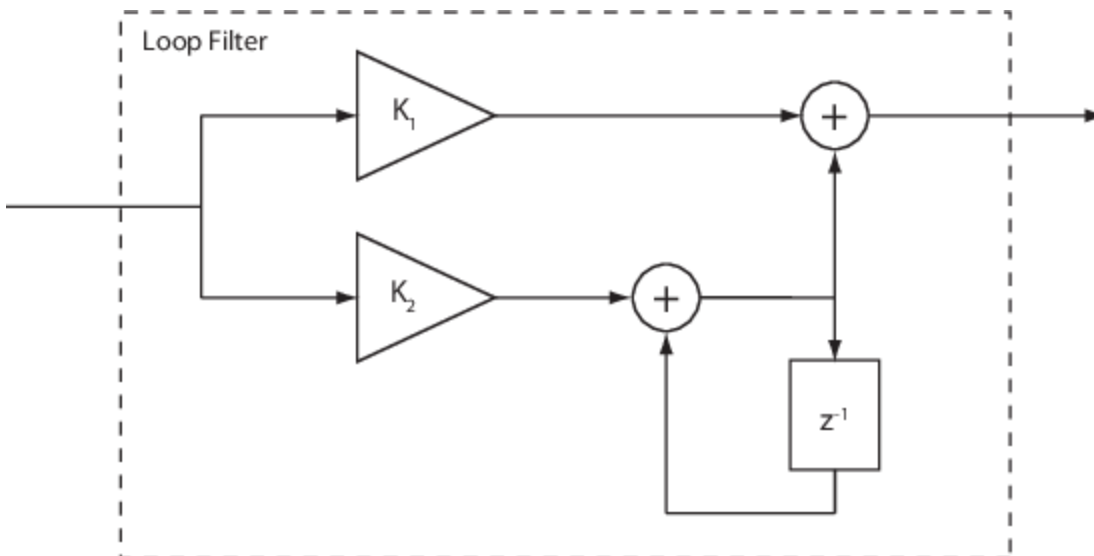

The interim term,  $\theta$ , is given by

$$\theta = \frac{\frac{B_n T_s}{N_{\text{sps}}}}{\zeta + \frac{1}{4\zeta}},$$

where:

- $N_{\text{sps}}$  is the number of samples per symbol.

- $\zeta$  is the damping factor.
- $B_n T_s$  is the normalized loop bandwidth.
- $K_p$  is the detector gain.

# comm.ThermalNoise

**Package:** comm

Add thermal noise to signal

## Description

The `comm.ThermalNoise` System object object simulates the effects of thermal noise on a complex baseband signal. For more information, see “Algorithms” on page 3-1331.

To add thermal noise to a complex baseband signal:

- 1 Create the `comm.ThermalNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
noise = comm.ThermalNoise  
noise = comm.ThermalNoise(Name=Value)
```

### Description

`noise = comm.ThermalNoise` creates a receiver thermal noise System object. This object adds thermal noise to the complex baseband input signal.

`noise = comm.ThermalNoise(Name=Value)` sets properties using one or more name-value arguments. For example, `SampleRate=2` sets the input signal sample rate to 2.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### NoiseMethod — Method used to set noise power

'Noise temperature' (default) | 'Noise figure' | 'Noise factor'

Method used to set the noise power, specified as 'Noise temperature', 'Noise figure', or 'Noise factor'.

**NoiseTemperature — Receiver noise temperature**

290 (default) | nonnegative scalar

Receiver noise temperature, specified in kelvins as a nonnegative scalar. Noise temperature is typically used to characterize receivers because the input noise temperature can vary and is often less than 290 K.

**Tunable:** Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise temperature'.

Data Types: double

**NoiseFigure — Noise figure**

3.01 (default) | nonnegative scalar

Noise figure in dB, specified as a nonnegative scalar. Noise figure describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise figure is the dB equivalent of the noise factor.

**Tunable:** Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise figure'.

Data Types: double

**NoiseFactor — Noise factor**2 (default) | scalar  $\geq 1$ 

Noise factor, specified as a scalar greater than or equal to 1. Noise factor describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise factor is the linear equivalent of the noise figure.

**Tunable:** Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise factor'.

Data Types: double

**ReferenceLoad — Reference load**

1 (default) | positive scalar

Reference load in ohms, specified as a positive scalar. The reference load value is used to compute the voltage levels based on the signal and noise power levels.

**Tunable:** Yes

Data Types: double

**SampleRate — Sample rate**

1 (default) | positive scalar

Sample rate in Hz, specified as a positive scalar. The object computes the variance of the noise added to the input signal as  $kT \times \text{SampleRate}$ . The value  $k$  is Boltzmann's constant and  $T$  is the noise temperature specified explicitly or implicitly via one of the noise methods.

Data Types: double

**Add290KAntennaNoise — Option to add 290 K antenna noise**

false or 0 (default) | true or 1

Option to add 290 K antenna noise to the input signal, specified as a logical 0 (false) or 1 (true). To add 290 K antenna noise, set this property to true. The total noise applied to the input signal is the sum of the circuit noise and the antenna noise.

**Dependencies**

To enable this property, set the NoiseMethod property to 'Noise factor' or 'Noise figure'.

**Usage****Syntax**

```
outsignal = noise(insignal)
```

**Description**

`outsignal = noise(insignal)` adds thermal noise to the complex baseband input signal `insignal` and returns the result in `outsignal`.

**Input Arguments****insignal — Input signal**

scalar | column vector

Baseband signal, specified as a scalar or column vector of complex values.

Data Types: single | double

Complex Number Support: Yes

**Output Arguments****outsignal — Output signal**

scalar | column vector

Output signal, returned as a scalar or column vector of complex values with the same length and data type as the input signal.

Data Types: single | double

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Add Thermal Noise to QPSK Signal

Create a thermal noise object with a noise temperature of 290 K and a sample rate of 5 MHz.

```
thNoise = comm.ThermalNoise('NoiseTemperature',290,'SampleRate',5e6);
```

Generate QPSK modulated data with an output power of 20 dBm.

```
data = randi([0 3],1000,1);  
modData = (10^((20-30)/20)) * pskmod(data,4,pi/4);
```

Attenuate the signal by the free space path loss assuming a 1000 m link distance and a carrier frequency of 2 GHz.

```
d = 1000;           % m  
f = 2e9;           % Hz  
c = 3e8;           % m/s  
fsl = (4*pi*d*f/c)^2;  
rxData = modData/sqrt(fsl);
```

Add thermal noise to the signal. Plot the noisy constellation.

```
noisyData = thNoise(rxData);  
scatterplot(noisyData)
```

### Add Antenna and Receiver Thermal Noise to 16-QAM Signal

Create a thermal noise object with a 5 dB noise figure and a 10 MHz sample rate. Include 290 K antenna noise.

```
thermalNoise = comm.ThermalNoise('NoiseMethod','Noise figure', ...
    'NoiseFigure',5, ...
    'SampleRate',10e6, ...
    'Add290KAntennaNoise',true);
```

Generate QPSK modulated data with an output power of 1 W.

```
data = randi([0 15],1000,1);
modSig = qammod(data,16,'UnitAveragePower',true);
```

Attenuate the signal by the free space path loss assuming a 1 km link distance and a 5 GHz carrier frequency.

```
d = 1000; % m
f = 5e9; % Hz
c = 3e8; % m/s
fsl = (4*pi*d*f/c)^2;
rxSig = modSig/sqrt(fsl);
```

Add thermal noise to the signal and plot its constellation.

```
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR.

```
mer = comm.MER;  
snrEst1 = mer(rxSig,noisySig)
```

```
snrEst1 = 22.6611
```

Decrease the noise figure to 0 dB and plot the resultant received signal. The signal is not completely noiseless because antenna noise is included.

```
thermalNoise.NoiseFigure = 0;  
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR. The SNR is 5 dB higher than in the first case, which is expected given the 5 dB decrease in the noise figure.

```
snrEst2 = mer(rxSig,noisySig)
```

```
snrEst2 = 27.8658
```

```
snrEst2 - snrEst1
```

```
ans = 5.2047
```

## Algorithms

Wireless receiver performance is often expressed as a noise factor or figure. The noise factor is defined as the ratio of the input signal-to-noise ratio,  $S_i/N_i$  to the output signal-to-noise ratio,  $S_o/N_o$ , such that

$$F = \frac{S_i/N_i}{S_o/N_o} .$$

Given the receiver gain  $G$  and receiver noise power  $N_{ckt}$ , the noise factor can be expressed as

$$\begin{aligned} F &= \frac{S_i/N_i}{GS_i/(N_{ckt} + GN_i)} \\ &= \frac{N_{ckt} + GN_i}{GN_i} . \end{aligned}$$

The IEEE defines the noise factor assuming that noise temperature at the input is  $T_0$ , where  $T_0 = 290$  K. The noise factor is then

$$\begin{aligned} F &= \frac{N_{ckt} + GN_i}{GN_i} \\ &= \frac{GkBT_{ckt} + GkBT_0}{GkBT_0} \\ &= \frac{T_{ckt} + T_0}{T_0} . \end{aligned}$$

$T_{ckt}$  is the equivalent input noise temperature of the receiver and is expressed as

$$T_{ckt} = T_0(F - 1) .$$

The overall noise temperature of an antenna and receiver  $T_{sys}$  is

$$T_{sys} = T_{ant} + T_{ckt} ,$$

where  $T_{ant}$  is the antenna noise temperature.

The noise figure  $NF$  is the dB equivalent of the noise factor and can be expressed as

$$NF = 10\log_{10}(F) .$$

The noise power can be expressed as

$$N = kTB = V^2/R ,$$

where  $V$  is the noise voltage expressed as

$$V^2 = kTBR ,$$

and  $R$  is the reference load.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

# comm.TurboDecoder

**Package:** comm

Decode input signal using parallel concatenated decoding scheme

## Description

The `comm.TurboDecoder` System object uses a parallel concatenated decoding scheme to decode a coded input signal. The input signal is typically the soft-decision output from the baseband demodulation operation. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1344.

To decode an input signal using a parallel concatenated decoding scheme:

- 1 Create the `comm.TurboDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
turbodec = comm.TurboDecoder
turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)
turbodec = comm.TurboDecoder( ___,Name,Value)
```

### Description

`turbodec = comm.TurboDecoder` creates a turbo decoder System object. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)` creates a turbo decoder System object with the `TrellisStructure`, `InterleaverIndices`, and `numiter`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property. The `numiter` input must be specified as described by the `NumIterations` property.

`turbodec = comm.TurboDecoder( ___,Name,Value)` sets properties using one or more name-value pairs in addition to any input argument combination from previous syntaxes. Enclose each property name in quotes. For example, `comm.TurboDecoder('InterleaverIndicesSource','Input port')` configures a turbo decoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **TrellisStructure** — Trellis description of constituent convolutional code

`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate  $K/N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

---

**Note**  $K$  must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1345.

---

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

#### **numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

#### **numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

#### **numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

#### **nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

#### **outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: struct

### InterleaverIndicesSource — Source of interleaver indices

'Property' (default) | 'Input port'

Source of interleaver indices, specified as 'Property' or 'Input port'.

- When you set this property to 'Input port', the object executes using the input argument `interlvrindices` when you call the object. The vector length and values for the interleaver indices and coded input signal can change with each call to the object.
- When you set this property to 'Property', the object executes using the interleaver indices that you specified with the `InterleaverIndices` property when configuring the object.

Data Types: char | string

### InterleaverIndices — Interleaver indices

(64:-1:1) .' (default) | column vector of integers

Interleaver indices that define the mapping used to permute the codeword bits input to the decoder, specified as a column vector of integers. The vector must be of length  $L$ . Each element of the vector must be an integer in the range  $[1, L]$  and must be unique.  $L$  is the length decoded output message, `decmsg`. Each element of the vector must be an integer in the range  $[1, L]$  and must be unique.

#### Dependencies

To enable this property, set the `InterleaverIndicesSource` property to 'Property'.

Data Types: double

### InputIndicesSource — Source of input indices

'Auto' (default) | 'Property' | 'Input port'

Source of input indices, specified as 'Auto', 'Property', or 'Input port'.

- When you set this property to 'Auto', the object computes input indices that assume the second systematic stream is punctured and all tail bits are included in the input.
- When you set this property to 'Property', the object uses the input indices that you specify for the `InputIndices` property.
- When this property is set to 'Input port', the object executes using the input indices specified by the input argument `inindices`. The vector length and values for the input indices and the coded input signal can change with each call to the object.

Data Types: char | string

### InputIndices — Input indices

`getTurboIOIndices(64,2,3)` (default) | column vector of integers

Input indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The length of this property must equal the length of the input data vector codeword.

**Dependencies**

To enable this property, set the `InputIndicesSource` property to `'Property'`.

Data Types: `double`

**Algorithm — Decoding algorithm**

`'True APP'` (default) | `'Max*'` | `'Max'`

Decoding algorithm, specified as `'True APP'`, `'Max*'`, or `'Max'`. When you set this property to `'True APP'`, the object implements true APP decoding. When you set this property to `'Max*'` or `'Max'`, the object uses approximations to increase the speed of the computations. For more information, see “APP Decoder” on page 3-1345.

Data Types: `char` | `string`

**NumScalingBits — Number of scaling bits**

3 (default) | integer in the range [0, 8]

Number of scaling bits, specified as an integer in the range [0, 8]. This property sets the number of bits the constituent decoders use to scale the input data to avoid losing precision during computations. The constituent decoders multiply the input by  $2^{\text{NumScalingBits}}$  and divide the pre-output by the same factor. For more information, see “APP Decoder” on page 3-1345.

**Dependencies**

To enable this property, set the `Algorithm` property to `'Max*'`.

Data Types: `double`

**NumIterations — Number of decoding iterations**

6 (default) | positive integer

Number of decoding iterations, specified as a positive integer. This property sets the number of decoding iterations used for each call to the object. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the object is the hard-decision output of the final LLR update.

Data Types: `double`

**Usage****Syntax**

```
decmsg = turbodec(codeword)
decmsg = turbodec(codeword,interlvindices)
decmsg = turbodec(codeword,interlvindices,inindices)
```

**Description**

`decmsg = turbodec(codeword)` decodes the input codeword using the parallel concatenated convolutional decoding scheme that is specified by the trellis structure and interleaver indices.

`turbodec` returns the binary decoded data. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1344.

`decmsg = turbodec(codeword, interlvrindices)` additionally specifies the interleaver indices. To enable this syntax, set the `InterleaverIndicesSource` property to `'Input port'`. The interleaver indices define the mapping used to permute the input at the decoder.

`decmsg = turbodec(codeword, interlvrindices, inindices)` additionally specifies the bit ordering and puncturing used on the fully encoded data. To enable this syntax, set the `InputIndicesSource` property to `'Input port'`. The input indices vector values must be relative to the fully encoded data, including the tail bits for the coding scheme for all streams.

## Input Arguments

### **codeword** — Parallel concatenated codeword

column vector

Parallel concatenated codeword, specified as a column vector of length  $M$ , where  $M$  is the length of the parallel concatenated codeword.

Data Types: `double` | `single`

### **interlvrindices** — Interleaver indices

column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length  $L$ , where  $L$  is the length of the decoded output message, `decmsg`. Each element of the vector must be an integer in the range  $[1, L]$  and must be unique. The interleaver indices define the mapping used to permute the input bits at the decoder.

**Tunable:** Yes

### **Dependencies**

To enable this property, set the `InterleaverIndicesSource` property to `'Input port'`.

Data Types: `double`

### **inindices** — Input indices

column vector of integers

Input indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The length of the `inindices` vector must equal the length of the input data vector `codeword`. Element values in the `inindices` vector must be relative to the fully encoded data, including the tail bits for the coding scheme for all streams.

### **Dependencies**

To enable this argument, set the `InputIndicesSource` property to `'Input port'`.

Data Types: `double`

## Output Arguments

### **decmsg** — Decoded message

binary column vector

Decoded message, returned as a binary column vector of length  $L$ , where  $L$  is the length of the decoded output message. This output signal is the same as data type of the codeword input.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

## Examples

### Define Output and Input Indices for Full-Length and Punctured Turbo Coding

Define output indices by using the `OutputIndices` property for turbo encoding and define the input indices by using the `InputIndices` property for turbo decoding. Show full-length punctured encoding and decoding for a rate 1/2 code and 10-bit block length.

#### Initialize Parameters

Define parameters to initialize the encoder.

```
blkLen = 10;  
trellis = poly2trellis(4,[13 15],13);  
n = log2(trellis.numOutputSymbols);  
mLen = log2(trellis.numStates);
```

#### Full-Length Encoding and Decoding

Initialize variables and turbo encoding and decoding System objects for full-length coding. Turbo encode and decode the message. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
fullOut = (1:(mLen+blkLen)*2*n)';  
outLen = length(fullOut);  
netRate = blkLen/outLen;  
data = randi([0 1],blkLen,1);  
intIndices = randperm(blkLen);  
  
turboEnc = comm.TurboEncoder('TrellisStructure',trellis);  
turboEnc.InterleaverIndices = intIndices;  
turboEnc.OutputIndicesSource = 'Property';  
turboEnc.OutputIndices = fullOut;  
  
turboDec = comm.TurboDecoder('TrellisStructure',trellis);  
turboDec.InterleaverIndices = intIndices;  
turboDec.InputIndicesSource = 'Property';
```

```

turboDec.InputIndices = fullOut;
encMsg = turboEnc(data);      % Encode
disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.19231
encOutLen = length(encMsg)   % Display encoded length
encOutLen = 52
isequal(encOutLen,outLen)    % Check lengths

ans = logical
     1

rxMsg = turboDec(2*encMsg-1); % Decode
isequal(data, rxMsg)        % Compare bits with decoded bits

ans = logical
     1

```

### Punctured Encoding and Decoding

Specify the output indices for puncturing of the second systematic stream by using the `getTurboIOIndices` function. Initialize variables and turbo encoding and decoding System objects for punctured coding. Turbo encode and decode the message. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```

puncOut = getTurboIOIndices(blkLen,n,mLen);
outLen = length(puncOut);
netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = puncOut;

turboDec = comm.TurboDecoder('TrellisStructure',trellis);
turboDec.InterleaverIndices = intIndices;
turboDec.InputIndicesSource = 'Property';
turboDec.InputIndices = puncOut;

encMsg = turboEnc(data);      % Encode

disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.25641
encOutLen = length(encMsg) % Display encoded length
encOutLen = 39

```

```

isequal(encOutLen, outLen) % Check lengths
ans = logical
     1

rxMsg = turboDec(2*encMsg-1); % Decode
isequal(data, rxMsg)          % Compare bits with decoded bits
ans = logical
     1

```

### Compare Full and Punctured Outputs

The output of the encoder interlaces the individual bit streams. The third bit of every 4-bit tuple is removed from the full-length code to produce the punctured code. This third output bit stream corresponds to the second systematic bit stream. Display the indices of the full-length code and the indices of the punctured code to show that the third bit of every 4-bit tuple is punctured.

```

fullOut'
ans = 1x52
      1      2      3      4      5      6      7      8      9     10     11     12     13     14     15     16

puncOut'
ans = 1x39
      1      2      4      5      6      8      9     10     12     13     14     16     17     18     20     21

```

### Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation,  $E_S/N_0$  equals  $E_b/N_0$  because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using  $E_S/N_0$  and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```

modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;

```

```

n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate

```

```

snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance

```

```

rng default

```

Generate random interleaver indices.

```

intrlvrIndices = randperm(L);

```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```

turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);

```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```

bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);

```

Create an AWGN channel object and an error rate object.

```

awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;

```

The main processing loop performs these steps.

- 1 Generate binary data.
- 2 Turbo encode the data.
- 3 Modulate the encoded data.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal by using LLR to output soft bits.
- 6 Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 7 Calculate the error statistics.

```

for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end

```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)

Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600
```

### Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object. Compare turbo coded bit error rate results to uncoded bit error rate results.

#### Initialize Simulation

Set the modulation order and range of  $E_b/N_0$  values. Compute the number of bits per symbol and the energy per symbol to noise ratio ( $E_s/N_0$ ) based on the modulation order and  $E_b/N_0$ . To get repeatable results, seed the random number.

```
modOrder = 16;           % Modulation order
bps = log2(modOrder);    % Bits per symbol
EbNo = (2:0.5:4);       % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng(1963);
```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;
```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

#### Main Processing Loop

The frame processing loop performs these steps.

- 1 Select a random packet length, and generate random binary data.
- 2 Compute the output codeword length and coding rate.
- 3 Compute the signal to noise ratio (SNR) and noise variance.
- 4 Generate interleaver indices.
- 5 Turbo encode the data.
- 6 Apply 16-QAM modulation, and normalize the average signal power.
- 7 Pass the modulated signal through an AWGN channel.

- 8 Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
- 9 Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 10 Calculate the error statistics.

```

ber = zeros(1,length(EbNo));
for k = 1:length(EbNo)
    % numFrames = 100;
    errorStats = zeros(1,3);
    %for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1); % Packet length in bits
    M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
    rate = L/M; % Coding rate for current packet
    snrdB = EsNo(k) + 10*log10(rate); % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10)); % Noise variance

    while errorStats(2) < 100 && errorStats(3) < 1e7
        data = randi([0 1],L,1);
        intrlvrIndices = randperm(L);
        encodedData = turboEnc(data,intrlvrIndices);
        modSignal = qammod(encodedData,modOrder, ...
            'InputType','bit','UnitAveragePower',true);
        rxSignal = awgn(modSignal,snrdB);
        demodSignal = qamdemod(rxSignal,modOrder,'OutputType','llr', ...
            'UnitAveragePower',true,'NoiseVariance',noiseVar);
        rxBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated
        errorStats = errRate(data,rxBits);
    end
    % Save the BER data and reset the bit error rate object
    ber(k) = errorStats(1);
    reset(errRate)
end

```

### Plot Results

Plot the bit error rate and compare it to the uncoded bit error rate.

```

semilogy(EbNo,ber,'-o')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
uncodedBER = berawgn(EbNo,'qam',modOrder); % Estimate of uncoded BER
hold on
semilogy(EbNo,uncodedBER)
legend('Turbo','Uncoded','location','sw')

```

## More About

### Parallel Concatenated Convolutional Decoding Scheme

The turbo decoder uses a parallel concatenated convolutional decoding scheme to decode a coded input signal. The parallel concatenated decoding scheme uses an iterative “APP Decoder” on page 3-1345 with two constituent decoders, an interleaver, and a deinterleaver. This figure shows the decoding scheme. Typically, the decoder input data comes from the demodulator output.

The two constituent decoders use the same trellis structure and decoding algorithm. The soft-input soft-output APP decoders (SISO 1 and SISO 2) output an updated sequence of log-likelihoods of the

encoder input bits,  $\pi(u;O)$ . The sequence is based on the received sequence of log-likelihoods of the channel (coded) bits,  $\pi(c;I)$ , and code parameters.

The decoder iteratively updates these likelihoods for a fixed number of decoding iterations and then outputs the decision bits. The interleaver used in the decoder is identical to the interleaver used in the encoder. The deinterleaver performs the inverse permutation with respect to the interleaver. The decoder does not assume knowledge of the tail bits and excludes these bits from the iterations.

For more information, see “Coding Rate” on page 3-1345.

### APP Decoder

The `comm.TurboDecoder` System object implements the soft-input soft-output APP decoding algorithm according to [1] and [2].

The 'True APP' option of the `Algorithm` property implements APP decoding as per equations 20-23 in section V of [1]. To gain speed, the 'Max\*' and 'Max' values of the `Algorithm` property approximate expressions like  $\log \sum_i \exp(a_i)$  by other quantities. The 'Max' option uses  $\max(a_i)$  as the approximation. The 'Max\*' option uses  $\max(a_i)$  plus a correction term given by the expression  $\ln(1 + \exp(-|a_{i-1} - a_i|))$ .

Setting the `Algorithm` property to 'Max\*' enables the `NumScalingBits` property of this System object. This property denotes the number of bits by which this System object scales the data it processes (multiplies the input by  $2^{\text{NumScalingBits}}$  and divides the pre-output by the same factor). Use this property to avoid losing precision during computations.

### Coding Rate

In general, the coding rate of a constituent convolutional code is represented as a rate  $K / N$  code.  $K$  is the number of input bit streams.  $N$  is the number of output bit streams.

---

**Note**  $K$  must be 1 to use the `comm.TurboEncoder` and `comm.TurboDecoder` System objects. Alternatively, the “High Rate Convolutional Codes for Turbo Coding” example performs turbo coding for  $K$  greater than 1 by using the `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

---

The decoder accepts an  $M$ -element column vector input signal and returns an  $L$ -element column vector containing the decoded binary output message.  $L$  is the interleaver block length.  $M$  is the length of the parallel concatenated codeword.

For a given input trellis, when you set the `InputIndicesSource` property to 'Auto',  $M$  and  $L$  are related by  $L = (M - 2 \times \text{numTails}) / (2 \times N - 1)$ , where:

- $\text{numTails} = \log_2(\text{trellis.numStates}) \times N$
- $N = \log_2(\text{trellis.numOutputSymbols})$ . For a rate 1 / 2 trellis,  $N = 2$ .

For more information about trellis structures, see the `poly2trellis` function. For more information about the constituent decoders, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1344.

## Version History

Introduced in R2012a

# comm.TurboEncoder

**Package:** comm

Encode input signal using parallel concatenated encoding scheme

## Description

The `comm.TurboEncoder` System object applies a parallel concatenated encoding scheme to a binary input message. This coding scheme uses two convolutional encoders and appends the termination bits at the end of the encoded data bit stream. For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1358.

To encode a binary input message using a parallel concatenated encoding scheme:

- 1 Create the `comm.TurboEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
turboenc = comm.TurboEncoder
turboenc = comm.TurboEncoder(Name,Value)
turboenc = comm.TurboEncoder(trellis,interlvrindices)
```

### Description

`turboenc = comm.TurboEncoder` creates a turbo encoder System object. This object performs turbo encoding using the default object configuration.

`turboenc = comm.TurboEncoder(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.TurboEncoder('InterleaverIndicesSource','Input port')` configures a turbo encoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called. Enclose each property name in quotes.

`turboenc = comm.TurboEncoder(trellis,interlvrindices)` creates a turbo encoder System object with the `TrellisStructure` and `InterleaverIndices` properties set to `trellis` and `interlvrindices`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**TrellisStructure** — Trellis description of constituent convolutional code

`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate  $K/N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

---

**Note**  $K$  must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1359.

---

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

**numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

**numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

**numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

**nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

**outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: struct

**InterleaverIndicesSource** — Source of interleaver indices

'Property' (default) | 'Input port'

Source of interleaver indices, specified as 'Property' or 'Input port'.

- When you set this property to 'Property', the object executes using the interleaver indices that you specified with the `InterleaverIndices` property when configuring the object.
- When you set this property to 'Input port', the object executes using the input argument `interlvIndices` when you call the object. The vector length and values for the interleaver indices and binary input message can change with each call to the object.

Data Types: char | string

### **InterleaverIndices — Interleaver indices**

(64:-1:1) (default) | column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length  $L$ , where  $L$  is the length of the binary input message. Each element of the vector must be an integer in the range  $[1, L]$  and must be unique. The interleaver indices define the mapping used to permute the input bits at the encoder.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the `InterleaverIndicesSource` property to 'Property'.

Data Types: double

### **OutputIndicesSource — Source of output indices**

'Auto' (default) | 'Property' | 'Input port'

Source of output indices, specified as 'Auto', 'Property', or 'Input port'.

- When you set this property to 'Auto', the object computes output indices that puncture the second systematic stream and include all tail bits.
- When you set this property to 'Property', the object uses the output indices that you specify for the `OutputIndices` property.
- When you set this property to 'Input port', the object executes using the output indices specified by the input argument `outIndices`. The vector length and values for the output indices, and the coded output signal can change with each call to the object.

Data Types: char | string

### **OutputIndices — Output indices**

`getTurboIOIndices(64,2,3)` (default) | column vector of integers

Output indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The number of bits output from the encoder equals the length of this property. The maximum length must not exceed the fully encoded length of  $(L+mLen) \times N \times 2$ , where  $L$  is the input block length,  $mLen$  is the memory length, and  $N$  is the number of encoded streams for the constituent coder.

**Dependencies**

To enable this property, set the `OutputIndicesSource` property to 'Property'.

Data Types: `double`

**Usage****Syntax**

```
codeword = turboenc(message)
codeword = turboenc(message,interlvrindices)
codeword = turboenc(message,interlvrindices,outindices)
```

**Description**

`codeword = turboenc(message)` encodes the input message using the parallel concatenated convolutional encoding scheme specified by the trellis structure and interleaver indices. `turboenc` returns the binary encoded codeword. `message` and `codeword` are column vectors of numeric, logical, or unsigned fixed-point values with word length 1 (`fi` object). For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1358.

`codeword = turboenc(message,interlvrindices)` additionally specifies the interleaver indices. `interlvrindices` must be a column vector containing integers in the range  $[1, L]$  with no repeated values.  $L$  is the length of the binary input message, `message`. This syntax applies when the `InterleaverIndicesSource` property is set to 'Input port'. The interleaver indices define the mapping used to permute the input bits at the encoder.

`codeword = turboenc(message,interlvrindices,outindices)` additionally specifies the bit ordering and puncturing used when encoding the message data. To enable this syntax, set the `OutputIndicesSource` property to 'Input port'. The output indices vector values must be relative to the fully encoded data for the coding scheme, including the tail bits for all streams.

**Input Arguments****message — Input message**

binary column vector

Input message, specified as a binary column vector of length  $L$ , where  $L$  is the length of the uncoded input message.

Data Types: `double` | `int8` | `fi(data,0,1)`

**interlvrindices — Interleaver indices**

column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length  $L$ , where  $L$  is the length of the binary input message. Each element of the vector must be an integer in the range  $[1, L]$  and must be unique. The interleaver indices define the mapping used to permute the input bits at the encoder.

**Dependencies**

To enable this argument, set the `InterleaverIndicesSource` property to 'Input port'.

Data Types: double

### **outindices — Output indices**

column vector of integers

Output indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. Element values in the `outindices` vector must be relative to the fully encoded data for the coding scheme, including the tail bits for all streams.

#### **Dependencies**

To enable this argument, set the `OutputIndicesSource` property to `'Input port'`.

Data Types: double

### **Output Arguments**

#### **codeword — Parallel concatenated codeword**

binary column vector

Parallel concatenated codeword, returned as a binary column vector of length  $M$ , where  $M$  is the number of bits in the parallel concatenated codeword. This output inherits its data type from the message input.

Data Types: double | int8 | `fi(data,0,1)`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

`step` Run System object algorithm

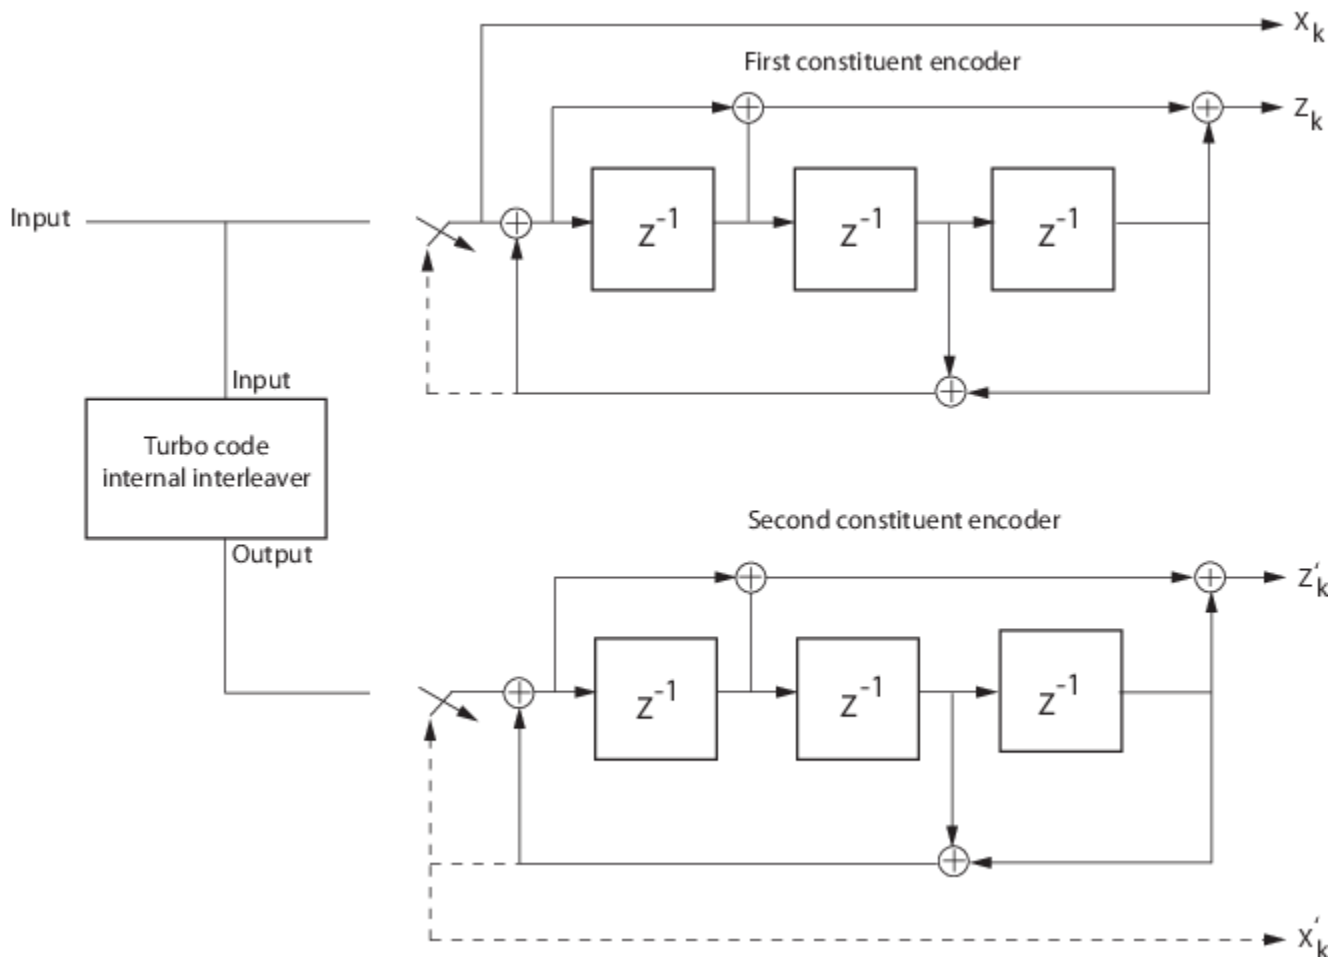

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## **Examples**

### **Perform Rate 1/3 Turbo Code Encoding**

Encode an input message by using a rate 1/3 turbo encoder configuration with the default trellis structure, `poly2trellis(4,[13 15],13)`, as represented in this figure.

For an input message with 64 bits, the codeword output from the encoder is 204 bits. The first 192 bits output correspond to the three 64 bit streams, interlaced as  $X_k$ ,  $Z_k$ , and  $Z'_k$ . The systematic bit stream,  $X_k$ , and parity bit stream,  $Z_k$ , are from the first encoder and the parity bit stream,  $Z'_k$ , is from the second encoder. When the switches are in the lower position, signals follow the dashed lines and the last 12 bits correspond to the tail bits from the two encoders. The first group of six bits (three systematic bits and three parity bits) are the output tail bits from the first constituent encoder. The second group of six bits (three systematic bits and three parity bits) are the output tail bits from the second constituent encoder.

Create a turbo encoder using the default settings. Generate a frame of binary message data, and then encode the message data.

```
rng default
turboenc = comm.TurboEncoder;
frameLen = 64; % Frame length
data = randi([0 1], frameLen, 1);
encData = turboenc(data);
codewordLen = length(encData);
```

Compute the coding rate. Due to the tail bits, the encoder output code rate is slightly less than 1/3.

```
codingrate = frameLen/codewordLen
```

```
codingrate = 0.3137
```

### Define Output Indices for Full-Length and Punctured Turbo Coding

Define output indices by using the `OutputIndices` property. Show full-length encoded output and punctured encoded output for a rate 1/2 code and 10-bit block length.

#### Initialize Parameters

Define parameters to initialize the encoder.

```
blkLen = 10;
trellis = poly2trellis(4,[13 15],13);
n = log2(trellis.numOutputSymbols);
mLen = log2(trellis.numStates);
```

#### Full-Length Encoded Output

Initialize variables and a turbo encoder System object for full-length coding. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
fullOut = (1:(mLen+blkLen)*2*n)';
outLen = length(fullOut);
netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = fullOut;

encMsg = turboEnc(data); % Encode

disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.19231

encOutLen = length(encMsg) % Display encoded length
encOutLen = 52

isequal(encOutLen,outLen) % Check lengths

ans = logical
     1
```

#### Punctured Encoded Output

Specify the output indices for puncturing of the second systematic stream by using the `getTurboIOIndices` function. Initialize variables and a turbo encoder System object for punctured coding. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
puncOut = getTurboIOIndices(blkLen,n,mLen);
outLen = length(puncOut);
```

```

netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = puncOut;

encMsg = turboEnc(data); % Encode

disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.25641

encOutLen = length(encMsg) % Display encoded length
encOutLen = 39

isequal(encOutLen, outLen) % Check lengths

ans = logical
     1

```

### Compare Full and Punctured Outputs

The output of the encoder interlaces the individual bit streams. The third bit of every 4-bit tuple is removed from the full-length code to produce the punctured code. This third output bit stream corresponds to the second systematic bit stream. Display the indices of the full-length code and the indices of the punctured code to show that the third bit of every 4-bit tuple is punctured.

```

fullOut'
ans = 1×52
     1     2     3     4     5     6     7     8     9    10    11    12    13    14    15    16

puncOut'
ans = 1×39
     1     2     4     5     6     8     9    10    12    13    14    16    17    18    20    21

```

### Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation,  $E_S/N_0$  equals  $E_b/N_0$  because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using  $E_S/N_0$  and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```

modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;
n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate

snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance

```

rng default

Generate random interleaver indices.

```
intrlvrIndices = randperm(L);
```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```
turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```
bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;
```

The main processing loop performs these steps.

- 1 Generate binary data.
- 2 Turbo encode the data.
- 3 Modulate the encoded data.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal by using LLR to output soft bits.
- 6 Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 7 Calculate the error statistics.

```
for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
end
```

```

    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end

```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)
```

```

Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600

```

### Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object. Compare turbo coded bit error rate results to uncoded bit error rate results.

#### Initialize Simulation

Set the modulation order and range of  $E_b/N_0$  values. Compute the number of bits per symbol and the energy per symbol to noise ratio ( $E_s/N_0$ ) based on the modulation order and  $E_b/N_0$ . To get repeatable results, seed the random number.

```

modOrder = 16;           % Modulation order
bps = log2(modOrder);   % Bits per symbol
EbNo = (2:0.5:4);       % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng(1963);

```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```

turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;

```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

#### Main Processing Loop

The frame processing loop performs these steps.

- 1 Select a random packet length, and generate random binary data.

- 2 Compute the output codeword length and coding rate.
- 3 Compute the signal to noise ratio (SNR) and noise variance.
- 4 Generate interleaver indices.
- 5 Turbo encode the data.
- 6 Apply 16-QAM modulation, and normalize the average signal power.
- 7 Pass the modulated signal through an AWGN channel.
- 8 Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
- 9 Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 10 Calculate the error statistics.

```

ber = zeros(1,length(EbNo));
for k = 1:length(EbNo)
    % numFrames = 100;
    errorStats = zeros(1,3);
    %for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1);           % Packet length in bits
    M = L*(2*n - 1) + 2*numTails;      % Output codeword packet length
    rate = L/M;                        % Coding rate for current packet
    snrdB = EsNo(k) + 10*log10(rate);  % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10));    % Noise variance

    while errorStats(2) < 100 && errorStats(3) < 1e7
        data = randi([0 1],L,1);
        intrlvrIndices = randperm(L);
        encodedData = turboEnc(data,intrlvrIndices);
        modSignal = qammod(encodedData,modOrder, ...
            'InputType','bit','UnitAveragePower',true);
        rxSignal = awgn(modSignal,snrdB);
        demodSignal = qamdemod(rxSignal,modOrder,'OutputType','llr', ...
            'UnitAveragePower',true,'NoiseVariance',noiseVar);
        rxBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated
        errorStats = errRate(data,rxBits);
    end
    % Save the BER data and reset the bit error rate object
    ber(k) = errorStats(1);
    reset(errRate)
end

```

## Plot Results

Plot the bit error rate and compare it to the uncoded bit error rate.

```

semilogy(EbNo,ber,'-o')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
uncodedBER = berawgn(EbNo,'qam',modOrder); % Estimate of uncoded BER
hold on
semilogy(EbNo,uncodedBER)
legend('Turbo','Uncoded','location','sw')

```

## More About

### Parallel Concatenated Convolutional Encoding Scheme

The turbo encoder uses a parallel concatenated convolutional encoding scheme to encode a binary input signal. The coding scheme uses two constituent encoders and one internal interleaver as shown in this figure. Each constituent encoder is terminated independently by tail bits.

The `OutputIndicesSource` property specifies the source for the output indices used for symbol puncturing and repetition.

- When you set the `OutputIndicesSource` property to 'Auto', the object computes the output indices. In this case, the constituent encoders have a rate  $1/N$  code, and the number of bits output from the turbo encoder is  $L \times (2 \times N - 1) + (2 \times \text{numTails})$ .  $L$  is the input vector length, and  $\text{numTails}$  is given by  $\log_2(\text{TrellisStructure.numStates}) \times N$ . The tail bits due to the termination are appended at the end after the encoded input bits.

The coding scheme uses two identical constituent encoders and one internal interleaver. Each constituent encoder is terminated independently by tail bits. The output of the turbo encoder consists of the systematic ( $X$ ) and parity ( $Z$ ) bit streams of the first encoder and only the parity ( $Z'$ ) bit streams of the second encoder. Tail bits are appended at the end for all streams.

- When you set the `OutputIndicesSource` property to 'Input port' or 'Property', you specify the output indices with the `outindices` input argument or the `OutputIndices` property, respectively. In this case, the object runs using the output indices you specify. The output indices are specified relative to the fully encoded output for all streams.

The output of the turbo encoder consists of the systematic ( $X$  and  $X'$ ) and parity ( $Z$  and  $Z'$ ) bit streams of first and second constituent encoders. The number of bits output equals the vector length of the output indices you provide.

For more information, see “Coding Rate” on page 3-1359 and “Tail bits” on page 3-1360.

### Coding Rate

In general, the coding rate of a constituent convolutional code is represented as a rate  $K/N$  code.  $K$  is the number of input bit streams.  $N$  is the number of output bit streams.

---

**Note**  $K$  must be 1 to use the `comm.TurboEncoder` and `comm.TurboDecoder` System objects. Alternatively, the “High Rate Convolutional Codes for Turbo Coding” example performs turbo coding for  $K$  greater than 1 by using the `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

---

The encoder accepts an  $L$ -element column vector input signal and returns an  $M$ -element column vector output signal. The effective code rate of the turbo encoder is  $L / M$ .  $L$  is the length of the binary input message, and  $M$  is the number of bits output in the parallel concatenated codeword.

- When you set the `OutputIndicesSource` property to 'Auto', systematic bits from the second encoder ( $X'$ , shown in the figure found in "Parallel Concatenated Convolutional Encoding Scheme" on page 3-1358) are not output to the parallel concatenated codeword. For a given trellis,  $M$  and  $L$  are related by  $M = L \times (2 \times N - 1) + 2 \times numTails$ , where  $numTails$  is the number of tail bits. For more information, see "Tail bits" on page 3-1360.
- When you set the `OutputIndicesSource` property to 'Input port' or 'Property',  $M$  equals the length of the output indices vector specified by the `outindices` input argument or the `OutputIndices` property, respectively.

### Tail bits

The turbo encoder treats each input independently. For each input message, extra bits are used to set the encoder states to an all-zeros state. Each constituent encoder is terminated independently by tail bits. The turbo encoder output consists of the interlaced systematic and parity streams, with the tail bits multiplexed to the end of the encoded data streams.

The number of tail bits,  $numTails$ , output by each constituent encoder depends on values in the trellis structure used by each coder.

- $numTails = \log_2(\text{trellis.numStates}) \times N$
- $N = \log_2(\text{trellis.numOutputSymbols})$ . For a rate 1 / 2 trellis,  $N = 2$ .

For more information about trellis structures, see `poly2trellis`. For more information about the constituent encoders, see "Parallel Concatenated Convolutional Encoding Scheme" on page 3-1358.

## Version History

Introduced in R2012a

## comm.ViterbiDecoder

**Package:** comm

Decode convolutionally encoded data using Viterbi algorithm

### Description

The `comm.ViterbiDecoder` System object decodes convolutionally encoded input symbols to produce binary output symbols by using the Viterbi algorithm the convolutional encoding scheme specified by a trellis structure. For more information, see the “Trellis Description of a Convolutional Code” topic.

To decode convolutionally encoded data using the Viterbi algorithm:

- 1 Create the `comm.ViterbiDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
viterbidecoder = comm.ViterbiDecoder  
viterbidecoder = comm.ViterbiDecoder(trellis)  
viterbidecoder = comm.ViterbiDecoder( ___,Name,Value)
```

#### Description

`viterbidecoder = comm.ViterbiDecoder` creates a Viterbi decoder System object. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`viterbidecoder = comm.ViterbiDecoder(trellis)` sets the `TrellisStructure` property set to `trellis`.

`viterbidecoder = comm.ViterbiDecoder( ___,Name,Value)` sets “Properties” on page 3-1362 using one or more name-value arguments in addition to any argument combinations in previous syntaxes. For example, `viterbidecoder = comm.ViterbiDecoder('TerminationMethod','Continuous')` specifies the termination method as continuous to save the internal state metric at the end of each frame for use with the next frame.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **TrellisStructure** — Trellis structure of convolutional code

`poly2trellis(7, [171 133])` (default) | structure

Trellis description of the convolutional code, specified as a structure that contains the trellis description for a rate  $K/N$  code.  $K$  is the number of input bit streams, and  $N$  is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

#### **numInputSymbols** — Number of symbols input to encoder

$2^K$

Number of symbols input to the encoder, specified as an integer equal to  $2^K$ , where  $K$  is the number of input bit streams.

#### **numOutputSymbols** — Number of symbols output from encoder

$2^N$

Number of symbols output from the encoder, specified as an integer equal to  $2^N$ , where  $N$  is the number of output bit streams.

#### **numStates** — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

#### **nextStates** — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates` by  $2^K$ .

#### **outputs** — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates` by  $2^K$ .

Data Types: `struct`

#### **InputFormat** — Input format to decoder

'Unquantized' (default) | 'Hard' | 'Soft'

Input format to the decoder, specified as 'Unquantized', 'Hard', or 'Soft'.

- 'Unquantized' — The input data must be a real-valued vector of double- or single-precision soft values that are unquantized. The object maps positive values to logical 1s and negative values to logical 0s
- 'Hard' — The input must be a vector of hard decision values, which are 0s or 1s. The data type of the inputs must be double precision, single precision, logical, or numeric.
- 'Soft' — The input requires a vector of quantized soft values that are represented as integers between 0 and  $2^{\text{SoftInputWordLength}} - 1$ . The data type of the inputs must be double precision, single precision, logical, or numeric. Alternatively, you can specify the data type as an unsigned and unscaled fixed-point object using the (fi) with a word length equal to the word length that you specify for the `SoftInputWordLength` property. 0 is considered as most confident 0 and  $2^{\text{SoftInputWordLength}} - 1$  as the most confident 1.

**SoftInputWordLength — Soft input word length**

4 (default) | integer

Soft input word length that represents the number of bits for each quantized soft input value, specified as an integer.

**Dependencies**

To enable this property, set the `InputFormat` property to 'Soft'.

Data Types: double

**InvalidQuantizedInputAction — Option to take action for invalid quantized input**

'Ignore' (default) | 'Error'

Option to take action for invalid quantized input (that is, when input values are out of range), specified as 'Ignore' or 'Error'. Set this property to 'Error' so that the object generates an error when the quantized input values are out of range.

**Dependencies**

To enable this property, set the `InputFormat` property to 'Soft' or 'Hard'.

**TracebackDepth — Traceback depth**

34 (default) | integer

Traceback depth, specified as an integer. For more information, see “Traceback and Decoding Delay” on page 3-1370 and “Traceback Depth Estimates” on page 3-1370.

Data Types: double

**TerminationMethod — Termination method of encoded frame**

'Continuous' (default) | 'Truncated' | 'Terminated'

Termination method of the encoded frame, specified as one of these values.

- 'Continuous' — The System object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently. This mode results in an output decoding delay of  $\text{TracebackDepth} \times K$  zero bits for a rate  $K/N$  convolutional code.  $K$  is the number of input symbols, and  $N$  is the number of output symbols.

- 'Truncated' — The System object treats each frame independently. The traceback path starts at the state with the best metric and ends in the all-zeros state. There is no output delay for this mode.
- 'Terminated' — The System object treats each frame independently. The traceback path always starts and ends in the all-zeros state. There is no output delay for this mode.

### **ResetInputPort — Option to enable decoder reset input**

false or 0 (default) | true or 1

Option to enable the decoder reset input, specified as a logical 1(true) or 0(false). Set this property to 1(true) to the object. When this additional reset input is a nonzero value, the internal states of the decoder reset to their initial conditions.

#### **Dependencies**

To enable this property, set the TerminationMethod property to 'Continuous'.

Data Types: logical

### **DelayedResetAction — Option to delay output reset**

false or 0 (default) | true or 1

Option to delay the output reset, specified as one of these logical values.

- 1(true) — The reset of the internal states of the decoder occurs after the object computes the decoded data.
- 0(false) — The reset of the internal states of the decoder occurs before the object computes the decoded data.

#### **Dependencies**

To enable this property, set the ResetInputPort property to true.

Data Types: logical

### **PuncturePatternSource — Source of puncture pattern**

'None' (default) | 'Property'

Source of the puncture pattern, specified as one of these values.

- 'None' — The object does not apply puncturing.
- 'Property' — The object decodes the punctured codewords based on a puncture pattern vector that you specify in the PuncturePattern property.

### **PuncturePattern — Puncture pattern vector**

[1;1;0;1;0;1] (default) | column vector

Puncture pattern vector to puncture the decoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of the punctured bits. This puncture pattern must match the puncture pattern used by the convolutional encoder.

**Dependencies**

To enable this property, set the `PuncturePatternSource` property to 'Property'.

Data Types: `double`

**ErasuresInputPort — Option to enable the specification of erasures in the input symbols**

`false` or `0` (default) | `true` or `1`

Option to enable the specification of erasures in the input symbols, specified as one of these numeric or logical values.

- `1` (`true`) — When you call the System object, it specifies a vector of erasures when calling it. This vector indicates which symbols of the input codewords to erase. Values of `1` indicate erased bits. The decoder does not update the branch metric for the erasures in the incoming data stream. The erasures input must be a double precision or logical column vector. The length of the erasure vector must equal the length of the input data.
- `0` (`false`) — The System object assumes no erasures.

Data Types: `logical`

**OutputDataType — Data type of output**

`"Full precision"` (default) | `"Smallest unsigned integer"` | `"double"` | `"single"` | `"int8"` | ...

Data type of the output, specified as a `"Full precision"`, `"Smallest unsigned integer"`, `"double"`, `"single"`, `"int8"`, `"uint8"`, `"int16"`, `"uint16"`, `"int32"`, `"uint32"`, `"logical"`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `"Smallest unsigned integer"` or `"Full precision"` mode.

**StateMetricDataType — Data type of state metric**

`'Full precision'` (default) | `'Custom'`

Data type of the state metric, specified as `'Full precision'` or `'Custom'`

When you set this property to `'Full precision'`, the object sets the state metric fixed-point type to `numerictype([],16)`.

- When you set the `InputFormat` property to `'Hard'`, the input data must be a column vector. This vector comprises unsigned, fixed-point numbers (`fi` objects) of word length `1` to enable fixed-point Viterbi decoding. Based on this input (either a `0` or `1`), the object calculates the internal branch metrics using an unsigned integer of word length  $L$ . In this case,  $L$  is the number of output bits as specified by the trellis structure.
- When you set the `InputFormat` property to `'Soft'`, the input data must be a column vector. This vector comprises unsigned, fixed point numbers (`fi` objects) of word length  $N$ . In this case,  $N$  is the number of soft-decision bits specified by the `SoftInputWordLength` property.

When you call the System object, the data inputs must be integers in the range from  $0$  to  $2^N-1$ . The object calculates the internal branch metrics using an unsigned integer of word length  $L = (N + N_{out} - 1)$ . In this case,  $N_{out}$  is the number of output bits as specified by the trellis structure.

## Dependencies

To enable this property, set the `InputFormat` property to 'Hard' or 'Soft'.

### CustomStateMetricDataType — Fixed-point data type of state metric

`numericType([],16)` (default) | unscaled `numericType` object

Fixed-point data type of the state metric, specified as an unscaled `numericType` object with a signedness of `Auto`.

## Dependencies

To enable this property, set the `StateMetricDataType` property to 'Custom'.

Data Types: `numeric`

## Usage

## Syntax

```
decmsg = viterbidecoder(codeword)
decmsg = viterbidecoder(codeword,erasures)
decmsg = viterbidecoder(codeword,resetstate)
```

## Description

`decmsg = viterbidecoder(codeword)` decodes the convolutionally encoded input data, `codeword`, by using the Viterbi algorithm. `decmsg` is the decoded data.

`decmsg = viterbidecoder(codeword,erasures)` specifies symbols of the input codewords for the object to erase. To enable this syntax, set the `ErasuresInputPort` property to 1 (`true`).

`decmsg = viterbidecoder(codeword,resetstate)` specifies the input to reset the internal states of the decoder. To enable this syntax, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to 1 (`true`).

## Input Arguments

### codeword — Convolutionally encoded message

numeric-valued column vector

Convolutionally encoded message, specified as a numeric-valued column vector. The data type and element value in `codeword` depend on how you set the `InputFormat` property.

When you set the `InputFormat` property to 'Unquantized', input values outside of the range  $[-10^{12}, 10^{12}]$  are clipped to  $-10^{12}$  and  $10^{12}$ , respectively.

If the convolutional code uses an alphabet of  $2^N$  possible output symbols, the length of this input vector must be  $L \times N$  for some positive integer  $L$ .

Data Types: `double`

### erasures — Erasure symbols in codeword

binary-valued vector

Erasures symbols in the codeword, specified as a binary-valued vector. The elements in `erasures` must be of data type `double` or `logical`. Values of 1 in the `erasures` vector correspond to erased symbols, and values of 0 correspond to nonerased symbols. The length of the codeword must equal the length of `erasures`.

**Dependencies**

To enable this argument, set the `ErasuresInputPort` property to 1 (`true`).

**resetstate — Reset for internal states of decoder**

`false` or 0 (default) | `true` or 1

Reset for internal states of the decoder, specified as a numeric or logical 1 (`true`) or 0 (`false`).

**Dependencies**

To enable this argument, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to `true`.

Data Types: `double` | `logical`

**Output Arguments****decmsg — Decoded message**

binary-valued column vector

Decoded message, returned as a binary-valued column vector. This output vector has the same data type as the `OutputDataType` property.

If the decoded data uses an alphabet of  $2^K$  possible output symbols, the length of this output vector is  $L \times K$ .

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

**Examples****Encode and Decode 8-DPSK Modulated Data**

Transmit a convolutionally encoded 8 differential phase shift keying (DPSK) modulated bit stream through an additive white Gaussian noise (AWGN) channel. Then, demodulate and decode the modulated bit stream using a Viterbi decoder.

Create the necessary System objects.

```

conEnc = comm.ConvolutionalEncoder;
modDPSK = comm.DPSKModulator('BitInput',true);
chan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demodDPSK = comm.DPSKDemodulator('BitOutput',true);
vDec = comm.ViterbiDecoder('InputFormat','Hard');
error = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',34);

```

Process the data by following these steps.

- 1 Generate random bits.
- 2 Convolutionally encode the data.
- 3 Apply DPSK modulation.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal.
- 6 Decode the data using a Viterbi algorithm.
- 7 Collect error statistics.

```

for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = conEnc(data);
    modSignal = modDPSK(encodedData);
    receivedSignal = chan(modSignal);
    demodSignal = demodDPSK(receivedSignal);
    receivedBits = vDec(demodSignal);
    errors = error(data,receivedBits);
end

```

Display the number of errors.

```
errors(2)
```

```
ans = 3
```

### Convolutionally Encode and Viterbi Decode with Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical.

Define a puncture pattern matrix, and then reshape it into vector form for use with the encoder and decoder System objects.

```

pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);

```

Create a convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.

```

conEnc = comm.ConvolutionalEncoder('PuncturePatternSource','Property','PuncturePattern',pPatternVec);
viDec = comm.ViterbiDecoder('InputFormat','Hard','PuncturePatternSource','Property', ...
    'PuncturePattern',pPatternVec);

```

Create an error rate counter with the appropriate receive delay.

```
error = comm.ErrorRate('ReceiveDelay',viDec.TracebackDepth);
```

Encode a sequence of random bits, and then decode the encoded message.

```
dataIn = randi([0 1],600,1);  
dataEncoded = conEnc(dataIn);  
dataOut = viDec(dataEncoded);
```

Verify that no errors exist in the output data.

```
errStats = error(dataIn,dataOut);  
errStats(2)
```

```
ans = 0
```

## More About

### Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

### Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times  $(ConstraintLength - 1) / (1 - coderate)$ . The constraint length of the code,  $ConstraintLength$ , is equal to  $(\log_2(trellis.numStates) + 1)$ . The  $coderate$  is equal to  $(K / N) \times (\text{length}(PuncturePattern) / \text{sum}(PuncturePattern))$ .

$K$  is the number of input symbols,  $N$  is the number of output symbols, and  $PuncturePattern$  is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate 1/2 code has a traceback depth of  $5(ConstraintLength - 1)$ .
- A rate 2/3 code has a traceback depth of  $7.5(ConstraintLength - 1)$ .
- A rate 3/4 code has a traceback depth of  $10(ConstraintLength - 1)$ .
- A rate 5/6 code has a traceback depth of  $15(ConstraintLength - 1)$ .

## Version History

### Introduced in R2012a

### R2022b: Version History

*Behavior changed in R2022b*

When you set the `InputFormat` property to 'Unquantized', input values outside of the range  $[-10^{12}, 10^{12}]$  are clipped to  $-10^{12}$  and  $10^{12}$ , respectively.

# comm.WalshCode

**Package:** comm

Generate bipolar Walsh code

## Description

The `comm.WalshCode` System object generates a bipolar Walsh code from an orthogonal set of codes.

To generate a Walsh code:

- 1 Create the `comm.WalshCode` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
walshCode = comm.WalshCode  
walshCode = comm.WalshCode(Name=Value)
```

### Description

`walshCode = comm.WalshCode` creates a Walsh code generator System object. This object generates a Walsh code from a set of orthogonal codes.

`walshCode = comm.WalshCode(Name=Value)` sets properties using one or more name-value arguments. For example, `Length=11` specifies a Walsh code of length 11.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Length — Length of generated code

64 (default) | power-of-two integer

Length of generated code, specified as a power-of-two integer.

Data Types: double

**Index — Index of desired code**`60` (default) | integer in the range  $[0, N-1]$ 

Index of desired code, from the available set of codes, specified as an integer in the range  $[0, N-1]$ .  $N$  is the value of the Length property.

The number of zero crossings in the generated code equals the value of the specified index.

Data Types: `double`

**SamplesPerFrame — Samples per output frame**`1` (default) | positive integer

Samples per output frame, specified as a positive integer. If you set this property to  $M$ , the object outputs a frame containing  $M$  samples using the Walsh code specified by the Index property. The object repeats the Walsh code sequence, as needed, to reach  $M$  samples. For more information, see “Algorithms” on page 3-1376 section.

Data Types: `double`

**OutputDataType — Output data type**`double` (default) | `int8`

Output data type, specified as `double` or `int8`.

## Usage

## Syntax

```
y = walshCode
```

## Description

`y = walshCode` outputs a bipolar Walsh code frame as a column vector. If the frame length exceeds the Walsh code length, the object fills the frame by repeating the Walsh code. For more information, see the “Algorithms” on page 3-1376 section.

## Output Arguments

**y — Walsh code**`column vector`

Walsh code, returned as a column vector.

The code is in a bipolar format with 0 and 1 mapped to 1 and -1. Set the data type of the output with the OutputDataType property.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

```
step    Run System object algorithm
release Release resources and allow changes to System object property values and input
        characteristics
reset   Reset internal states of System object
```

## Examples

### Generate Walsh Code Sequence

Generate a Walsh code of length 128. Specify the sequence with 16 samples per frame.

```
walsh = comm.WalshCode;
walsh.Length = 128;
walsh.SamplesPerFrame = 16;
disp(walsh)
```

```
comm.WalshCode with properties:
```

```
        Length: 128
        Index: 60
SamplesPerFrame: 16
OutputDataType: 'double'
```

Display the bipolar Walsh code.

```
seq = walsh()
```

```
seq = 16×1
```

```

### Walsh Code Sequence at Desired Index

Generate a Walsh code of length 256. Set the index of the desired code to 64 and the code sequence to 4 samples per frame.

```
walsh = comm.WalshCode;
walsh.Length = 256;
```

```
walsh.Index = 64;
walsh.SamplesPerFrame = 4;
disp(walsh)

comm.WalshCode with properties:

    Length: 256
     Index: 64
SamplesPerFrame: 4
  OutputDataType: 'double'
```

Display the bipolar Walsh code.

```
seq = walsh()

seq = 4x1

     1
     1
    -1
    -1
```

## Algorithms

Walsh codes are defined as a set of  $N$  codes, denoted  $W_j$ , for  $j = 0, 1, \dots, N - 1$ , which have the following properties:

- $W_j$  takes on the values +1 and -1.
- $W_j[0] = 1$  for all  $j$ .
- $W_j$  has exactly  $j$  zero crossings, for  $j = 0, 1, \dots, N - 1$ .
- $W_j W_k^T = \begin{cases} 0 & j \neq k \\ N & j = k \end{cases}$
- Each code  $W_j$  is either even or odd with respect to its midpoint.

Walsh codes are defined using a Hadamard matrix of order  $N$ , where  $N$  is a nonnegative power of 2 that you specify in the Length property. The `comm.WalshCode` System object outputs a row of the Hadamard matrix. Use the Index property to choose the row of the Hadamard matrix. If you set the Index property equal to an integer  $j$ , the output code has exactly  $j$  zero crossings, for  $j = 0, 1, \dots, N - 1$ .

Note, however, that the indexing in Walsh code is different from the indexing in Hadamard code.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

## comm.WINNER2Channel

**Package:** comm

Filter input signal through WINNER II fading channel

---

**Note Download Required:** To use , first download the WINNER II Channel Model for Communications Toolbox add-on.

---

### Description

The `comm.WINNER2Channel` System object filters an input signal through a WINNER II fading channel. The object utilizes the basic model defined and provided by the WINNER II Channel Models [1].

To filter an input signal through a WINNER II fading channel:

- 1 Create the `comm.WINNER2Channel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
winchannel = comm.WINNER2Channel  
winchannel = comm.WINNER2Channel(Name,Value)  
winchannel = comm.WINNER2Channel(cfgModel)  
winchannel = comm.WINNER2Channel(cfgModel,cfgLayout)
```

#### Description

`winchannel = comm.WINNER2Channel` creates a WINNER II fading channel System object to model single or multiple links. `winchannel` generates channel coefficients using the WINNER II spatial channel model (SCM). It also filters a real or complex input signal through the fading channel for each link.

`winchannel = comm.WINNER2Channel(Name,Value)` specifies properties using one or more name-value arguments. For example, `'NormalizeChannelOutputs','false'` specifies to not normalize the channel outputs.

`winchannel = comm.WINNER2Channel(cfgModel)` sets the `ModelConfig` property to `cfgModel`.

`winchannel = comm.WINNER2Channel(cfgModel,cfgLayout)` set the `LayoutConfig` property to `cfgLayout`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### ModelConfig — WINNER II model parameter configuration

`winner2.wimparset` (default) | structure

WINNER II model parameter configuration, specified as a structure. You can either use the `winner2.wimparset` function to create the default model configuration structure or create it manually. The Winner II channel model parameter configuration contains these fields.

### NumTimeSamples — Number of time samples

100 (default) | scalar

Number of time samples, specified as a scalar.

---

**Note** If the number of samples in the input signal ( $N_S$ ) does not match `NumTimeSamples`, then update `NumTimeSamples` to match  $N_S$ .

---

Data Types: `double`

### FixedPdpUsed — Option to use predefined path delays and powers for specific scenarios

'no' (default) | 'yes'

Option to use predefined path delays and powers for specific scenarios, specified as 'no' or 'yes'.

### FixedAnglesUsed — Option to use predefined path AoDs and AoAs for specific scenarios

'no' (default) | 'yes'

Option to use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'no' or 'yes'.

### IntraClusterDsUsed — Option to divide each of the two strongest clusters into three subclusters per link

'yes' (default) | 'no'

Option to divide each of the two strongest clusters into three subclusters per link, specified as 'yes' or 'no'.

### PolarisedArrays — Option to use dual-polarized arrays

'yes' (default) | 'no'

Option to use dual-polarized arrays, specified as 'yes' or 'no'.

### UseManualPropCondition — Option to use manually defined propagation conditions

'yes' (default) | 'no'

Option to use manually defined propagation conditions, specified as 'yes' or 'no'. Set this field to 'yes' to enforce the use of manually defined propagation conditions (LOS or NLOS) of the PropagConditionVector field. Set this field to 'no' to draw propagation conditions from predefined LOS probabilities.

**CenterFrequency — Carrier frequency**

5.25e9 (default) | scalar

Carrier frequency in Hz, specified as a scalar.

Data Types: double

**UniformTimeSampling — Option to enforce uniform time sampling**

'no' (default) | 'yes'

Option to enforce uniform time sampling, specified as 'no' or 'yes'.

**SampleDensity — Number of time samples per half wavelength**

2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

Data Types: double

**DelaySamplingInterval — Sampling interval**

5e-9 (default) | scalar

Sampling interval, specified as a scalar indicating the input signal sample time in seconds. DelaySamplingInterval defines the sampling grid to which the path delays are rounded.

- A value of 0 seconds indicates no rounding on path delays. When performing channel filtering, the object sets DelaySamplingInterval to 0 to obtain the original path delays.
- Ignore any nonzero value of DelaySamplingInterval. Specifically, the path delays values that are not rounded to be multiples of the DelaySamplingInterval values and are nonzero.

Data Types: double

**ShadowingModelUsed — Option to use shadow fading**

'no' (default) | 'yes'

Option to use shadow fading, specified as 'no' or 'yes'.

**PathLossModelUsed — Option to use path loss model**

'no' (default) | 'yes'

Option to use path loss model, specified as 'no' or 'yes'.

**PathLossModel — Path loss model**

'pathloss' (default) | character vector

Path loss model, specified as a character vector representing a valid function name. Path loss model uses the internal pathloss function from the "WINNER II Channel" add-on to model the path loss.

**Dependencies**

To enable this property, set the PathLossModelUsed field to 'yes'.

Data Types: char

### PathLossOption — Wall material

'CR\_light' (default) | 'CR\_heavy' | 'RR\_light' | 'RR\_heavy'

Wall material, specified as 'CR\_light', 'CR\_heavy', 'RR\_light', or 'RR\_heavy'. This field indicates the wall material for the A1 scenario NLOS path loss calculation.

#### Dependencies

To enable this property, set the PathLossModelUsed field to 'yes'.

Data Types: char

### RandomSeed — Seed for random number generators

[] (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [], indicate the use of global random stream.

Data Types: double

Data Types: struct

### LayoutConfig — WINNER II layout parameter configuration

winner2.layoutparset (default) | structure

WINNER II layout parameter configuration, specified as a structure. You can either use the winner2.layoutparset function to create the default layout configuration structure or create it manually. The Winner II channel layout parameter configuration contains these fields.

### Stations — Active stations

row vector of structures (default)

Active stations, specified as a row vector of structures describing the antenna arrays for active stations. Stations is created from the arrays input. The row ordering specifies base station (BS) sectors first, followed by mobile stations (MS). The assignment of BS sector and MS positions is random. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

Data Types: struct

### NofSect — Number of sectors

vector (default)

Number of sectors, specified as a vector indicating the number of sectors in each BS.

Data Types: double

### Pairing — BS to MS pairing

2-by- $N_L$  matrix (default)

BS to MS pairing, specified as a 2-by- $N_L$  matrix, where  $N_L$  specifies the number of links to be modeled. For BS and MS row ordering, see the Stations field.

Data Types: double

**ScenarioVector — Spatial scenario**1 (default) | 1-by- $N_L$  vector | scalar

Spatial scenario, specified as a 1-by- $N_L$  vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenario numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see Section 2.3 of WINNER II Channel Models [1].

**PropagConditionVector — Propagation conditions**1 (default) | 1-by- $N_L$  vector | scalar

Propagation conditions, specified as a 1-by- $N_L$  vector. For each link, specify LOS as 1 and NLOS as 0.

Data Types: double

**StreetWidth — Street width**20 (default) | 1-by- $N_L$  vector | scalar

Street width, specified as a 1-by- $N_L$  vector of identical values that specify the average width (in meters) of the streets. Use `StreetWidth` for the path loss model of the B1 and B2 scenarios. For the scenario number mapping, see the `ScenarioVector` field.

**Dependencies**

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

**Dist1 — Distances from BS to last LOS point**NaN (default) | 1-by- $N_L$  vector

Distances from the BS to the last LOS point, specified as a 1-by- $N_L$  vector. Use the `Dist1` field for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in the path loss function. For the scenario number mapping, see the `ScenarioVector` field.

For more information, see Figure 4-3 of WINNER II Channel Models [1].

**Dependencies**

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

**NumFloors — Floor numbers**1 (default) | 1-by- $N_L$  vector | scalar

Floor numbers where the indoor BS or MS is located, specified as a 1-by- $N_L$  vector. Use the `NumFloors` field for the path loss model of the A2 and B4 scenarios only. For the scenario number mapping, see the `ScenarioVector` field.

**Dependencies**

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

### NumPenetratedFloors — Number of floors penetrated

0 (default) | 1-by- $N_L$  vector | scalar

Number of floors penetrated between the BS and the MS, specified as a 1-by- $N_L$  vector. Use the `NumPenetratedFloors` field for the NLOS path loss model of the A1 scenario. For the scenario number mapping, see the `ScenarioVector` field.

For more information, see Table 4-4 of WINNER II Channel Models [1].

#### Dependencies

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

Data Types: struct

### NormalizeChannelOutputs — Option to normalize channel outputs

'true' (default) | 'false'

Option to normalize channel outputs, specified as 'true' or 'false'. Set this property to 'true' to normalize the channel outputs by the number of receive antennas at the MS for each link.

For more information, see “Channel Power” on page 3-1387.

Data Types: char | string

## Usage

### Syntax

```
outsignal = winchannel(insignal)
[outsignal,pathgains] = winchannel(insignal)
```

### Description

`outsignal = winchannel(insignal)` filters the input signal through a WINNER II fading channel and returns the resulting signal.

`[outsignal,pathgains] = winchannel(insignal)` also returns the channel path gains of the underlying fading process.

### Input Arguments

#### insignal — Input signal

$N_L$ -by-1 cell array |  $N_S$ -by- $N_T$  matrix

Input signal, specified as an  $N_L$ -by-1 cell array or an  $N_S$ -by- $N_T$  matrix.  $N_L$  is the number of links, as specified by the `LayoutConfig` property of the `winchannel` object. The  $i$ th element of the `insignal` argument must be an  $N_S$ -by- $N_T(i)$  matrix of data type `double`.

- $N_S$  is the number of samples to be generated and must be the same value for all elements of the `insignal` argument.

- $N_T$  is the number of transmit antennas at the BS for the  $i$ th link, as specified by the `LayoutConfig` property of the `winchannel` object.

### Output Arguments

#### **outsignal** — Output signal

$N_L$ -by-1 cell array (default)

Output signal, returned as an  $N_L$ -by-1 cell array. If the channel has only one link or if all links have the same number of transmit antennas, the `insignal` argument must be an  $N_S$ -by- $N_T$  matrix, and the  $i$ th element of the `outsignal` argument is an  $N_S$ -by- $N_R(i)$  matrix.  $N_R(i)$  is the number of receive antennas at the MS for the  $i$ th link, as specified by the `LayoutConfig` property of the `winchannel` object.

#### **pathgains** — Channel path gains

$N_L$ -by-1 cell array (default)

Channel path gains, returned as an  $N_L$ -by-1 cell array.

The  $i$ th element of the `pathgains` argument is an  $N_R(i)$ -by- $N_T(i)$ -by- $N_P(i)$ -by- $N_S$  array of complex values of data type `double`.  $N_P(i)$  is the number of paths for the  $i$ th link, as specified by the `LayoutConfig` property of the `winchannel` object.

$N_R$ ,  $N_T$ , and  $N_P$  are link-specific.  $N_S$  is the same for all of the links.

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

---

**Note** When you use the `reset` object function, if the `ModelConfig.RandomSeed` property of object is empty, `reset` resets the filters only. Otherwise, `reset` resets the filters and reinitializes the random number stream to the value of the `ModelConfig.RandomSeed` field.

---

### Examples

#### **Simulate WINNER II Channel with Two Mobile Stations**

Simulate a system that has two MSs connected to one BS. One MS is 8 meters away from the BS, and the other is 20 meters away from the BS. Send the impulse signals through the two links. The spectrum of the received signals at the MS shows frequency selectivity.

Specify a random number generator seed for repeatability.

```
rng(100);
```

Initialize the frame length and sample rate.

```
frmLen = 1024;
```

Configure the winner II channel layout parameters.

```
BSAA = winner2.AntennaArray("UCA",8,0.02); % UCA-8 antenna array for BS
MSAA1 = winner2.AntennaArray("ULA",2,0.01); % ULA-2 antenna array for MS
MSAA2 = winner2.AntennaArray("ULA",4,0.005); % ULA-4 antenna array for MS
MSIdx = [2 3];
BSIdx = {1};
NL = 2;
maxRange = 100;
rndSeed = 101;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL, ...
    [BSAA,MSAA1,MSAA2],maxRange,rndSeed);
```

Adjust BS and MS positions.

```
cfgLayout.Stations(1).Pos(1:2) = [10, 10];
cfgLayout.Stations(2).Pos(1:2) = [18, 10]; % 8 meters away from BS
cfgLayout.Stations(3).Pos(1:2) = [22, 26]; % 20 meters away from BS
```

Specify the NLOS for both links.

```
cfgLayout.Pairing = [1 1; 2 3];
cfgLayout.PropagConditionVector = [0 0];
```

Configure the winner II channel model parameters.

```
cfgModel = winner2.wimparset;
cfgModel.NumTimeSamples = frmLen; % Frame length
cfgModel.IntraClusterDsUsed = "no"; % No cluster splitting
cfgModel.SampleDensity = 2e5; % For lower sample rate
cfgModel.PathLossModelUsed = "yes"; % Turn on path loss
cfgModel.ShadowingModelUsed = "yes"; % Turn on shadowing
```

Create a WINNER II fading channel System object.

```
winChannel = comm.WINNER2Channel(cfgModel,cfgLayout);
```

Get system information.

```
chanInfo = info(winChannel)
```

```
chanInfo = struct with fields:
    NumLinks: 2
    NumBSElements: [8 8]
    NumMSElements: [2 4]
    NumPaths: [16 16]
    SampleRate: [1.0000e+07 1.0000e+07]
    ChannelFilterDelay: [7 7]
    NumSamplesProcessed: 0
```

Get the number of transmitters and sample rate of the system.

```
numTx = chanInfo.NumBSElements(1);
Rs = chanInfo.SampleRate(1);
```

Create a spectrum analyzer System object.

```
sa = spectrumAnalyzer( ...
    SampleRate=Rs, ...
    YLimits=[-170, -100], ...
    ShowLegend=true, ...
    ChannelNames=["MS 1 (8 meters away)", "MS 2 (20 meters away)"]);
```

Pass impulse signals through the two links and show the spectra of the received signals at the two MSs.

```
for i = 1:10
    x = [ones(1,numTx);
        zeros(frmLen-1,numTx)];
    y = winChannel(x);
    sa([y{1}(:,1),y{2}(:,1)]);
end
release(sa)
```

## More About

### WINNER II Sampling Rate

The signal sample rate ( $R_S$ ) for generating channel coefficients and performing channel filtering is calculated per link using the mobile station speed ( $V_{MS}$ ), half wavelength distance, and sample density. The sample rate for each link is available as a field in the output of the info object function.

$$R_S = V_{MS} / (C / F_{center} / 2 / N_{SD})$$

- For the MS speed:  $V_{MS}$ ,
  - When you set the `ModelConfig.UniformTimeSampling` field to 'no',  $V_{MS}$  is the speed of the MS for the corresponding link, derived from the `LayoutConfig.Stations(i).Velocity` field.
  - When you set the `ModelConfig.UniformTimeSampling` field to 'yes',  $V_{MS}$  is the maximum speed of the MS for all links.
- $C$  is the speed of light (2.99792458e8 m/s).
- $F_{center}$  is the `ModelConfig.CenterFrequency` field.
- $N_{SD}$  is the `ModelConfig.SampleDensity` field.

### Channel Power

These conditions apply to the channel power of the `comm.WINNER2Channel` System object:

- When path loss and shadowing are off, path gains are normalized. Specifically, path gains are normalized when you set the `ModelConfig.ShadowingModelUsed` and `ModelConfig.PathLossModelUsed` fields to 'no'.
- When you set the `NormalizeChannelOutputs` property to 'true', the average gain of the channel is 0 dB.

# networkTrafficFTP

FTP application traffic pattern generator

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Description

The networkTrafficFTP object specifies the configuration parameters to generate a file transfer protocol (FTP) application traffic pattern based on the 3GPP TR 36.814 specification and the IEEE 802.11ax™ Evaluation Methodology.

You can use the FTP application traffic pattern in system-level simulations to model the real-world data traffic.

## Creation

### Syntax

```
cfgFTP = networkTrafficFTP
cfgFTP = networkTrafficFTP(Name=Value)
```

### Description

cfgFTP = networkTrafficFTP creates a default FTP application traffic pattern object.

cfgFTP = networkTrafficFTP(Name=Value) sets properties using one or more name-value arguments. For example, GeneratePacket=true generates an FTP packet.

## Properties

### FixedFileSize — Custom size of file to be transmitted

[ ] (default) | positive scalar

Custom size in megabytes of the file to be transmitted, specified as a positive scalar. If you do not specify this property, the object uses the truncated lognormal distribution to calculate the file size.

Data Types: double

### LogNormalMu — Truncated lognormal distribution mu value

14.45 (default) | positive scalar

Truncated lognormal distribution mu value, specified as a positive scalar. The object uses this property to calculate the file size.

### Dependencies

To enable this property, set the FixedFileSize property to [ ].

Data Types: double

### **LogNormalSigma — Truncated lognormal distribution sigma value**

0.35 (default) | positive scalar

Truncated lognormal distribution sigma value, specified as a positive scalar. The object uses this value to calculate the file size.

#### **Dependencies**

To enable this property, set the `FixedSize` property to [ ].

Data Types: double

### **UpperLimit — Truncated lognormal distribution upper limit**

5 (default) | positive scalar

Truncated lognormal distribution upper limit, specified as a positive scalar. The object uses this value to calculate the file size. The generated file size value must be less than or equal to the `UpperLimit` value. If the generated file size value is greater than `UpperLimit`, the object discards the file size and creates a new one.

#### **Dependencies**

To enable this property, set the `FixedSize` property to [ ].

Data Types: double

### **ReadingTime — Time interval between two successive file transfers**

[ ] (default) | positive scalar

Time interval in milliseconds between two consecutive file transfers, specified as a positive scalar. To specify a customized value for the reading time, specify this property. If you do not specify this property, the object uses the exponential distribution to calculate the reading time.

Data Types: double

### **ExponentialMean — Exponential distribution mean value**

180000 (default) | nonnegative scalar

Exponential distribution mean value in milliseconds, specified as a nonnegative scalar. The object uses this property to calculate the reading time.

#### **Dependencies**

To enable this property, set the `ReadingTime` property to [ ].

Data Types: double

### **PoissonMean — Poisson distribution mean value**

[ ] (default) | nonnegative scalar

Poisson distribution mean value in milliseconds, specified as a nonnegative scalar. The object uses this property to calculate the packet interarrival time.

Data Types: double

### **PacketInterArrivalTime — Time interval between two successively generated packets**

0 (default) | nonnegative scalar

Time interval in milliseconds between two successively generated packets, specified as a nonnegative scalar.

**Dependencies**

To enable this property, set the `PoissonMean` property to `[ ]`.

Data Types: `double`

**GeneratePacket — Flag to indicate whether to generate FTP packet**

`false` or `0` (default) | `true` or `1`

Flag to indicate whether the object generates an FTP packet, specified as a logical `0` (`false`) or `1` (`true`).

Data Types: `logical`

**ApplicationData — Application data to be added in FTP packet**

1500-by-1 vector of `1`s (default) | column vector of integers in the range `[0, 255]`

Application data to be added in the FTP packet, specified as a column vector of integers in the range `[0, 255]`. If the size of the application data is greater than the packet size, the object truncates the application data. If the size of the application data is less than the packet size, the object appends zeros.

**Dependencies**

To enable this property, set the `GeneratePacket` property to `true`.

Data Types: `double`

**Object Functions****Specific to This Object**

`generate` Generate next FTP, On-Off, VoIP, or video conference application traffic packet

**Examples****Generate FTP Application Traffic Pattern**

Create a default FTP application traffic pattern object.

```
cfgFTP = networkTrafficFTP;
```

Generate an FTP application traffic pattern.

```
[dt,packetSize] = generate(cfgFTP);
```

**Generate FTP Application Traffic Pattern Using Reading Time**

Create an FTP application traffic pattern object, specifying the reading time.

```
cfgFTP = networkTrafficFTP(ReadingTime=5);
```

Generate an FTP application traffic pattern.

```
[dt,packetSize] = generate(cfgFTP);
```

### Generate FTP Application Traffic Pattern and Data Packet

Create an FTP application traffic pattern object to generate an FTP data packet.

```
cfgFTP = networkTrafficFTP(GeneratePacket=true);
```

Generate an FTP application traffic pattern and data packet.

```
[dt,packetSize,packet] = generate(cfgFTP);
```

### Generate FTP Application Traffic Pattern to Visualize Packet Sizes and Intervals

Create a default FTP application traffic pattern object.

```
cfgFTP = networkTrafficFTP;
```

Generate an FTP application traffic pattern with 20,000 FTP packets.

```
numPkts = 20000;
dt = zeros(1,numPkts);
packetSize = zeros(1,numPkts);
for packetCount = 1:numPkts
    [dt(packetCount),packetSize(packetCount)] = generate(cfgFTP);
end
```

Visualize the FTP packet sizes.

```
stem(packetSize);
title('Packet Size Versus Packet Number');
xlabel('Packet Number');
ylabel('Packet Size in Bytes');
```

Visualize the FTP packet intervals.

```
figure;  
stem(dt);  
title('dt Versus Packet Number');  
xlabel('Packet Number');  
ylabel('dt in milliseconds');
```

## Version History

# networkTrafficOnOff

On-Off application traffic pattern generator

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Description

The `networkTrafficOnOff` object specifies the configuration parameters to generate an On-Off application traffic pattern.

You can use the On-Off application traffic pattern in system-level simulations to model the real-world data traffic.

## Creation

### Syntax

```
cfgOnOff = networkTrafficOnOff  
cfgOnOff = networkTrafficOnOff(Name=Value)
```

### Description

`cfgOnOff = networkTrafficOnOff` creates a default On-Off application traffic pattern object.

`cfgOnOff = networkTrafficOnOff(Name=Value)` sets properties using one or more name-value arguments. For example, `GeneratePacket=true` generates an application packet.

## Properties

### OnTime — On state duration

[ ] (default) | positive scalar

On state duration, specified as a positive scalar. Units are in seconds. To specify a customized value for the On time, specify this property. If you do not specify this property, the object uses the exponential distribution to calculate the On time.

Data Types: `double`

### OffTime — Off state duration

[ ] (default) | nonnegative scalar

Off state duration in seconds, specified as a nonnegative scalar. To specify a customized value for the Off time, specify this property. If you do not specify this property, the object uses the exponential distribution to calculate the Off time.

Data Types: `double`

**OnExponentialMean — Exponential distribution mean value to calculate On state duration**

1 (default) | positive scalar

Exponential distribution mean value in seconds to calculate the On state duration, specified as a positive scalar.

**Dependencies**

To enable this property, set the OnTime property to [ ].

Data Types: double

**OffExponentialMean — Exponential distribution mean value to calculate Off state duration**

2 (default) | nonnegative scalar

Exponential distribution mean value in seconds to calculate the Off state duration, specified as a nonnegative scalar.

**Dependencies**

To enable this property, set the OffTime property to [ ].

Data Types: double

**DataRate — Packet generation rate during On state**

5 (default) | positive scalar

Packet generation rate in Kbps during the On state, specified as a positive scalar.

---

**Note** If the value of this property is low and the PacketSize property value is large, the object might not generate packets in the On state.

---

Data Types: double

**PacketSize — Length of packet to be generated**

1500 (default) | positive scalar

Length in bytes of the packet to be generated, specified as a positive scalar. If the value of this property is greater than the DataRate property value, the object accumulates the data across multiple On times to generate a packet.

Data Types: double

**GeneratePacket — Flag to indicate whether to generate application packet**

false or 0 (default) | true or 1

Flag to indicate whether the object generates an application packet, specified as a logical 0 (false) or 1 (true).

Data Types: logical

**ApplicationData — Application data to be added in packet**

1500-by-1 vector of 1s (default) | column vector of integers in the range [0, 255]

Application data to be added in the packet, specified as a column vector of integers in the range [0, 255]. If the size of the application data is greater than the PacketSize property value, the object

truncates the application data. If the size of the application data is less than the `PacketSize` property value, the object appends zeros.

### Dependencies

To enable this property, set the `GeneratePacket` property to `true`.

Data Types: `double`

## Object Functions

### Specific to This Object

`generate` Generate next FTP, On-Off, VoIP, or video conference application traffic packet

## Examples

### Generate On-Off Application Traffic Pattern

Create a default On-Off application traffic pattern object.

```
cfgOnOff = networkTrafficOnOff;
```

Generate an On-Off application traffic pattern.

```
[dt,packetSize] = generate(cfgOnOff);
```

### Generate On-Off Application Traffic Pattern Using On State Mean Value

Create an On-Off application traffic pattern object, specifying the exponentially distributed mean value of the On state.

```
cfgOnOff = networkTrafficOnOff(OnExponentialMean=5);
```

Generate an On-Off application traffic pattern.

```
[dt,packetSize] = generate(cfgOnOff);
```

### Generate On-Off Application Traffic Pattern and Data Packet

Create an On-Off application traffic pattern object to generate an On-Off data packet.

```
cfgOnOff = networkTrafficOnOff(GeneratePacket=true);
```

Generate an On-Off application traffic pattern and data packet.

```
[dt,packetSize,packet] = generate(cfgOnOff);
```

### Generate On-Off Application Traffic Pattern to Visualize Packet Sizes and Intervals

Create a default On-Off application traffic pattern object.

```
cfgOnOff = networkTrafficOnOff;
```

Generate an On-Off application traffic pattern with 200 On-Off packets.

```
numPkts = 200;  
dt = zeros(1,numPkts);  
packetSize = zeros(1,numPkts);  
for packetCount = 1:numPkts  
    [dt(packetCount),packetSize(packetCount)] = generate(cfgOnOff);  
end
```

Visualize the On-Off packet sizes.

```
stem(packetSize);  
title('Packet Size Versus Packet Number');  
xlabel('Packet Number');  
ylabel('Packet Size in Bytes');
```

Visualize the On-Off packet intervals.

```
figure;  
stem(dt);  
title('dt Versus Packet Number');  
xlabel('Packet Number');  
ylabel('dt in milliseconds');
```

## Version History

# networkTrafficVideoConference

Video conference application traffic pattern generator

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Description

The `networkTrafficVideoConference` object specifies the configuration parameters to generate a video conference application traffic pattern based on the IEEE 802.11ax Evaluation Methodology.

You can use the video conference application traffic pattern in system-level simulations to model real-world data traffic.

## Creation

### Syntax

```
cfgVideo = networkTrafficVideoConference  
cfgVideo = networkTrafficVideoConference(Name=Value)
```

### Description

`cfgVideo = networkTrafficVideoConference` creates a default video application traffic pattern object.

`cfgVideo = networkTrafficVideoConference(Name=Value)` sets properties using one or more name-value arguments. For example, `HasJitter=false` specifies that the video application pattern does not model jitter.

## Properties

### FrameInterval — Time interval between two consecutive video frames

40 (default) | positive integer

Time interval between two consecutive video frames, specified as a positive integer. This value is expressed in milliseconds.

Data Types: double

### FrameSizeMode — Option to set source for video frame size

'WeibullDistribution' (default) | 'FixedSize'

Option to set a source for the video frame size, specified as one of these values.

- 'WeibullDistribution' — Use the video frame size value calculated by the Weibull probability distribution function.

- 'FixedSize' — Use the video frame size value specified by the FixedFrameSize property.

**FixedFrameSize — Size of video frame**

5000 (default) | integer in the range [1, 15,000]

Size of the video frame, specified as an integer in the range [1, 15,000]. This value is expressed in bytes. The video frame can be segmented into multiple network packets based on this value.

**Dependencies**

To enable this property, set the FrameSizeMethod property to 'FixedSize'.

Data Types: double

**WeibullScale — Scale parameter for Weibull distribution**

6950 (default) | scalar in the range (0, 54,210]

Scale parameter for the Weibull distribution to calculate the video frame size, specified as a scalar in the range (0, 54,210].

**Dependencies**

To enable this property, set the FrameSizeMethod property to 'WeibullDistribution'.

Data Types: double

**WeibullShape — Shape parameter for Weibull distribution**

0.8099 (default) | scalar in the range (0, 1]

Shape parameter for the Weibull distribution to calculate the video frame size, specified as a scalar in the range (0, 1].

**Dependencies**

To enable this property, set the FrameSizeMethod property to 'WeibullDistribution'.

Data Types: double

**HasJitter — Flag to indicate whether to model network jitter**

true or 1 (default) | false or 0

Flag to indicate whether to model network jitter, specified as a logical 1 (true) or 0 (false). The object applies jitter between the segmented packets. If you set this property to 1 (true), the object models jitter using the Gamma probability distribution function.

Data Types: logical

**GammaShape — Shape parameter for Gamma distribution**

0.2463 (default) | scalar in the range (0, 5]

Shape parameter for the Gamma distribution to calculate network jitter, specified as a scalar in the range (0, 5].

**Dependencies**

To enable this property, set the HasJitter property to true.

Data Types: double

**GammaScale — Scale parameter for Gamma distribution**

6.227 (default) | scalar in the range (0, 10]

Scale parameter for the Gamma distribution to calculate network jitter, specified as a scalar in the range (0, 10].

**Dependencies**

To enable this property, set the `HasJitter` property to `1` (`true`).

Data Types: `double`

**ProtocolOverhead — Protocol overheads in network traffic**

28 (default) | integer in the range [0, 60]

Protocol overheads in network traffic, specified as an integer in the range [0, 60]. To add layer 3, layer 4, and application protocol overheads in network traffic, enable this property. This value is expressed in bytes.

Data Types: `double`

**GeneratePacket — Flag to indicate whether to generate video packet with payload**`false` or `0` (default) | `true` or `1`

Flag to indicate whether to generate a video packet with payload, specified as a logical `0` (`false`) or `1` (`true`). To generate a video packet with payload, set this property to `true`. If you set this property to `false`, the `generate` object function generates no application data packet.

Data Types: `logical`

**ApplicationData — Application data to be added in video packet**

1500-by-1 vector of 1s (default) | column vector of integers in the range [0, 255]

Application data to be added in the video packet, specified as a column vector of integers in the range [0, 255].

- If the size of the application data is greater than the packet size, the object truncates the application data.
- If the size of the application data is less than the packet size, the object appends zeros.

**Dependencies**

To enable this property, set the `GeneratePacket` property to `true`.

Data Types: `double`

**Object Functions****Specific to This Object**

`generate` Generate next FTP, On-Off, VoIP, or video conference application traffic packet

**Examples**

### Generate Video Conference Traffic Using Default Values

Create a default video application traffic pattern object.

```
cfgVideo = networkTrafficVideoConference
cfgVideo =
    networkTrafficVideoConference with properties:
        FrameInterval: 40
        FrameSizeMethod: 'WeibullDistribution'
        WeibullScale: 6950
        WeibullShape: 0.8099
        HasJitter: 0
        ProtocolOverhead: 28
        GeneratePacket: 0
```

Generate a video application traffic pattern.

```
[dt,packetSize] = generate(cfgVideo);
```

### Generate Video Conference Traffic with Frame Interval and Data Packet

Create a video application traffic pattern object to generate a video data packet. Specify the frame interval in milliseconds.

```
cfgVideo = networkTrafficVideoConference(GeneratePacket=true);
cfgVideo.FrameInterval = 60;
```

Generate a video application traffic pattern and data packet.

```
[dt,packetSize,packet] = generate(cfgVideo);
```

### Generate Multiple Video Data Packets Using Elapsed Time

Create a video application traffic pattern object to generate a video frame of size 400 bytes.

```
cfgVideo = networkTrafficVideoConference( ...
    FrameSizeMethod='FixedSize', ...
    FixedFrameSize=400);
```

Specify the elapsed time in milliseconds.

```
elapsedTime = 10;
```

After every elapsed time value, invoke the video application traffic pattern object to generate five video data packets.

```
numPkts = 5;
for i = 1:numPkts
    while true
        [dt,packetSize] = generate(cfgVideo,elapsedTime);
```

```
        if packetSize
            fprintf('Video data packet %d generated\n',i);
            break;
        end
    end
end
end

Video data packet 1 generated
Video data packet 2 generated
Video data packet 3 generated
Video data packet 4 generated
Video data packet 5 generated
```

### **Generate Video Conference Traffic Pattern to Visualize Packet Sizes and Intervals**

Create a default video application traffic pattern object.

```
cfgVideo = networkTrafficVideoConference;
```

Generate a video application traffic pattern with 100 video packets.

```
numPkts = 100;
dt = zeros(1,numPkts);
packetSize = zeros(1,numPkts);
for packetCount = 1:100
    [dt(packetCount),packetSize(packetCount)] = generate(cfgVideo);
end
```

Visualize the video packet sizes.

```
stem(packetSize);
title('Packet Size Versus Packet Number');
xlabel('Packet Number');
ylabel('Packet Size in Bytes');
```

Visualize the video packet intervals.

```
figure;  
stem(dt);  
title('dt Versus Packet Number');  
xlabel('Packet Number');  
ylabel('dt in milliseconds');
```

## Version History

# networkTrafficVoIP

VoIP application traffic pattern generator

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Description

The `networkTrafficVoIP` object specifies the configuration parameters to generate a voice over Internet protocol (VoIP) application traffic pattern based on the IEEE 802.11ax Evaluation Methodology.

You can use the VoIP application traffic pattern in system-level simulations to model the real-world data traffic.

## Creation

### Syntax

```
cfgVoIP = networkTrafficVoIP  
cfgVoIP = networkTrafficVoIP(Name=Value)
```

### Description

`cfgVoIP = networkTrafficVoIP` creates a default VoIP application traffic pattern object.

`cfgVoIP = networkTrafficVoIP(Name=Value)` sets properties using one or more name-value arguments. For example, `HasJitter=false` specifies that the VoIP application pattern does not model jitter.

## Properties

### ExponentialMean — Mean value for exponential distribution

1250 (default) | nonnegative integer

Mean value for the exponential distribution, specified as a nonnegative integer. The object uses this property to calculate the exponentially distributed active or silent state duration in the VoIP traffic.

Data Types: `double`

### HasJitter — Flag to indicate whether to model jitter

`true` or `1` (default) | `false` or `0`

Flag to indicate whether the object models jitter, specified as a logical `1` (`true`) or `0` (`false`).

Data Types: `logical`

**LaplaceScale — Scale parameter for Laplace distribution**

5.11 (default) | scalar in the range [1, 100]

Scale parameter for the Laplace distribution, specified as a scalar in the range [1, 100]. The object uses this property and the `LaplaceMu` property to calculate the packet arrival delay jitter in milliseconds.

**Dependencies**

To enable this property, set the `HasJitter` property to `true`.

Data Types: `double`

**LaplaceMu — Location parameter for Laplace distribution**

0 (default) | scalar in the range [0, 100]

Location parameter for the Laplace distribution, specified as a scalar in the range [0, 100]. The object uses this property and the `LaplaceScale` property to calculate packet arrival delay jitter in milliseconds.

**Dependencies**

To enable this property, set the `HasJitter` property to `true`.

Data Types: `double`

**GeneratePacket — Flag to indicate whether to generate a VoIP packet**`false` or 0 (default) | `true` or 1

Flag to indicate whether the object generates a VoIP packet, specified as a 0 (`false`) or logical 1 (`true`).

Data Types: `logical`

**ApplicationData — Application data to be added in VoIP packet**

36-element column vector of 1s (default) | column vector of integers in the range [0, 255]

Application data to be added in the VoIP packet, specified as a column vector of integers in the range [0, 255]. If the size of the application data is greater than the packet size, the object truncates the application data. If the size of the application data is less than the packet size, the object appends zeros.

**Dependencies**

To enable this property, set the `GeneratePacket` property to 1 (`true`).

Data Types: `double`

**Object Functions****Specific to This Object**

`generate` Generate next FTP, On-Off, VoIP, or video conference application traffic packet

**Examples**

**Generate VoIP Application Traffic Pattern**

Create a default VoIP application traffic pattern object.

```
cfgVoIP = networkTrafficVoIP;
```

Generate a VoIP application traffic pattern.

```
[dt,packetSize] = generate(cfgVoIP);
```

**Generate VoIP Application Traffic Pattern Using Mean Value of Exponential Distribution**

Create a VoIP application traffic pattern object, specifying the mean value of the exponential distribution.

```
cfgVoIP = networkTrafficVoIP(ExponentialMean=5);
```

Generate a VoIP application traffic pattern.

```
[dt,packetSize] = generate(cfgVoIP);
```

**Generate VoIP Application Traffic Pattern and Data Packet**

Create a VoIP application traffic pattern object to generate a VoIP data packet.

```
cfgVoIP = networkTrafficVoIP('GeneratePacket',true);
```

Generate a VoIP application traffic pattern and data packet.

```
[dt,packetSize,packet] = generate(cfgVoIP);
```

**Generate VoIP Application Traffic Pattern to Visualize Packet Sizes and Intervals**

Create a default VoIP application traffic pattern object.

```
cfgVoIP = networkTrafficVoIP;
```

Generate a VoIP application traffic pattern with 200 VoIP packets.

```
numPkts = 200;  
dt = zeros(1,numPkts);  
packetSize = zeros(1,numPkts);  
for packetCount = 1:numPkts  
    [dt(packetCount),packetSize(packetCount)] = generate(cfgVoIP);  
end
```

Visualize the VoIP packet sizes.

```
stem(packetSize);  
title('Packet Size Versus Packet Number');
```

```
xlabel('Packet Number');  
ylabel('Packet Size in Bytes');
```

Visualize the VoIP packet intervals.

```
figure;  
stem(dt);  
title('dt Versus Packet Number');  
xlabel('Packet Number');  
ylabel('dt in Milliseconds');
```

## Version History

Introduced in R2020b

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from 5G Toolbox and WLAN Toolbox**

Previously, networkTrafficVoIP required 5G Toolbox or WLAN Toolbox.

# wirelessNetworkSimulator

Wireless network simulator

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Description

The `wirelessNetworkSimulator` object simulates different wireless network scenarios with different types of wireless nodes. Use the Object Functions to add nodes to the simulator, interact with the nodes, schedule actions to perform during simulation, plug in custom channel models, and run simulations.

## Creation

### Syntax

```
networkSimulator = wirelessNetworkSimulator.init()
```

### Description

`networkSimulator = wirelessNetworkSimulator.init()` creates a `wirelessNetworkSimulator` object with default property values. If the `wirelessNetworkSimulator` object `networkSimulator` already exists in the MATLAB workspace, the function resets the object to its default state.

## Properties

### CurrentTime — Current simulation time

0 (default) | non-negative scalar

This property is read-only.

Current simulation time, stored as a non-negative scalar. Units are in seconds.

Data Types: `double`

### ChannelFunction — Channel model

"fsp1" (default) | function handle

This property is read-only.

Channel model, stored as a function handle. By default, the simulator uses the `fsp1` function to model the channel. To specify a custom channel model, use the `addChannelModel` function.

Data Types: `function_handle`

**EndTime – Simulation end time**

0 (default) | non-negative scalar

This property is read-only.

Simulation end time, stored as a non-negative scalar. Units are in seconds.

Data Types: double

**Object Functions**

wirelessNetworkSimulator.getInstance	Get instance of wirelessNetworkSimulator object
addNodes	Add nodes to simulation
addChannelModel	Add custom channel or path loss model
scheduleAction	Schedule action to perform during simulation
cancelAction	Cancel scheduled action
run	Run simulation

**Examples****Simulate Bluetooth BR Network with Default Channel Effects**

Create a wirelessNetworkSimulator object by using the wirelessNetworkSimulator.init() function. By default, the wirelessNetworkSimulator object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...
    cfgConnection,centralNode,peripheralNode);
```

Create and configure a networkTrafficOnOff object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff( ...
    DataRate=200, ...
    PacketSize=27, ...
    GeneratePacket=true, ...
    OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic, ...  
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator,simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel.

Retrieve application, baseband, and physical layer (PHY) statistics corresponding to the Central and Peripheral nodes.

```
centralStats = statistics(centralNode)
```

```
centralStats = struct with fields:  
    Name: "Node1"  
    ID: 1  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

```
peripheralStats = statistics(peripheralNode)
```

```
peripheralStats = struct with fields:  
    Name: "Node2"  
    ID: 2  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

### **Simulate Bluetooth BR Network without Channel Effects**

Create a wirelessNetworkSimulator object.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");  
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection(cfgConnection,centralNode,peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff(DataRate=200,PacketSize=27, ...
    GeneratePacket=true,OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic, ...
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects. You can add custom channel effects by using the `addChannelModel` function. However, to model the channel without any channel effects, specify a custom MATLAB™ function, `removeChannelEffect` on page 3-1417, in which the input transmitted packets are returned at the output without any changes.

```
addChannelModel(networkSimulator,@removeChannelEffect);
```

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator,simulationTime);
```

Retrieve application, baseband, and physical layer (PHY) statistics corresponding to the Central and Peripheral nodes.

```
centralStats = statistics(centralNode)
```

```
centralStats = struct with fields:
    Name: "Node1"
    ID: 1
    App: [1x1 struct]
    Baseband: [1x1 struct]
    PHY: [1x1 struct]
```

```
peripheralStats = statistics(peripheralNode)
```

```
peripheralStats = struct with fields:
    Name: "Node2"
    ID: 2
    App: [1x1 struct]
    Baseband: [1x1 struct]
    PHY: [1x1 struct]
```

```
function outputData = removeChannelEffect(~,txData)
outputData = txData;
end
```

# lrwpanHRPConfig

Configure HRP transmission

---

**Note Download Required:** To use , first download the Communications Toolbox Library for ZigBee and UWB add-on.

---

## Description

The lrwpanHRPConfig object is a configuration object for the WPAN high-rate pulse (HRP) ultra-wideband (UWB) physical layer (PHY) format of IEEE 802.15.4 a/z. For a detailed description of the HRP UWB format, see [1] and for HRP in general, see [2].

## Creation

### Syntax

```
cfgHRP = lrwpanHRPConfig
cfgHRP = lrwpanHRPConfig(Name=Value)
```

### Description

cfgHRP = lrwpanHRPConfig creates a configuration object that initializes transmit parameters for an HRP IEEE 802.15.4 a/z UWB waveform. This object parameterizes the higher pulse repetition frequency (HPRF), base pulse repetition frequency (BPRF), and the traditional 802.15.4a modes. The PHY service data unit (PSDU) rate-dependent parameters and timing-related parameters for BPRF and 802.15.4a modes are summarized in Table 15-3 of [2].

cfgHRP = lrwpanHRPConfig(Name=Value) sets properties using one or more name-value arguments. For example, lrwpanHRPConfig(Channel=3) specifies an HRP transmission assigned on channel 3.

## Properties

### Channel — Channel number

0 (default) | scalar in the set [0:3 5:6 8:10 12:14]

Channel number, specified as a scalar in the set of [0:3 5:6 8:10 12:14] values.

This property constrains the allowed CodeIndex values for the BPRF and 802.15.4a modes. For transmission over the air, you must upconvert the baseband waveform generated by lrwpanWaveformGenerator to a carrier frequency. Table 15-11 of [2] specifies carrier frequencies and HRP UWB PHY band allocations.

Data Types: double | single

### Mode — Operation mode

'HPRF' (default) | 'BPRF' | '802.15.4a'

Operation mode, specified as 'HPRF', 'BPRF', or '802.15.4a'. The BPRF and 802.15.4a modes use burst position modulation with BPSK (BPM-BPSK) modulation scheme. HPRF mode uses the HRP-ERDEV modulation scheme, which has more regular chip transmissions.

When you set this property to:

- 'HPRF' — The mean PRF is either 124.8 or 249.6 MHz.
- 'BPRF' — The mean PRF is 62.4 MHz and the data rate is 6.81 Mbps.
- '802.15.4a' — The mean PRF is either 3.9 or 15.6 MHz, or 62.4 MHz with a data rate different than 6.81 Mbps.

Data Types: `string` | `char`

### **MeanPRF — Mean pulse repetition frequency**

249.6 (default) | 3.9 | 15.6 | 62.4 | 124.8

Mean pulse repetition frequency in MHz, specified as 3.9, 15.6, 62.4, 124.8, or 249.6.

When you set Mode to:

- 'HPRF' — The mean PRF is either 124.8 or 249.6 MHz.
- 'BPRF' — The mean PRF is 62.4 MHz.
- '802.15.4a' — The mean PRF is either 3.9, 15.6, or 62.4 MHz.

For the 802.15.4a and BPRF modes, the mean PRF equals the ratio of peak PRF and bursts per symbol ( $499.2/\text{BurstsPerSymbol}$ ). To return characteristic information about the configuration object, use the `info` object function.

Data Types: `double` | `single`

### **DataRate — Payload data rate**

0.85 (default) | 0.11 | 1.7 | 6.81 | 27.24

Payload data rate in Mbps, specified as 0.11, 0.85, 1.7, 6.81, or 27.24.

This property specifies the number of payload information bits (not including parity bits) that are conveyed in a unit of time, specifically, the number of chips per burst for the payload. When you set Mode to:

- '802.15.4a' — You can set the data rate as specified in Table 15.3 of [2].
  - For mean PRF data rates 3.9, 15.6, and 62.4 Mbps, you can set the payload data rate to 0.11, 0.85, or 6.81 Mbps.
  - When the mean PRF data rate is 3.9 Mbps, you also can set the payload data rate to 1.7 Mbps.
  - When the mean PRF data rate is 15.6 or 62.4 Mbps, you also can set the payload data rate to 27.24 Mbps.
- 'BPRF' — The payload data rate is 6.81 Mbps.
- 'HPRF' — The payload data rate is set as specified by Table 15.10b in [1].

### **Dependencies**

This property applies when you set Mode to '802.15.4a'.

Data Types: `double` | `single`

**PHRDataRate — PHR data rate**

0.85 (default) | 6.81

PHY header (PHR) data rate in Mbps, specified as 0.85 or 6.81.

This property determines the number of chips per burst for the PHR. When you set Mode to:

- 'BPRF' — You can set the PHR data rate to 0.85 or 6.81 Mbps.
- 'HPRF' — If you set ConstraintLength to 7, the PHR data rate equals the payload data rate. For other constraint lengths, the PHR data rate is approximately DataRate/2, as specified by Table 15.10b in [1].
- '802.15.4a' — If you set DataRate to 0.11, the PHR data rate is 0.11 Mbps. For other data rates, the PHR data rate is 0.85 Mbps.

**Dependencies**

This property applies when you set Mode to 'BPRF'.

Data Types: double | single

**SamplesPerPulse — Number of samples per Butterworth pulse**

4 (default) | scalar value greater than 1

Number of samples per Butterworth pulse, specified as a scalar value greater than 1.

This property determines how many samples are used to construct an 8th-order Butterworth pulse. The sample rate of the HRP waveform equals the product of SamplesPerPulse and the peak PRF value of 499.2 MHz.

Data Types: double | single

**STSPacketConfiguration — Control STS placement within packet**

1 (default) | 0 | 2 | 3

Control the scrambled timestamp sequence (STS) placement within the packet, specified as 0, 1, 2, or 3.

When you set this property to:

- 0 — The packet contains the PHR and payload, but no STS.
- 1 — The STS is placed before the PHR.
- 2 — The STS is placed after the payload union.
- 3 — The packet contains the STS, but no PHR or payload.

When the STS field is enabled, it is created with STS key = "4a5572bc90798c8e518d2449092f1b55" and STS counter ([upper96 lower32]) = ["68debd3a599939dd57fdbb0e" "2a10fac0"]. Test vectors specified by IEEE widely use these STS key and counter values.

Data Types: double | single

**NumSTSSegments — Number of contiguous STS segments**

1 (default) | 2 | 3 | 4

Number of contiguous STS segments, specified as 1, 2, 3, or 4.

When you set Mode to:

- 'HPRF' — You can set the number of contiguous STS segments to 1, 2, 3, or 4.
- 'BPRF' — The number of contiguous STS segments is 1.
- '802.15.4a' — The packet has no STS.

**Dependencies**

This property applies when you set Mode to 'HPRF'.

Data Types: double | single

**STSSegmentLength — Length of active STS segments**

64 (default) | 16 | 32 | 128 | 256

Length of active STS segments as a multiple of 512 chips, specified as 16, 32, 64, 128, or 256.

This property specifies the number of 512 chip chunks in the active STS. For example, setting this property to 64, corresponds to 32768 chips total in the STS. When you set Mode to:

- 'HPRF' — You can set the length of active STS segments to 16, 32, 64, 128, or 256.
- 'BPRF' — The length of active STS segments is 64.
- '802.15.4a' — The packet has no STS.

**Dependencies**

This property applies when you set Mode to 'HPRF'.

Data Types: double | single

**ExtraSTSGapLength — Length of extra STS gap**

0 (default) | integer the range [0, 127]

Length of extra STS gap as a multiple of 4 chips, specified as an integer in the range [0, 127]. This property specifies the length of an optional additional gap between the payload and the STS. For example, setting this property to 5 corresponds to a gap of 20 chips between the payload and the STS.

**Dependencies**

This property applies when you set Mode to 'HPRF' and STSPacketConfiguration to 2.

Data Types: double | single

**ExtraSTSGapIndex — Index of extra STS gap**

0 (default) | 1 | 2 | 3

Index of extra STS gap, specified as 0, 1, 2, or 3. This property determines which attribute conveys the ExtraSTSGapLength value and is used to construct the first two bits (A0, A1) of the PHR.

**Dependencies**

This property applies when you set Mode to 'HPRF' and STSPacketConfiguration to 2.

Data Types: double | single

**CodeIndex — SYNC code index**

25 (default) | scalar from set of [1:6 9:16 21:32]

SYNC code index, specified as a scalar from the set of [1:6 9:16 21:32]. The SYNC field of the PPDU contains the ternary codes associated with the SYNC code index specified by this property. The codes are comprised of ternary symbols (-1, 0, 1). For details, see Section 15.2.6.2 and Tables 15-6, 15-7, and 15-7a in [2].

- Values in the range [1, 8] correspond to a code that is 31 symbols long (Table 15-6) and apply only when you set `Mode` to '802.15.4a' and the mean PRF is less than 62.4 MHz.
- Values in the range [9, 24] correspond to a code that is 127 symbols long (Table 15-7) and apply only when the mean PRF is 62.4 MHz.
- Values in the range [25, 32] correspond to a code that is 91 symbols long (Table 15-7a) and apply only when you set `Mode` to 'HPRF' or 'BPRF' and the mean PRF is less than 62.4 MHz.

Data Types: double | single

### **PreambleMeanPRF — Mean PRF of preamble**

16.1 (default) | 4.03

Mean pulse repetition frequency (PRF) of the preamble in MHz, specified as 4.03 or 16.1.

- When you set `Mode` to '802.15.4', you can set the preamble code length to 4.03 or 16.1.
- When `PreambleCodeLength` is 127, the preamble mean PRF is 62.89 MHz.
- When `PreambleCodeLength` is 91, the preamble mean PRF is 111.09 MHz.

To return characteristic information about the configuration object, use the `info` object function.

### **Dependencies**

This property applies when you set `Mode` to '802.15.4', which corresponds to a code index value less than 8 and preamble code length of 31.

Data Types: double | single

### **PreambleDuration — Number of repetitions of spread preamble SYNC codes**

64 (default) | 16 | 24 | 32 | 48 | ...

Number of repetitions of spread preamble SYNC codes, specified as 16, 24, 32, 48, 6496, 128, 256, 1024, or 4096.

This property determines how many times the code indexed by `CodeIndex` is repeated, after it is spread according to the `PreambleSpreadingFactor`. To return characteristic information about the configuration object, use the `info` object function. When you set `Mode` to:

- 'HPRF' — You can set the preamble duration to 16, 24, 32, 48, 64, 96, 128, or 256.
- 'BPRF' or '802.15.4a' — You can set the preamble duration to 16, 64, 1024, or 4096. The preamble duration cannot be set to 4096 when you set `PreambleMeanPRF` to 4.03 MHz.

Data Types: double | single

### **SFDNumber — Index of SFD choice**

0 (default) | 1 | 2 | 3 | 4

Index of the start-of-frame delimiter (SFD) choice from Table 15-7c in [1], specified as 0, 1, 2, 3, or 4.

This property determines the length and value of the SFD in the synchronization header (SHR). Setting the SFD number to 0 or 2 enables an 8-symbol SFD. Setting the SFD number to 1, 3 or 4 enables a 4-, 16-, or 32-symbol SFD, respectively. When you set Mode to:

- 'HPRF' — You can set the SFD number to 0, 1, 2, 3, or 4.
- 'BPRF' — You can set the preamble duration to 0 or 2.
- '802.15.4a' — When you set the payload data rate to 0.11 Mbps, the SFD is 64 symbols. For all other payload data rates, the SFD is 8 symbols.

**Dependencies**

This property applies when you set Mode to 'BPRF' or 'HPRF'.

Data Types: double | single

**Ranging — PHY frame to be used for ranging**

0 or false (default) | 1 or true

PHY frame to be used for ranging, specified as a numeric or logical 0 (false) or 1 (true). When you set this property to:

- false — The ranging value is not encoded in the PHY header (PHR).
- true — The ranging value is encoded in the PHY header (PHR).

Data Types: logical

**ConstraintLength — Constraint length of convolutional coding**

3 (default) | 7

Constraint length of convolutional coding, specified as 3 or 7.

The chosen constraint length selects between the two rate ½ convolutional encoders defined in Section 15.3.3.3 of [1].

**Dependencies**

This property applies when you set Mode to 'HPRF'.

Data Types: double | single

**PSDULength — Length of PSDU**

127 (default) | positive integer in the range [0, 4095]

Length of PHY service data unit (PSDU) payload in bytes, specified as a positive integer in the range [0, 4095].

When you set Mode to:

- 'HPRF' and ExtraSTSGapLength to 0 — The PSDU length must be in the range [0, 4095].
- 'HPRF' and ExtraSTSGapLength to a nonzero value — The PSDU length must be in the range [0, 1023].
- 'BPRF' or '802.15.4a' — The PSDU length must be in the range [0, 127].

Data Types: double | single

**SampleRate — Sample rate of output waveform**

1.9968e9 (default) | positive scalar

This property is read-only.

Sample rate of the output waveform in Hz, specified as a positive scalar.

Data Types: double | single

**Object Functions**

info Characteristic information about WPAN high-rate pulse configuration object

**Examples****Create HPRF IEEE 802.15.4z Waveform**

Generate random data for a PHY Service Data Unit (PSDU) payload. Create an HPRF IEEE 802.15.4z `lrwpanHRPConfig` object.

```
psdu = randi([0,1],8*200,1);
cfgHPRF = lrwpanHRPConfig(Mode='HPRF', ...
    Channel=3, ... % Mandatory low-band channel
    MeanPRF=124.8, ... % 16 chips per payload symbol
    STSPacketConfiguration=1, ... % Enable STS before payload
    NumSTSSegments=2, ... % 2 STS segments
    CodeIndex=27, ... % One 91-symbols long SYNC code
    PreambleDuration=32, ... % Repetitions for spread SYNC code
    SFDNumber=1, ... % Choose a 4-symbol long SFD
    ConstraintLength=7, ... % Convolutional encoder, no RS coding
    PSDULength=100); % PSDU length in bytes
```

Generate an HPRF IEEE 802.15.4z waveform by using the `lrwpanWaveformGenerator` function and `cfgHPRF` configuration object. The waveform generator loops PSDU length as needed to use all input PSDU payload bits. Display the waveform by using a `spectrumAnalyzer` object.

```
waveHPRF = lrwpanWaveformGenerator(psdu,cfgHPRF);
sa = spectrumAnalyzer(SampleRate=cfgHPRF.SampleRate);
sa(waveHPRF);
```

### Create BPRF IEEE 802.15.4z Waveform

Generate random data for a PHY Service Data Unit (PSDU) payload. Create a BPRF IEEE 802.15.4z `lrwpanHRPConfig` object. BPRF payload data rate is always at 6.81 Mbps.

```
psdu = randi([0,1],8*100,1);
cfgBPRF = lrwpanHRPConfig(Mode='BPRF', ...
    STSPacketConfiguration=0, ... % Turn off STS
    PHRDataRate=6.81, ... % PSDU header data rate in Mbps
    CodeIndex=9, ... % A 127-symbols long SYNC code
    PSDULength=length(psdu)/8); % PSDU length in bytes
```

Generate an BPRF IEEE 802.15.4z waveform by using the `lrwpanWaveformGenerator` function and `cfgBPRF` configuration object. The waveform generator loops PSDU length as needed to use all input PSDU payload bits. Display the waveform by using a `spectrumAnalyzer` object.

```
waveBPRF = lrwpanWaveformGenerator(psdu,cfgBPRF);
sa = spectrumAnalyzer(SampleRate=cfgBPRF.SampleRate);
sa(waveBPRF);
```

### Create IEEE 802.15.4a Waveform

Generate random data for a PHY Service Data Unit (PSDU) payload. Create an IEEE 802.15.4a `lrwpanHRPConfig` object.

```
psdu = randi([0,1],50,1);
cfg4a = lrwpanHRPConfig(Mode='802.15.4a', ...
    Channel=9, ...           % High-band mandatory chan for code index 3
    MeanPRF=15.6, ...       % 8 candidate bursts
    DataRate=27.24, ...    % 1 chip per burst (PHR at 850 kbps max)
    CodeIndex=3, ...       % 3rd code with length 31
    PreambleMeanPRF=4.03, ... % PreambleSpreadingFactor = 64
    PSDULength=100);      % PSDU length in bytes
```

Generate an 4a IEEE 802.15.4z waveform by using the `lrwpanWaveformGenerator` function and `cfg4a` configuration object. The waveform generator loops input PSDU payload bits as needed to fill PSDU length. Display the waveform by using a `spectrumAnalyzer` object.

```
wave4a = lrwpanWaveformGenerator(psdu,cfg4a);
sa = spectrumAnalyzer(SampleRate=cfg4a.SampleRate);
sa(wave4a);
```

Configure O-QPSK IEEE 802.15.4 transmission

---

**Note Download Required:** To use , first download the Communications Toolbox Library for ZigBee and UWB add-on.

---

### Description

The `lrwpanOQPSKConfig` object is a configuration object for the WPAN O-QPSK physical layer (PHY) format of IEEE 802.15.4. Higher layer standards, such as ZigBee, use this PHY. For a detailed description of the waveform format, see [1].

### Creation

#### Syntax

```
cfgHRP = lrwpanOQPSKConfig  
cfgHRP = lrwpanOQPSKConfig(Name=Value)
```

#### Description

`cfgHRP = lrwpanOQPSKConfig` creates a configuration object that initializes transmit parameters for an O-QPSK IEEE 802.15.4 ZigBee waveform.

`cfgHRP = lrwpanOQPSKConfig(Name=Value)` sets properties using one or more name-value arguments. For example, `lrwpanOQPSKConfig(PSDULength=64)` specifies a PSDU length of 64 bytes.

### Properties

#### Band — Center frequency of operating range

2450 (default) | 780 | 868 | 915 | 2380

Center frequency of operating range in MHz, specified as 780, 868, 915, 2380, or 2450. The configuration object uses this property when determining the spreading factor and filtering type.

Data Types: double | single

#### SamplesPerChip — Number of samples per chip pulse

4 (default) | even positive integer

Number of samples per chip pulse, specified as an even positive integer. The configuration object uses this property when determining the number of samples used to construct a filtered O-QPSK chip.

Data Types: double | single

#### PSDULength — Length of PSDU

127 (default) | positive integer in the range [0, 127]

Length of the PHY service data unit (PSDU) in bytes, specified as a positive integer in the range [0, 127].

Data Types: double | single

### **SampleRate — Sample rate of output waveform**

4e6 (default) | positive scalar

Sample rate of the output waveform in Hz, specified as a positive scalar.

Data Types: double | single

## **Examples**

### **Create OQPSK IEEE 802.15.4 Waveform**

Generate random data for a PHY Service Data Unit (PSDU) payload. Create an OQPSK IEEE 802.15.4 `lrwpanOQPSKConfig` object. Create an OQPSK IEEE 802.15.4 waveform.

```
psdu = randi([0,1],127*8,1);
spc = 8;
cfgOQPSK = lrwpanOQPSKConfig( ...
    SamplesPerChip=spc, ...
    PSDULength=length(psdu)/8); % PSDU length in bytes
```

Generate an OQPSK IEEE 802.15.4 waveform by using the `lrwpanWaveformGenerator` function and `cfgOQPSK` configuration object. The waveform generator loops PSDU length as needed to use all input PSDU payload bits. Display the waveform by using the `eyediagram` function.

```
waveOQPSK = lrwpanWaveformGenerator(psdu,cfgOQPSK);
eyediagram(waveOQPSK(1+spc:end-spc), 2*spc);
```

## rxsite

Create RF receiver site

### Description

Use the `rxsite` object to create a radio frequency receiver site.

A receiver consists of an RF circuit and an antenna, where the antenna intercepts radio waves and converts them to a current that is decoded by the RF circuit (e.g. demodulated) into a signal. Key characteristics of a receiver include its sensitivity and its antenna radiation pattern.

### Creation

#### Syntax

```
rx = rxsite
rx = rxsite(coordsys)
rx = rxsite(Name,Value)
```

#### Description

`rx = rxsite` creates a radio frequency receiver site.

`rx = rxsite(coordsys)` creates a receiver site with coordinate system set to 'geographic' or 'cartesian'.

`rx = rxsite(Name,Value)` sets properties using one or more name-value pairs. For example, `rx = rxsite('Name','RX Site')` creates a receiver site with name `RX Site`. Enclose each property name in quotes.

Create a 1-by- $N$  array of receiver sites by specifying a property value as an array of  $N$  columns. Other property values must be specified with either 1 or  $N$  columns. The `Name`, `Latitude`, and `Longitude` properties may be specified as either a row vector or column vector with  $N$  elements. The `CoordinateSystem` property must be a string scalar or a character vector.

### Properties

#### Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or as a row or column vector or as a string.

Example: 'Name','Site 3'

Example: `rx.Name = 'Site 3'`

Example: If you want to assign multiple values then `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]`; `rx = rxsite('Name',names)`

Data Types: char | string

### **CoordinateSystem — Coordinate system of site location**

'geographic' (default) | 'cartesian'

Coordinate system of the site location, specified as 'geographic' or 'cartesian'. If this property is 'geographic', the site location is defined using the properties `Latitude`, `Longitude`, and `AntennaHeight`. If this property is 'cartesian', the site location is defined using `AntennaPosition`.

Example: 'CoordinateSystem','cartesian'

Example: `tx.CoordinateSystem = 'cartesian'`

### **Latitude — Site latitude coordinates**

42.3021 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar or a row or column vector in the range of range -90 to 90. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.

Example: 'Latitude',45.098

Example: `rx.Latitude = 45.098`

Example: If you want to assign multiple values then - `latitude = [42.3467,42.3598,42.3763]; rx = rxsite('Latitude',latitude)`

#### **Dependencies**

To use this property, `CoordinateSystem` must be set to 'geographic'.

### **Longitude — Site longitude coordinates**

-71.3764 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or a row or column vector. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: 'Longitude',-68.890

Example: `rx.Longitude = -68.890`

Example: If you want to assign multiple values then - `longitude = [-71.0972,-71.0545,-71.0611]; rx = rxsite('Longitude',longitude)`

#### **Dependencies**

To use this property, `CoordinateSystem` must be set to 'geographic'.

### **Antenna — Antenna element or array**

'isotropic' (default) | object | row vector

Antenna element or array specified as one of these:

- 'isotropic' to model an antenna that radiates uniformly in all directions.
- An `arrayConfig` object.
- If you have Antenna Toolbox™, an antenna element from the “Antenna Catalog” (Antenna Toolbox).

- If you have Phased Array System Toolbox, any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox) or any array object in “Array Geometries and Analysis” (Phased Array System Toolbox).

Example: 'Antenna',cfgArray, where cfgArray is an arrayConfig object

Example: rx.Antenna = arrayConfig('Size',[8 1]); specifies an 8-element ULA along z-axis

### **AntennaAngle — Angle of antenna local X-axis**

0 (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Angle of antenna local Cartesian coordinate system X-axis, specified as a numeric scalar representing azimuth angle in degrees or a 2-by-1 vector representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise to the antenna X-axis, either from the east ( for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites).

The elevation angle is measured from the horizontal plane or X-Y plane to the antenna X-axis in the range -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: tx.AntennaAngle = [25,-80]

### **AntennaHeight — Antenna height above surface**

1 (default) | non-negative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise,the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: rx.AntennaHeight = 15

### **Dependencies**

To use this property, CoordinateSystem must be set to 'geographic'.

Data Types:

### **AntennaPosition — Position of antenna center**

[0;0;0] (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing [x;y;z] Cartesian coordinates with each element in meters.

Example: 'AntennaPosition',[0;2;4]

Example: tx.AntennaPosition = [0;2;4]

### **Dependencies**

To use this property, choose CoordinateSystem must be set to 'cartesian'.

Data Types:

**SystemLoss — System loss**

0 (default) | nonnegative numeric scalar | row vector

System loss, specified as a non-negative numeric scalar or a row vector in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: 'SystemLoss',10

Example: rx.SystemLoss = 10

Data Types:

**ReceiverSensitivity — Minimum received power to detect signal**

-100 (default) | numeric scalar | row vector

Minimum received power to detect the signal, specified as a numeric scalar or a row vector in dBm.

Example: 'ReceiverSensitivity',-80

Example: rx.ReceiverSensitivity = -80

Data Types: double

**Object Functions**

show	Show site in Site Viewer
hide	Hide site from Site Viewer
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Coordinates at distance and angle from site
sigstrength	Received signal strength
los	Display or compute line-of-sight (LOS) visibility status
link	Display or compute communication link status
pattern	Display antenna radiation pattern in Site Viewer

**Examples****Default Receiver Site**

Create and show the default receiver site.

```
rx = rxsite
```

```
rx =
```

```
rxsite with properties:
```

```

        Name: 'Site 2'
        Latitude: 42.3021
        Longitude: -71.3764
        Antenna: 'isotropic'
        AntennaAngle: 0
        AntennaHeight: 1
        SystemLoss: 0
        ReceiverSensitivity: -100
```

show(rx)

[arrayConfig](#) | [txsite](#) | [siteviewer](#)

# siteviewer

Create Site Viewer

## Description

Display transmitter sites, receiver sites, and RF propagation visualizations by using a `siteviewer` object. By default, Site Viewer displays a 3-D view of the globe. When you display sites on the globe, they are referenced to geographic coordinates. You can customize the globe using custom terrain, high-zoom-level or custom basemaps, and buildings.

You can also import and view 3-D models represented by standard tessellation language (STL) files or triangulation objects. When you display sites on a 3-D model, they are referenced to Cartesian coordinates.

Site Viewer requires hardware graphics support for WebGL™.

## Creation

### Syntax

```
viewer = siteviewer  
viewer = siteviewer(Name,Value)
```

### Description

`viewer = siteviewer` creates a Site Viewer.

`viewer = siteviewer(Name,Value)` specifies Site Viewer properties using name-value arguments. For example, import and view a 3-D model file by using the `SceneModel` name-value argument.

## Properties

### Site Viewer

#### Name — Caption to display on map viewer window

'Site Viewer' (default) | character vector | string scalar

Caption to display on map viewer window, specified as a character vector or a string scalar.

Data Types: `char` | `string`

#### Position — Size and location of map viewer window in pixels

four-element integer-valued vector

Size and location of map viewer window in pixels, specified as a four-element integer-valued vector in the form `[left bottom width height]`. The default value depends on the screen resolution such that the window lies in the center of the screen with a width of 800 pixels and a height of 600 pixels.

Data Types: double

**CoordinateSystem – Coordinate reference system**

'geographic' (default) | 'cartesian'

This property is read-only.

Coordinate reference system, specified as 'geographic' or 'cartesian'. The value of CoordinateSystem depends on how you create the Site Viewer.

- By default, the value of CoordinateSystem is 'geographic' and visualizations are referenced to the WGS84 reference ellipsoid.
- When you create the Site Viewer by specifying the SceneModel argument, the value of CoordinateSystem is 'cartesian' and the coordinates are defined by the origin of the 3-D model.

When CoordinateSystem is 'geographic', you can view the latitude and longitude coordinates for a location by right-clicking the map and selecting **Show Location**. To remove the location, right-click and select **Remove Location**.

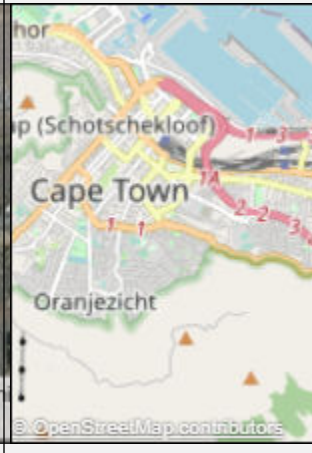

Data Types: char | string

**Geographic Coordinate System**

**Basemap – Map imagery used to visualize sites**

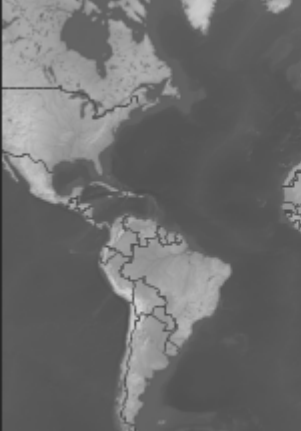

'satellite' (default) | 'openstreetmap' | 'streets' | 'streets-light' | 'streets-dark' | 'topographic' | ...

Map imagery used to visualize sites, specified as one of the basemap names in this table or as a custom basemap defined using the addCustomBasemap function.

	<p>'satellite' (default)</p> <p>Full global basemap composed of high-resolution satellite imagery.</p> <p>Hosted by Esri.</p> <p>Earthstar Geograph CNES/Airbus DS</p>		<p>'openstreetmap'</p> <p>Street map provided by OpenStreetMap.</p> <p>OpenStreetMap contributors</p>
---	--	--	---

	<p>'streets'</p> <p>General-purpose road map that emphasizes accurate, legible styling of roads and transit networks.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, NGA, USGS</p>		<p>'streets-light'</p> <p>Map designed to provide geographic context while highlighting user data on a light background.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, NGA, USGS</p>
	<p>'streets-dark'</p> <p>Map designed to provide geographic context while highlighting user data on a dark background.</p> <p>Hosted by Esri.</p> <p>Esri, HERE, Garmin, NGA, USGS</p>		<p>'topographic'</p> <p>General-purpose map with styling to depict topographic features.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, USGS, NGA</p>
	<p>'landcover'</p> <p>Map that combines satellite-derived land cover data, shaded relief, and ocean-bottom relief. The light, natural palette is suitable for thematic and reference maps.</p> <p>Created using Natural Earth.</p>		<p>'colorterrain'</p> <p>Shaded relief map blended with a land cover palette. Humid lowlands are green and arid lowlands are brown.</p> <p>Created using Natural Earth.</p>

	<p><b>'grayterrain'</b></p> <p>Terrain map in shades of gray. Shaded relief emphasizes both high mountains and micro-terrain found in lowlands.</p> <p>Created using Natural Earth.</p>		<p><b>'bluegreen'</b></p> <p>Two-tone, land-ocean map with light green land areas and light blue water areas.</p> <p>Created using Natural Earth.</p>
	<p><b>'grayland'</b></p> <p>Two-tone, land-ocean map with gray land areas and white water areas.</p> <p>Created using Natural Earth.</p>		<p><b>'darkwater'</b></p> <p>Two-tone, land-ocean map with light gray land areas and dark gray water areas. This basemap is installed with MATLAB.</p> <p>Created using Natural Earth.</p>

The basemaps hosted by Esri update periodically. As a result, you might see differences in your visualizations over time.

Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks®.

This property applies only when `CoordinateSystem` is `'geographic'`.

Data Types: `char` | `string`

**Terrain — Data on which to visualize sites and perform terrain calculations**

`'gmted2010'` (default) | `'none'` | `character vector` | `scalar`

Data on which to visualize sites and perform terrain calculations, specified as a character vector or a scalar previously added using `addCustomTerrain` or one of the following options:

- `'none'` — Terrain elevation is 0 everywhere.
- `'gmted2010'` — USGS GMTED2010 terrain data. This option requires an internet connection.

This property applies only when `CoordinateSystem` is `'geographic'`.

This property is read-only after you create the Site Viewer.

For limitations, see “Limitations” on page 3-1455.

Data Types: char | string

### **Buildings — Name of OpenStreetMap (.osm) file to use as buildings data**

string scalar | character vector

Name of the OpenStreetMap (.osm) file to use as buildings data, specified as a string scalar or a character vector. The file must be in the current directory, in a directory on the MATLAB path. You can also use a full or relative path to the file to specify the data. By default, this value is empty.

This property applies only when `CoordinateSystem` is 'geographic'.

This property is read-only after you create the Site Viewer.

For limitations, see “Limitations” on page 3-1455.

Data Types: char | string

### **Cartesian Coordinate System**

#### **SceneModel — Name of 3-D model file or triangulation**

character vector | string scalar | triangulation object

Name of the 3-D model file or triangulation, specified as a string scalar, a character vector, or a triangulation object.

When `SceneModel` is the name of a 3-D model file, you must specify an STL file with extension `.stl`. The way you specify the file depends on the location of the file.

- If the file is in your current folder or in a folder on the MATLAB path, then specify the name of the file, such as 'myFile.stl'.
- If the file is not in the current folder or in a folder on the MATLAB path, then specify the full or relative path name, such as 'C:\myfolder\myFile.stl' or 'dataDir\myFile.stl'.

This property applies only when `CoordinateSystem` is 'cartesian'.

This property is read-only after you create the Site Viewer.

Data Types: char | string

#### **Transparency — Transparency of model**

scalar in the range [0, 1]

Transparency of the model, specified as a scalar in the range [0, 1], where 0 is transparent and 1 is opaque. The default is 0.1 when `ShowEdges` is 1 (true), and 1 otherwise.

This property applies only when `CoordinateSystem` is 'cartesian'.

Data Types: double

#### **ShowOrigin — Option to show origin**

true or 1 (default) | false or 0

Option to show the origin of the model, specified as numeric or logical 1 (true) or 0 (false). The x-axis appears in red, the y-axis appears in green, and the z-axis appears in blue. The z-axis of the scene points up.

This property applies only when `CoordinateSystem` is 'cartesian'.

Data Types: `logical`

#### **ShowEdges — Option to show edges of model**

`true` or `1` (default) | `false` or `0`

Option to show the edges of the model using black lines, specified as numeric or logical `1` (`true`) or `0` (`false`). Site Viewer defines edges as two adjacent facets with normals that differ by more than two degrees.

This property applies only when `CoordinateSystem` is `'cartesian'`.

This property is read-only after you create the Site Viewer.

Data Types: `logical`

#### **Object Functions**

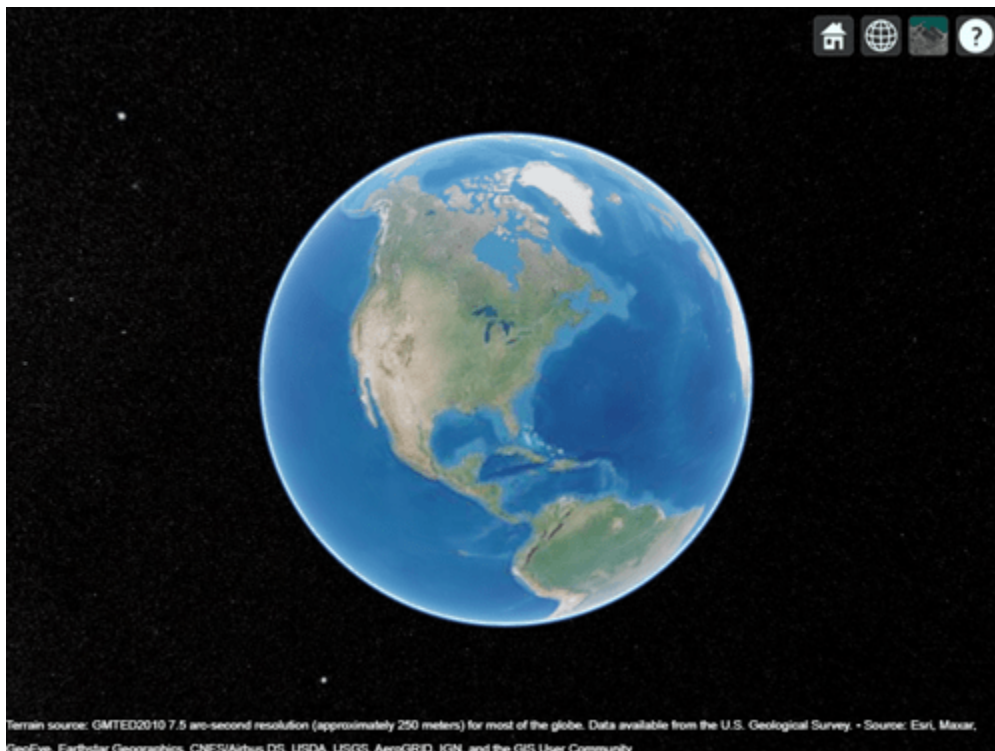

`clearMap`    Clear plots  
`close`        Close Site Viewer

### **Examples**

#### **Default Site Viewer Map Display**

Create a default Site Viewer.

```
viewer = siteviewer;
```

Pan by left-clicking and dragging, zoom by right-clicking and dragging or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking or dragging. View the coordinates for a location by right-clicking and selecting **Show location**.

For this example, navigate to a region containing New England and view the coordinates for a location near Cape Cod.

A gray marker appears at the location you selected. Remove the marker by right-clicking the location and selecting **Remove location**.

### Site Viewer with 3-D Model

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer("SceneModel", "conferenceroom.stl");
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

**View Transmitter Site On Site Viewer**

Launch a Site Viewer with streets basemap.

```
viewer = siteviewer("Basemap", "streets");
```

View a transmitter site on this map.

```
tx = txsite;  
show(tx)
```

### Compare Coverage Maps

Launch two Site Viewer windows. One Site Viewer window uses the terrain model and the other window does not use the terrain model.

```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");  
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```

Create a transmitter site.

```
tx = txsite;
```

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx,"Map",viewer1)
```

The map without terrain uses the free-space model by default.

coverage(tx, "Map", viewer2)

#### Site Viewer with Buildings

Launch Site Viewer with a basemap and buildings file for Manhattan. For more information about the osm file, see [1] on page 3-1452.

```
viewer = siteviewer("Basemap", "openstreetmap", ...  
                  "Buildings", "manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...  
           "Longitude",-74.0114,...  
           "AntennaHeight",50);  
show(tx)
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap.

Specify values for these arguments:

- A name that identifies the custom basemap.
- The URL of the map tiles. For load balancing, this provider has three servers that you can use (a, b, or c).
- An attribution that gives credit to the provider of the map tiles. When you plot data, this attribution appears at the bottom of the map. Map tile providers can define specific requirements for the attribution.
- A display name for the custom basemap. This name appears in the Imagery tab of Site Viewer.

```
name = "opentopomap";  
url = "a.tile.opentopomap.org/{z}/{x}/{y}.png";  
copyright = char(uint8(169));
```

```
attribution = copyright + "OpenStreetMap contributors";  
displayName = "Open Topo Map";
```

Use `addCustomBasemap` to load the custom basemap, and then create a Site Viewer that uses the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution,'DisplayName',displayName)  
viewer = siteviewer('Basemap',name);
```

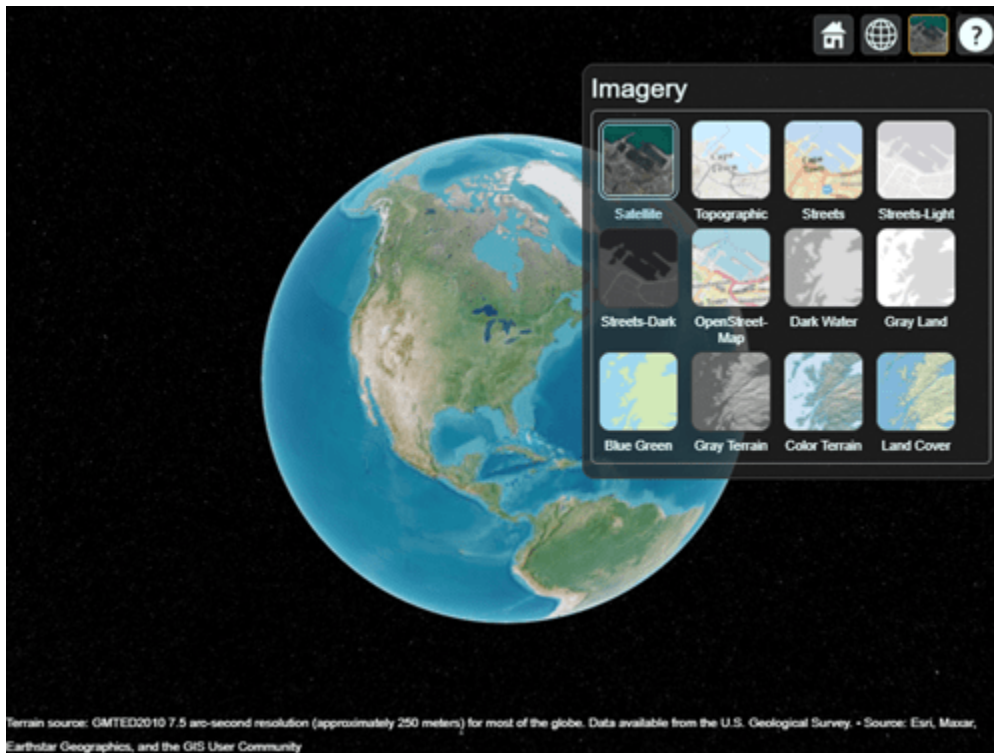

After you add a custom basemap, the custom map is available in new Site Viewer windows. Note the Open Topo Map basemap icon in the Imagery tab.

```
siteviewer;
```

Use `removeCustomBasemap` to remove the custom basemap. Then, open a new Site Viewer. Note the Open Topo Map basemap option is no longer available in the Imagery tab.

```
removeCustomBasemap(name)  
siteviewer;
```

## Limitations

### Terrain

- Default terrain access requires an internet connection. If no internet connection exists, then Site Viewer automatically uses 'none' in the property Terrain.
- Custom DTED terrain files for use with `addCustomTerrain` must be acquired outside of MATLAB for example by using USGS EarthExplorer.
- When using custom terrain, analysis is restricted to the terrain region. For example, an error occurs if you are trying to show a transmitter or receiver site outside of the region.

### Buildings

- OpenStreetMap files obtained from <https://www.openstreetmap.org> represent crowd-sourced map data, and the completeness and accuracy of the buildings data may vary depending on the map location.
- When downloading data from <https://www.openstreetmap.org>, select an export area larger than the desired area to ensure that all expected building features are fully captured. Building features at the edge of the selected export area may be missing.
- Building geometry and features are interpreted from the file according to the recommendations of OpenStreetMap for 3-D buildings.

### MATLAB Online

- In MATLAB Online, if you refresh the URL, then the Site Viewer window remains open but the visualizations disappear.

### More About

#### Site Viewer Navigation

You can interactively navigate Site Viewer by using your mouse.

- Pan by left-clicking and dragging.
- Zoom by scrolling or by right-clicking and dragging.
- Tilt and rotate by holding **Ctrl** and dragging or by middle-clicking and dragging.

When `CoordinateSystem` is 'geographic', you can restore the default view by selecting  **Restore View** from the toolbar.

#### Dimension Picker

When `CoordinateSystem` is 'geographic', you can choose between three view options by using the **Dimension Picker** in the toolbar.

-  **3-D View** — A smooth globe. This is the default view.
-  **2-D View** — A flat map in the Mercator projection.
-  **Columbus View** — A flat map in the Mercator projection that supports tilt and rotation.

Some interactions are not supported for **2-D View** and **Columbus View**.

# txsite

Create RF transmitter site

## Description

Use the `txsite` object to create a radio frequency transmitter site.

A transmitter consists of an RF circuit and an antenna, where the RF circuit excites the antenna with a signal and power. Key characteristics of a transmitter include its output power, operating frequency, and antenna radiation pattern.

## Creation

### Syntax

```
tx = txsite
tx = txsite(coordsys)
tx = txsite( ___,Name,Value)
```

### Description

`tx = txsite` creates a radio frequency transmitter site.

`tx = txsite(coordsys)` creates a transmitter site with the specified coordinate system. You can specify either 'geographic' or 'cartesian' coordinate system.

`tx = txsite( ___,Name,Value)` sets properties using one or more name-value pairs. For example, `tx = txsite('Name','TX Site')` creates a transmitter site with the name `TX Site`. Enclose each property name in quotes.

You can create multiple transmitter sites by using `Name`, `Latitude`, and `Longitude` properties. For example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; lats = [42.3467,42.3598,42.3763]; lons = [-71.0972,-71.0545,-71.0611];`. The `CoordinateSystem` property must be a string scalar or a character vector.

## Properties

### Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or string or as a row or column vector of  $N$  elements. Specifying name as a row or column vector creates multiple sites.

Example: 'Name','Site 2'

Example: `tx.Name = 'Fenway Park'`

Example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; tx = txsite('Name',names)`

Data Types: char | string

**CoordinateSystem — Coordinate system used to site location**

'geographic' (default) | 'cartesian'

Coordinate system used to the site location, specified as 'geographic' or 'cartesian'. If you specify 'geographic', the site location is defined using the Latitude, Longitude, and AntennaHeight properties. If you specify 'cartesian', the site location is defined using the AntennaPosition property.

Example: 'CoordinateSystem','cartesian'

Example: tx.CoordinateSystem = 'cartesian'

**Latitude — Site latitude coordinates**

42.3001 (default) | numeric scalar in the range [-90 90] | row or column vector

Site latitude coordinates, specified as a numeric scalar in the range of -90 to 90, or as a row or column vector of  $N$  elements in the range [-90 90]. Specifying latitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Latitude specifies north-south position.

Example: 'Latitude',45.098

Example: tx.Latitude = 45.098

Example: latitude = [42.3467,42.3598,42.3763]; tx = txsite('Latitude',latitude)

**Dependencies**

To enable this property, set CoordinateSystem to 'geographic'.

**Longitude — Site longitude coordinates**

-71.3504 (default) | numeric scalar in the range [-180 180] | row or column vector

Site longitude coordinates, specified as a numeric scalar in the range [-180 180] or as a row or column vector of  $N$  elements in the range [-180 180]. Specifying longitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Longitude specifies the east-west the position.

Example: 'Longitude',-68.890

Example: tx.Longitude = -71.0972

Example: longitude = [-71.0972,-71.0545,-71.0611]; tx = txsite('Longitude',longitude)

**Dependencies**

To enable this property, set the CoordinateSystem to 'geographic'.

**Antenna — Antenna element or array**

'isotropic' (default) | object | row vector

Antenna element or array specified as one of these options.

- 'isotropic' to model an antenna that radiates uniformly in all directions.
- An arrayConfig object.

- If you have Antenna Toolbox, an antenna element from the “Antenna Catalog” (Antenna Toolbox).
- If you have Phased Array System Toolbox, any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox) or any array object in “Array Geometries and Analysis” (Phased Array System Toolbox).

Example: 'Antenna',cfgArray, where cfgArray is an arrayConfig object

Example: tx.Antenna = arrayConfig('Size',[8 1]); specifies an 8-element ULA along z-axis

### **AntennaAngle — Antenna X-axis angle**

0 (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Antenna X-axis angle defined with reference to a local Cartesian coordinate system, specified as a numeric scalar representing an azimuth angle in degrees or as a 2-by-1 vector or a 2-by-*N* matrix representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise from the east along the antenna X-axis (for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites). Specify the azimuth angle between -180 to 180. degrees.

The elevation angle is measured from antenna X-axis along the horizontal or XY plane. Specify the elevation angle between -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: tx.AntennaAngle = [25,-80]

### **AntennaHeight — Antenna height above surface**

10 (default) | nonnegative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a nonnegative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site location coincides with the building location, the antenna height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: tx.AntennaHeight = 15

### **Dependencies**

To enable this property, set CoordinateSystem to 'geographic'.

Data Types:

### **AntennaPosition — Position of antenna center**

[0;0;0] (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing X-, Y-, and Z-axis Cartesian coordinates with each element in meters.

Example: 'AntennaPosition',[0;2;4]

Example: tx.AntennaPosition = [0;2;4]

#### Dependencies

To enable this property, set `CoordinateSystem` to `'cartesian'`.

Data Types:

#### SystemLoss – System loss

0 (default) | nonnegative scalar | row vector

System loss, specified as a nonnegative scalar in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: `'SystemLoss',10`

Example: `txsite.SystemLoss = 10`

Data Types:

#### TransmitterFrequency – Transmitter operating frequency

1.9000e+09 (default) | positive scalar | row vector

Transmitter operating frequency, specified as a positive scalar in Hz. in the range [1e3 200e9].

Example: `'TransmitterFrequency',30e9`

Example: `txsite.TransmitterFrequency = 30e9`

Data Types: double

#### TransmitterPower – Signal power at transmitter output

10 (default) | positive scalar

Signal power at transmitter output, specified as a positive scalar in watts. The transmitter out is connected to the antenna.

Example: `'TransmitterPower',30`

Example: `txsite.TransmitterPower = 30`

Data Types: double

#### Object Functions

<code>show</code>	Show site in Site Viewer
<code>hide</code>	Hide site from Site Viewer
<code>distance</code>	Distance between sites
<code>angle</code>	Angle between sites
<code>elevation</code>	Elevation of site
<code>location</code>	Coordinates at distance and angle from site
<code>los</code>	Display or compute line-of-sight (LOS) visibility status
<code>coverage</code>	Display or compute coverage map
<code>sinr</code>	Display or compute signal-to-interference-plus-noise (SINR) ratio
<code>pattern</code>	Display antenna radiation pattern in Site Viewer

#### Examples

## Default Transmitter Site

Create a transmitter site at a latitude of 42.3001 degrees and a longitude of -71.3504 degrees.

```
tx = txsite("Name","MathWorks Apple Hill", ...  
           "Latitude",42.3001,"Longitude",-71.3504)
```

```
tx =
```

```
txsite with properties:
```

```
           Name: 'MathWorks Apple Hill'  
  CoordinateSystem: 'geographic'  
           Latitude: 42.3001  
           Longitude: -71.3504  
           Antenna: 'isotropic'  
   AntennaAngle: 0  
   AntennaHeight: 10  
     SystemLoss: 0  
 TransmitterFrequency: 1.9000e+09  
   TransmitterPower: 10
```

View the coverage of the site.

```
pattern(tx)
```

# CloseIn

Close-in propagation model

## Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through urban macro cell scenarios [1] by using a `CloseIn` object. Close-in propagation models have no enforced frequency range.

## Creation

Create a `CloseIn` object by using the `propagationModel` function.

## Properties

### ReferenceDistance — Free-space reference distance

1 (default) | scalar

Free-space reference distance, specified as a scalar in meters.

---

**Note** The close-in model is valid for distances greater than or equal to the `ReferenceDistance`. Path loss is 0 for distances less than `ReferenceDistance`.

---

Data Types: `double`

### PathLossExponent — Path loss exponent

2.9 (default) | scalar

Path loss exponent, specified as a scalar.

Data Types: `double`

### Sigma — Standard deviation

5.7 (default) | scalar

Standard deviation of the zero-mean Gaussian random variable, specified as a scalar in decibels (dB).

Data Types: `double`

### NumDataPoints — Number of data points

1869 (default) | integer

Number of data points of the zero-mean Gaussian random variable, specified as an integer.

Data Types: `double`

### Object Functions

pathloss Path loss of radio wave propagation  
range Range of radio wave propagation  
add Add propagation models

### Examples

#### Model Coverage Using Close-In Model

Display the coverage area for a transmitter using the close-in propagation model.

```
pm = propagationModel("close-in");  
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);  
coverage(tx, pm)
```

## Fog

Fog propagation model

### Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through fog or clouds [1] by using a Fog object. Propagation models for fog are valid from 10 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

### Creation

Create a Fog object by using the `propagationModel` function.

### Properties

#### Temperature — Air temperature

15 (default) | scalar

Air temperature, specified as a scalar in degrees Celsius (C).

Data Types: `double`

#### WaterDensity — Liquid water density

0.5 (default) | scalar

Liquid water density, specified as a scalar in grams per cubic meter ( $\text{g}/\text{m}^3$ ).

Data Types: `double`

### Object Functions

<code>pathloss</code>	Path loss of radio wave propagation
<code>range</code>	Range of radio wave propagation
<code>add</code>	Add propagation models

### Examples

#### Model Coverage in Thick Fog

Display the coverage area for a transmitter in thick fog.

Create a propagation model for fog. Specify the water density as 0.5 grams per cubic meter.

```
pm = propagationModel("fog", "WaterDensity", 0.5);
```

Create a transmitter site. Display the coverage area for the transmitter. Propagation models for fog require transmitter frequencies between 10 and 1000 GHz.

```
tx = txsite("Name","Apple Hill","TransmitterFrequency",1e10, ...
  "Latitude",42.3001,"Longitude",-71.3604);
coverage(tx,pm)
```

## FreeSpace

Free space propagation model

### Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through free space by using a `FreeSpace` object. Free space propagation models have no enforced frequency range, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

`FreeSpace` objects have no properties.

### Creation

Create a `FreeSpace` object by using the `propagationModel` function.

### Object Functions

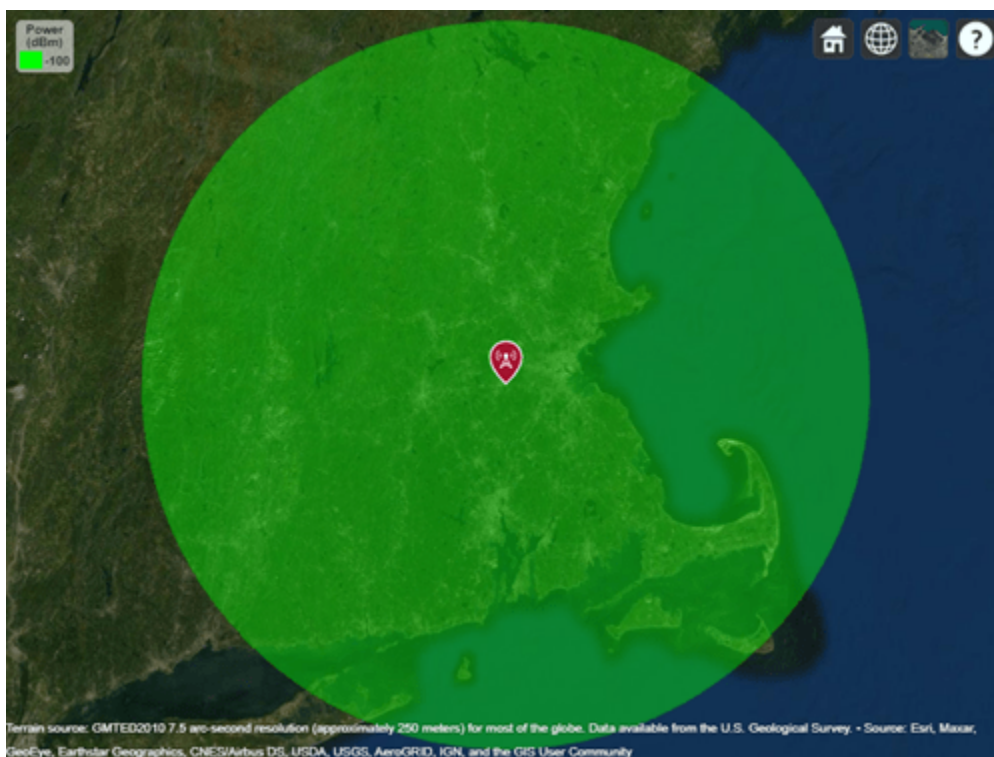

<code>pathloss</code>	Path loss of radio wave propagation
<code>range</code>	Range of radio wave propagation
<code>add</code>	Add propagation models

### Examples

#### Model Coverage in Free Space

Display the coverage area for a transmitter in free space.

```
pm = propagationModel("freespace");  
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);  
coverage(tx, pm)
```

# Gas

Gas propagation model

## Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through gas [1] by using a Gas object. Propagation models for gas are valid from 1 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

## Creation

Create a Gas object by using the `propagationModel` function.

## Properties

### Temperature — Air temperature

15 (default) | scalar

Air temperature, specified as a scalar in degrees Celsius (C).

Data Types: `double`

### AirPressure — Dry air pressure

101300 (default) | scalar

Dry air pressure, specified as a scalar in pascals (Pa).

Data Types: `double`

### WaterDensity — Water vapor density

7.5 (default) | scalar

Water vapor density, specified as a scalar in grams per cubic meter ( $\text{g/m}^3$ ).

Data Types: `double`

## Object Functions

### Model Coverage in Hot Air

Display the coverage area for a transmitter in hot air. Specify the air temperature as 35 degrees Celsius.

```
pm = propagationModel("gas", "Temperature", 35);
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);
coverage(tx, pm)
```

# LongleyRice

Longley-Rice propagation model

## Description

Model the behavior of electromagnetic radiation from a point of transmission over irregular terrain, including buildings, by using the Longley-Rice model, also known as the Irregular Terrain Model (ITM) [1]. Represent the model by using a LongleyRice object.

The Longley-Rice model:

- Is designed for frequencies from 20 MHz to 20 GHz, distances from 1 to 2000 km, and antenna heights from 0.5 to 3000 m.
- Calculates path loss from free-space loss, terrain and obstacle diffraction, ground reflection, atmospheric refraction, and tropospheric scatter.
- Provides path loss estimates by combining physics with empirical data.

## Creation

Create a LongleyRice object by using the propagationModel function.

## Properties

### AntennaPolarization — Polarization of transmitter and receiver antennas

"horizontal" (default) | "vertical"

Polarization of transmitter and receiver antennas, specified as "horizontal" or "vertical". This object assumes both antennas have the same polarization.

Data Types: char | string

### GroundConductivity — Conductivity of ground

0.005 (default) | scalar

Conductivity of the ground, specified as a scalar in siemens per meter (S/m). The model uses this value to calculate path loss due to ground reflection and diffraction. The default value corresponds to average ground.

Data Types: double

### GroundPermittivity — Real relative permittivity of ground

15 (default) | scalar

Real relative permittivity of the ground, specified as a scalar. Real relative permittivity is expressed as the real part of the ratio of complex absolute material permittivity to the absolute permittivity of vacuum. The model uses this value to calculate the path loss due to ground reflection and diffraction. The default value corresponds to average ground.

Data Types: double

**AtmosphericRefractivity — Atmospheric refractivity near ground**

301 (default) | scalar in N-Units

Atmospheric refractivity near the ground, specified as a scalar in “N-Units” on page 3-1476. The model uses this value to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

Data Types: double

**ClimateZone — Radio climate zone**

"continental-temperate" (default) | "equatorial" | "continental-subtropical" | "maritime-subtropical" | "desert" | "maritime-over-land" | "maritime-over-sea"

Radio climate zone, specified as one of these options:

- "continental-temperate"
- "equatorial"
- "continental-subtropical"
- "maritime-subtropical"
- "desert"
- "maritime-over-land"
- "maritime-over-sea"

The model uses this value to calculate the variability due to changing atmospheric conditions. The default value corresponds to average atmospheric conditions in a particular climate zone.

Data Types: char | string

**TimeVariabilityTolerance — Time variability tolerance level**

0.5 (default) | scalar in the range [0.001, 0.999]

Time variability tolerance level of the path loss, specified as a scalar in the range [0.001, 0.999]. Time variability represents long-term variability (including atmospheric conditions) but neglects short-term variability such as fast multipath fading. This value gives the required system reliability expressed as the fraction of time during which the actual path loss is expected to be less than or equal to the model prediction.

Data Types: double

**SituationVariabilityTolerance — Situation variability tolerance level**

0.5 (default) | scalar in the range [0.001, 0.999]

Situation variability tolerance level of the path loss, specified as a scalar in the range [0.001, 0.999]. Situation variability occurs due to uncontrolled or hidden random variables. This value gives the required system confidence expressed as the fraction of similar situations for which the actual path loss is expected to be less than or equal to the model prediction.

Data Types: double

**Object Functions**

pathloss Path loss of radio wave propagation  
add Add propagation models

## Examples

### Model Coverage Using Longley-Rice Model

Display the coverage area for a transmitter using the Longley-Rice model.

```
pm = propagationModel("longley-rice");  
tx = txsite("Name","Apple Hill","Latitude",42.3001,"Longitude",-71.3604);  
coverage(tx,pm,"SignalStrengths",-100:-5)
```

Increase the time and situation variability tolerance levels from 0.5 (the default) to 0.9. Display the coverage area for the transmitter using the updated propagation model.

```
pm.TimeVariabilityTolerance = 0.9;  
pm.SituationVariabilityTolerance = 0.9;  
coverage(tx,pm,"SignalStrengths",-100:5)
```

The coverage area is smaller for the model with higher variability tolerance levels.

## More About

### N-Units

The refractive index of air,  $n$ , is related to the dielectric constants of the gas constituents of an air mixture. The numerical value of  $n$  is only slightly larger than 1. To make the calculation more convenient, you can use  $N$  units, which are given by the formula:  $N = (n - 1) \times 10^6$ .

# Rain

Rain propagation model

## Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through rain [1] by using a `Rain` object. Propagation models for rain are valid from 1 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

## Creation

Create a `Rain` object by using the `propagationModel` function.

## Properties

### **RainRate** — Rain rate

16 (default) | nonnegative scalar

Rain rate, specified as a nonnegative scalar in millimeters per hour (mm/h).

Data Types: `double`

### **Tilt** — Polarization tilt angle of signal

0 (default) | scalar

Polarization tilt angle of the signal, specified as a scalar in degrees.

Data Types: `double`

## Object Functions

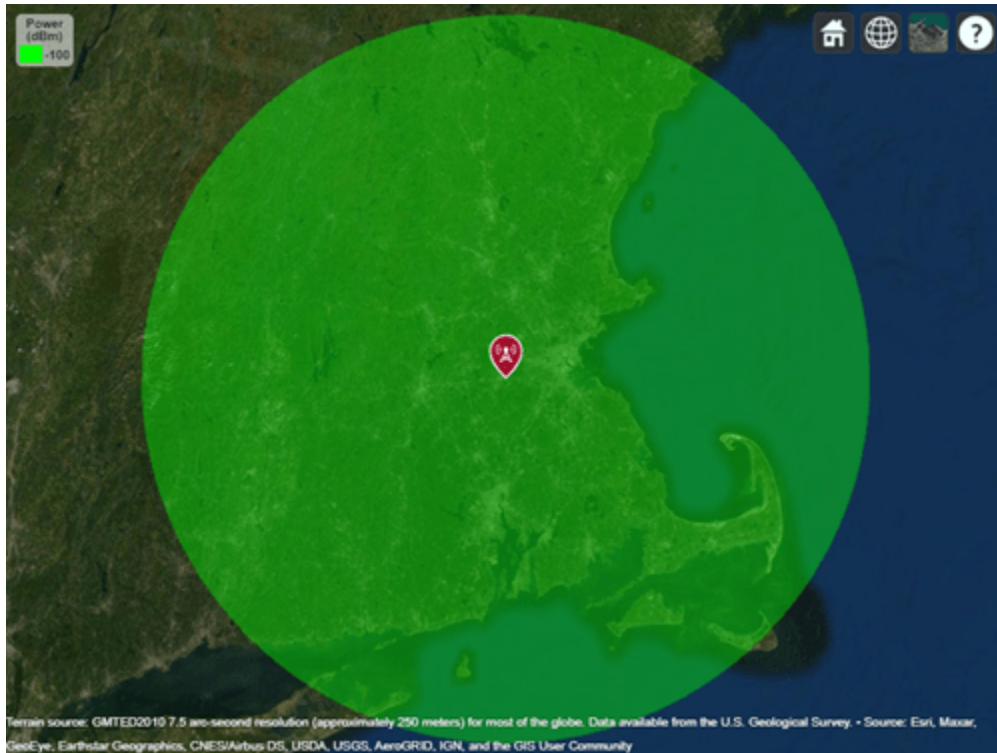

<code>pathloss</code>	Path loss of radio wave propagation
<code>range</code>	Range of radio wave propagation
<code>add</code>	Add propagation models

## Examples

### **Model Coverage in Heavy Rain**

Display the coverage area for a transmitter in heavy rain. Specify the rain rate as 50 millimeters per hour.

```
pm = propagationModel("rain", "RainRate", 50);  
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);  
coverage(tx, pm)
```

# RayTracing

Ray tracing propagation model

## Description

RayTracing objects are propagation models that compute propagation paths using 3-D environment geometry [1][2]. Represent a ray tracing model by using a RayTracing object.

This ray tracing model:

- Is reasonable from 100 MHz to 100 GHz.
- Computes multiple propagation paths. Other propagation models compute only single propagation paths.
- Supports 3-D outdoor and indoor environments.
- Determines the path loss and phase shift of each ray using electromagnetic analysis, including tracing the horizontal and vertical polarizations of a signal through the propagation path. The path loss calculations include free-space loss, reflection losses, and diffraction losses. For each reflection and diffraction, the model calculates losses on the horizontal and vertical polarizations by using the Fresnel equation, the Uniform Theory of Diffraction (UTD), the geometric angle, and the complex permittivity of the interface materials [3][4] at the specified frequency.

You can create ray tracing models that use either the shooting and bouncing rays (SBR) method on page 3-1492 or the image method on page 3-1493.

## Creation

Create a RayTracing object by using the `propagationModel` function.

## Properties

### Ray Tracing

#### Method — Ray tracing method

"sbr" (default) | "image"

Ray tracing method, specified as one of these values:

- "sbr" — Use the shooting and bouncing rays (SBR) method on page 3-1492, which supports up to ten path reflections and two edge diffractions. The SBR method calculates an approximate number of propagation paths with exact geometric accuracy. The SBR method is generally faster than the image method. The model calculates path loss from free-space loss, reflection and diffraction losses due to interactions with materials, and antenna polarizations.
- "image" — Use the image method on page 3-1493, which supports up to two path reflections. The image method calculates an exact number of propagation paths with exact geometric accuracy. The model calculates path loss from free-space loss plus reflection losses due to material and antenna polarizations.

Specify the maximum number of path reflections by using the `MaxNumReflections` property. Specify the maximum number of edge diffractions by using the `MaxNumDiffractions` property.

When both the image and SBR methods find the same path, the points along the path are the same within a tolerance of machine precision for single-precision floating-point values. For more information about differences between the image and SBR methods, see “Choose a Propagation Model”.

Data Types: `char` | `string`

### AngularSeparation — Average number of degrees between launched rays

"medium" (default) | "high" | "low" | numeric scalar in degrees in the range [0.05, 10]

Average number of degrees between launched rays, specified as "high", "medium", "low", or a numeric scalar in degrees in the range [0.05, 10]. If you specify a numeric value, then the ray tracing algorithm might use a lower value than the value you specify.

This table describes the behavior of the "high", "medium", and "low" options.

Option	Approximate Numeric Equivalent	Range of Numeric Values	Number of Launched Rays
"high"	1.0781	[0.9912, 1.1845]	40,962
"medium"	0.5391	[0.4956, 0.5923]	163,842
"low"	0.2695	[0.2478, 0.2961]	655,362

To improve the accuracy of the number of paths found by the SBR method, decrease the value of `AngularSeparation`. Decreasing the value of `AngularSeparation` increases the amount of time MATLAB requires to perform the analysis.

When you first use a given value of `AngularSeparation` in a MATLAB session, MATLAB caches the geodesic sphere associated with that value for the duration of the session. As a result, the first use of that value of `AngularSeparation` takes longer than subsequent uses within the same session. For more information about geodesic spheres, see “Shooting and Bouncing Rays Method” on page 3-1492.

#### Tips

When you perform ray tracing with diffractions or create coverage maps using the `coverage` function, you can speed up the calculations by choosing a lower angular separation and maximum number of reflections.

#### Dependencies

To enable this argument, the value of the `Method` property must be "sbr" (the default).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `string`

### MaxNumReflections — Maximum number of path reflections

2 (default) | integer in the range [0,10]

Maximum number of path reflections to search for using ray tracing, specified as an integer. Supported values depend on the value of the `Method` property.

- When Method is "image", supported values are 0, 1, and 2.
- When Method is "sbr", supported values are in the range [0, 10].

#### **MaxNumDiffractions — Maximum number of edge diffractions**

0 (default) | 1 | 2

Maximum number of edge diffractions to search for using ray tracing, specified as 0, 1, or 2.

When you use a RayTracing object as input to the coverage or sinr function, the value of this property must be 0 or 1.

#### **Dependencies**

To enable MaxNumDiffractions, the value of Method must be "sbr".

#### **MaxAbsolutePathLoss — Maximum absolute path loss**

Inf (default) | positive numeric scalar

Maximum absolute path loss, in dB, specified as a positive numeric scalar. This property enables you to discard propagation paths based on an absolute threshold. For example, you can discard paths with more than 100 dB of path loss by specifying this property as 100. The default is Inf, which does not discard propagation paths based on absolute threshold.

The MaxAbsolutePathLoss and MaxRelativePathLoss properties work together. For a propagation path with path loss pl, the ray tracing model discards the path when pl is more than whichever is lower between MaxAbsolutePathLoss and MaxRelativePathLoss + plsr, where plsr is the path loss of the strongest ray.

#### **MaxRelativePathLoss — Maximum relative path loss**

40 (default) | nonnegative numeric scalar

Maximum relative path loss, in dB, specified as a nonnegative numeric scalar. This property enables you to discard propagation paths based on a threshold relative to the strongest ray. The default is 40, which discards paths that are more than 40 dB weaker than the strongest path.

The MaxRelativePathLoss and MaxAbsolutePathLoss properties work together. For a propagation path with path loss pl, the ray tracing model discards the path when pl is more than whichever is lower between MaxAbsolutePathLoss and MaxRelativePathLoss + plsr, where plsr is the path loss of the strongest ray.

#### **CoordinateSystem — Coordinate system of map and site location**

"geographic" (default) | "cartesian"

Coordinate system of the site location, specified as "geographic" or "cartesian". If you specify "geographic", define material types by using the BuildingsMaterial and TerrainMaterial properties. If you specify "cartesian", define material types by using the SurfaceMaterial property.

Data Types: string | char

#### **Buildings Material**

##### **BuildingsMaterial — Surface material of geographic buildings**

"concrete" (default) | "perfect-reflector" | "brick" | "wood" | "glass" | "metal" | "custom"

Surface material of geographic buildings, specified as one of these values: "perfect-reflector", "concrete", "brick", "wood", "glass", "metal", or "custom". The model uses the material type to calculate path loss involving interactions with building surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1494.

When BuildingsMaterial is "custom", specify the material permittivity and conductivity by using the BuildingsMaterialPermittivity and BuildingsMaterialConductivity properties.

#### Dependencies

To enable BuildingsMaterial, you must set CoordinateSystem to "geographic".

Data Types: char | string

#### BuildingsMaterialPermittivity – Real relative permittivity of surface materials of buildings

5.31 (default) | nonnegative scalar

Real relative permittivity of the surface materials of the buildings, specified as a nonnegative scalar. Real relative permittivity is expressed as the real part of the ratio of complex absolute material permittivity to the absolute permittivity of vacuum. The model uses this value to calculate path loss involving interactions with building surfaces. The default value corresponds to concrete at 1.9 GHz.

#### Dependencies

To enable BuildingsMaterialPermittivity, you must set CoordinateSystem to "geographic" and BuildingsMaterial to "custom".

Data Types: double

#### BuildingsMaterialConductivity – Conductivity of surface materials of buildings

0.0548 (default) | nonnegative scalar

Conductivity of the surface materials of the buildings, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss involving interactions with building surfaces. The default value corresponds to concrete at 1.9 GHz.

#### Dependencies

To enable BuildingsMaterialConductivity, you must set CoordinateSystem to "geographic" and BuildingsMaterial to "custom".

Data Types: double

### Terrain Material

#### TerrainMaterial – Surface material of geographic terrain

"concrete" (default) | "perfect-reflector" | "brick" | "water" | "vegetation" | "loam" | "custom"

Surface material of the geographic terrain, specified as one of these values: "perfect-reflector", "concrete", "brick", "water", "vegetation", "loam", or "custom". The model uses the material type to calculate path loss involving interactions with terrain surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1494.

When TerrainMaterial is "custom", specify the material permittivity and conductivity by using the TerrainMaterialPermittivity and TerrainMaterialConductivity properties.

**Dependencies**

To enable `TerrainMaterial`, you must set `CoordinateSystem` to "geographic".

Data Types: char | string

**TerrainMaterialPermittivity — Real relative permittivity of terrain materials**

5.31 (default) | nonnegative scalar

Real relative permittivity of the terrain material, specified as a nonnegative scalar. Real relative permittivity is expressed as the real part of the ratio of complex absolute material permittivity to the absolute permittivity of vacuum. The model uses this value to calculate path loss involving interactions with terrain surfaces. The default value corresponds to concrete at 1.9 GHz.

**Dependencies**

To enable `TerrainMaterialPermittivity`, you must set `CoordinateSystem` to "geographic" and `TerrainMaterial` to "custom".

Data Types: double

**TerrainMaterialConductivity — Conductivity of terrain materials**

0.0548 (default) | nonnegative scalar

Conductivity of the terrain material, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss involving interactions with terrain surfaces. The default value corresponds to concrete at 1.9 GHz.

**Dependencies**

To enable `TerrainMaterialConductivity`, you must set `CoordinateSystem` to "geographic" and set `TerrainMaterial` to "custom".

Data Types: double

**Surface Material****SurfaceMaterial — Surface material of Cartesian map surface**

"plasterboard" (default) | "perfect-reflector" | "ceilingboard" | "chipboard" | "floorboard" | "concrete" | "brick" | "wood" | "glass" | "metal" | "water" | "vegetation" | "loam" | "custom"

Surface material of Cartesian map surface, specified as one of these values: "plasterboard", "perfect-reflector", "ceilingboard", "chipboard", "floorboard", "concrete", "brick", "wood", "glass", "metal", "water", "vegetation", "loam", or "custom". The model uses the material type to calculate path loss involving interactions with surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1494.

When `SurfaceMaterial` is "custom", specify the material permittivity and conductivity by using the `SurfaceMaterialPermittivity` and `SurfaceMaterialConductivity` properties.

**Dependencies**

To enable `SurfaceMaterial`, you must set `CoordinateSystem` to "cartesian".

Data Types: char | string

**SurfaceMaterialPermittivity — Real relative permittivity of surface materials**

2.94 (default) | nonnegative scalar

Real relative permittivity of the surface material, specified as a nonnegative scalar. Real relative permittivity is expressed as the real part of the ratio of complex absolute material permittivity to the absolute permittivity of vacuum. The model uses this value to calculate path loss involving interactions with surfaces. The default value corresponds to plaster board at 1.9 GHz.

**Dependencies**

To enable `SurfaceMaterialPermittivity`, you must set `CoordinateSystem` to "cartesian" and `SurfaceMaterial` to "custom".

Data Types: double

**SurfaceMaterialConductivity — Conductivity of surface materials**

0.0183 (default) | nonnegative scalar

Conductivity of the surface material, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss involving interactions with surfaces. The default value corresponds to plaster board at 1.9 GHz.

**Dependencies**

To enable `SurfaceMaterialConductivity`, you must set `CoordinateSystem` to "cartesian" and set `SurfaceMaterial` to "custom".

Data Types: double

**Object Functions**

`pathloss` Path loss of radio wave propagation  
`add` Add propagation models

**Examples****Model Propagation Paths Using SBR and Image Methods**

Show reflected propagation paths in Chicago by using the SBR and image methods.

Create a Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 3-1487.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
show(tx)
rx = rxsite("Latitude",41.8813452, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
show(rx)
```

Create a ray tracing propagation model, which MATLAB® represents using a RayTracing object. Configure the model to use the image method and to calculate paths with up to one reflection. Then, display the propagation paths.

```
pm = propagationModel("raytracing", "Method", "image", ...  
    "MaxNumReflections", 1);  
raytrace(tx, rx, pm)
```

For this ray tracing model, there is one propagation path from the transmitter to the receiver.

Update the ray tracing model to use the SBR method and to calculate paths with up to two reflections and up to one diffraction. Display the propagation paths.

```
pm.Method = "sbr";  
pm.MaxNumReflections = 2;  
pm.MaxNumDiffractions = 1;  
raytrace(tx, rx, pm)
```

The updated ray tracing model shows more propagation paths from the transmitter to the receiver.

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Model Coverage Using Ray Tracing

Launch Site Viewer with buildings in Chicago. For more information about the .osm file, see [1] on page 3-1488.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
show(tx)
```

Create a ray tracing propagation model, which MATLAB® represents using a RayTracing object. Configure the model to find paths with up to 2 surface reflections and up to 1 edge diffraction. By default, the model uses the SBR method.

```
pm = propagationModel("raytracing", ...  
    "MaxNumReflections",2,"MaxNumDiffractions",1);
```

Display the coverage map.

```
coverage(tx,pm,"SignalStrengths",-100:5)
```

## Appendix

[1] The .osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Discard Paths Based on Path Loss

Ray tracing models enable you to discard propagation paths based on path loss thresholds.

- Specify a threshold relative to the strongest propagation path by using the `MaxRelativePathLoss` property.
- Specify an absolute threshold by using the `MaxAbsolutePathLoss` property.

Create a Site Viewer with buildings in Chicago. For more information about the OSM file, see [1] on page 3-1492.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```

tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
show(tx)
rx = rxsite("Latitude",41.8813452, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
show(rx)

```

Create a ray tracing propagation model, which MATLAB represents using a RayTracing object. Configure the model to find paths with up to 2 surface reflections and up to 1 edge diffraction. By default, the model uses the SBR method.

```

pm = propagationModel("raytracing", ...
                     "MaxNumReflections",2, ...
                     "MaxNumDiffractions",1);

```

Perform the ray tracing analysis. By default, the model discard paths that are more than 40 dB weaker than the strongest path.

```

raytrace(tx, rx, pm, "Type", "pathloss")

```

### Discard Paths Based on Relative Path Loss

Discard paths that are more than 50 dB weaker than the strongest path by changing the MaxRelativePathLoss property of the RayTracing object. Then, perform the ray tracing analysis again.

```

pm.MaxRelativePathLoss = 50;
raytrace(tx, rx, pm, "Type", "pathloss")

```

To avoid discarding propagation paths, set the MaxRelativePathLoss property to Inf.

```
pm.MaxRelativePathLoss = Inf;  
raytrace(tx,rx,pm,"Type","pathloss")
```

### Discard Paths Based on Absolute Path Loss

Discard paths with more than 115 dB of path loss by setting the `MaxAbsolutePathLoss` property of the `RayTracing` object.

```
pm.MaxAbsolutePathLoss = 115;  
raytrace(tx, rx, pm, "Type", "pathloss")
```

## Appendix

[1] The OSM file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## More About

### Shooting and Bouncing Rays Method

The shooting and bouncing rays (SBR) method finds an approximate number of propagation paths with exact geometric accuracy. You can use this method to find paths with up to 10 path reflections.

The computational complexity of the SBR method increases linearly with the number of reflections and exponentially with the number of diffractions. The SBR method is generally faster than the image method.

This figure illustrates the SBR method for calculating propagation paths from a transmitter,  $T_x$ , to a receiver,  $R_x$ .

The SBR method launches many rays from a geodesic sphere centered at  $T_x$ . The geodesic sphere enables the model to launch rays that are approximately uniformly spaced.

Then, the method traces every ray from  $T_x$  and can model different types of interactions between the rays and surrounding objects, such as reflections, diffractions, refractions, and scattering. Note that the current implementation of the SBR method considers only reflections and edge diffractions.

- When a ray hits a flat surface, shown as  $R$ , the ray reflects based on the law of reflection.
- When a ray hits an edge, shown as  $D$ , the ray spawns many diffracted rays based on the law of diffraction [5][6]. Each diffracted ray has the same angle with the diffracting edge as the incident ray. The diffraction point then becomes a new launching point and the SBR method traces the diffracted rays in the same way as the rays launched from  $T_x$ . A continuum of diffracted rays forms a cone around the diffracting edge, which is commonly known as a Keller cone [6].

For each launched ray, the SBR method surrounds  $R_x$  with a sphere, called a reception sphere, with a radius that is proportional to the distance the ray travels and the average number of degrees between the launched rays. If the ray intersects the sphere, then the model considers the ray a valid path from  $T_x$  to  $R_x$ . The SBR method corrects the valid paths so that the paths have exact geometric accuracy.

When you increase the number of rays by decreasing the number of degrees between rays, the reception sphere becomes smaller. As a result, in some cases, launching more rays results in fewer or different paths. This situation is more likely to occur with custom 3-D scenarios created from STL files or triangulation objects than with scenarios that are automatically generated from OpenStreetMap buildings and terrain data.

The SBR method finds paths using double-precision floating-point computations.

### Image Method

The image method finds an exact number of propagation paths with exact geometric accuracy. You can use this method to find paths with up to 2 path reflections. The computational complexity of the image method increases exponentially with the number of reflections.

This figure illustrates the image method for calculating the propagation path of a single reflection ray for the same transmitter and receiver as the SBR method. The image method locates the image of  $T_x$

with respect to a planar reflection surface,  $Tx'$ . Then, the method connects  $Tx'$  and  $Rx$  with a line segment. If the line segment intersects the planar reflection surface, shown as  $R$  in the figure, then a valid path from  $Tx$  to  $Rx$  exists. The method determines paths with multiple reflections by recursively extending these steps. The image method finds paths using single-precision floating-point computations.

#### ITU Permittivity and Conductivity Values for Common Materials

ITU-R P.2040-1 [3] and ITU-R P.527-5 [4] present methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity for common materials.

- For information about the values computed for building materials specified in ITU-R P.2040-1, see `buildingMaterialPermittivity`.
- For information about the values computed for terrain materials specified in ITU-R P.527-5, see `earthSurfacePermittivity`.

## Version History

Introduced in R2019b

#### R2023a: Ray tracing models discard paths based on path loss

*Behavior changed in R2023a*

`RayTracing` objects enable you to discard propagation paths based on path loss thresholds. To specify the thresholds, set the `MaxAbsolutePathLoss` and `MaxRelativePathLoss` properties of the object.

The default value of the `MaxRelativePathLoss` property is 40. As a result, code from previous releases that does not specify a `MaxRelativePathLoss` value can be affected in these ways:

- The `raytrace` function can return fewer `comm.Ray` objects in R2023a compared to previous releases.

- The `sigstrength`, `coverage`, `sinr`, and `link` functions can return different values in R2023a compared to previous releases.
- The `pathloss` function can return different path loss values in R2023a compared to previous releases.

To avoid discarding propagation paths based on relative path loss thresholds, set the `MaxRelativePathLoss` property of the ray tracing object to `Inf`.

### **R2022b: Customize spacing of launched rays for ray tracing with SBR method**

When performing ray tracing using the SBR method, you can customize the spacing of launched rays by specifying the `AngularSeparation` property of the `RayTracing` object as a numeric value in degrees. In previous releases, the `AngularSeparation` property supported only the options "high", "medium", and "low".

### **R2022b: SBR method calculates propagation paths with exact geometric accuracy**

*Behavior changed in R2022b*

When you find propagation paths using the SBR method, MATLAB corrects the results so that the geometric accuracy of each path is exact. In previous releases, the paths have approximate geometric accuracy.

### **R2021b: Default modeling method is shooting and bouncing rays method**

*Behavior changed in R2021b*

Starting in R2021b, when you create a propagation model using the syntax `propagationModel("raytracing")`, MATLAB returns a `RayTracing` model with the `Method` value set to "sbr" and two reflections (instead of "image" and one reflection, as in previous releases).

To create ray tracing propagation models that use the image method, use the syntax `propagationModel("raytracing", "Method", "image")`.

# propagationData

Create RF propagation data from measurements

## Description

Use the `propagationData` object to import and visualize geolocated propagation data. The measurement data can be path loss data, signal strength measurements, signal-to-noise-ratio (SNR) data, or cellular information.

## Creation

### Syntax

```
pd = propagationData(filename)
pd = propagationData(table)
```

```
pd = propagationData(latitude,longitude,varname,varvalue)
pd = propagationData( ___,Name,Value)
```

### Description

`pd = propagationData(filename)` creates a propagation data object by reading data from a file specified by `filename`.

`pd = propagationData(table)` creates a propagation data container object from a table object specified by `table`.

`pd = propagationData(latitude,longitude,varname,varvalue)` creates a propagation data container object using `latitude` and `longitude` coordinates with data specified using `varname` and `varvalue`.

`pd = propagationData( ___,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

### Input Arguments

#### **filename** — Name of file containing propagation data

character vector | string scalar

Name of the file containing propagation data, specified as a character vector or a string scalar. The file must be in the current directory, in a directory on the MATLAB path, or be specified using a full or relative path. The file must be compatible with the `readtable` function. Call the `readtable` function if customized parameters are required to import the file and then pass the `table` object to the `propagationData` object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: `string` | `char`

**table — Table containing propagation data**

table object

Table containing propagation data, specified as a table object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: table

**latitude — Latitude coordinate values**

vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid model WGS-84. The latitude coordinates must be in the range [-90 90].

Data Types: double

**longitude — Longitude coordinate values**

vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to earth's ellipsoid. model WGS-84.

Data Types: double

**varname — Variable name**

character vector | string scalar

Variable name, specified as a character vector or a string scalar. This variable name must correspond to the variable with numeric data other than latitude or longitude. The variable name and the corresponding values are stored as a column in the Data property table object.

Data Types: string | char

**varvalue — Variable values**

numeric vector

Variable values, specified as a numeric vector. The numeric vectors must be the same size as latitude and longitude. The variable name and corresponding values are stored as a column in the Data property table object.

Data Types: double

**Output Arguments****pd — Propagation data**

propagationData object

Propagation data, returned as a propagationData object.

**Properties****Name — Propagation data name**

'Propagation Data' (default) | character vector | string scalar

Propagation data name, specified as a character vector or string scalar.

Example: 'Name', 'propdata'

Example: pd.Name = 'propdata'

Data Types: char | string

### Data — Propagation data table

scalar table object

This property is read-only.

Propagation data table, specified as a scalar table object containing a column corresponding to latitude coordinates, a column corresponding to longitude coordinates, and one or more columns corresponding to associated propagation data.

Data Types: table

### DataVariableName — Name of data variable to plot

character vector | string scalar

Name of the data variable to plot, specified as a character vector or string scalar corresponding to a variable name in the **Data** table used to create propagation data container object. The variable name must correspond to a variable with numeric data and cannot correspond to the latitude or longitude variables. The default value for this property is the name of the first numeric data variable name in the **Data** table that is not a latitude or longitude variable.

Data Types: char | string

## Object Functions

plot	Display RF propagation data in Site Viewer
contour	Display contour map of RF propagation data in Site Viewer
location	Coordinates of RF propagation data
getDataVariable	Get data variable values
interp	Interpolate RF propagation data

## Examples

### Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the osm file, see [1] on page 3-1502.

```
viewer = siteviewer("Basemap","streets_dark",...
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...  
           "Longitude",-74.0114,...  
           "AntennaHeight",80);  
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
            linspace(40.71416, 40.715505, 25), ...
            linspace(40.715505, 40.7133, 25), ...
            linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
             linspace(-74.00627, -74.0092, 25), ...
             linspace(-74.0092, -74.0110, 25), ...
             linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a `propagationData` object to hold computed signal strength data.

```
tbl = table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
```

Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

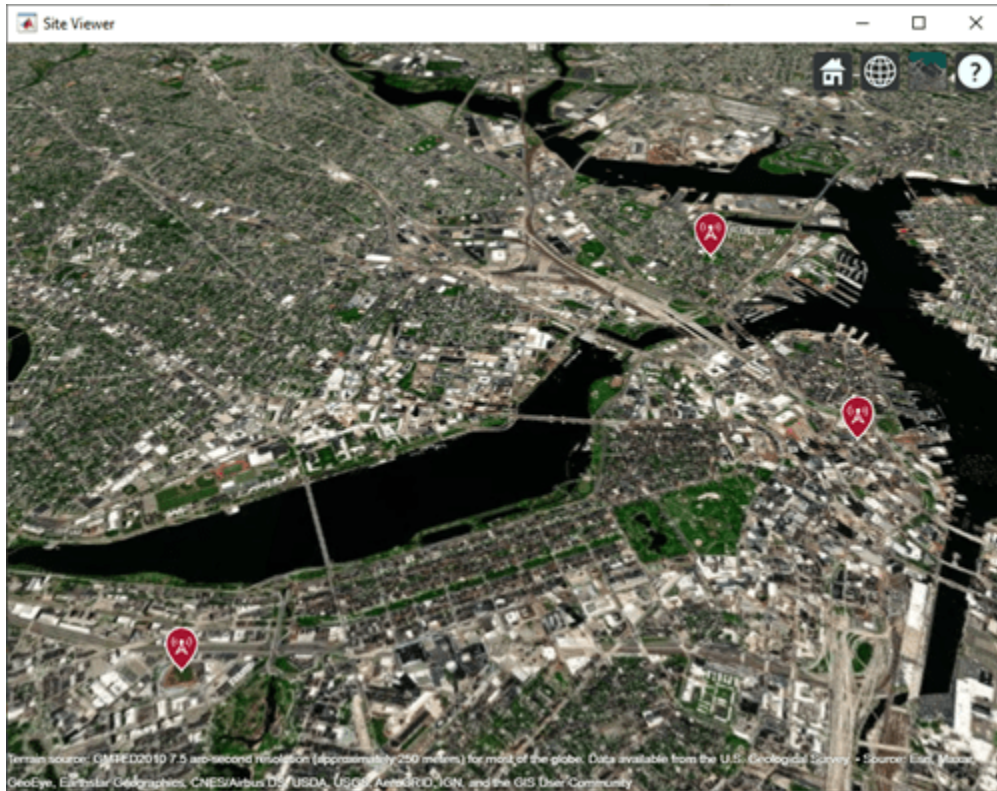

### Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];  
lats = [42.3467, 42.3598, 42.3763];  
lons = [-71.0972, -71.0545, -71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name", names, ...  
            "Latitude", lats, ...  
            "Longitude", lons, ...  
            "TransmitterFrequency", 2.5e9);  
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

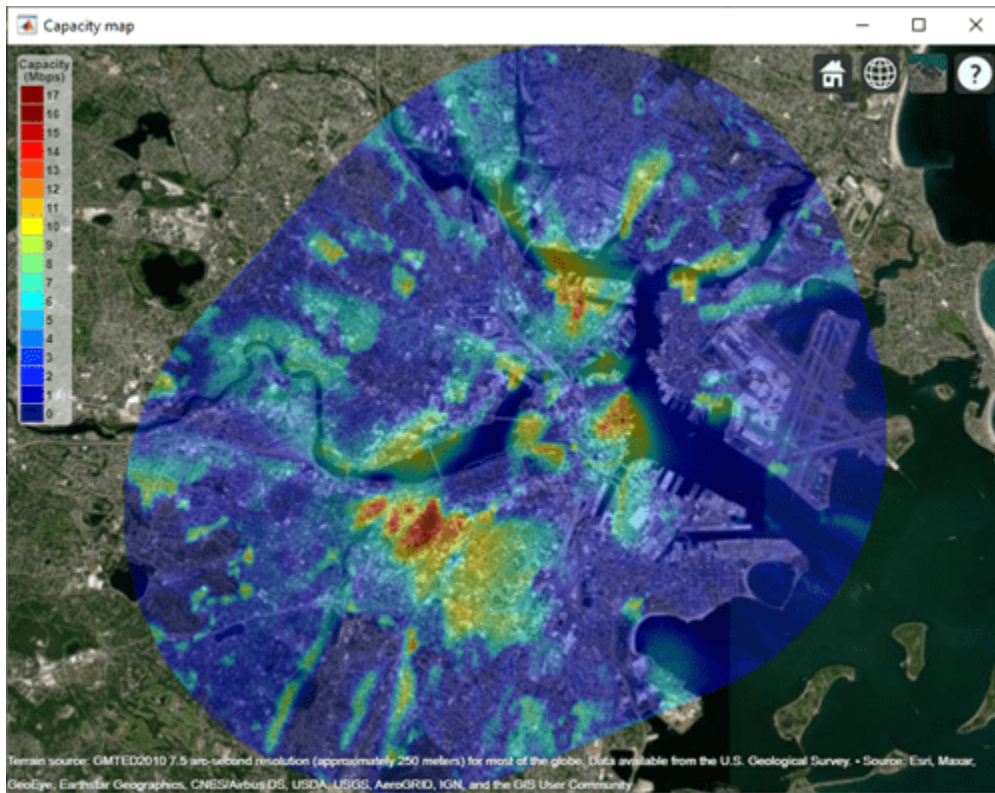

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

## Version History

Introduced in R2020a

## comm.Ray

Create RF propagation ray

### Description

A `comm.Ray` object contains the properties of an RF propagation ray. The object contains the geometric and electromagnetic information of a radio wave (approximated as a ray) that propagates from one point to another point.

### Creation

Typically you create `comm.Ray` objects by using the `raytrace` function.

### Syntax

```
ray = comm.Ray  
ray = comm.Ray(Name, Value)
```

### Description

`ray = comm.Ray` creates a default RF propagation ray object.

`ray = comm.Ray(Name, Value)` sets properties using one or more name-value pair arguments. For example, `comm.Ray("CoordinateSystem", "Geographic", "TransmitterLocation", [40.730610, -73.935242, 0])` creates a ray referenced to a geographic coordinate system with a transmitter located in New York City.

### Properties

#### PathSpecification — Propagation path specification method

'Locations' (default) | 'Delay and angles'

Propagation path specification method, specified as one of these values.

- 'Locations' — The ray object path between waypoints are conveyed as  $(x, y, z)$  coordinate points by the `TransmitterLocation`, `ReceiverLocation`, and, if applicable, `Interactions` properties.
- 'Delay and angles' — The ray object path between waypoints are conveyed by the `PropagationDelay`, `AngleOfDeparture`, and `AngleOfArrival` properties.

Data Types: `char` | `string`

#### CoordinateSystem — Coordinate system

'Cartesian' (default) | 'Geographic'

Coordinate system, specified as 'Cartesian' or 'Geographic'. When you set the `CoordinateSystem` property to 'Geographic', the coordinate system is defined relative to the

WGS-84 Earth ellipsoid model and the object defines angles relative to the local East-North-Up (ENU) coordinate system at the transmitter and receiver.

#### Dependencies

To enable this property, the `PathSpecification` property must be `'Locations'`.

Data Types: `char` | `string`

#### SystemScale — Cartesian coordinate system scale

1 (default) | positive scalar

Cartesian coordinate system scale, in meters, specified as a positive scalar.

#### Dependencies

To enable this property, the `PathSpecification` property must be `'Locations'` and the `CoordinateSystem` property must be `'Cartesian'`.

Data Types: `double`

#### TransmitterLocation — Transmitter location

[0;0;0] (default) | three-element numeric column vector

Transmitter location, specified as a three-element numeric column vector of coordinates in one of these forms.

- `[x; y; z]` — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for `x`, `y`, and `z`.
- `[latitude; longitude; height]` — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. `latitude` must be in the range `[-90, 90]`. The object does not perform range validation for `longitude` and `height`. `height` is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

#### Dependencies

To enable this property, the `PathSpecification` property must be `'Locations'`.

Data Types: `double`

#### ReceiverLocation — Receiver location

[10;10;10] (default) | three-element numeric column vector

Receiver location, specified as a three-element numeric column vector of coordinates in one of these forms.

- `[x; y; z]` — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for `x`, `y`, and `z`.
- `[latitude; longitude; height]` — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. `latitude` must be in the range `[-90, 90]`. The object does not perform range validation for `longitude` and `height`. `height` is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

#### Dependencies

To enable this property, the `PathSpecification` property must be `'Locations'`.

Data Types: `double`

**LineOfSight — Line-of-sight indicator**

true or 1 (default) | false or 0

Line-of-sight indicator, specified as logical 1 (true) or 0 (false).

- A value of 1 (true) means that the ray has an unobstructed path from the transmitter to the receiver.
- A value of 0 (false) means that path from the transmitter to the receiver is obstructed.

**Dependencies**

To enable this property, the PathSpecification property must be 'Locations'.

Data Types: logical

**Interactions — Ray-interface interactions along propagation path**

1-by- $N_I$  structure

Ray-interface interactions along the propagation path, specified as a 1-by- $N_I$  structure containing these fields.  $N_I$  is the number of interactions.

**Type — Type of ray-interface interaction**

'Reflection' (default) | 'Diffraction'

Type of ray-interface interaction, specified as 'Reflection' or 'Diffraction'.

Data Types: char | string

**Location — Location of ray-interface interaction**

[10;10;0] (default) | 3-by-1 numeric vector

Location of the ray-interface interaction, specified as a 3-by-1 numeric vector containing the coordinates of one interaction point on the ray.

- When the CoordinateSystem property is set to 'Cartesian', the form is [x; y; z]. The object does not perform range validation for x, y, and z.
- When the CoordinateSystem property is set to 'Geographic', the form is [latitude; longitude; height]. The latitude must be in the range [-90, 90]. The object does not perform range validation for longitude and height. height is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

Data Types: double

**Dependencies**

To enable this property, the PathSpecification property must be 'Locations' and the LineOfSight property must be 0 (false).

Data Types: struct

**PropagationDelay — Propagation delay**

5.7775e-08 (default) | nonnegative scalar

Propagation delay, in seconds, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Locations', this property is read-only and the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.

Data Types: double

### **PropagationDistance — Propagation distance**

[17.3205 (default) | nonnegative scalar

This property is read-only.

Propagation distance, in meters, specified as a nonnegative scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Locations', the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When you set the `PathSpecification` property to 'Delay and angles', the value is derived from `PropagationDelay`.

Data Types: double

### **AngleOfDeparture — Angle of departure**

[45; 35.2644] (default) | numeric vector of the form [az; el]

Angle of departure, in degrees, of the ray departing the transmitter, specified as a numeric vector of the form [az; el]. The azimuth angle, *az*, is measured from the positive *x*-axis counterclockwise around the *z*-axis and must be in the range (-180, 180]. The elevation angle, *el*, is measured from the *xy*-plane and must be in the range [-90, 90]. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.
- When you set the `PathSpecification` property to 'Locations', this property is read-only and the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When `CoordinateSystem` is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at transmitter.

Data Types: double

### **AngleOfArrival — Angle of arrival**

[-135; -35.2644] (default) | numeric vector of the form [az; el]

Angle of arrival, in degrees, of the ray arriving at the receiver, specified as a numeric vector of the form [az; el]. The azimuth angle, *az*, is measured from the positive *x*-axis counterclockwise around the *z*-axis and must be in the range (-180, 180]. The elevation angle, *el*, is measured from the *xy*-plane and must be in the range [-90, 90]. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.

- When you set the `PathSpecification` property to 'Locations', this property is read-only and the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When `CoordinateSystem` is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at receiver.

Data Types: double

**NumInteractions — Number of ray-interface interactions**

0 (default) | nonnegative integer

This property is read-only.

Number of ray-interface interactions for the ray object from the transmitter to the receiver, specified as a nonnegative integer. The value is derived from `LineOfSight` and, if applicable, `Interactions`.

**Dependencies**

To enable this property, the `PathSpecification` property must be 'Locations'.

Data Types: double

**Frequency — Signal frequency**

1.9e+09 (default) | positive scalar

Signal frequency in Hz, specified as a positive scalar.

Data Types: double

**PathLossSource — Path loss source**

'Free space model' (default) | 'Custom'

Path loss source, specified as 'Free space model' or 'Custom'.

Data Types: char | string

**PathLoss — Path loss**

62.7941 (default) | nonnegative scalar

Path loss in dB, specified as a nonnegative scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathLossSource` property to 'Free space model', the `PathLoss` property is read-only and derived from the `PropagationDistance` and `Frequency` properties by using the free space propagation model.
- When you set the `PathLossSource` property to 'Custom', you can set the `PathLoss` property, independent of the geometric properties.

Data Types: double

**PhaseShift — Phase shift**

4.8537 (default) | numeric scalar

Phase shift in radians, specified as a numeric scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the PathLossSource property to 'Free space model', the PhaseShift property is read-only and derived from the PropagationDistance and Frequency properties by using the free space propagation model.
- When you set the PathLossSource property to 'Custom', you can set the PhaseShift property, independent of the geometric properties.

Data Types: double

## Object Functions

plot (rays) Display RF propagation rays in Site Viewer

## Examples

### Perform Ray Tracing Between Two Sites in Hong Kong

Perform ray tracing in Hong Kong and return the rays in comm.Ray objects. The comm.Ray objects contain geometric and electromagnetic information for propagation paths between the transmitter and receiver sites.

Launch Site Viewer with buildings in Hong Kong. For more information about the osm file, see [1] on page 3-1514.

```
viewer = siteviewer("Buildings","hongkong.osm");
```

Create transmitter and receiver sites.

```
tx = txsite("Latitude",22.2789,"Longitude",114.1625, ...
           "AntennaHeight",10,"TransmitterPower",5, ...
```

```
    "TransmitterFrequency",28e9);  
rx = rxsite("Latitude",22.2799,"Longitude",114.1617, ...  
    "AntennaHeight",1);
```

Create a ray tracing propagation model, which MATLAB® represents using a `RayTracing` object. Configure the model to find paths with up to 3 surface reflections and up to 1 edge diffraction. By default, the model uses the shooting and bouncing rays (SBR) method.

```
pm = propagationModel("raytracing", "MaxNumReflections",3,"MaxNumDiffractions",1);
```

Perform the ray tracing analysis. The `raytrace` function returns a cell array containing the `comm.Ray` objects. By default, ray tracing models discard rays that are more than 40 decibels weaker than the strongest path.

```
rays = raytrace(tx,rx,pm)
```

```
rays = 1×1 cell array  
      {1×15 comm.Ray}
```

Display the properties of the first `comm.Ray` object. The value of the `LineOfSight` property is 1, and value of the `NumInteractions` property is 0. This combination indicates that the ray defines a line-of-sight path.

```
rays{1}(1)
```

```
ans =
```

```
Ray with properties:
```

```
    PathSpecification: 'Locations'  
    CoordinateSystem: 'Geographic'  
    TransmitterLocation: [3×1 double]  
    ReceiverLocation: [3×1 double]  
    LineOfSight: 1  
    Frequency: 2.8000e+10  
    PathLossSource: 'Custom'  
    PathLoss: 104.2656  
    PhaseShift: 4.6360
```

```
Read-only properties:
```

```
    PropagationDelay: 4.6442e-07  
    PropagationDistance: 139.2294  
    AngleOfDeparture: [2×1 double]  
    AngleOfArrival: [2×1 double]  
    NumInteractions: 0
```

Display the properties of the third `comm.Ray` object. The value of the `LineOfSight` property is 0, and the value of the `NumInteractions` property is 2. This combination indicates that the ray defines a path with two interface interactions.

```
rays{1}(3)
```

```
ans =
```

```
Ray with properties:
```

```
    PathSpecification: 'Locations'  
    CoordinateSystem: 'Geographic'
```

```
TransmitterLocation: [3×1 double]
ReceiverLocation: [3×1 double]
LineOfSight: 0
Interactions: [1×2 struct]
    Frequency: 2.8000e+10
PathLossSource: 'Custom'
    PathLoss: 142.3763
    PhaseShift: 0.7160
```

```
Read-only properties:
    PropagationDelay: 8.3065e-07
    PropagationDistance: 249.0217
    AngleOfDeparture: [2×1 double]
    AngleOfArrival: [2×1 double]
    NumInteractions: 2
```

Display the types and locations of the interactions by querying the Interactions property.

```
rays{1}(3).Interactions(1)
```

```
ans = struct with fields:
    Type: 'Diffraction'
    Location: [3×1 double]
```

```
rays{1}(3).Interactions(2)
```

```
ans = struct with fields:
    Type: 'Reflection'
    Location: [3×1 double]
```

Visualize the sites and the ray tracing paths.

```
show(tx)
show(rx)
plot(rays{1})
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Plot Propagation Rays Between Sites in Chicago

Perform ray tracing in Chicago and return the rays in `comm.Ray` objects. Then, display the rays without performing the ray tracing analysis again.

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 3-1517.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on one building and a receiver site on another building. Show the line-of-sight path between the sites using the `los` function.

```
tx = txsite("Latitude",41.8800, ...  
           "Longitude",-87.6295, ...  
           "TransmitterFrequency",2.5e9);  
rx = rxsite("Latitude",41.881352, ...  
           "Longitude",-87.629771, ...  
           "AntennaHeight",30);  
los(tx,rx)
```

Create a ray tracing propagation model, which MATLAB® represents using a `RayTracing` object. By default, the model uses the SBR method and calculates propagation paths with up to two reflections.

```
pm = propagationModel("raytracing");
```

Perform the ray tracing analysis. The `raytrace` function returns a cell array containing the `comm.Ray` objects.

```
rays = raytrace(tx,rx,pm)
```

```
rays = 1x1 cell array
      {1x3 comm.Ray}
```

View the properties of the first ray object.

```
rays{1}(1)
```

```
ans =
  Ray with properties:
    PathSpecification: 'Locations'
    CoordinateSystem: 'Geographic'
    TransmitterLocation: [3x1 double]
    ReceiverLocation: [3x1 double]
    LineOfSight: 0
    Interactions: [1x1 struct]
      Frequency: 2.5000e+09
    PathLossSource: 'Custom'
      PathLoss: 92.7740
      PhaseShift: 1.2933
```

```

Read-only properties:
  PropagationDelay: 5.7088e-07
  PropagationDistance: 171.1462
  AngleOfDeparture: [2x1 double]
  AngleOfArrival: [2x1 double]
  NumInteractions: 1

```

Close Site Viewer.

```
close(viewer)
```

Create another Site Viewer with the same buildings, transmitter site, and receiver site. Then, display the propagation paths. Alternatively, you can plot individual paths by specifying a single ray object, for example `rays{1}(2)`.

```

siteviewer("Buildings", "chicago.osm");
show(tx)
show(rx)
plot(rays{1}, "Type", "power", ...
     "TransmitterSite", tx, "ReceiverSite", rx)

```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Version History

**Introduced in R2020a**

**R2021b: ReflectionLocations and NumReflections properties have been removed**

*Errors starting in R2021b*

The ReflectionLocations and NumReflections properties have been removed. To accommodate reflections, use the Interactions property to replace the ReflectionLocations property and use the NumInteractions property to replace the NumReflections property.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

# tdmsDatastore

Datastore for collection of TDMS-files

## Description

Use the `TDMSDatastore` object to access data from a collection of TDMS-files.

## Creation

### Syntax

```
tdmsds = tdmsDatastore(location)
tdmsds = tdmsDatastore(__,Name=Value)
```

### Description

`tdmsds = tdmsDatastore(location)` creates a `TDMSDatastore` object based on a TDMS-file or a collection of files in the folder specified by `location`. Within the folder, all files with the extension `.tdms` are included in the datastore.

`tdmsds = tdmsDatastore(__,Name=Value)` specifies function options and properties of `tdmsds` using optional name-value pairs.

### Input Arguments

#### location — Location of TDMS datastore files

string | character vector | cell array

Location of TDMS datastore files, specified as a string, character vector, or cell array identifying either files or folders. The path can be relative or absolute, and can contain the wildcard characters `?` and `*`. If `location` specifies a folder, the datastore includes all files in that folder with the extension `.tdms`.

Example: `"C:\data\tdms_set1"`

Data Types: `char` | `string` | `cell`

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

You can specify file information or object "Properties" on page 3-1520. Allowed options are `IncludeSubfolders`, `AlternateFileSystemRoots`, and the properties `SelectedChannelGroup`, `SelectedChannels`, `RowTimes`, and `ReadSize`.

Example: `SelectedChannelGroup="Acceleration"`

**IncludeSubfolders — Include files in subfolders**

false (default) | true

Include files in subfolders, specified as a logical. Specify `true` to include files in each folder and recursively in subfolders.

Example: `IncludeSubfolders=true`

Data Types: `logical`

**AlternateFilesystemRoots — Root paths for different platforms**

string array | cell array

Root paths to the TDMS-files for different platforms, specified as an array of strings.

Example: `AlternateFilesystemRoots=["Z:\datasets", "/tdms/datasets"]`

Data Types: `char` | `string` | `cell`

**Properties****Files — Files included in datastore**

char | string | cell

This property is read-only.

Files included in the datastore, specified as a character vector or string identifying a relative or absolute path to a file or folder. The wildcard characters `?` and `*` are supported. All TDMS-files in the specified folder are included in the datastore. The property value is stored as a string vector of file names.

Example: `"file*.tdms"`

Data Types: `char` | `string`

**ChannelList — All channels present in first TDMS-file**

table

This property is read-only.

All channels present in first TDMS-file, returned as a table.

Those channels targeted for reading must have the same name and belong to the same channel group in each file of the TDMS datastore.

Data Types: `table`

**SelectedChannelGroup — Channel group containing the channels to read from**

string | char

Channel group containing the channels to read from, specified as a string or character vector.

Example: `"Torque"`

Data Types: `string` | `char`

**SelectedChannels — Names of channels to read**

char | string | cell

Names of channels to read, specified as a character vector, string, or array of either. The channels must be in the channel group specified by `SelectedChannelGroup` in each file of the TDMS datastore.

Example: `["Torque1" "Torque2"]`

Data Types: `char` | `string` | `cell`

### RowTimes — Times associated with rows of table

`datetime` | `duration` | `channel name`

Times associated with rows of the table, specified as a selected time channel name, a `datetime` vector, or a `duration` vector. Setting this property causes the `read` and `readall` functions to output a cell array of timetables. Each time element labels a row in the output timetable.

Example: `duration(seconds([1:1000]/1000))`

Data Types: `datetime` | `duration` | `string`

### ReadSize — Size of data returned by read

`20000` (default) | `numeric` | `"file"`

Size of data returned by the `read` function, specified as `"file"` or a numeric value. A string value of `"file"` causes a read of one TDMS-file at a time; a numeric value specifies the number of records to read. The `readall` function ignores this property.

If you change the `ReadSize` property value after creating the `TDMSDatastore` object, the datastore resets.

Example: `5000`

Data Types: `double` | `string` | `char`

## Object Functions

<code>read</code>	Read data in TDMS datastore
<code>readall</code>	Read all data in TDMS datastore
<code>preview</code>	Read first 8 records from TDMS datastore
<code>hasdata</code>	Determine if data is available to read from TDMS datastore
<code>reset</code>	Reset TDMS datastore to initial state
<code>combine</code>	Combine data from multiple datastores
<code>transform</code>	Transform datastore

## Examples

### Read Data from a TDMS Datastore

Create a TDMS datastore from all the TDMS-files in the folder `C:\data\tdms`, and read the data into tables.

Set up the datastore and view its channel list.

```
td = tdmsDatastore("C:\data\tdms");
td.ChannelList(:,1:4)
```

```
ans =
```

6x4 table

ChannelGroupNumber	ChannelGroupName	ChannelGroupDescription	ChannelName
1	"Acceleration"	"CGAcceleration"	"Acceleration1"
1	"Acceleration"	"CGAcceleration"	"Acceleration2"
2	"Force"	"CGForce"	"Force1"
2	"Force"	"CGForce"	"Force2"
3	"Torque"	"CGTorque"	"Torque1"
3	"Torque"	"CGTorque"	"Torque2"

Read all available data.

```
td.SelectedChannelGroup = "Force"
data_set = readall(td)
```

data\_set =

1x3 cell array

```
{9936x2 table} {9936x2 table} {9936x2 table}
```

View the data from the first channel group.

```
data_set{1}
```

ans =

9936x2 table

Acceleration1	Acceleration2
-1.9851	0
-3.9702	0
11.911	1.5521
5.9553	-1.5521
1.9851	-4.6562
5.9553	4.6562
3.9702	-1.5521
3.9702	-4.6562
13.896	0
:	:
-4.8046	-2.2609
-4.8046	6.7826
-7.2068	2.2609
-7.2068	4.5218
-7.2068	6.7826
-2.4023	9.0435
-2.4023	4.5218
-9.6091	2.2609
-12.011	4.5218

Display all 9936 rows.

Read all available data for the channel group Force.

```
td.SelectedChannelGroup = "Force";
data_set = readall(td)
```

```
data_set =  
    1×1 cell array  
    {9936×2 table}
```

Read 500 entries of data.

```
td.ReadSize = 500;  
data_set = read(td)
```

```
data_set =  
    1×1 cell array  
    {500×2 table}
```

## Limitations

- TDMS functions are supported on Windows platforms only.
- As a special case of a datastore, the `TDMSDatastore` object does not support the following functionality:
  - Partitioning for parallel computing
  - Shuffling

## Version History

Introduced in R2022a

## info

**Package:** comm

Characteristic information about baseband file reader

### Syntax

```
S = info(bbr)
```

### Description

`S = info(bbr)` returns a structure containing characteristic information about the specified baseband file reader.

### Examples

#### Display Baseband File Reader Characteristic Information

Configure a baseband file reader object to read the `baseband_samples_1ghz.bb` baseband signal file. Then read the characteristic information of the baseband file reader by using the `info` object function.

```
bbr = comm.BasebandFileReader('baseband_samples_1ghz.bb');  
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 10000  
        DataType: 'double'  
    NumSamplesRead: 0
```

Release the baseband file reader object and reconfigure the object to read the `ais_capture.bb` baseband signal file. Then, read the characteristic information about the reconfigured baseband file reader object by using the `info` object function.

```
release(bbr)  
bbr = comm.BasebandFileReader('ais_capture.bb');  
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 262144  
        DataType: 'single'  
    NumSamplesRead: 0
```

### Input Arguments

**bbr** — Baseband file reader

`comm.BasebandFileReader` System object

Baseband file reader, specified as a `comm.BasebandFileReader` System object.

## Output Arguments

### **S** — Characteristic information about baseband file reader

structure

Characteristic information about the baseband file reader, returned as a structure containing these fields.

#### **NumSamplesInData** — Total number of baseband data samples

positive integer

Total number of baseband data samples in the file, returned as a positive integer.

Data Types: double

#### **Data Type** — Data type of baseband signal

'double' | 'single' | 'uint8' | 'uint16' | 'uint32' | 'uint64' | 'int8' | 'int16' | 'int32' | 'int64'

Data type of the baseband signal in the file, returned as 'double', 'single', 'uint8', 'uint16', 'uint32', 'uint64', 'int8', 'int16', 'int32', or 'int64'.

#### **NumSamplesRead** — Number of samples read

nonnegative integer

Number of samples read from the file, returned as a nonnegative integer. The returned value does not exceed the value of the `NumSamplesInData` property of the baseband file reader when the `CyclicRepetition` property in that object is `false`.

Data Types: double

## info

**Package:** comm

Characteristic information about baseband file writer

### Syntax

```
S = info(bbw)
```

### Description

`S = info(bbw)` returns a structure containing characteristic information about the specified baseband file writer.

---

**Note** All fields are determined and viewable after the object is run and locked. When the object is unlocked, only the `Filename` and `NumSamplesWritten` fields are available and viewable.

---

## Examples

### Write Baseband Signal to File

Create a baseband file writer object specifying a sample rate of 1 kHz and a 0 Hz center frequency.

```
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
```

Save the date for today in the `Metadata` structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);  
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file `baseband_data.bb`.

```
bbw(x)
```

Display information about the baseband file writer. Then, release the object.

```
info(bbw)
```

```
ans = struct with fields:
```

```
    Filename: 'C:\TEMP\Bdoc23a_2213998_7084\ib967011\13\tp78e86220\comm-ex66490302\baseband_data.bb'  
    SamplesPerFrame: 1000  
    NumChannels: 2  
    DataType: 'double'  
    NumSamplesWritten: 1000
```

```
release(bbw)
```

Create a baseband file reader object to read the saved data. Display the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb', ...
    'SamplesPerFrame',100);
bbr.Metadata
ans = struct with fields:
    Date: '05-Mar-2023'
```

Read the data from the file.

```
z = [];
while ~isDone(bbr)
    y = bbr();
    z = cat(1,z,y);
end
```

Display information about the baseband file reader. Then, release object.

```
info(bbr)
ans = struct with fields:
    NumSamplesInData: 1000
    DataType: 'double'
    NumSamplesRead: 1000
```

```
release(bbr)
```

Confirm that the original modulated data  $x$ , matches the data  $z$ , read from file `baseband_data.bb`.

```
isequal(x,z)
ans = logical
     1
```

## Input Arguments

### **bbw** — Baseband file writer

`comm.BasebandFileWriter` System object

Baseband file writer, specified as a `comm.BasebandFileWriter` System object.

## Output Arguments

### **S** — Characteristic information about baseband file writer

structure

Characteristic information about the baseband file writer, returned as a structure containing these fields.

### **Filename** — Name of baseband file to write

character vector

Name of the baseband file to write, returned as a character vector. The filename shows the absolute path.

Data Types: char

**SamplesPerFrame — Number of samples in each frame**

positive integer

Number of samples in each frame, returned as a positive integer.

**Dependencies**

To enable this field, you must first run the baseband file writer object.

Data Types: double

**NumChannels — Number of channels in baseband signal**

positive integer

Number of channels in the baseband signal written to the file, returned as a positive integer.

**Dependencies**

To enable this field, you must first run the baseband file writer object.

Data Types: double

**DataType — Data type of baseband signal**

'double' | 'single' | 'uint8' | 'uint16' | 'uint32' | 'uint64' | 'int8' | 'int16' | 'int32' | 'int64'

Data type of the baseband signal written to the file, returned as 'double', 'single', 'uint8', 'uint16', 'uint32', 'uint64', 'int8', 'int16', 'int32', or 'int64'.

**Dependencies**

To enable this field, you must first run the baseband file writer object.

**NumSamplesWritten — Total number of baseband data samples written**

positive integer

Total number of baseband data samples written to the file, returned as a positive integer. This field returns the smaller of the total number of samples processed by the input baseband file writer object and the NumSamplesWritten property of that object.

Data Types: double

## info

**Package:** comm

Characteristic information about carrier synchronizer

### Syntax

```
infostruct = info(carrSynch)
```

### Description

`infostruct = info(carrSynch)` returns a structure containing characteristic information for the CarrierSynchronizer System object.

### Examples

#### Determine Carrier Synchronizer Loop Parameters

Create a carrier synchronizer object.

```
csync = comm.CarrierSynchronizer;
```

Determine the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay by using the `info` method.

```
syncInfo = info(csync)
```

```
syncInfo = struct with fields:  
  NormalizedPullInRange: 0.0628  
  MaxFrequencyLockDelay: 1.5787e+04  
  MaxPhaseLockDelay: 130
```

The normalized pull-in range is 0.0628 rad/sec. Convert the pull-in range to Hz. This represents the maximum normalized frequency offset that can be corrected by the carrier synchronizer.

```
foffsetmax = syncInfo.NormalizedPullInRange/(2*pi)
```

```
foffsetmax = 0.0100
```

The time to acquire a frequency lock is 15787 s, and the time to acquire a phase lock is 130 s.

The overall acquisition time, `Tlock`, is well approximated by the sum of the frequency and phase lock terms.

```
Tlock = syncInfo.MaxFrequencyLockDelay + syncInfo.MaxPhaseLockDelay
```

```
Tlock = 1.5917e+04
```

## Input Arguments

### **carrSynch** — System object to get information from

System object

System object to get information from.

## Output Arguments

### **infostruct** — Structure containing object information

struct

Structure containing these fields with information about the System object.

### **NormalizedPullInRange** — Normalized pull in range

scalar

Normalized pull in range in radians, returned as a scalar. `NormalizedPullInRange` is the largest frequency offset (rad), normalized by the loop bandwidth, for which the synchronizer can acquire lock.

### **MaxFrequencyLockDelay** — Maximum frequency lock delay

positive integer

Maximum frequency lock delay, returned as a positive integer. `MaxFrequencyLockDelay` is the number of samples required for the synchronizer to acquire frequency lock.

### **MaxPhaseLockDelay** — Maximum phase lock delay

positive integer

Maximum phase lock delay, returned as a positive integer. `MaxPhaseLockDelay` is the number of samples required for the synchronizer to acquire phase lock.

Data Types: struct

## Version History

Introduced in R2015a

### Objects

`comm.CarrierSynchronizer`

## getPercentileRelativePower

**Package:** comm

(Not recommended) Relative power value for given percentile using CCDF

---

**Note** comm.CCDF is not recommended. Use `powermeter` instead. For information on updating your code, see “Version History”.

---

### Syntax

```
R = getPercentileRelativePower(ccdf,P)
```

### Description

`R = getPercentileRelativePower(ccdf,P)` returns the relative power value of a signal for the specified percentile value `P`. The input `ccdf` specifies the complementary cumulative distribution function (CCDF) curves of the signal of interest. The function returns the power level by which the signal is above its average power `P` percent of the time. A percentile of `P = 100` corresponds to a probability of 1.0. For the  $i$ th channel in the input signal, the function evaluates the inverse of the corresponding CCDF curve at probability value  $P(i)/100$ .

Before calling the `getPercentileRelativePower` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

### Examples

#### Obtain CCDF Curves and Relative Power Levels

Generate a unit variance AWGN signal and a dual-tone signal.

```
n = [0:5e3-1].';  
s1 = randn(5e3,1); % AWGN signal  
s2 = sin(0.01*pi*n) + sin(0.03*pi*n); % Dual-tone signal
```

Create a CCDF measurement object.

```
ccdf = comm.CCDF;
```

Obtain the CCDF curves of the signals.

```
ccdf([s1 s2]);
```

Plot the resulting curves.

```
plot(ccdf)  
legend('AWGN', 'Dual-tone')
```

Find the relative power levels of the signals. The AWGN signal is 8.1929 dB above its average power 1 percent of the time. The dual-tone signal is 3.5493 dB above its average power 10 percent of the time.

```
RPW = getPercentileRelativePower(ccdf,[1 10])
```

```
RPW = 2×1
```

```
    8.1923
```

```
    3.5493
```

## Input Arguments

### ccdf — CCDF measurements

comm.CCDF System object

CCDF measurements, specified as a `comm.CCDF System` object. The object must contain CCDF curves. To obtain CCDF curves, call the object on the input signal of interest.

### P — Percentile

numeric scalar | numeric row vector

Percentile, specified as one of these options.

- Numeric scalar in the range [0, 100] — The function evaluates the inverse of each CCDF curve at probability value  $P/100$ .
- Numeric row vector with values in the range [0, 100] — The function evaluates the inverse of the  $i$ th CCDF curve in the input `ccdf` at probability value  $P(i)/100$ .

## Output Arguments

### R — Relative power value

numeric column vector

Relative power value, returned as a numeric column vector.  $R(i)$  is the relative power value returned for the channel corresponding to  $i$ th CCDF curve in the input `ccdf`. The `PowerUnits` property of the object specifies whether the relative power value is returned in a dB scale or linear scale.

Data Types: `double`

## Version History

**Introduced in R2012a**

### R2023a: To be removed

*Not recommended starting in R2023a*

The `comm.CCDF System` object runs without warning, but the Code Analyzer indicates that `com.CCDF` will be removed in a future release. Use `powermeter` instead.

## See Also

## getProbability

**Package:** comm

(Not recommended) Probability of relative power value using CCDF

---

**Note** comm.CCDF is not recommended. Use `powermeter` instead. For information on updating your code, see “Version History”.

---

### Syntax

```
P = getProbability(ccdf,R)
```

### Description

`P = getProbability(ccdf,R)` returns the probability, as a percentage in the range [0, 100], that the power level of a signal is above its average power by the specified level `R`. The input `ccdf` specifies the complementary cumulative distribution function (CCDF) curves of the signal of interest. For the  $i$ th channel in the input signal, the function evaluates the corresponding CCDF curve at relative power value  $R(i)$ .

Before calling the `getProbability` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

### Examples

#### Obtain CCDF Curves and Probabilities

Generate a unit variance AWGN signal and a dual-tone signal.

```
n = [0:5e3-1].';  
s1 = randn(5e3,1); % AWGN signal  
s2 = sin(0.01*pi*n) + sin(0.03*pi*n); % Dual-tone signal
```

Create a CCDF measurement object.

```
ccdf = comm.CCDF;
```

Obtain the CCDF curves of the signals.

```
ccdf([s1 s2]);
```

Plot the resulting CCDF curves.

```
plot(ccdf)  
legend('AWGN', 'Dual-tone')
```

Find the probability that the AWGN signal power is 5 dB above its average power and the probability that the dual-tone signal power is 3 dB above its average power.

```
P = getProbability(ccdf,[5 3])
```

```
P = 2x1
    7.9551
    21.1421
```

## Input Arguments

### **ccdf** — CCDF measurements

`comm.CCDF` System object

CCDF measurements, specified as a `comm.CCDF` System object. The object must contain CCDF curves. To obtain CCDF curves, call the object on the input signal of interest.

### **R** — Relative power value

numeric scalar | numeric row vector

Relative power value, specified as one of these options.

- Numeric scalar — The function evaluates each CCDF curve at the relative power value  $R$ .
- Numeric row vector — The function evaluates the  $i$ th CCDF curve in the input `ccdf` at relative power value  $R(i)$ .

The `PowerUnits` property of the object specifies whether the relative power value is returned in a dB scale or linear scale.

Data Types: `double`

## Output Arguments

### **P** — CCDF probability of relative power value

numeric column vector

CCDF probability of the relative power value, returned as a numeric column vector with values in the range  $[0, 100]$ . A value of 100 corresponds to a probability of 1.0.  $P(i)/100$  is the probability value of the channel corresponding to the  $i$ th CCDF curve in the input `ccdf`.

Data Types: `double`

## Version History

**Introduced in R2012a**

### **R2023a: To be removed**

*Not recommended starting in R2023a*

The `comm.CCDF` System object runs without warning, but the Code Analyzer indicates that `com.CCDF` will be removed in a future release. Use `powermeter` instead.

## See Also

### Objects

`powermeter`

## plot

**Package:** comm

(Not recommended) 2-D line plots of CCDF curves

---

**Note** comm.CCDF is not recommended. Use `powermeter` instead. For information on updating your code, see “Version History”.

---

### Syntax

```
lines = plot(ccdf)
lines = plot(ccdf,Name,Value)
```

### Description

`lines = plot(ccdf)` creates 2-D line plots corresponding to the complementary cumulative distribution function (CCDF) curves of a signal of interest specified by `ccdf`. The number of curves is equal to the number of channels in the signal. The function returns a column vector of chart line objects corresponding to the plots.

Before calling the `plot` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

`lines = plot(ccdf,Name,Value)` specifies options using one or more name-value arguments. For a complete list of name-value arguments, see Line Properties. For example, `plot(ccdf, 'LineWidth', 2)` creates the plots such that the line width of each curve is 2 points.

### Examples

#### Obtain CCDF Curves for 16-QAM and QPSK Signals

Generate 16-QAM and QPSK modulated signals.

```
qamTxSig = qammod(randi([0 15],20e3,1),16, 'UnitAveragePower', true);
qpskTxSig = pskmod(randi([0 3],20e3,1),4,pi/4);
```

Pass the signals through an AWGN channel.

```
qamRxSig = awgn(qamTxSig,15);
qpskRxSig = awgn(qpskTxSig,15);
```

Create a CCDF measurement object enabling outputs for the average power measurements and peak power measurements.

```
ccdf = comm.CCDF( ...
    'AveragePowerOutputPort', true, ...
    'PeakPowerOutputPort', true);
```

Obtain the CCDF measurements of the two waveforms.

```
[ccdfy,ccdfx,avg,peak] = ccdf([qamRxSig qpskRxSig]);
```

Plot the CCDF curves for both signals.

```
plot(ccdf)
legend('16-QAM', 'QPSK')
```

## Input Arguments

### **ccdf** — CCDF measurements

`comm.CCDF System` object

CCDF measurements, specified as a `comm.CCDF System` object. The object must contain CCDF curves. To obtain the CCDF curves, call the object on the input signal of interest.

## Output Arguments

### **lines** — Plotted CCDF curves

column vector of `Line` objects

Plotted CCDF curves, returned as a column vector of `Line` objects. The length of this vector is equal to the number of CCDF curves specified by the input `ccdf`. These `Line` objects uniquely identify the plotted 2-D CCDF curves. Use these objects to query and modify the properties of the curves in the plots. For a complete list of object properties, see `Line Properties`.

## Version History

**Introduced in R2012a**

**R2023a: To be removed**

*Not recommended starting in R2023a*

The `comm.CCDF System` object runs without warning, but the Code Analyzer indicates that `com.CCDF` will be removed in a future release. Use `powermeter` instead.

## info

**Package:** comm

Return characteristic information about channel filter

### Syntax

```
infostruct = info(chanFilt)
```

### Description

`infostruct = info(chanFilt)` returns a structure containing characteristic information about the `comm.ChannelFilter` System object.

### Examples

#### Determine Channel Filter Structure Dimensions

In a distributed MIMO system, send the same signal from two geographically separate transmitters (Tx) and combine the received signals at one single receiver (Rx) to explore spatial diversity. The two Txs are not co-located and they experience different multipath (path delays) to the Rx. Specify the path delays respectively.

```
delay1 = [0 1.5 2.3 5.2 6.6];  
delay2 = [0 3.7 6.2];
```

Configure one channel filter object per Tx.

```
chanFilt1 = comm.ChannelFilter('PathDelays', delay1);  
chanFilt2 = comm.ChannelFilter('PathDelays', delay2);
```

Use the `info` object function to get the `ChannelFilterDelay` and `ChannelFilterCoefficients`.

```
info(chanFilt1)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 6  
    ChannelFilterCoefficients: [5x21 double]
```

```
info(chanFilt2)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 4  
    ChannelFilterCoefficients: [3x19 double]
```

## Input Arguments

### **chanFilt** – Channel filter

System object

Channel filter, specified as a `comm.ChannelFilter` System object.

## Output Arguments

### **infostruct** – Characteristic information about channel filter

struct

Characteristic information about channel filter, returned as a structure containing these fields:

### **ChannelFilterDelay** – Channel filter delay

positive real scalar

Channel filter delay, returned as a positive real scalar.

Data Types: `double`

### **ChannelFilterCoefficients** – Channel filter coefficients

vector | matrix

Channel filter coefficients, returned as a vector or a matrix.

Data Types: `double`

## Version History

Introduced in R2020b

## info

**Package:** comm

Characteristic information about fading channel object

### Syntax

```
infostruct = info(obj)
```

### Description

`infostruct = info(obj)` returns a structure containing characteristic information about the fading channel System object.

### Examples

#### Get `comm.RayleighChannel` Info

Use the `info` object function to get information from a `comm.RayleighChannel` object.

Create a Rayleigh channel object and some data to pass through the channel.

```
rayleighchan = comm.RayleighChannel( ...  
    SampleRate=1000, ...  
    PathDelays=[0 0], ...  
    AveragePathGains=[0 0])
```

```
rayleighchan =  
    comm.RayleighChannel with properties:
```

```
        SampleRate: 1000  
        PathDelays: [0 0]  
    AveragePathGains: [0 0]  
    NormalizePathGains: true  
    MaximumDopplerShift: 1.0000e-03  
        DopplerSpectrum: [1x1 struct]  
    ChannelFiltering: true  
    PathGainsOutputPort: false
```

Show all properties

```
data = randi([0 1],600,1);
```

Check the Rayleigh channel object information.

```
info(rayleighchan)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 0  
    ChannelFilterCoefficients: [2x1 double]
```

```
NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x1 double]
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a 1.5e-3 second path delay to the second delay path.

```
release(rayleighchan)
rayleighchan.PathDelays = [0 1.5e-3]

rayleighchan =
    comm.RayleighChannel with properties:

        SampleRate: 1000
        PathDelays: [0 0.0015]
        AveragePathGains: [0 0]
        NormalizePathGains: true
        MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
        ChannelFiltering: true
        PathGainsOutputPort: false

    Show all properties
```

Pass data through the channel and check the object information again.

```
rayleighchan(data);
info(rayleighchan)

ans = struct with fields:
    ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
    NumSamplesProcessed: 600
```

### Get comm.RicianChannel Info

Use the `info` object function to get information from a `comm.RicianChannel` object.

Create a Rician channel object and some data to pass through the channel.

```
ricianchan = comm.RicianChannel('SampleRate',500)

ricianchan =
    comm.RicianChannel with properties:
```

```
        SampleRate: 500
        PathDelays: 0
    AveragePathGains: 0
    NormalizePathGains: true
        KFactor: 3
    DirectPathDopplerShift: 0
    DirectPathInitialPhase: 0
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
    PathGainsOutputPort: false
```

Show all properties

```
data = randi([0 1],600,1);
```

Check the Rician channel object information.

```
info(ricianchan)
```

```
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
```

```
ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a second path delay with a delay of 3.1e-3 second and an average path gain of -3 dB.

```
release(ricianchan)
ricianchan.PathDelays = [0 3.1e-3];
ricianchan.AveragePathGains = [0 -3]
```

```
ricianchan =
    comm.RicianChannel with properties:

        SampleRate: 500
        PathDelays: [0 0.0031]
    AveragePathGains: [0 -3]
    NormalizePathGains: true
        KFactor: 3
    DirectPathDopplerShift: 0
    DirectPathInitialPhase: 0
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
```

```
PathGainsOutputPort: false
```

```
Show all properties
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)

ans = struct with fields:
    ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
    NumSamplesProcessed: 600
```

### Get comm.MIMOChannel Info

Use the `info` object function to get information from a `comm.MIMOChannel` object.

Create a MIMO channel object and some data to pass through the channel.

```
mimo = comm.MIMOChannel(SampleRate=1000);
data = randi([0 1],600,2);
```

Check the MIMO channel object information.

```
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
mimo(data);
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a  $2.5e-3$  second path delay. Recheck the object information.

```
release(mimo)
mimo.PathDelays = 2.5e-3;
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 5
    ChannelFilterCoefficients: [-0.0326 0.0403 -0.0504 0.0646 -0.0861 0.1238 -0.2101 0.6359 0.6359]
```

```
NumSamplesProcessed: 0
```

### Model MIMO Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using MIMO channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5;             % Maximum Doppler shift (Hz)
ns = 1000;         % Number of samples
nsdel = 100;      % Number of samples for delayed paths
```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response starting at time 0 and three 100-sample channel responses starting at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a flat-fading 2-by-2 MIMO channel System object, disabling channel filtering and specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
mimoChan1 = comm.MIMOChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the MIMO channel System object. Change the number of samples for the delayed paths and the source for the initial time so that you can specify the fading channel offset time as an input argument when calling the System object.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
mimoChan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `mimoChan1` object and for the discontinuous delayed channel responses by using the `mimoChan2` object with initial time offsets provided as input arguments.

```
pg0 = mimoChan1();
pg1 = mimoChan2(to1);
pg2 = mimoChan2(to2);
pg3 = mimoChan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` method. The results show that `mimoChan1` processed 1000 samples and that `mimoChan2` processed only 300 samples.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
      1000      300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. The results show that the gains for the three segments match the gain for the continuous case. The alignment of the two shows that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data because the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
title('Continuous and Discontinuous Channel Response')
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```

## Input Arguments

### **obj** — System object to get information from

System object

System object to get information from, specified as a `comm.MIMOChannel`, `comm.RayleighChannel`, or `comm.RicianChannel` System object.

## Output Arguments

### **infostruct** — Structure containing object information

structure

Structure containing these fields with information about the System object.

### **ChannelFilterDelay** — Channel filter delay

positive integer

Channel filter delay in samples, returned as a positive integer.

### **ChannelFilterCoefficients** — Channel filter coefficients

matrix

---

Channel filter coefficients, returned as a matrix. The coefficient matrix is used to convert path gains to channel filter tap gains for each sample and each pair of transmit and receive antennas.

**NumSamplesProcessed — Number of samples processed by the channel object**

positive integer

Number of samples processed by the channel object since the last reset, returned as a positive integer.

**LastFrameTime — Last frame ending time**

positive scalar

Last frame ending time in seconds, returned as a positive scalar. Use this value to confirm the simulation time.

**Dependencies**

This property applies when the `FadingTechnique` property is 'Sum of sinusoids' and the `InitialTimeSource` property is 'Input port'.

## info

**Package:** comm

Characteristic information about the equalizer object

### Syntax

```
infostruct = info(obj)
```

### Description

`infostruct = info(obj)` returns a structure containing characteristic information for the System object.

### Examples

#### Display Decision Feedback Equalizer Latency

Display latency value for a decision feedback equalizer object.

Create a decision feedback equalizer object.

```
dfe = comm.DecisionFeedbackEqualizer;
```

Display latency value for a decision feedback equalizer object by using the `info` object function.

```
info(dfe)
```

```
ans = struct with fields:  
    Latency: 2
```

### Input Arguments

**obj** — System object to get information from

System object

System object to get information from.

### Output Arguments

**infostruct** — Structure containing object information

structure

Structure containing fields with information about the System object.

**Latency** — Equalizer latency

scalar

Equalizer latency, returned as a scalar.

## **Version History**

**Introduced in R2012a**

## maxstep

**Package:** comm

Maximum step size for LMS equalizer convergence

### Syntax

```
mumax = maxstep(eq,x)
```

### Description

`mumax = maxstep(eq,x)` predicts a bound on the step size to provide convergence of the mean values of the coefficients of the equalizer defined by the `eq` System object. The set input signal sequences in `x` are assumed to have zero mean or nearly so.

### Examples

#### Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;  
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...  
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));  
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

### Input Arguments

**eq** — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` or `comm.DecisionFeedbackFEqualizer` System object.

**x — Input signal**

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the `InputSamplesPerSymbol` property. For more information, see “Symbol Tap Spacing” on page 3-409.

Data Types: `double`

Complex Number Support: Yes

**Output Arguments****mumax — Prediction of maximum step size for LMS equalizer convergence**

scalar

Prediction of maximum step size for LMS equalizer convergence, returned as a scalar.

## mmseweights

**Package:** comm

Linear equalizer MMSE tap weights

### Syntax

```
weights = mmseweights(eq, chTaps, EbN0)
```

### Description

`weights = mmseweights(eq, chTaps, EbN0)` calculated minimum mean squared error (MMSE) solution for the linear equalizer, `eq` System object given the channel delay taps, `chTaps`, and signal to noise ratio, `EbN0`.

### Examples

#### Calculate MMSE Weights for Linear Equalizer

Calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps, 1, tx), 25, 'measured');
```

Create a linear equalizer System object configured to use CMA algorithm and input the taps weights. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm', 'CMA', 'AdaptWeights', false, 'InitialWeightsSource', 'Property
```

```
eq =
```

```
comm.LinearEqualizer with properties:
```

```
    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i -0.7071 - 0.7071i 0.7071 - 0.7071i]
    InputSamplesPerSymbol: 1
```

```
    AdaptWeightsSource: 'Property'  
        AdaptWeights: false  
InitialWeightsSource: 'Property'  
    InitialWeights: [5x1 double]  
    WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

```
wgts = 5x1 complex
```

```
    0.0005 - 0.0068i  
    0.0103 + 0.0117i  
    0.9694 - 0.0019i  
   -0.3987 + 0.2186i  
    0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);  
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))  
grid on; xlabel('Symbols'); ylabel('|e|')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 139.1636
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 -0
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```

## Input Arguments

### eq — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` System object.

### chTaps — Channel delay taps

vector

Channel delay taps, specified as a vector.

Data Types: `double`

Complex Number Support: Yes

### EbN0 — Signal to noise ratio

scalar

Signal to noise ratio of the channel, specified as a scalar.

Data Types: `double`

## Output Arguments

**weights** — Weights for linear equalizer

vector

Weights for linear equalizer, returned as a vector.

## Version History

Introduced in R2019a

## coeffs

**Package:** comm

Coefficients for filters

### Syntax

```
coefInfo = coeffs(rcfilter)
coefInfo = coeffs(rcfilter, 'Arithmetic', arithType)
```

### Description

`coefInfo = coeffs(rcfilter)` obtain the coefficients for the specified filter System object.

`coefInfo = coeffs(rcfilter, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

### Examples

#### Obtain Coefficients of Raised Cosine Filters

Create a receive raised cosine filter and obtain its numerator coefficients.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols', 25);
srx = coeffs(rxfilter);
```

Calculate the expected number of numerator coefficients and confirm the value equals the length of `srx.Numerator`.

```
numcoefs = rxfilter.FilterSpanInSymbols * rxfilter.InputSamplesPerSymbol + 1
```

```
numcoefs = 201
```

```
isequal (numcoefs, length(srx.Numerator))
```

```
ans = logical
      1
```

Display the first ten coefficients.

```
srx.Numerator(1:10)
```

```
ans = 1×10
      10-3 ×
```

```
      0.9094      0.8559      0.6136      0.2320     -0.2074     -0.6071     -0.8759     -0.9486     -0.8021     -0.4
```

Display the impulse response of the receive raised cosine filter.

```
impz(srx.Numerator)
```

Create a transmit raised cosine filter and obtain its numerator coefficients.

```
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.5);
stx = coeffs(txfilter);
```

Display the first ten filter coefficients.

```
stx.Numerator(1:10)
```

```
ans = 1×10
```

```
-0.0002    0.0011    0.0021    0.0024    0.0018    0.0004   -0.0014   -0.0029   -0.0036   -0.0042
```

Display the impulse response of the transmit raised cosine filter.

```
impz(stx.Numerator)
```

## Input Arguments

### **rcfilter** — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

### **arithType** — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

## Output Arguments

### **coefInfo** — Filter coefficient information

structure

Filter coefficient information, returned as a structure containing the filter coefficients in the `Numerator` field. When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

## Version History

Introduced in R2013b

## cost

**Package:** comm

Computational cost of implementing filter System object

### Syntax

```
filtcost = cost(rcfilter)
filtcost = cost(rcfilter,'Arithmetic',arithType)
```

### Description

`filtcost = cost(rcfilter)` returns a structure of fields that contain information about the computational cost of implementing the specified filter.

`filtcost = cost(rcfilter,'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the filter response.

### Examples

#### Compute Cost of RRC Filter

Compute the cost of implementing various root-raised-cosine (RRC) filters that are created by using a `comm.RaisedCosineTransmitFilter` System object™. Increasing the filter span or output samples per symbol increases the cost of implementing the filter.

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",20, ...
    "OutputSamplesPerSymbol",8);
costFilt = cost(rrcFilt)
```

```
costFilt = struct with fields:
    NumCoefficients: 161
    NumStates: 20
    MultiplicationsPerInputSample: 161
    AdditionsPerInputSample: 153
```

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",200, ...
    "OutputSamplesPerSymbol",8);
costFilt = cost(rrcFilt)
```

```
costFilt = struct with fields:
    NumCoefficients: 1601
    NumStates: 200
    MultiplicationsPerInputSample: 1601
    AdditionsPerInputSample: 1593
```

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",200, ...
```

```

    "OutputSamplesPerSymbol",16);
costFilt = cost(rrcFilt)

costFilt = struct with fields:
    NumCoefficients: 3201
    NumStates: 200
    MultiplicationsPerInputSample: 3201
    AdditionsPerInputSample: 3185

```

## Input Arguments

### rcfilter — Filter

comm.RaisedCosineReceiveFilter System object | comm.RaisedCosineTransmitFilter System object

Filter, specified as one of these System objects.

- comm.RaisedCosineReceiveFilter
- comm.RaisedCosineTransmitFilter

### arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: char | string

## Output Arguments

### **filtcost** – Cost estimate

structure

Cost estimate, returned as a structure containing these fields.

Field	Description
NumCoefficients	Number of filter coefficients (excluding coefficients with values 0, 1, or -1)
NumStates	Number of filter states
MultiplicationsPerInputSample	Number of multiplication operations performed for each input sample
AdditionsPerInputSample	Number of addition operations performed for each input sample

Data Types: struct

# info

**Package:** comm

Information about filter System object

## Syntax

```
filtInfo = info(rcfilter)
filtInfo = info(rcfilter,infoType)
filtInfo = info(___, 'Arithmetic', arithType)
```

## Description

`filtInfo = info(rcfilter)` obtains information about the specified filter System object. The type of information returned by the function depends on the filter type and configuration.

`filtInfo = info(rcfilter,infoType)` obtains the amount of filter information as specified by `infoType`.

`filtInfo = info(___, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`. Specify this option with any of the input combinations from previous syntaxes.

For more input options, see the `info` function.

## Examples

### Obtain Raised Cosine Filter Information

Obtain short-format and long-format information about a raised cosine filter.

```
txfilter = comm.RaisedCosineTransmitFilter;
info(txfilter)
```

```
ans = 10x62 char array
'Discrete-Time FIR Multirate Filter (real)
'-----
'Filter Structure      : Direct-Form FIR Polyphase Interpolator'
'Interpolation Factor : 8
'Polyphase Length     : 11
'Filter Length        : 81
'Stable               : Yes
'Linear Phase         : Yes (Type 1)
'
'Arithmetic           : double
```

```
info(txfilter, 'Long')
```

```
ans = 17x62 char array
'Discrete-Time FIR Multirate Filter (real)
'
```

```

'-----'
'Filter Structure      : Direct-Form FIR Polyphase Interpolator'

'Number of Multipliers      : 81
'Number of Adders          : 73
'Number of States          : 10
'Multiplications per Input Sample : 81
'Additions per Input Sample  : 73

```

## Input Arguments

### **rcfilter** — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

### **infoType** — Amount of information to display

'short' (default) | 'long'

Amount of filter information to display, specified as one of these values.

- 'short' -- The function displays the basic filter information. This information is the same as the information output by `info(rcfilter)`.
- 'long' -- The function returns this information about the filter.
  - Specifications such as the filter structure and filter order.
  - Information about the design method and options.
  - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
  - Cost of implementing the filter in terms of operations required to apply the filter to data.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

Data Types: `char` | `string`

### **arithType** — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a

double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

## Output Arguments

### **filtInfo** – Filter information

character array

Filter information, returned as a character array.

- When you set the `infoType` input to 'short', the function displays basic filter information.
- When you set the `infoType` input to 'long', the function displays this.
  - Specifications such as the filter structure and filter order.
  - Information about the design method and options.
  - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
  - Cost of implementing the filter in terms of operations required to apply the filter to data.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter. The information includes the arithmetic setting and details about the filter internals.

# fvtool

**Package:** comm

Plot frequency response of filter

## Syntax

```
fvtool(rcfilter)
fvtool(rcfilter,options)
fvtool(____,Name,Value)
```

## Description

`fvtool(rcfilter)` plots the magnitude response of the specified filter.

`fvtool(rcfilter,options)` plots the response that is specified by options.

For example, to plot the impulse response of the specified filter, set options to 'impulse'.

```
fvtool(rcfilter,'impulse');
```

`fvtool(____,Name,Value)` specifies additional options using one or more name-value arguments in addition to any input argument combination from the previous syntaxes.

For more input options, see the **FVTool** function.

## Examples

### Create Square-Root-Raised-Cosine Transmit Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) transmit filter System object™, and then plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is greater than 0 dB.

```
txfilter = comm.RaisedCosineTransmitFilter;
fvtool(txfilter)
```

Obtain the filter coefficients by using the `coeffs` object function and adjust the filter gain to unit energy.

```
b = coeffs(txfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response again. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(txfilter)
```

## Input Arguments

### rcfilter – Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

### options – Filter analysis options

'magnitude' (default) | 'phase' | 'freq' | 'grpdelay' | 'phasedelay' | 'impulse' | 'step' | 'polezero' | 'coefficients' | 'info' | 'magesestimate' | 'noisepower'

Filter analysis options, specified as one of these values:

- 'magnitude' -- Magnitude response
- 'phase' -- Phase response
- 'freq' -- Frequency response
- 'grpdelay' -- Group delay
- 'phasedelay' -- Phase delay

- 'impulse' -- Impulse response
- 'step' -- Step response
- 'polezero' -- Pole zero plot
- 'coefficients' -- Coefficients vector
- 'info' -- Filter information
- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `fvtool(rcfilter,'Arithmetic','single')`

### **Fs — Sampling rate**

scalar

Sampling rate, specified as a scalar. This value,  $F_s$ , determines the Nyquist interval  $[-F_s/2, F_s/2]$  in which the function shows the frequency response of the filters in the channelizer.

Data Types: `single` | `double`

### **Arithmetic — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Specify the arithmetic used during analysis. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is unlocked. The 'Arithmetic' property set to 'Fixed' applies only to filter System objects with fixed-point properties.

When you specify this argument as 'Fixed', the function plots the double-precision reference filter and the quantized version of the filter. The function uses the `CoefficientsDataType` property of the respective filter System object to create the quantized version of the filter analysis values in options except for these:

- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

For these two analysis options, the function uses all of the fixed-point settings to analyze the quantized version of the filter.

Data Types: `char` | `string`

## freqz

**Package:** comm

Frequency response of discrete-time filter

### Syntax

```
[filtresp,w] = freqz(rcfilter)
[filtresp,w] = freqz(rcfilter,n)
[filtresp,w] = freqz( ____, 'Arithmetic',arithType)

freqz(rcfilter)
```

### Description

`[filtresp,w] = freqz(rcfilter)` returns `filtresp`, the complex frequency response of the specified filter. The output `w` contains the frequencies (in radians per sample) at which the function evaluates the frequency response.

`[filtresp,w] = freqz(rcfilter,n)` returns the complex frequency response of the specified filter and the corresponding frequencies at `n` points that are equally spaced around the upper-half of the unit circle (from 0 to  $\pi$ ).

This function uses the transfer function that is associated with the specified filter to calculate the frequency response of the filter with the current coefficient values.

`[filtresp,w] = freqz( ____, 'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the filter response. You can use any input combination from the previous syntaxes.

`freqz(rcfilter)` plots the magnitude and unwrapped phase of the frequency response of the specified filter by using the `fvtool` object function.

For more input options, see the `freqz` function.

### Examples

#### Evaluate RRC Filter Frequency Response

Evaluate the frequency response of an RRC filter.

Create a transmit RRC filter System object™. Evaluate the frequency response by using the `freqz` object function.

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",30, ...
    "RolloffFactor",0.25);
freqz(rrcFilt)
```

## Input Arguments

### rcfilter – Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

### n – Number of points over which the frequency response is computed

8192 (default) | positive integer

Number of points over which the frequency response is computed, specified as positive integer. For faster computations (performed using FFTs), specify `n` as a power of two.

Data Types: double

### arithType – Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a

double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

## Output Arguments

### **filtresp** — Frequency response

column vector

Frequency response, returned as a complex-valued column vector of length  $n$ . The function evaluates the frequency response at  $n$  points that are equally spaced around the upper-half of the unit circle (from 0 to  $\pi$ ).

Data Types: `double`

### **w** — Frequencies used for frequency response evaluation

column vector

Frequencies used for frequency response evaluation, returned as a column vector of length  $n$ . Units are in radians per sample. The frequencies are equally spaced around the upper-half of the unit circle (from 0 to  $\pi$ ).

Data Types: `double`

## Tips

- Several ways exist for analyzing the frequency response of filters. The `freqz` function accounts for quantization effects in the filter coefficients but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, see the `noisepsd` function.
- For faster computations (performed using FFTs), specify  $n$ , the number of points over which the function computes the frequency response, as a power of two.

## Algorithms

The `freqz` function calculates the frequency response for a filter from the filter transfer function  $Hq(z)$ . The complex-valued frequency response is calculated by evaluating  $Hq(e^{j\omega})$  at discrete values of  $\omega$ . The input argument `n` specifies the number of equally-spaced points around the upper-half of the unit circle at which the function evaluates the frequency response.

- When you do not specify scalar sampling frequency `fs` as an input argument, the frequency ranges from 0 to  $\pi$  radians per sample.
- When you specify scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to `fs/2` Hz. For more information about `fs`, see the `freqz` function.

## grpdelay

**Package:** comm

Group delay response of discrete-time filter

### Syntax

```
[gd,w] = grpdelay(rcfilter)
[gd,w] = grpdelay(rcfilter,n)
[gd,w] = grpdelay( ____, 'Arithmetic', arithType)
```

```
grpdelay(rcfilter)
```

### Description

`[gd,w] = grpdelay(rcfilter)` returns `gd`, the group delay of the specified filter based on the filter coefficients. The output `w` contains the frequencies (in radians per sample) at which the function evaluates the group delay. The group delay is defined as  $-\frac{d}{dw}(\text{angle}(w))$ .

`[gd,w] = grpdelay(rcfilter,n)` returns the group delay of the specified filter and the corresponding frequencies at `n` points that are equally spaced around the upper-half of the unit circle (from 0 to  $\pi$ ).

`[gd,w] = grpdelay( ____, 'Arithmetic', arithType)` computes the group delay of the filter System object, specifies the type of arithmetic that the function uses to compute the group delay. You can use any input combination from the previous syntaxes.

`grpdelay(rcfilter)` plots the group delay of the specified filter by using the `fvtool` object function.

For more input options, see the `grpdelay` function.

### Examples

#### Compute Group Delay of RRC Filter

Compute the group delay of an RRC filter.

```
rcfilter = comm.RaisedCosineTransmitFilter;
gd = grpdelay(rcfilter,32);
gd(1:5)'
```

```
ans = 1×5
```

```
40    40    40    40    40
```

## Input Arguments

### rcfilter — Filter

comm.RaisedCosineReceiveFilter System object | comm.RaisedCosineTransmitFilter System object

Filter, specified as one of these System objects.

- comm.RaisedCosineReceiveFilter
- comm.RaisedCosineTransmitFilter

### n — Number of points over which the group delay is computed

8192 (default) | positive integer

Number of points over which the group delay is computed, specified as a positive integer. For faster computations (performed using FFTs) specify n as a power of two.

Data Types: double

### arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the isLocked function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: char | string

## Output Arguments

### gd — Group delay

column vector

Group delay, returned as a column vector of length  $n$ .

Data Types: `double`

**w — Frequencies used for group delay evaluation**

column vector

Frequencies in radians/sample used for group delay evaluation, returned as a column vector of length  $n$ . Unit are in radians per sample. The frequencies are equally spaced around the upper-half of the unit circle (from 0 to  $\pi$ ).

Data Types: `double`

### Tips

- For faster computations (performed using FFTs), specify  $n$ , the number of points over which the function computes the group delay, as a power of two.

# impz

**Package:** comm

Impulse response of discrete-time filter

## Syntax

```
[impresp,t] = impz(rcfilter)
[impresp,t] = impz(rcfilter,n)
[impresp,t] = impz(rcfilter,n,fs)
[impresp,t] = impz(rcfilter,[],fs)
[impresp,t] = impz( ____, 'Arithmetic',arithType)
```

```
impz(rcfilter)
```

## Description

`[impresp,t] = impz(rcfilter)` returns `impresp`, the impulse response of the specified filter. The output `t` represents the sample intervals and equals `[0 1 2 ...k-1]'`.  $k$  is the number of filter coefficients.

`[impresp,t] = impz(rcfilter,n)` computes the impulse response at `floor(n)` 1 second intervals. In this case, `t` equals `(0:floor(n) - 1)'`.

`[impresp,t] = impz(rcfilter,n,fs)` computes the impulse response at `floor(n)`  $1/fs$  second intervals. In this case, `t` equals `(0:floor(n) - 1)/fs`.

`[impresp,t] = impz(rcfilter,[],fs)` computes the impulse response at  $k$   $1/fs$  second intervals.  $k$  is the number of filter coefficients. In this case, `t` equals `(0:k - 1)/fs`.

`[impresp,t] = impz( ____, 'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the impulse response. You can use any input combination from the previous syntaxes.

`impz(rcfilter)` plots the magnitude and unwrapped phase of the impulse response of the specified filter by using the `fvtool` object function.

You can use the `impz` object function for real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

For more input options, see the Signal Processing Toolbox™ `impz` function.

## Examples

### Evaluate RRC Filter Impulse Response

Evaluate the impulse response of an RRC filter.

Create a transmit RRC filter System object™. Evaluate the impulse response by using the `impz` object function.

```
rcfilter = comm.RaisedCosineTransmitFilter;
impz(rcfilter)
```

## Input Arguments

### **rcfilter** — Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

### **n** — Number of filter coefficients

positive integer

Number of filter coefficients, specified as a positive integer. This value determines the length of the output impulse response vector, `impResp`.

Data Types: double

### **fs** — Sampling frequency

1 (default) | positive scalar

Sampling frequency that the function uses to compute the impulse response, specified as a positive scalar.

Data Types: `double`

### **arithType — Arithmetic type**

`'double'` (default) | `'single'` | `'Fixed'`

Arithmetic used in the filter analysis, specified as `'double'`, `'single'`, or `'Fixed'`. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Fixed'` value applies to filter System objects with fixed-point properties only.

When you specify this input as `'Fixed'` and the filter object has the data type of the coefficients set to `'Same word length as input'`, the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

## **Output Arguments**

### **impresp — Impulse response**

column vector

Impulse response, returned as a column vector of length `n`. If `n` is not specified, the length of the impulse response vector equals the number of coefficients in the filter.

Data Types: `double`

### **t — Sample intervals**

column vector

Sample intervals in seconds, returned as a column vector of equally spaced points. Units are in seconds. The syntax used determines the range of the output.

Data Types: `double`

# order

**Package:** comm

Order of discrete-time filter System object

## Syntax

```
filtOrder = order(rcfilter)
```

## Description

`filtOrder = order(rcfilter)` returns the order of the filter System object. The order depends on the filter structure and the reference double-precision floating-point coefficients.

## Examples

### Determine Group Delay for RRC Filter Pair

Create a square root raised cosine (RRC) filter pair using the `comm.RaisedCosineTransmitFilter` and `comm.RaisedCosineReceiveFilter` System objects. Determine the group delay of the overall filter pair.

```
txrcfilt = comm.RaisedCosineTransmitFilter
```

```
txrcfilt =  
comm.RaisedCosineTransmitFilter with properties:
```

```
           Shape: 'Square root'  
           RolloffFactor: 0.2000  
           FilterSpanInSymbols: 10  
           OutputSamplesPerSymbol: 8  
           Gain: 1
```

```
rxrcfilt = comm.RaisedCosineReceiveFilter
```

```
rxrcfilt =  
comm.RaisedCosineReceiveFilter with properties:
```

```
           Shape: 'Square root'  
           RolloffFactor: 0.2000  
           FilterSpanInSymbols: 10  
           InputSamplesPerSymbol: 8  
           DecimationFactor: 8  
           DecimationOffset: 0  
           Gain: 1
```

```
groupDelay = order(txrcfilt)/2 + order(rxrcfilt)/2
```

```
groupDelay = 80
```

## Input Arguments

### **rcfilter** — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

## Output Arguments

### **filtOrder** — Filter order

scalar

Filter order, returned as a scalar. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Data Types: `double`

## Version History

Introduced in R2013b

# info

**Package:** comm

Information about FM broadcast modulator or demodulator

## Syntax

```
fmbInfo = info(fmb)
```

## Description

`fmbInfo = info(fmb)` returns a structure containing information for the `comm.FMBroadcastModulator` or `comm.FMBroadcastDemodulator` System object

---

### Note

- The modulator input sequence length for the audio input must be a multiple of `AudioDecimationFactor`.
  - The modulator input sequence length for the RDS/RBDS input must be a multiple of `RBDSDecimationFactor`.
  - When `RBDS` is `true`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor` and `RBDSDecimationFactor`.
  - When `RBDS` is `false`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor`.
- 

## Examples

### Modulate and Demodulate Streaming Audio Signals Using FM Broadcast Method

Modulate and demodulate an audio signal with the FM broadcast modulator and demodulator System objects. Plot the frequency responses to compare the input and demodulated audio signals.

Load the audio file `guitartune.wav` by using an audio file reader System object™. Set the samples per frame to 44,100, which is large enough to include the entire audio file.

```
audiofilereader = dsp.AudioFileReader("guitartune.wav", ...
    SamplesPerFrame=44100);
x = audiofilereader();
```

Create spectrum analyzer System objects to plot the spectra of the modulated and demodulated signals.

```
saFM = spectrumAnalyzer( ...
    SampleRate=152e3, ...
```

```

    Title="FM Broadcast Signal");
saAudio = spectrumAnalyzer( ...
    SampleRate=44100, ...
    ShowLegend=true, ...
    Title="Audio Signal", ...
    ChannelNames=["Input signal" "Demodulated signal"]);

```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Configure the demodulator to match the specified modulator.

```

fmbMod = comm.FMBroadcastModulator( ...
    AudioSampleRate=audiofilereader.SampleRate, ...
    SampleRate=200e3);
fmbDemod = comm.FMBroadcastDemodulator(fmbMod)

```

```

fmbDemod =
comm.FMBroadcastDemodulator with properties:

    SampleRate: 200000
    FrequencyDeviation: 75000
    FilterTimeConstant: 7.5000e-05
    AudioSampleRate: 44100
    PlaySound: false
    Stereo: false
    RBDS: false

```

The length of the sequence input to the object must be an integer multiple of the decimation factor. To determine the audio decimation factor of the filter in the modulator and demodulator, use the `info` object function.

```
info(fmbMod)
```

```

ans = struct with fields:
    AudioDecimationFactor: 441
    AudioInterpolationFactor: 2000
    RBDSDecimationFactor: 19
    RBDSInterpolationFactor: 320

```

```
info(fmbDemod)
```

```

ans = struct with fields:
    AudioDecimationFactor: 50
    AudioInterpolationFactor: 57
    RBDSDecimationFactor: 50
    RBDSInterpolationFactor: 57

```

The audio decimation factor of the modulator is a multiple of the audio frame length of 44,100. The audio decimation factor of the demodulator is an integer multiple of the 200,000 samples data sequence length of the modulator output.

Modulate the audio signal and plot the spectrum of the modulated signal.

```

y = fmbMod(x);
saFM(y)

```

Demodulate the modulated audio signal and plot the resultant spectrum. Compare the input signal spectrum with the demodulated signal spectrum. The spectra are similar except that the demodulated signal has smaller high-frequency components.

```
z = fmbDemod(y);
saAudio([x z])
```

## Input Arguments

### fmb — FM broadcast object

`comm.FMBroadcastModulator` System object | `comm.FMBroadcastDemodulator` System object

FM broadcast object, specified as one of these System objects.

- `comm.FMBroadcastModulator`
- `comm.FMBroadcastDemodulator`

## Output Arguments

### fmbInfo — FM broadcast object information

structure

FM broadcast object information, returned as a structure containing these fields.

Field	Description
<code>AudioDecimationFactor</code>	Decimation factor of the audio modulator or demodulator filter.

<b>Field</b>	<b>Description</b>
AudioInterpolationFactor	Interpolation factor of the audio modulator or demodulator filter.
RBDSDecimationFactor	Decimation factor of the RDS/RBDS modulator or demodulator filter.
RBDSInterpolationFactor	Interpolation factor of the RDS/RBDS modulator or demodulator filter.

## info

**Package:** comm

Characteristic information of GPU-based Viterbi decoder

### Syntax

```
infostruct = info(gpuVitDec)
```

### Description

`infostruct = info(gpuVitDec)` returns characteristic information of the specified graphics processing unit (GPU) based Viterbi decoder.

### Examples

#### Get Characteristic Information of GPU-based Viterbi Decoder

Create a GPU-based Viterbi decoder System object™ that accepts an input vector of hard decision values, which are zeros or ones.

```
gpuVitDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Get the characteristic information of the GPU-based Viterbi decoder.

```
infostruct = info(gpuVitDec)  
  
infostruct = struct with fields:  
    AcquisitionDepth: 70
```

### Input Arguments

#### **gpuVitDec** — GPU-based Viterbi decoder

`comm.gpu.ViterbiDecoder` System object

GPU-based Viterbi decoder, specified as a `comm.gpu.ViterbiDecoder` System object.

### Output Arguments

#### **infostruct** — Characteristic information

structure

Characteristic information of the input GPU-based Viterbi decoder, returned as a structure that contains this field.

#### **AcquisitionDepth** — Acquisition depth used in GPU implementation

integer

Acquisition depth used in the GPU implementation, returned as an integer.

The acquisition depth is the number of depunctured codewords that are used to overlap subsequences of the received data in the GPU implementation of the Viterbi decoder. For unpunctured codes, `AcquisitionDepth` is the greater of ten times the constraint length or two times the `TracebackDepth` property of the decoder. For punctured codes, `AcquisitionDepth` is scaled by a multiple of the number of codewords in the puncture pattern vector.

## Version History

Introduced in R2012a

## hide

**Package:** comm

Hide scope window

### Syntax

```
hide(scope)
```

### Description

`hide(scope)` hides the window of the System object scope.

### Examples

#### Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

#### Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

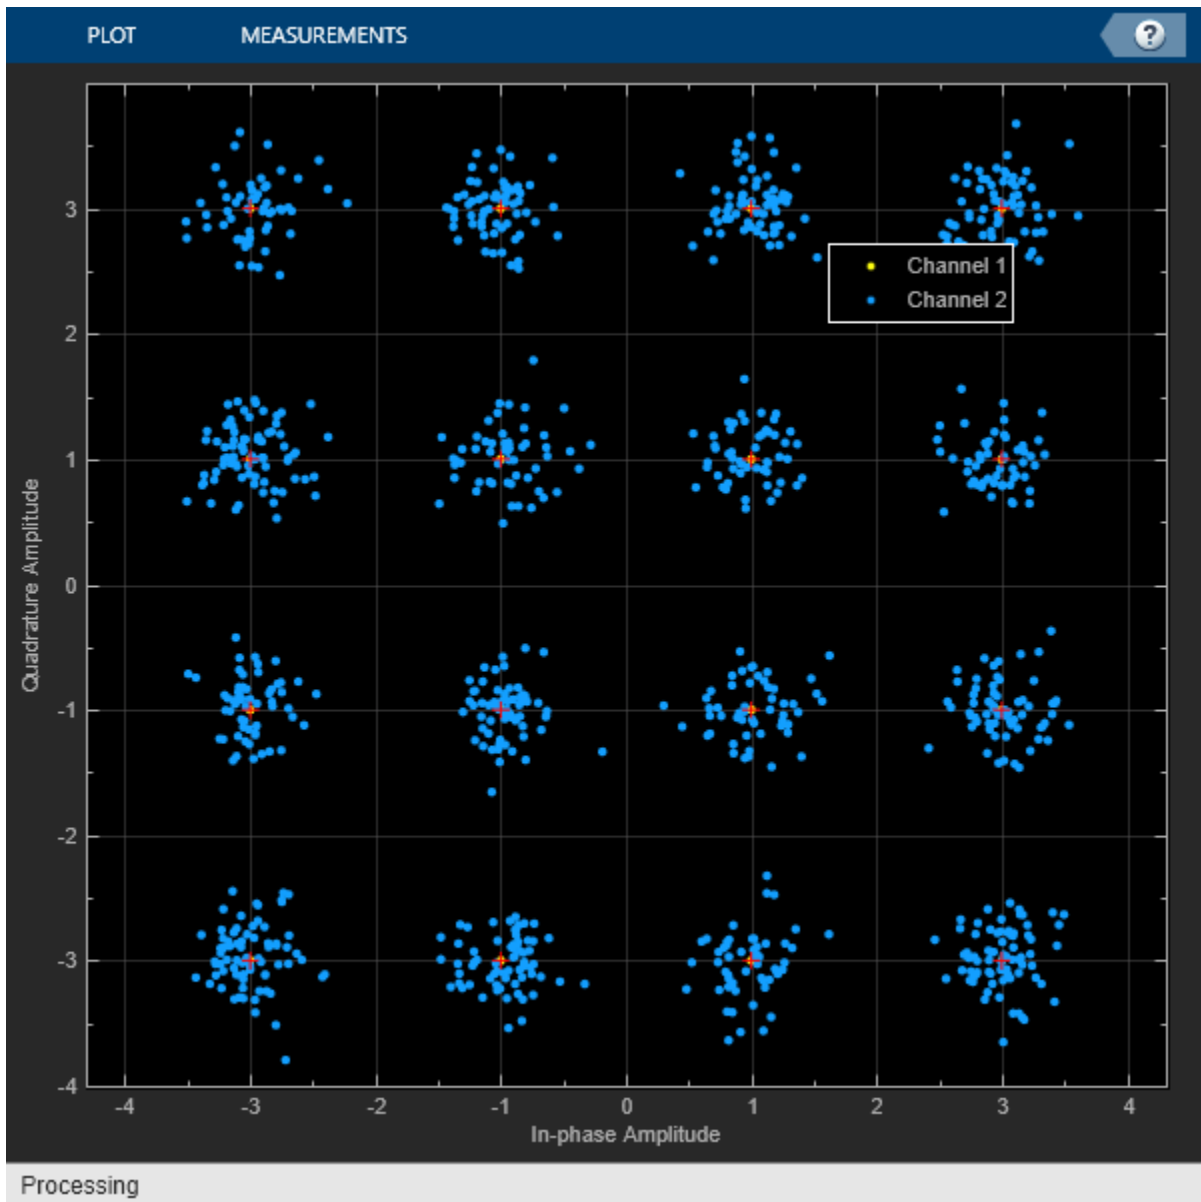

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

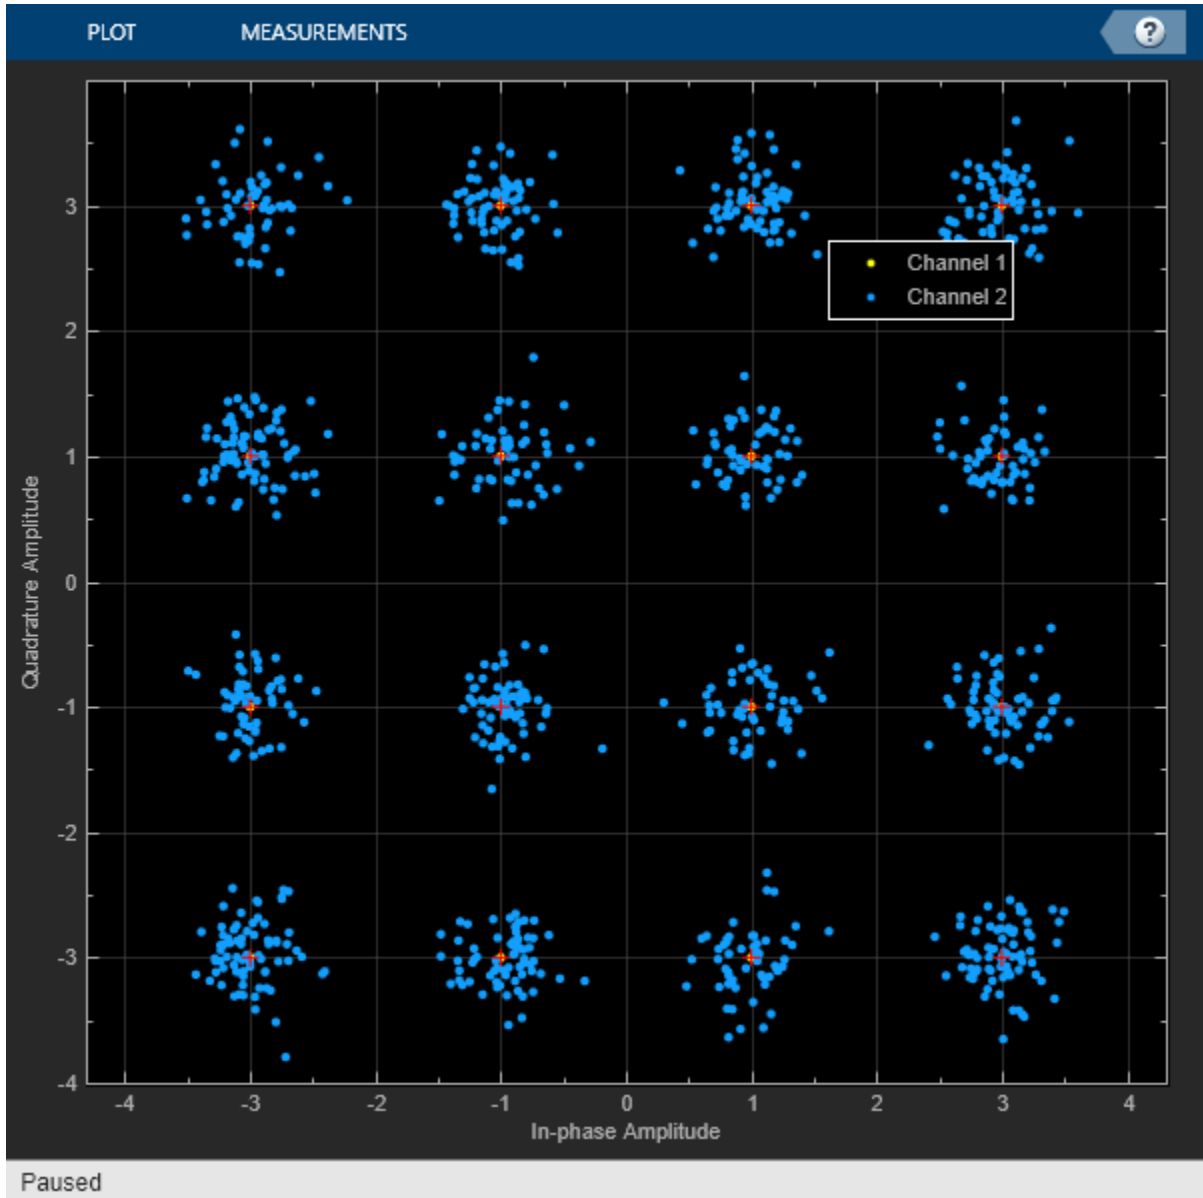

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

### **scope — Scope System object**

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

## Version History

Introduced in R2013a

## isVisible

**Package:** comm

Determine visibility of scope window

### Syntax

```
visibility = isVisible(scope)
```

### Description

`visibility = isVisible(scope)` returns a logical to verify in the System object scope is open. `visibility` is 1 if the scope window is open and 0 otherwise.

### Examples

#### Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

#### Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

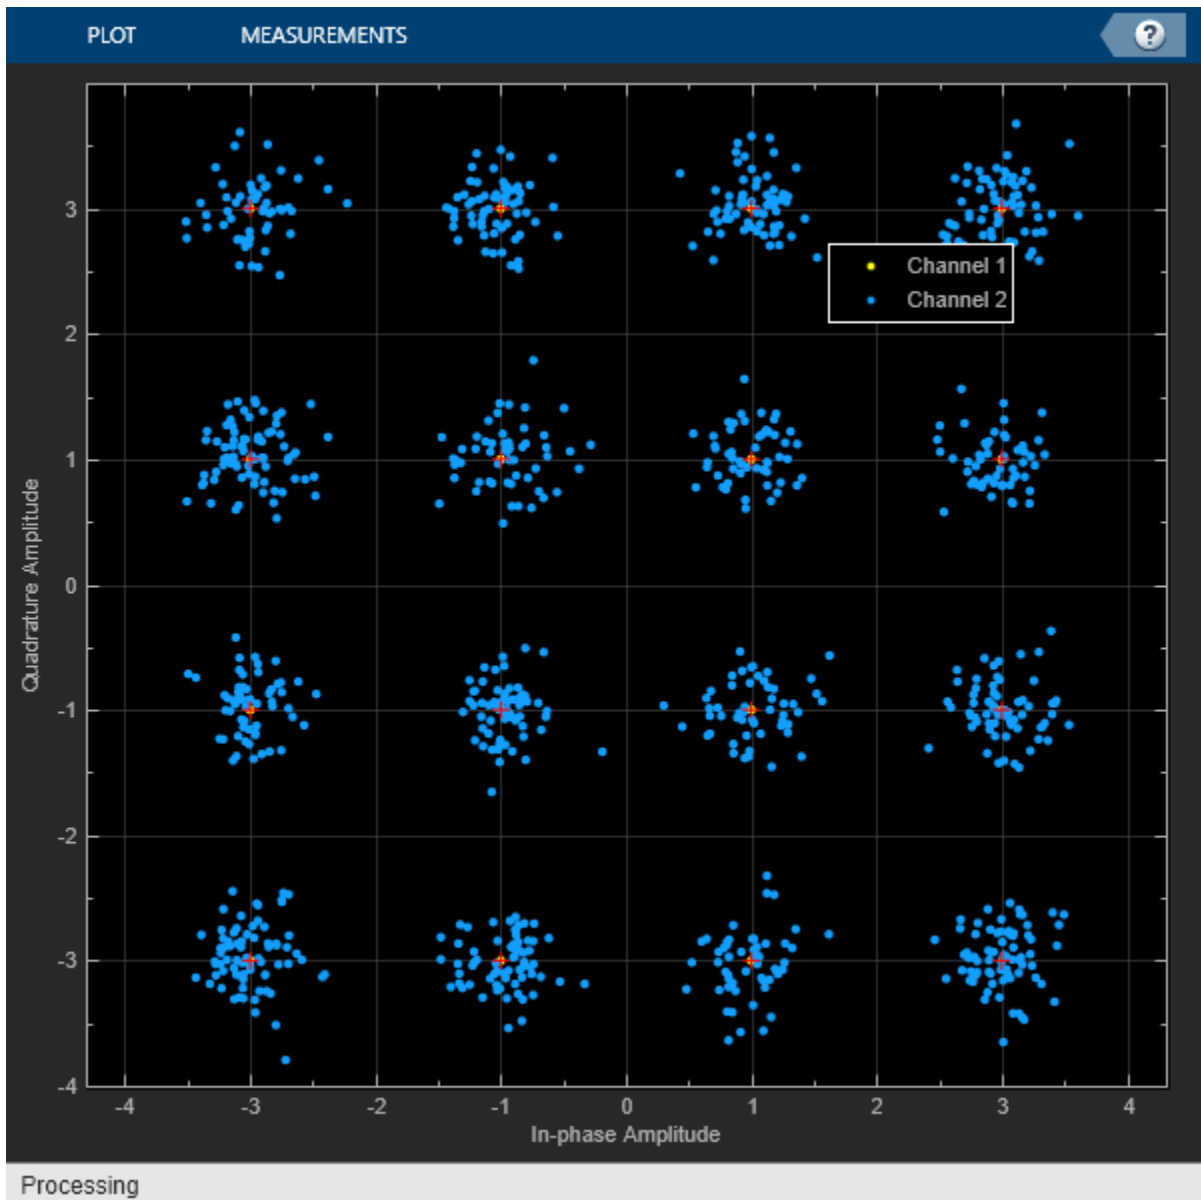

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## Input Arguments

### **scope — Scope System object**

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

**Package:** comm

Characteristic information about multiband combining

### Syntax

```
mbcInfo = info(multibandcombiner)
```

### Description

`mbcInfo = info(multibandcombiner)` returns a structure containing characteristic information about the multiband combiner.

### Examples

#### Show Multiband Combiner Characteristic Information

Create a multiband combiner System object™ and show the characteristic information for the configured object.

Create a multiband combine object. Use the `info` object function to view the characteristic information.

```
mutlibandcombiner = comm.MultibandCombiner()
```

```
mutlibandcombiner =  
    comm.MultibandCombiner with properties:
```

```
        InputSampleRate: 1000000  
        FrequencyOffsets: [0 1000000]  
        OutputSampleRateSource: 'Auto'
```

```
info(mutlibandcombiner)
```

```
ans = struct with fields:  
    OutputSampleRate: 3000000  
        Delay: 36
```

### Input Arguments

**multibandcombiner** — Multiband combiner

`comm.MultibandCombiner` System object

Multiband combiner, specified as a `comm.MutlibandCombiner` System object.

---

## Output Arguments

### **mbcInfo — Multiband combiner characteristic information**

structure

Multiband combiner characteristic information, returned as a structure containing these fields. The multiband combiner is specified by the input `multibandcombiner`.

### **OutputSampleRate — Sample rate of output signal**

positive scalar

Sample rate of the output signal in Hz, returned as a positive scalar.

### **Delay — Delay between input and output**

positive scalar

Delay between input and output signals in samples at the output sampling rate.

## Version History

**Introduced in R2021b**

## See Also

### **Objects**

`comm.MultibandCombiner`

### **Functions**

## plot

**Package:** comm

Plot nonlinearity AM/AM and AM/PM characteristics

### Syntax

```
plot(mnl)
plot(mnl, 'Gain')
mnlplot = plot( __ )
```

### Description

`plot(mnl)` plots the output signal power and the phase change versus the input signal power. This syntax is equivalent to `plot(mnl, 'Pout')`.

`plot(mnl, 'Gain')` plots the gain and the phase change versus the input signal power.

`mnlplot = plot( __ )` returns a handle to the figure containing the generated plot. Specify an input argument combination from any of the previous syntaxes.

### Examples

#### Plot Output Response for Amplifier Model

Plot the amplifier output power and phase response for various model methods.

Create a memoryless nonlinearity impairment System object™ for each of the nonlinearity modeling methods.

```
ampCubicPoly= comm.MemorylessNonlinearity('Method','Cubic polynomial');
ampHyperbolic = comm.MemorylessNonlinearity('Method','Hyperbolic tangent');
ampGhorbani = comm.MemorylessNonlinearity('Method','Ghorbani model');
ampSaleh = comm.MemorylessNonlinearity('Method','Saleh model');
ampModRapp = comm.MemorylessNonlinearity('Method','Modified Rapp model');
ampLookupTable = comm.MemorylessNonlinearity('Method','Lookup table','ReferenceImpedance',50);
```

Use the `plot` object function of the `comm.MemorylessNonlinearity` System object to show the response curves for the output power and phase for the each of the amplifier models.

```
plot(ampCubicPoly);
```

plot(ampHyperbolic);

```
plot(ampSaleh);
```

```
plot(ampLookupTable);
```

```
plot(ampGhorbani);
```

```
plot(ampModRapp);
```

## Input Arguments

### **mnl** — Memoryless nonlinearity

`comm.Memoryless Nonlinearity System` object

Memoryless nonlinearity, specified as a `comm.MemorylessNonlinearity System` object.

## Output Arguments

### **mnlplot** — Plot figure

Figure object

Plot figure, returned as a Figure object created using the `figure` function. Use the Figure object to query or modify properties of the figure after it is created.

## Version History

Introduced in R2021a

## See Also

`comm.MemorylessNonlinearity`

# constellation

**Package:** comm

Calculate or plot ideal signal constellation

## Syntax

```
symbols = constellation(obj)
constellation(obj)
```

## Description

`symbols = constellation(obj)` returns the numerical values of the constellation.

`constellation(obj)` generates a constellation plot for the object.

## Examples

### Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4×1 complex
```

```
 0.7071 + 0.7071i
-0.7071 + 0.7071i
-0.7071 - 0.7071i
 0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Reconfigure the object for bit input and plot the constellation to show the binary values of the Gray-encoded mapping.

```
release(mod)
mod.BitInput = true;
constellation(mod)
```

Create a QPSK demodulator having phase offset set to  $\theta$ .

```
demod = comm.QPSKDemodulator(theta);
```

Plot the reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

### Plot PSK Reference Constellation

Create a PSK modulator.

```
mod = comm.PSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 8×1 complex
```

```
0.9239 + 0.3827i
0.3827 + 0.9239i
-0.3827 + 0.9239i
-0.9239 + 0.3827i
-0.9239 - 0.3827i
-0.3827 - 0.9239i
0.3827 - 0.9239i
0.9239 - 0.3827i
```

Plot the constellation.

```
constellation(mod)
```

Create a PSK demodulator having modulation order 16.

```
demod = comm.PSKDemodulator(16);
```

Plot its reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

### Plot BPSK Reference Constellation

Create a BPSK modulator.

```
mod = comm.BPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 2x1 complex
```

```
1.0000 + 0.0000i  
-1.0000 + 0.0000i
```

Plot the constellation.

```
constellation(mod)
```

Create a BPSK demodulator having phase offset set to  $\frac{\pi}{2}$ .

```
demod = comm.BPSKDemodulator(pi/2);
```

Determine the reference constellation points.

```
refC = constellation(demod)
```

```
refC = 2x1 complex
```

```
0.0000 + 1.0000i
```

```
-0.0000 - 1.0000i
```

Plot the reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

## Input Arguments

**obj** — System object to return constellation for

System object

System object to return constellation for, specified as a modulator System object.

Data Types: object

## Output Arguments

**symbols** — Constellation points

complex vector (default)

Constellation points, returned as a complex vector.

Data Types: double | single

Complex Number Support: Yes

## Version History

Introduced in R2012a

## info

**Package:** comm

Provide dimensioning information for OFDM modulator

### Syntax

```
S = info(obj)
```

### Description

`S = info(obj)` returns a structure with fields that identify the input and output signal dimensions for the `comm.OFDMModulator` System object, `obj`.

### Examples

#### Determine OFDM Modulator Data Dimensions

Get the OFDM modulator data dimensions by using the `info` object function.

Create an OFDM modulator object with pilot indices, a DC null, and two transmit antennas.

```
ofdmMod = comm.OFDMModulator( ...  
    NumGuardBandCarriers=[4; 3], ...  
    PilotInputPort=true, ...  
    PilotCarrierIndices=cat(3,[12; 26; 40; 54],[11; 25; 39; 53]), ...  
    InsertDCNull=true, ...  
    NumTransmitAntennas=2);
```

Use the `info` object function to get the modulator input data, pilot input data, and output data sizes.

```
info(ofdmMod)  
  
ans = struct with fields:  
    DataInputSize: [48 1 2]  
    PilotInputSize: [4 1 2]  
    OutputSize: [80 2]
```

### Input Arguments

**obj** — System object to return dimensional information for

`comm.OFDMModulator`

System object to return dimensional information for, specified as a `comm.OFDMModulator` System object.

## Output Arguments

### S — Dimensions for OFDM modulator signals

structure

Dimensions for OFDM modulator signals, returned as a structure with fields that identify the input and output signal dimensions for the `comm.OFDMModulatorSystem` object, `obj`.

### DataInputSize — Dimensions of input data signal

column vector

Dimensions of input data signal, returned as a column vector. The element values are computed as  $[N_{\text{Data}}, N_{\text{Sym}}, N_{\text{T}}]$ , based on the configuration of the input `obj`.

For variable definitions, see “List of Variables” on page 4-99.

Data Types: `double`

### PilotInputSize — Dimensions of pilot input signal

column vector

Dimensions of the pilot input signal, returned as a column vector. The element values are computed as  $[N_{\text{Pilot}}, N_{\text{Sym}}, N_{\text{T}}]$ , based on the configuration of the input `obj`.

For variable definitions, see “List of Variables” on page 4-99.

Data Types: `double`

### OutputSize — Modulator output dimensions

column vector

Modulator output signal matrix dimensions, returned as a column vector. The element values are computed as  $[(N_{\text{CPTotal}} + (N_{\text{FFT}} \times N_{\text{Sym}})), N_{\text{T}}]$ , based on the configuration of the input `obj`.

For variable definitions, see “List of Variables” on page 4-99.

Data Types: `double`

Data Types: `struct`

## More About

### List of Variables

These variables describe the dimensions of the input and output signals for the `comm.OFDMModulatorSystem` object.

Variable	Description
$N_{\text{Data}}$	Number of data subcarriers, such that $N_{\text{Data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{Pilot}} - N_{\text{CustNull}}$ .
$N_{\text{FFT}}$	Number of subcarriers, <code>obj.FFTLength</code> .
$N_{\text{leftG}}$ and $N_{\text{rightG}}$	Left and right guard bands specified by <code>obj.NumGuardBandCarriers</code> .

Variable	Description
$N_{\text{DCNull}}$	Number of DC null subcarriers specified as either 0 or 1, <code>obj.InsertDCNull</code> .
$N_{\text{Pilot}}$	Number of pilot subcarriers. <ul style="list-style-type: none"> <li>When you set <code>obj.PilotOutputPort</code> to 1, <math>N_{\text{Pilot}} = \text{size}(\text{obj.PilotCarrierIndices}, 1)</math>.</li> <li>When you set <code>obj.PilotOutputPort</code> to 0, <math>N_{\text{Pilot}} = 0</math> for the calculation of <math>N_{\text{Data}}</math>.</li> </ul>
$N_{\text{CustNull}}$	Number of subcarriers used for custom nulls. This variable applies only when the <code>obj.PilotCarrierIndices</code> is a 3D array.
$N_{\text{Sym}}$	Number of symbols, <code>obj.NumSymbols</code> .
$N_{\text{T}}$	Number of receive antennas, <code>obj.NumTransmitAntennnas</code> .
$N_{\text{CPTotal}}$	Cyclic prefix length over all the symbols. <ul style="list-style-type: none"> <li><math>N_{\text{CP}}</math> represents the cyclic prefix length as determined by <code>obj.CyclicPrefixLength</code>.</li> <li>When <code>obj.CyclicPrefixLength</code> is a scalar, <math>N_{\text{CPTotal}} = N_{\text{CP}} \times N_{\text{Sym}}</math>.</li> <li>When <code>obj.CyclicPrefixLength</code> is a row vector, <math>N_{\text{CPTotal}} = \sum N_{\text{CP}}</math>.</li> </ul>

Provide dimensioning information for OFDM demodulator

## Syntax

```
S = info(obj)
```

## Description

`S = info(obj)` returns a structure with fields that identify the input and output signal dimensions for the `comm.OFDMDemodulator` System object, `obj`.

## Examples

### Create and Modify OFDM Demodulator

Create an OFDM demodulator System object™ with default properties. Modify some of the properties. Inspect the object configuration by using the `info` object function.

```
ofdmDemod = comm.OFDMDemodulator

ofdmDemod =
  comm.OFDMDemodulator with properties:

      FFTLength: 64
  NumGuardBandCarriers: [2x1 double]
      RemoveDCCarrier: false
      PilotOutputPort: false
  CyclicPrefixLength: 16
  OversamplingFactor: 1
      NumSymbols: 1
  NumReceiveAntennas: 1

info(ofdmDemod)

ans = struct with fields:
      InputSize: [80 1]
      DataOutputSize: [53 1]
```

Modify the number of subcarriers, symbols, and receive antennas. Also enable the pilot output.

```
ofdmDemod.FFTLength = 128;
ofdmDemod.PilotOutputPort = 1;
ofdmDemod.NumSymbols = 2;
ofdmDemod.NumReceiveAntennas = 2;
```

Verify that the number of subcarriers and the number of symbols changed. Reinspect the input and output signal dimensions by using the `info` object function. Notice the addition of the pilot output

dimensions to the information structure. because the number of receive antennas is greater than 1, the data and pilot output dimensions are 3D arrays rather than matrices.

`ofdmDemod`

```
ofdmDemod =  
    comm.OFDMDemodulator with properties:
```

```
        FFTLength: 128  
    NumGuardBandCarriers: [2x1 double]  
        RemoveDCCarrier: false  
        PilotOutputPort: true  
    PilotCarrierIndices: [4x1 double]  
    CyclicPrefixLength: 16  
    OversamplingFactor: 1  
        NumSymbols: 2  
    NumReceiveAntennas: 2
```

`info(ofdmDemod)`

```
ans = struct with fields:  
    InputSize: [288 2]  
    DataOutputSize: [113 2 2]  
    PilotOutputSize: [4 2 2]
```

## Input Arguments

**obj** — System object to return dimensional information for

`comm.OFDMDemodulator`

System object to return dimensional information for, specified as a `comm.OFDMDemodulator` System object.

Data Types: object

## Output Arguments

**S** — Dimensions for OFDM demodulator signals

structure

Dimensions for OFDM demodulator signals, returned as a structure with fields that identify the dimensions of the input and output signals for the OFDM demodulator object, `obj`.

**InputSize** — Demodulator input data dimensions

column vector

Demodulator input signal dimensions, specified as a column vector. The element values are computed as  $[(N_{\text{CPTotal}} + (N_{\text{FFT}} \times N_{\text{Sym}})), N_{\text{R}}]$ , based on the configuration of the input `obj`.

For variable definitions, see “List of Variables” on page 4-103.

Data Types: double

**OutputDataSize – Dimensions of output data signal**

column vector

Dimensions of output data signal, specified as a column vector. The element values are computed as  $[N_{\text{Data}}, N_{\text{Sym}}, N_{\text{R}}]$ , based on the configuration of the input obj.

For variable definitions, see “List of Variables” on page 4-103.

Data Types: double

**OutputPilotSize – Dimensions of pilot output signal**

column vector

Dimensions of the pilot output signal, specified as a column vector. The element values are computed as  $[N_{\text{Pilot}}, N_{\text{Sym}}, N_{\text{R}}]$ , based on the configuration of the input obj.

For variable definitions, see “List of Variables” on page 4-103.

Data Types: double

**More About****List of Variables**

These variables describe the dimensions of the input and output signals for the comm.OFDMDemodulator System object.

Variable	Description
$N_{\text{Data}}$	Number of data subcarriers, such that $N_{\text{Data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{Pilot}} - N_{\text{CustNull}}$ .
$N_{\text{FFT}}$	Number of subcarriers, obj.FFTLength.
$N_{\text{leftG}}$ and $N_{\text{rightG}}$	Left and right guard bands specified by obj.NumGuardBandCarriers.
$N_{\text{DCNull}}$	Number of DC null subcarriers specified as either 0 or 1, obj.InsertDCNull.
$N_{\text{Pilot}}$	Number of pilot subcarriers. <ul style="list-style-type: none"> <li>When you set obj.PilotOutputPort to 1, <math>N_{\text{Pilot}} = \text{size}(\text{obj.PilotCarrierIndices}, 1)</math>.</li> <li>When you set obj.PilotOutputPort to 0, <math>N_{\text{Pilot}} = 0</math> for the calculation of <math>N_{\text{Data}}</math>.</li> </ul>
$N_{\text{CustNull}}$	Number of subcarriers used for custom nulls. This variable applies only when the obj.PilotCarrierIndices is a 3D array.
$N_{\text{Sym}}$	Number of symbols, obj.NumSymbols.

Variable	Description
$N_R$	Number of receive antennas, <code>obj.NumReceiveAntennnas</code> .
$N_{CP\text{Total}}$	Cyclic prefix length over all the symbols. <ul style="list-style-type: none"> <li>• <math>N_{CP}</math> represents the cyclic prefix length as determined by <code>obj.CyclicPrefixLength</code>.</li> <li>• When <code>obj.CyclicPrefixLength</code> is a scalar, <math>N_{CP\text{Total}} = N_{CP} \times N_{\text{Sym}}</math>.</li> <li>• When <code>obj.CyclicPrefixLength</code> is a row vector, <math>N_{CP\text{Total}} = \sum N_{CP}</math>.</li> </ul>

# showResourceMapping

**Package:** comm

Show subcarrier mapping of OFDM symbols created by OFDM modulator or demodulator System object

## Syntax

```
showResourceMapping(obj)
showResourceMapping(obj, freqIndex)
showResourceMapping(obj, freqIndex, antennaIndex)
```

## Description

`showResourceMapping(obj)` shows a visualization of the subcarrier mapping for the OFDM symbols used by the OFDM modulator or demodulator System object.

`showResourceMapping(obj, freqIndex)` shows the resource mapping with custom y-axis labeling specified by `freqIndex`.

`showResourceMapping(obj, freqIndex, antennaIndex)` displays subcarrier mapping plots for selected transmit antennas indicated by `antennaIndex`. This syntax applies only when each transmit antenna has its own mapping plot, specifically, when the `PilotCarrierIndices` property of `obj` is a 3D array.

## Examples

### Visualize Time-Frequency Resource Assignments for OFDM Modulator

The `showResourceMapping` object function displays the time-frequency resource mapping for each transmit antenna.

Create an OFDM modulator.

```
ofdmMod = comm.OFDMModulator;
```

Apply the `showResourceMapping` object function.

```
showResourceMapping(ofdmMod)
```

Insert a DC null.

```
ofdmMod.InsertDCNull = true;
```

Show the resource mapping after adding the DC null.

```
showResourceMapping(ofdmMod)
```

## Input Arguments

### **obj** — System object to plot resource mapping for

`comm.OFDMModulator` | `comm.OFDMDemodulator`

System object to plot resource mapping for, specified as a `comm.OFDMModulator` or `comm.OFDMDemodulator` System object.

Data Types: object

### **freqIndex** — Custom y-axis frequency subcarrier index

[1, FFTLength (default)] | 2-element row vector

Custom y-axis frequency subcarrier index, specified as a two-element row vector of integers so that  $\text{freqIndex}(2) - \text{freqIndex}(1) = \text{FFTLength} - 1$ . Numbering of the y-axis spans the range  $[\text{freqIndex}(1), \text{freqIndex}(2)]$ .

### **antennaIndex** — List of indices indicating antennas

1 (default) | integer scalar | row vector

List of indices indicating which antennas to plot resource mapping for, specified as a positive, integer scalar or row vector of unique integer values in the range  $[1, N_{\text{Ant}}]$ , where  $N_{\text{Ant}}$  is the number of antennas specified by the input `obj`. The number of elements in `antennaIndex` cannot exceed 16.

- When the input is a `comm.OFDMModulator` object, this property indicates indices for the desired transmit antennas.
- When the input is a `comm.OFDMDemodulator` object, this property indicates indices for the desired receive antennas.

### Functions

`info` | `info`

# visualize

**Package:** comm

Visualize spectrum mask of phase noise

## Syntax

```
visualize(phznoise)
```

## Description

`visualize(phznoise)` displays the magnitude response of the filter defined by the `comm.PhaseNoise` System object. The function uses the **FVTool** function to display the magnitude response.

## Examples

### Visualize Spectrum Mask of Phase Noise

Create a phase noise object and display the spectral mask.

```
pnoise = comm.PhaseNoise( ...  
    Level=[-40 -70], ...  
    FrequencyOffset=[100 200], ...  
    SampleRate=1000);  
visualize(pnoise)
```

### Input Arguments

#### **phznoise** — Phase noise

`comm.PhaseNoise` System object

Phase noise that defines the spectrum mask that is displayed, specified as a `comm.PhaseNoise` System object.

## info

**Package:** comm

Characteristic information about ray-tracing channel

## Syntax

```
chanInfo = info(rtchan)
```

## Description

`chanInfo = info(rtchan)` returns a structure containing characteristic information about the input ray-tracing channel.

## Examples

### Return Information for Ray-Tracing Channel Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, China, build a multipath channel model using the ray-tracing result, and view the ray-tracing channel information.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the osm file, see [1] on page 4-112.

```
sv = siteviewer("Buildings","hongkong.osm");
```

Create transmitter and receiver sites.

```
tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ... % azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ... % azimuth angle
    "AntennaHeight",1);
```

Create a ray tracing model that calculates paths with up to 3 reflections. By default, ray tracing models use the shooting and bouncing rays (SBR) method. Then, perform the ray tracing analysis.

```
pm = propagationModel("raytracing", "MaxNumReflections",3);
rays = raytrace(tx,rx,pm);
```

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites. Return information from the ray-tracing channel.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
info(rtchan)
```

```
ans = struct with fields:
    CarrierFrequency: 2.8000e+10
    CoordinateSystem: 'Geographic'
    TransmitArrayLocation: [3×1 double]
    ReceiveArrayLocation: [3×1 double]
    NumTransmitElements: 1
    NumReceiveElements: 1
    ChannelFilterDelay: 4
    ChannelFilterCoefficients: [11×30 double]
    NumSamplesProcessed: 0
    LastFrameTime: 0
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### **rtchan** — Ray-tracing channel

`comm.RayTracingChannel` System object

Ray-tracing channel, specified as a `comm.RayTracingChannel` System object.

## Output Arguments

### **chanInfo — Ray tracing channel characteristic information**

structure

Ray tracing channel characteristic information, returned as a structure containing these fields. The ray tracing channel is specified by the input `rtchan`.

### **CarrierFrequency — Carrier frequency**

positive scalar

Carrier frequency in Hz, returned as a positive scalar.

### **CoordinateSystem — Coordinate system**

'Cartesian' | 'Geographic'

Coordinate system, returned as 'Cartesian' or 'Geographic'. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `CoordinateSystem` property setting.

#### **Dependencies**

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

### **TransmitArrayLocation — Transmit array location**

three element column vector

Transmit array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `TransmitterLocation` property setting.

#### **Dependencies**

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

### **ReceiveArrayLocation — Receive array location**

three element column vector

Receive array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `ReceiverLocation` property setting.

#### **Dependencies**

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

### **NumTransmitElements — Number of elements in transmit array**

positive integer

Number of elements in the transmit array, returned as a positive integer.

### **NumReceiveElements — Number of elements in receive array**

positive integer

Number of elements in the receive array, returned as a positive integer.

**ChannelFilterDelay — Channel filter delay**

nonnegative integer

Channel filter delay in samples, returned as a nonnegative integer.

**ChannelFilterCoefficients — Channel filter coefficients**

$N_P$ -by- $N_H$  matrix

Channel filter coefficients, returned as an  $N_P$ -by- $N_H$  matrix. This coefficient matrix is used to convert channel impulse responses to channel filter tap gains for each sample, and then for each pair of transmit and receive antenna elements.  $N_P$  is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property of the `rtchan` input).  $N_H$  is the number of impulse response samples (specifically, the number of channel filter taps).

**NumSamplesProcessed — Number of samples processed by channel object**

nonnegative integer

Number of samples processed by the channel object since its last reset, returned as a nonnegative integer.

**LastFrameTime — End time of last frame**

nonnegative integer

End time of last frame in seconds, returned as a nonnegative integer.

## Version History

Introduced in R2020b

**Objects**

`arrayConfig` | `comm.Ray` | `comm.RayTracingChannel`

**Functions**

`showProfile`

# showProfile

**Package:** comm

Plot temporal and spatial profiles of ray-tracing channel

## Syntax

```
showProfile(rtchan)
showProfile(rtchan, 'ArrayPattern', false)
```

## Description

`showProfile(rtchan)` plots the power delay profile (PDP), angle of departure (AoD), and angle of arrival (AoA) information for the ray-tracing channels in a single figure with three subplots.

- The PDP subplot is derived from the propagation delay, path loss, phase shift, pattern gain at transmit array and pattern gain at receive array for each ray specified by the `PropagationRays` property of the `rtchan` input.
- The AoD and AoA subplots show the 3-D directions of the rays in the local coordinate system (LCS).
  - When the `TransmitArray` or `ReceiveArray` properties are objects from the “Phased Array System Toolbox” software, the AoD and AoA subplots also show the directivity pattern of the arrays.

`showProfile(rtchan, 'ArrayPattern', false)` optionally turns off the directivity pattern in the AoD and AoA subplots. This option applies only when the `TransmitArray` or `ReceiveArray` property in the `comm.RayTracingChannel` System object are objects from the “Phased Array System Toolbox” software.

## Examples

### Show Temporal and Spatial Profiles of Ray-Tracing Channel

Perform ray-tracing between two sites in Chicago. Build a multipath channel model using the ray tracing result, and show the temporal and spatial profiles of the channel.

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-118.

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site, a receiver site, and a ray tracing propagation model for up to five reflections. By default, ray tracing models use the shooting and bouncing rays (SBR) method.

```
tx = txsite("Latitude", 41.8800, ...
           "Longitude", -87.6295, ...
           "AntennaAngle", 30, "AntennaHeight", 10, ...
           "TransmitterFrequency", 28e9);
```

```
rx = rxsite("Latitude",41.881352, ...  
          "Longitude",-87.629771, ...  
          "AntennaHeight",30);  
pm = propagationModel("raytracing","MaxNumReflections",5);
```

Show the obstruction to the line-of-sight path.

```
los(tx,rx)
```

Show the reflected propagation paths using ray tracing.

```
raytrace(tx,rx,pm)
```

Perform ray tracing to find rays between the transmitter and receiver sites for the specified SBR propagation model. Create a channel model using transmitter site, receiver site, and calculated rays between the sites. Show temporal and spatial profiles of the channel.

```
rays = raytrace(tx,rx,pm);  
rtchan = comm.RayTracingChannel(rays{1},tx,rx);  
showProfile(rtchan);
```

Angle of Departure

Angle of Arrival

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### rtchan — Ray-tracing channel

`comm.RayTracingChannel` System object

Ray-tracing channel, specified as a `comm.RayTracingChannel` System object.

## Version History

Introduced in R2020b

## See Also

### Objects

`comm.Ray` | `comm.RayTracingChannel`

### Functions

`info`

# show

**Package:** comm

Show scope window

## Syntax

```
show(scope)
```

## Description

`show(scope)` shows the window of the System object scope.

## Examples

### Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

### Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

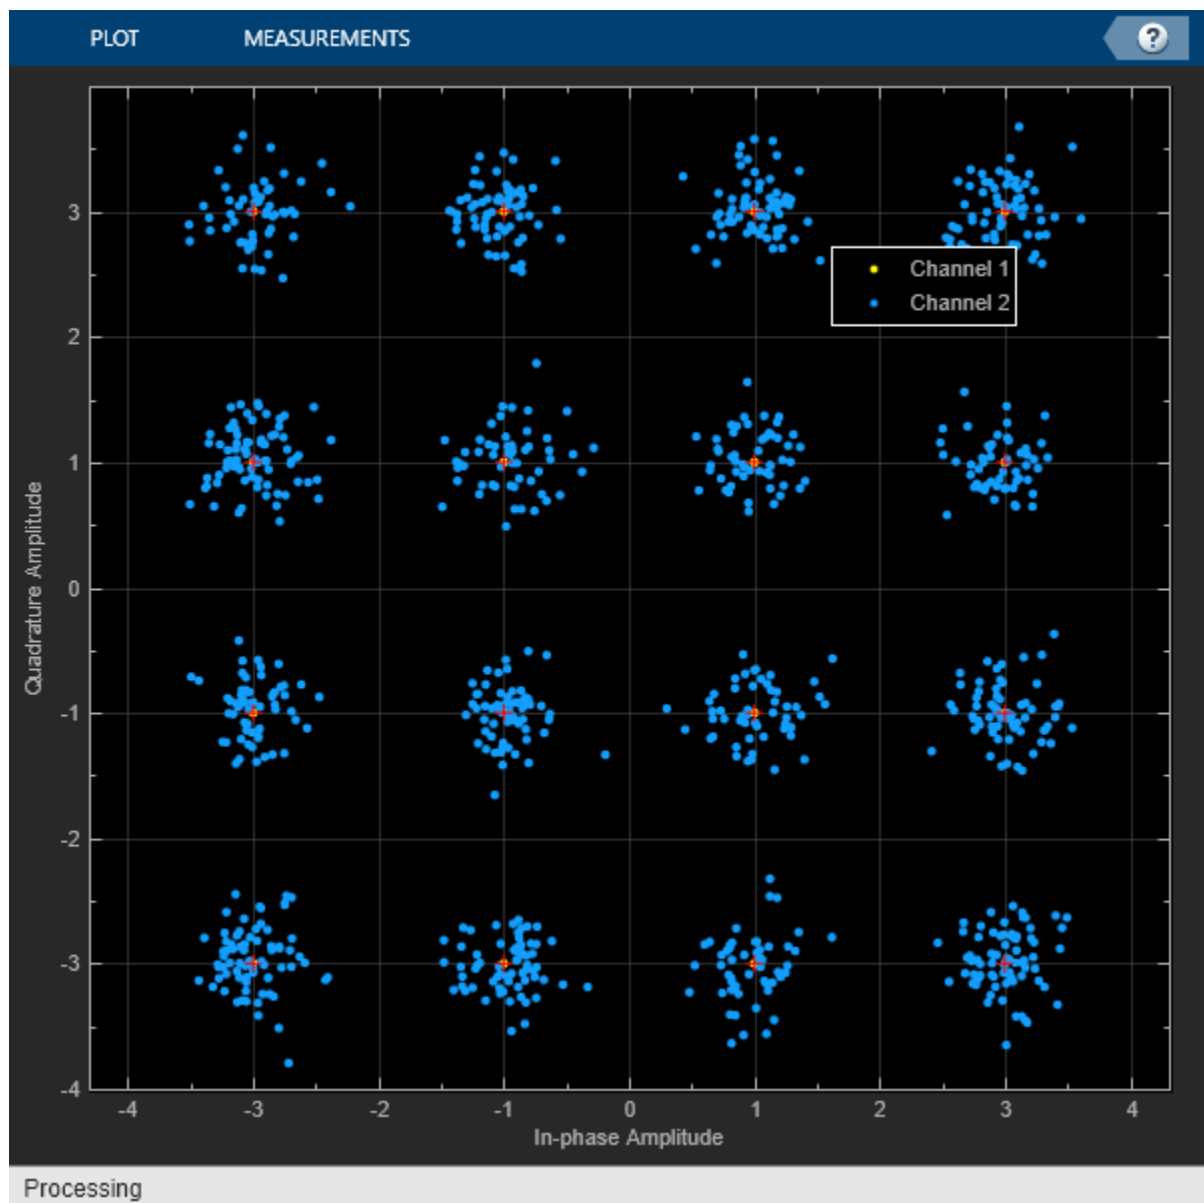

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```

if(isVisible(scope))
    hide(scope)
end

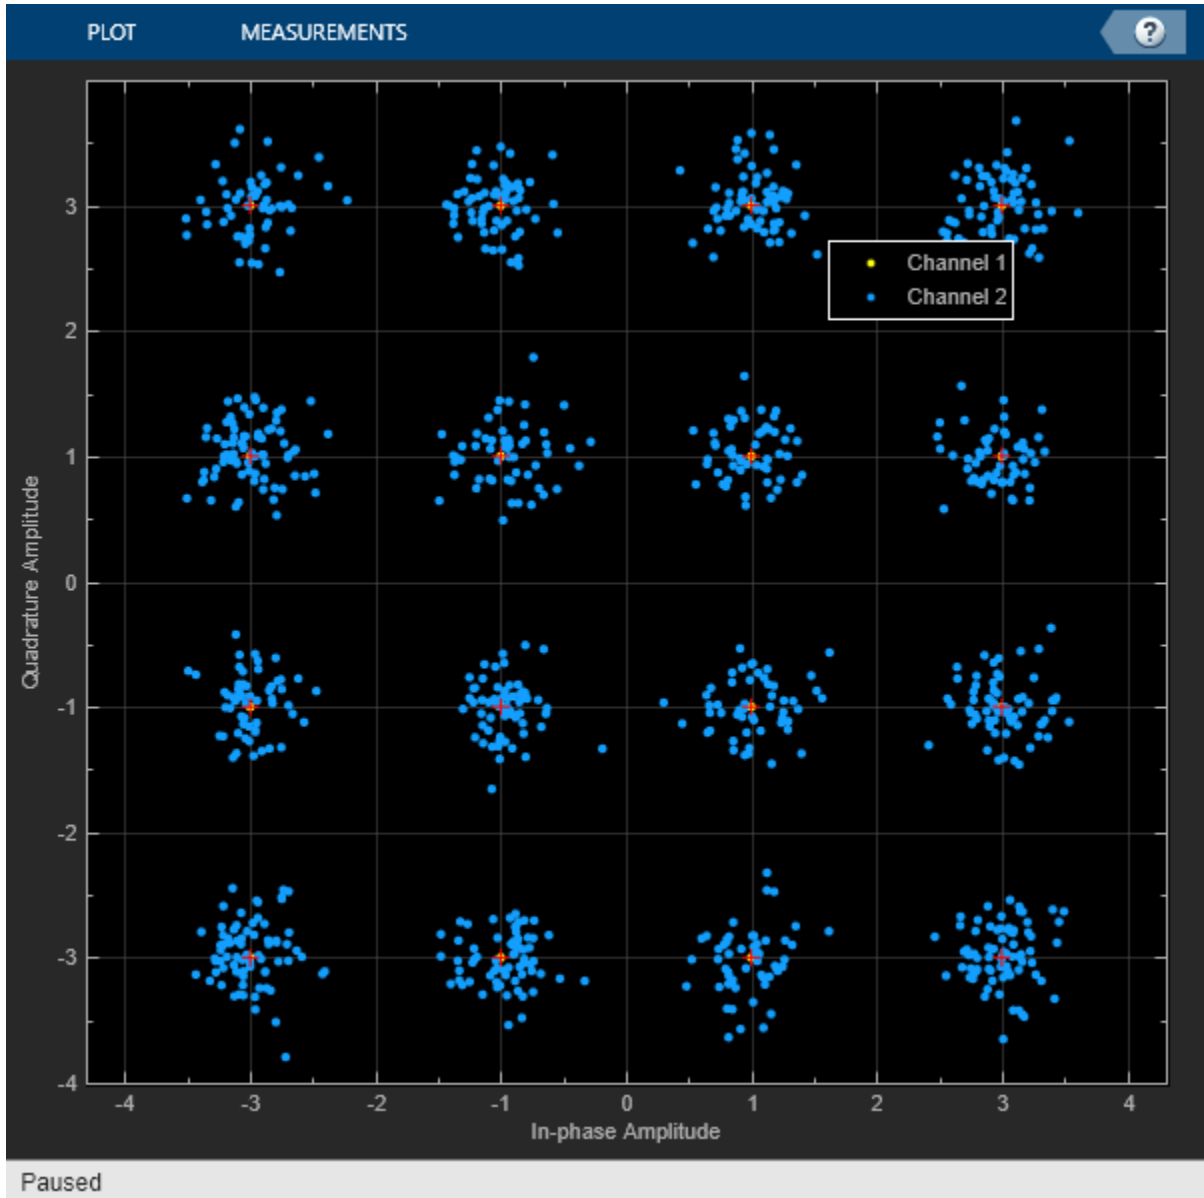

```

Show the constellation diagram scope window.

```

if(~isVisible(scope))
    show(scope)
end

```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

## **Input Arguments**

### **scope — Scope System object**

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

## **Version History**

**Introduced in R2013a**

## **See Also**

### **Functions**

`hide` | `isVisible`

### **Objects**

`comm.ConstellationDiagram`

## info

**System object:** comm.WINNER2Channel

**Package:** comm

Display information about WINNER2Channel object

---

**Note Download Required:** To use , first download the WINNER II Channel Model for Communications Toolbox add-on.

---

### Syntax

```
s = info(obj)
```

### Description

`s = info(obj)` returns a structure containing information about the Winner2Channel System object characteristics. The information structure contains:

- NumLinks - Number of links in the system
- NumBSElements - Number of transmit antennas at the BS for each link
- NumMSElements - Number of receive antennas at the MS for each link
- NumPaths - Number of delay paths for each link
- SampleRate - Sample rate for each link
- ChannelFilterDelay - Channel filter delay per link, measured in samples
- NumSamplesProcessed - Number of samples the channel has processed since the last reset

### Version History

**Introduced in R2016b**

## generate

Generate next FTP, On-Off, VoIP, or video conference application traffic packet

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

### Syntax

```
[dt,packetSize] = generate(cfg)
[dt,packetSize] = generate(cfg,elapsedTime)
[ ____,packet] = generate( ____ )
```

### Description

[dt,packetSize] = generate(cfg) generates the next FTP, On-Off, VoIP, or video application traffic pattern based on the specified configuration object, `cfg`. The object function returns the time remaining to generate the next packet, `dt`, and the size of the current packet, `packetSize`.

[dt,packetSize] = generate(cfg,elapsedTime) specifies the time elapsed, `elapsedTime`, since the previous call of this object function.

[ \_\_\_\_,packet] = generate( \_\_\_\_ ) returns the FTP, On-Off, VoIP, or video application traffic packet. Specify an argument combination from any of the previous syntaxes.

### Examples

#### Generate VoIP Application Traffic Pattern Without Jitter

Create a VoIP application traffic pattern object, disabling modeling of jitter.

```
cfgVoIP = networkTrafficVoIP(HasJitter=false);
```

Generate a VoIP application traffic pattern.

```
[dt,packetSize] = generate(cfgVoIP);
```

#### Generate On-Off Application Traffic Pattern and Data Packet

Create an On-Off application traffic pattern object to generate an On-Off data packet.

```
cfgOnOff = networkTrafficOnOff(GeneratePacket=true);
```

Generate an On-Off application traffic pattern and data packet.

```
[dt,packetSize,packet] = generate(cfgOnOff);
```

## Input Arguments

**cfg** — Configuration object to generate FTP, On-Off, VoIP, or video application traffic pattern

networkTrafficFTP object | networkTrafficOnOff object | networkTrafficVoIP object | networkTrafficVideoConference object

Configuration object to generate FTP, On-Off, VoIP, or video application traffic pattern, specified as a networkTrafficFTP, networkTrafficOnOff, networkTrafficVoIP, or networkTrafficVideoConference object.

**elapsedTime** — Time elapsed since previous call of this object function

nonnegative scalar

Time elapsed in milliseconds since the previous call of this object function, specified as a nonnegative scalar.

Data Types: double

## Output Arguments

**dt** — Time remaining to generate next packet

nonnegative scalar

Time remaining in milliseconds to generate the next packet, returned as a nonnegative scalar.

Data Types: double

**packetSize** — Size of current packet

positive scalar

Size of the current packet in bytes, returned as a positive scalar.

Data Types: double

**packet** — Application data packet

column vector of integers in the range [0, 255]

Application data packet, returned as a column vector of integers in the range [0, 255]. This value contains the application data specified by the cfg.ApplicationData property. If the ApplicationData property is not specified, packet is a column vector of 1s.

### Dependencies

To enable this output argument, set the GeneratePacket property of the input cfg to true.

Data Types: double

## Version History

Introduced in R2020b

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from 5G Toolbox, WLAN Toolbox, and Bluetooth Toolbox**

Previously, this network traffic object function required 5G Toolbox, WLAN Toolbox, or Bluetooth Toolbox.

### **Extended Capabilities**

#### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

### **See Also**

#### **Objects**

`networkTrafficFTP` | `networkTrafficOnOff` | `networkTrafficVideoConference` | `networkTrafficVoIP`

# addChannelModel

Add custom channel or path loss model

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Syntax

```
addChannelModel(networkSimulator,customMdl)
```

## Description

`addChannelModel(networkSimulator,customMdl)` adds a custom channel model or path loss model to the wireless network simulation. The `addChannelModel` function sets the `ChannelFunction` property of the `wirelessNetworkSimulator` object to the custom model that you specified by `customMdl`.

## Examples

### Simulate Bluetooth BR Network without Channel Effects

Create a `wirelessNetworkSimulator` object.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection(cfgConnection,centralNode,peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff(DataRate=200,PacketSize=27, ...
    GeneratePacket=true,OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic, ...
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects. You can add custom channel effects by using the `addChannelModel` function. However, to model the channel without any channel effects, specify a custom MATLAB™ function, `removeChannelEffect` on page 4-128, in which the input transmitted packets are returned at the output without any changes.

```
addChannelModel(networkSimulator,@removeChannelEffect);
```

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator,simulationTime);
```

Retrieve application, baseband, and physical layer (PHY) statistics corresponding to the Central and Peripheral nodes.

```
centralStats = statistics(centralNode)
```

```
centralStats = struct with fields:  
    Name: "Node1"  
    ID: 1  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

```
peripheralStats = statistics(peripheralNode)
```

```
peripheralStats = struct with fields:  
    Name: "Node2"  
    ID: 2  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

```
function outputData = removeChannelEffect(~,txData)  
outputData = txData;  
end
```

## Input Arguments

### **networkSimulator** — Wireless network simulator

`wirelessNetworkSimulator` object

Wireless network simulator, specified as a `wirelessNetworkSimulator` object.

**customMdl — Function for computing custom channel or path loss model**

MATLAB function handle

Function for computing the custom channel or path loss model, specified as a MATLAB function handle. The syntax for the custom function must be of the format:

```
rxData = customFcnName(rxInfo,txData)
```

The `rxInfo` input is the receiver node information, and the `txData` input specifies the transmitted packets. The simulator automatically passes information about the receiver node and the packets transmitted by a transmitter node as inputs to the custom function.

The receiver node information is a structure with these fields.

Field	Description
ID	Unique receiver node identifier.
Position	Position of the receiver node in 3-D Cartesian coordinates (x, y, z). Units are in meters.
Velocity	Velocity of the receiver node ( $V_{rx}$ , $V_{ry}$ , $V_{rz}$ ) in the x-, y-, and z-directions. Units are in meters per second.
NumReceiveAntennas	Number of antennas at the receiver.

The packets from the transmitter node is a structure with these fields.

Field	Description
Type	Type of input signal packet, specified as one of these values: 0, 1, 2, 3, and 4. <ul style="list-style-type: none"> <li>• 0 — Invalid packet</li> <li>• 1 — WLAN packet</li> <li>• 2 — 5G packet</li> <li>• 3 — Bluetooth LE packet</li> <li>• 4 — Bluetooth BR/EDR packet</li> </ul>
TransmitterID	Unique transmitter node identifier, specified as a positive scalar integer.
TransmitterPosition	Position of the transmitter node in 3-D Cartesian coordinates (x, y, z). Units are in meters.
TransmitterVelocity	Velocity of the transmitter node ( $V_{tx}$ , $V_{ty}$ , $V_{tz}$ ) in the x-, y-, and z-directions. Units are in meters per second.
StartTime	Time at which the transmitter starts transmitting the packets, specified as a nonnegative scalar. Units are in seconds.
Duration	Duration of the transmitter packet, specified as a positive scalar. Units are in seconds.

Power	Average power consumption during transmission. Units are in dBm.
CenterFrequency	Center frequency of the carrier signal. Units are in Hz.
Bandwidth	Carrier signal bandwidth. Units are in Hz.
Abstraction	Type of abstraction, specified as a logical scalar. <ul style="list-style-type: none"> <li>• 1 — Abstracted physical layer</li> <li>• 0 — Full physical layer</li> </ul> <p>The default value is 0.</p>
SampleRate	Sample rate of the packet, specified as a numeric scalar in samples per second. This field is applicable only if the value of the <code>Abstraction</code> field is set to 0. The default value is [ ].
DirectToDestination	Information about the transmitted packet, specified as a numeric scalar integer. <ul style="list-style-type: none"> <li>• The value is 0 if a normal packet is transmitted over the channel.</li> <li>• The value is a nonzero scalar integer if the packet bypasses the channel model and is transmitted directly to the destination node. In this case, this field value specifies the destination node identifier.</li> </ul>
Data	Time-domain samples or frame information. <ul style="list-style-type: none"> <li>• The field contains time-domain samples of the transmitted packet for the full physical layer. In this case, the value of the <code>Abstraction</code> field is 0.</li> <li>• The field contains frame information for the abstracted physical layer. In this case, the value of the <code>Abstraction</code> field is 1.</li> </ul>

Metadata	<p>A structure representing the technology-specific and abstraction-specific information of the packet. The structure contains this field.</p> <ul style="list-style-type: none"> <li>• <b>Channel</b> — A structure representing the information about the channel. The structure contains these fields. <ul style="list-style-type: none"> <li>• <b>PathGains</b> — Complex path gains at each snapshot in time. It is a matrix of size <math>N_{cs}</math>-by-<math>N_p</math>-by-<math>N_t</math>-by-<math>N_r</math>.</li> <li>• <b>PathDelays</b> — Delays corresponding to each path, in seconds. It is a vector of size 1-by-<math>N_p</math>.</li> <li>• <b>PathFilters</b> — Filter coefficients for each path. It is a matrix of size <math>N_p</math>-by-<math>N_f</math>.</li> <li>• <b>SampleTimes</b> — Simulation time corresponding to each path gains snapshot, in seconds. It is a vector of size <math>N_{cs}</math>-by-1.</li> </ul> </li> </ul> <p>The variables <math>N_{cs}</math>, <math>N_p</math>, <math>N_t</math>, <math>N_r</math>, and <math>N_f</math> represents the number of channel snapshots, number of paths, the number of transmit antennas, the number of receive antennas, and the number of filter coefficients, respectively.</p>
----------	---

The custom channel model function applies channel effects to the packets transmitted by the simulator. The modified packets are then sent back to the simulator. The packets returned at the output must be a structure with same fields as those of the transmitted packets.

The custom channel model function must update the following fields in the transmitted packet to include channels effects.

- **Power** - Use this field to include large scale effects.
- **Data** - If `Abstraction = false`, scale the data to include small and large scale effects.
- **Metadata.Channel** - If `Abstraction = true`, include all small scale effects.
- **Duration** - Set the value as actual packet duration + final transient (delay spread + filter length - implementation delay). Updating this field is optional.

Data Types: `function_handle`

## Version History

**Introduced in R2022b**

# addNodes

Add nodes to simulation

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Syntax

```
addNodes(networkSimulator,nodes)
```

## Description

`addNodes(networkSimulator,nodes)` adds the specified wireless nodes to the `wirelessNetworkSimulator` object. You must add the nodes to the simulator before running the simulation.

## Examples

### Simulate Bluetooth BR Network with Default Channel Effects

Create a `wirelessNetworkSimulator` object by using the `wirelessNetworkSimulator.init()` function. By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...
    cfgConnection,centralNode,peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff( ...
    DataRate=200, ...
    PacketSize=27, ...
    GeneratePacket=true, ...
    OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode, traffic, ...  
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator, [centralNode peripheralNode]);
```

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator, simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel.

Retrieve application, baseband, and physical layer (PHY) statistics corresponding to the Central and Peripheral nodes.

```
centralStats = statistics(centralNode)
```

```
centralStats = struct with fields:  
    Name: "Node1"  
    ID: 1  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

```
peripheralStats = statistics(peripheralNode)
```

```
peripheralStats = struct with fields:  
    Name: "Node2"  
    ID: 2  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

## Input Arguments

### **networkSimulator** — Wireless network simulator

wirelessNetworkSimulator object

Wireless network simulator, specified as a wirelessNetworkSimulator object.

### **nodes** — Nodes to transmit and receive data

bluetoothLENode object | bluetoothNode object | wlanNode object | nrGNB object | nrUE object

Nodes to transmit and receive data, specified as a bluetoothLENode object, bluetoothNode object, wlanNode object, nrGNB object, or nrUE object.

## Version History

Introduced in R2022b

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from Bluetooth Toolbox**

Previously, this `wirelessNetworkSimulator` object function required Bluetooth Toolbox.

## cancelAction

Cancel scheduled action

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

### Syntax

```
cancelAction(networkSimulator,actionID)
```

### Description

`cancelAction(networkSimulator,actionID)` cancels an action scheduled to be performed during the specified wireless network simulation.

### Examples

#### Schedule and Cancel Actions During Network Simulation

##### Simulate Bluetooth BR Network

Create a `wirelessNetworkSimulator` object by using the `wirelessNetworkSimulator.init()` function. By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");  
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...  
    cfgConnection,centralNode,peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff(DataRate=200,PacketSize=27, ...  
    GeneratePacket=true,OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic,DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

### Schedule Action

Create a custom function `statusInfo` on page 4-139 to define an one time action and periodic action for the simulator to perform during simulation. The input data for the custom function is stored as a structure and passed using the `scheduleAction` function. For the one time action, the `statusInfo` function displays the node details when the simulation time is 0.001s. For the periodic action, the `statusInfo` function displays the physical layer statistics of the central node in the Bluetooth BR network.

Specify the `ActionType` input argument of `statusInfo` function as "OneTime". Also, specify the names of the nodes in the network as input.

```
userdata = struct( ...
    ActionType="OneTime", ...
    Nodes=[centralNode peripheralNode]);
```

Configure the simulator by using the `scheduleAction` function to display the node details when the simulation time is 0.001s.

```
startTime = 0.001;
actionID1 = scheduleAction( ...
    networkSimulator,@statusInfo,userdata,startTime);
```

Specify the `ActionType` input argument value of `statusInfo` function as "Periodic". Also, specify the central node and the simulator as inputs.

```
userdata = struct( ...
    ActionType="Periodic", ...
    CentralNode=centralNode, ...
    Simulator=networkSimulator);
```

Configure the simulator by using the `scheduleAction` function to display the physical layer statistics of the central node at a time interval of 0.02s starting from the beginning of the simulation.

```
startTime = 0;
periodicity = 0.02;
actionID2 = scheduleAction( ...
    networkSimulator,@statusInfo,userdata,startTime,periodicity);
```

### Cancel Action

To cancel a scheduled action, use the `cancelAction` function. Specify the value of the unique identifier denoting the action. The identifier is returned by the `scheduleAction` function.

```
cancelAction(networkSimulator,actionID1)
```

### Run Simulation

Specify the simulation time in seconds.

```
simulationTime = 0.1;
```

Run the simulation for the specified simulation time. You can notice that the one time action scheduled to perform at 0.001s is cancelled. The simulator performs only the scheduled periodic action.

```
run(networkSimulator,simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel

end
end

```

## Input Arguments

**networkSimulator** — Wireless network simulator

wirelessNetworkSimulator object

Wireless network simulator, specified as a `wirelessNetworkSimulator` object.

**actionID — Unique identifier of action to cancel**

positive scalar integer

Unique identifier of action to cancel, specified as a positive scalar integer. The unique identifier is returned by the `scheduleAction` function.

## Version History

**Introduced in R2022b**

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from Bluetooth Toolbox**

Previously, this `wirelessNetworkSimulator` object function required Bluetooth Toolbox.

# wirelessNetworkSimulator.getInstance

Get instance of wirelessNetworkSimulator object

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

## Syntax

```
networkSimulator = wirelessNetworkSimulator.getInstance()
```

## Description

`networkSimulator = wirelessNetworkSimulator.getInstance()` gets an instance of the `wirelessNetworkSimulator` object initialized by using the `wirelessNetworkSimulator.init()` function.

## Examples

### Get wirelessNetworkSimulator Object

Initialize the wireless network simulator. The `wirelessNetworkSimulator.init()` function creates a `wirelessNetworkSimulator` object in the MATLAB® workspace.

```
wirelessNetworkSimulator.init();
```

Get an instance of the initialized `wirelessNetworkSimulator` object.

```
networkSimulator = wirelessNetworkSimulator.getInstance();
```

## Output Arguments

**networkSimulator** — Wireless network simulator

`wirelessNetworkSimulator` object

Wireless network simulator, returned as a `wirelessNetworkSimulator` object.

## Version History

Introduced in R2022b

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from Bluetooth Toolbox**

Previously, this `wirelessNetworkSimulator` object function required Bluetooth Toolbox.

## run

Run simulation

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

### Syntax

```
run(networkSimulator, simDuration)
```

### Description

`run(networkSimulator, simDuration)` runs the wireless network simulation for the specified simulation time duration. If any action is scheduled at a particular simulation time, the `run` function performs the scheduled action. Use the `scheduleAction` function to schedule an action to be performed during the simulation process.

You must call the `run` function only once after initializing the `wirelessNetworkSimulator` object.

### Examples

#### Simulate Bluetooth BR Network with Default Channel Effects

Create a `wirelessNetworkSimulator` object by using the `wirelessNetworkSimulator.init()` function. By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral", Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...
    cfgConnection, centralNode, peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff( ...
    DataRate=200, ...
```

```
PacketSize=27, ...  
GeneratePacket=true, ...  
OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode, traffic, ...  
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator, [centralNode peripheralNode]);
```

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator, simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel.

Retrieve application, baseband, and physical layer (PHY) statistics corresponding to the Central and Peripheral nodes.

```
centralStats = statistics(centralNode)
```

```
centralStats = struct with fields:
```

    PHY: [1x1 struct]
```

```
peripheralStats = statistics(peripheralNode)
```

```
peripheralStats = struct with fields:
```

```
    Name: "Node2"  
    ID: 2  
    App: [1x1 struct]  
    Baseband: [1x1 struct]  
    PHY: [1x1 struct]
```

## **Schedule Action to Perform During Network Simulation**

### **Simulate Bluetooth BR Network**

Create a `wirelessNetworkSimulator` object by using the `wirelessNetworkSimulator.init()` function. By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral",Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...
    cfgConnection,centralNode,peripheralNode);
```

Create and configure a networkTrafficOnOff object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff( ...
    DataRate=200, ...
    PacketSize=27, ...
    GeneratePacket=true, ...
    OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic, ...
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

### Schedule Action

Create a custom function `displayInfo` on page 4-158 to define the actions for the simulator to perform during simulation. You can define an one time action, periodic action, and action when simulator advances in time. The input data for the custom function is stored as a structure and passed using the `scheduleAction` function.

#### A) Schedule One Time Action

For the one time action, the `displayInfo` function displays the details of the nodes in the network.

Specify the `ActionType` input argument value of `displayInfo` function as "OneTime". Specify the names of the nodes in the network as input to `displayInfo` function.

```
userdata = struct( ...
    ActionType="OneTime", ...
    Nodes=[centralNode peripheralNode]);
```

Configure the simulator by using the `scheduleAction` function to display the node details when the simulation time is 0.001s.

```
startTime = 0.001;
scheduleAction(networkSimulator,@displayInfo,userdata,startTime);
```

### B) Schedule Periodic Action

For the periodic action, the `displayInfo` function displays the physical layer statistics of the central node in the Bluetooth BR network.

Specify the `ActionType` input argument value of `displayInfo` function as "Periodic". Specify the central node and the simulator as inputs to `displayInfo` function.

```
userdata = struct( ...
    ActionType="Periodic", ...
    CentralNode=centralNode, ...
    Simulator=networkSimulator);
```

Configure the simulator by using the `scheduleAction` function to display the physical layer statistics of the central node at a time interval of 0.02s starting from the beginning of the simulation.

```
startTime = 0;
periodicity = 0.02;
scheduleAction( ...
    networkSimulator,@displayInfo,userdata,startTime,periodicity);
```

### C) Schedule Action When Simulator Advances in Time

When the simulator advances in time, the `displayInfo` function displays the next event time of the simulator.

Specify the `ActionType` input argument value of `displayInfo` function as "TimeAdvance". Specify the simulator as input to the `displayInfo` function.

```
userdata = struct( ...
    ActionType="TimeAdvance", ...
    Simulator=networkSimulator);
```

Set the periodicity value to 0. Configure the simulator by using the `scheduleAction` function to display the time of the next event.

```
startTime = 0;
periodicity = 0;
scheduleAction( ...
    networkSimulator,@displayInfo,userdata,startTime,periodicity);
```

### Run Simulation

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator,simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel.

```
-----Periodic Action -----

## Input Arguments

### networkSimulator — Wireless network simulator

wirelessNetworkSimulator object

Wireless network simulator, specified as a wirelessNetworkSimulator object.

**simDuration — Duration of simulation**

positive scalar

Duration of simulation, specified as a positive scalar. Units are in seconds.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Version History

**Introduced in R2022b**

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from Bluetooth Toolbox**

Previously, this `wirelessNetworkSimulator` object function required Bluetooth Toolbox.

## scheduleAction

Schedule action to perform during simulation

---

**Note Download Required:** To use , first download the Communications Toolbox Wireless Network Simulation Library add-on.

---

### Syntax

```
scheduleAction(networkSimulator, callbackFcn, userData, startTime)
scheduleAction( ____, periodicity)
actionID = scheduleAction( ____, periodicity)
```

### Description

`scheduleAction(networkSimulator, callbackFcn, userData, startTime)` schedules an action to perform during the wireless network simulation. The `callbackFcn` argument specifies the action to be performed at the specified time, `startTime`, and `userData` specifies the input data to use for the specified action.

`scheduleAction( ____, periodicity)` specifies to repeat the action at regular or irregular time intervals, in addition to all input arguments from the previous syntax.

`actionID = scheduleAction( ____, periodicity)` returns an identifier specifying the action scheduled.

### Examples

#### Schedule Action to Perform During Network Simulation

##### Simulate Bluetooth BR Network

Create a `wirelessNetworkSimulator` object by using the `wirelessNetworkSimulator.init()` function. By default, the `wirelessNetworkSimulator` object applies free-space path loss model for the channel effects.

```
networkSimulator = wirelessNetworkSimulator.init();
```

Create two Bluetooth BR nodes, one with the "central" role and other with the "peripheral" role. Specify the position of the Peripheral node in meters.

```
centralNode = bluetoothNode("central");
peripheralNode = bluetoothNode("peripheral", Position=[1 0 0]);
```

Create a default Bluetooth BR connection configuration object to configure and share a connection between Bluetooth BR Central and Peripheral nodes.

```
cfgConnection = bluetoothConnectionConfig;
```

Configure connection between the Central and the Peripheral nodes.

```
connection = configureConnection( ...
    cfgConnection,centralNode,peripheralNode);
```

Create and configure a `networkTrafficOnOff` object to generate an On-Off application traffic pattern.

```
traffic = networkTrafficOnOff( ...
    DataRate=200, ...
    PacketSize=27, ...
    GeneratePacket=true, ...
    OnTime=inf);
```

Add application traffic from the Central to the Peripheral node.

```
addTrafficSource(centralNode,traffic, ...
    DestinationNode=peripheralNode);
```

Add the Central and Peripheral nodes to the wireless network simulator.

```
addNodes(networkSimulator,[centralNode peripheralNode]);
```

### Schedule Action

Create a custom function `displayInfo` on page 4-174 to define the actions for the simulator to perform during simulation. You can define an one time action, periodic action, and action when simulator advances in time. The input data for the custom function is stored as a structure and passed using the `scheduleAction` function.

#### A) Schedule One Time Action

For the one time action, the `displayInfo` function displays the details of the nodes in the network.

Specify the `ActionType` input argument value of `displayInfo` function as "OneTime". Specify the names of the nodes in the network as input to `displayInfo` function.

```
userdata = struct( ...
    ActionType="OneTime", ...
    Nodes=[centralNode peripheralNode]);
```

Configure the simulator by using the `scheduleAction` function to display the node details when the simulation time is 0.001s.

```
startTime = 0.001;
scheduleAction(networkSimulator,@displayInfo,userdata,startTime);
```

#### B) Schedule Periodic Action

For the periodic action, the `displayInfo` function displays the physical layer statistics of the central node in the Bluetooth BR network.

Specify the `ActionType` input argument value of `displayInfo` function as "Periodic". Specify the central node and the simulator as inputs to `displayInfo` function.

```
userdata = struct( ...
    ActionType="Periodic", ...
    CentralNode=centralNode, ...
    Simulator=networkSimulator);
```

Configure the simulator by using the `scheduleAction` function to display the physical layer statistics of the central node at a time interval of 0.02s starting from the beginning of the simulation.

```
startTime = 0;
periodicity = 0.02;
scheduleAction( ...
    networkSimulator,@displayInfo,userdata,startTime,periodicity);
```

### C) Schedule Action When Simulator Advances in Time

When the simulator advances in time, the `displayInfo` function displays the next event time of the simulator.

Specify the `ActionType` input argument value of `displayInfo` function as "TimeAdvance". Specify the simulator as input to the `displayInfo` function.

```
userdata = struct( ...
    ActionType="TimeAdvance", ...
    Simulator=networkSimulator);
```

Set the periodicity value to 0. Configure the simulator by using the `scheduleAction` function to display the time of the next event.

```
startTime = 0;
periodicity = 0;
scheduleAction( ...
    networkSimulator,@displayInfo,userdata,startTime,periodicity);
```

### Run Simulation

Specify the simulation time in seconds.

```
simulationTime = 0.05;
```

Run the simulation for the specified simulation time.

```
run(networkSimulator,simulationTime);
```

Custom channel model is not added. Using free space path loss (fspl) model as the default channel

        fprintf("Node details:\n")
        for idx=1:numel(userdata.Nodes)
            fprintf("Name: %s ID: %d Role: %s\n", ...
                userdata.Nodes(idx).Name, ...
                userdata.Nodes(idx).ID, ...
                userdata.Nodes(idx).Role)
        end
        fprintf("-----End-----\n")
    case "TimeAdvance"
        fprintf("-----Action When Simulator Advances in Time-----\n")
        fprintf("Simulator next event time is at %.5f seconds\n", ...
            userdata.Simulator.CurrentTime)
        fprintf("-----End-----\n")
end
end

```

## Input Arguments

### **networkSimulator** — Wireless network simulator

wirelessNetworkSimulator object

Wireless network simulator, specified as a wirelessNetworkSimulator object.

### **callbackFcn** — Callback function to run at specified time

function handle

Callback function to run at the specified time, specified as a function handle. The callback function is a custom function defining an action to be performed during the wireless network simulation. The syntax for the callback function must be:

```
callbackFcn(actionID,userData)
```

### **userData** — Input to callback function

[ ] | structure | cell array | numeric value | character vector | string scalar

Input to the callback function, specified as a numeric value, character vector, or string scalar. If the callback function does not require any input, specify the `userData` value as `[]`. To pass multiple values as input to the callback function, specify the input as a structure or a cell array.

### **startTime** — Absolute simulation time to perform the action

nonnegative scalar

Absolute simulation time at which a scheduled action is to be performed, specified as a nonnegative scalar. Units are in seconds.

- If you specify the simulation time as zero, the simulator performs the scheduled action at the start of simulation.
- If you specify both `startTime` and `periodicity`, the simulator performs the scheduled action at the specified simulation time and repeats the action until the end of simulation. The time interval for repeating the action is specified by the periodic time in `periodicity`.

### **periodicity** — Periodic time

nonnegative scalar

Periodic time, specified as a nonnegative scalar. The periodic time is the time interval at which the scheduled action repeats. Units are in seconds.

- For periodic actions, the periodicity value must be greater than zero.
- If the periodic time value is 0, the scheduled action is performed whenever the simulator advances in time in response to an event. The events can occur at regular or irregular time intervals. In this case, the simulator ignores the value of `startTime`.

## **Output Arguments**

### **actionID** — Unique identifier for action

integer

Unique identifier for action, returned as an integer. You can also use this value to cancel a scheduled action by using the `cancelAction` function.

## **Version History**

**Introduced in R2022b**

**R2023a: Moved to Communications Toolbox Wireless Network Simulation Library from Bluetooth Toolbox**

Previously, this `wirelessNetworkSimulator` object function required Bluetooth Toolbox.

# info

**Package:** comm

Characteristic information about WPAN high-rate pulse configuration object

---

**Note Download Required:** To use , first download the Communications Toolbox Library for ZigBee and UWB add-on.

---

## Syntax

```
infostruct = info(cfg)
```

## Description

`infostruct = info(cfg)` returns a structure containing information about the characteristics of the WPAN high-rate pulse (HRP) configured by the input `lrwpanHRPConfig` object.

## Examples

### Return Configuration Information for `lrwpanHRPConfig` object

Generate random data for a PHY Service Data Unit (PSDU) payload. Create an HPRF IEEE 802.15.4z `lrwpanHRPConfig` object.

```
psdu = randi([0,1],8*200,1);
cfgHPRF = lrwpanHRPConfig(Mode='HPRF', ...
    Channel=3, ... % Mandatory low-band channel
    MeanPRF=124.8, ... % 16 chips per payload symbol
    STSPacketConfiguration=1, ... % Enable STS before payload
    NumSTSSegments=2, ... % 2 STS segments
    CodeIndex=27, ... % One 91-symbols long SYNC code
    PreambleDuration=32, ... % Repetitions for spread SYNC code
    SFDNumber=1, ... % Choose a 4-symbol long SFD
    ConstraintLength=7, ... % Convolutional encoder, no RS coding
    PSDULength=100); % PSDU length in bytes
```

Return information about the characteristics of the high-rate pulse configured by the `lrwpanHRPConfig` object.

```
info(cfgHPRF)

ans = struct with fields:
    PeakPRF: 249.6000
    ChipsPerSymbol: 16
    ConvolutionalCoding: 1
    PreambleCodeLength: 91
    PreambleSpreadingFactor: 4
```

## Input Arguments

### **cfg** — Configuration object to get information from

l<sub>rwpan</sub>HRPConfig object

Configuration object to get information from, specified as an l<sub>rwpan</sub>HRPConfig object.

## Output Arguments

### **infostruct** — Structure containing object information

structure

Structure containing these fields with information about the configuration object.

### **PeakPRF** — Peak pulse repetition frequency

positive scalar

Peak pulse repetition frequency in MHz, returned as a positive scalar.

- When Mode is 'HPRF' and MeanPRF is 124.8 MHz, the chip (or pulse) spacing is  $1 / (249.6 \text{ MHz}) = 4 \text{ ns}$  apart.
- For other Mode and MeanPRF setting combinations, the chip (or pulse) spacing is  $1/(499.2 \text{ MHz}) = 2 \text{ ns}$  apart.

### **BurstsPerSymbol** — Number of burst durations per symbol

positive scalar

Number of burst durations per symbol, returned as a positive scalar.

The number of burst durations within a symbol consists of candidate active bursts and the guard intervals. It equals the symbol duration divided by the  $(\text{ChipsPerBurst} \times \text{ChipDuration})$  and ChipDuration is 0.2 ns. The value of BurstsPerSymbol is 128, 32, or 8 for MeanPRF values of 3.9, 15.6, or 62.4, respectively.

### **Dependencies**

This field is present when Mode is 'BPRF' or '802.15.4a'.

### **NumHopBursts** — Number of candidate bursts per symbol

positive integer

Number of candidate bursts per symbol, returned as a positive integer that is computed as  $\text{BurstsPerSymbol} / 4$ . This property indicates the number of candidate burst durations within a symbol where transmissions may occur. The value excludes guard intervals and bursts that are excluded based on the value of the systematic bit.

### **Dependencies**

This field is present when Mode is 'BPRF' or '802.15.4a'.

### **ChipsPerBurst** — Number of chips per burst

scalar | two-element vector

Number of chips per burst, returned as a scalar or two-element vector containing values from the set [1, 2, 4, 8, 16, 32, 64, 128, or 512].

- When the data rate is 110 or 850 kbps, the `ChipsPerBurst` value is a scalar.
- For other data rates, the `ChipsPerBurst` value is a two-element vector. The first element is the chips per burst for the PHR and the second element is the chips per burst for the payload.

The selected values depend on the `MeanPRF` and `DataRate` combination.

### Dependencies

This field is present when `Mode` is 'BPRF' or '802.15.4a'.

### **ChipsPerSymbol — Number of chips per symbol**

scalar | two-element vector

Number of chips per symbol, returned as a scalar or two-element vector.

- When `Mode` is 'HPRF' — The number of chips per symbol is either 8, 16, or 32.
- When `Mode` is 'BPRF' or '802.15.4a' — The number of chips per symbol equals (`ChipsPerBurst` × `BurstsPerSymbol`).
- When the data rate is 110 or 850 kbps, or the constraint length is 7, the `ChipsPerSymbol` value is a scalar.
- For other data rates or constraint lengths, the `ChipsPerSymbol` value is a two-element vector. The first element is the chips per symbol for the PHR and the second element is the chips per symbol for the payload.

### **ConvolutionalCoding — Flag for activation of rate ½ convolutional encoder for payload**

0 | 1

Flag for activation of the rate ½ convolutional encoder for the payload, returned as 0 or 1. The payload uses convolutional encoding when `ConvolutionalCoding` is 1.

Convolutional coding is disabled when the mean PRF is 15.6 MHz and the payload data rate is 27.24 Mbps, or when the mean PRF is 3.9 MHz and the data rate is 6.81 Mbps.

The PHR transmission data rate is either 110 or 850 kbps and always applies convolutional encoding.

### **PreambleCodeLength — Length of preamble**

31 | 91 | 127

Length of the preamble in symbols, returned as a 31, 91, or 127. `PreambleCodeLength` represents the length of the ternary (-1, 0, 1) code field within the synchronization header (SHR), and is the length of the code before spreading and before repetitions.

When `CodeIndex` is in the range:

- [0, 8] — `PreambleCodeLength` is 31.
- [9, 24] — `PreambleCodeLength` is 127.
- [25, 32] — `PreambleCodeLength` is 91.

### **PreambleSpreadingFactor — Length of delta function spreading code**

4 | 16 | 64

Length of the delta function spreading code in chips, returned as a 4, 16, or 64.

- When `PreambleCodeLength` is 91 or 127], `PreambleSpreadingFactor` is 4.
- When `PreambleCodeLength` is 31,
  - If `PreambleMeanPRF` is 16.1 MHz, `PreambleSpreadingFactor` is 16.
  - If `PreambleMeanPRF` is 4.03 MHz, `PreambleSpreadingFactor` is 64.
- For other configurations, `PreambleCodeLength` is 91.

# addCustomTerrain

Add custom terrain data

## Syntax

```
addCustomTerrain(terrainName,files)
addCustomTerrain( ____,Name,Value)
```

## Description

`addCustomTerrain(terrainName,files)` adds the terrain data specified with a user-defined `terrainName` and `files`. You can use this function to add custom terrain data in Site Viewer and other RF propagation functions. You can access the custom terrain data in the current and future sessions of MATLAB until you call `removeCustomTerrain`.

---

**Note** In Antenna Toolbox, `addCustomTerrain` function converts terrain elevation data from orthometric to ellipsoidal for visualization and when performing Euclidean distance or angle calculations between locations for example for free space path loss.

---

`addCustomTerrain( ____,Name,Value)` adds custom terrain data with additional options specified by one or more name-value pairs.

## Examples

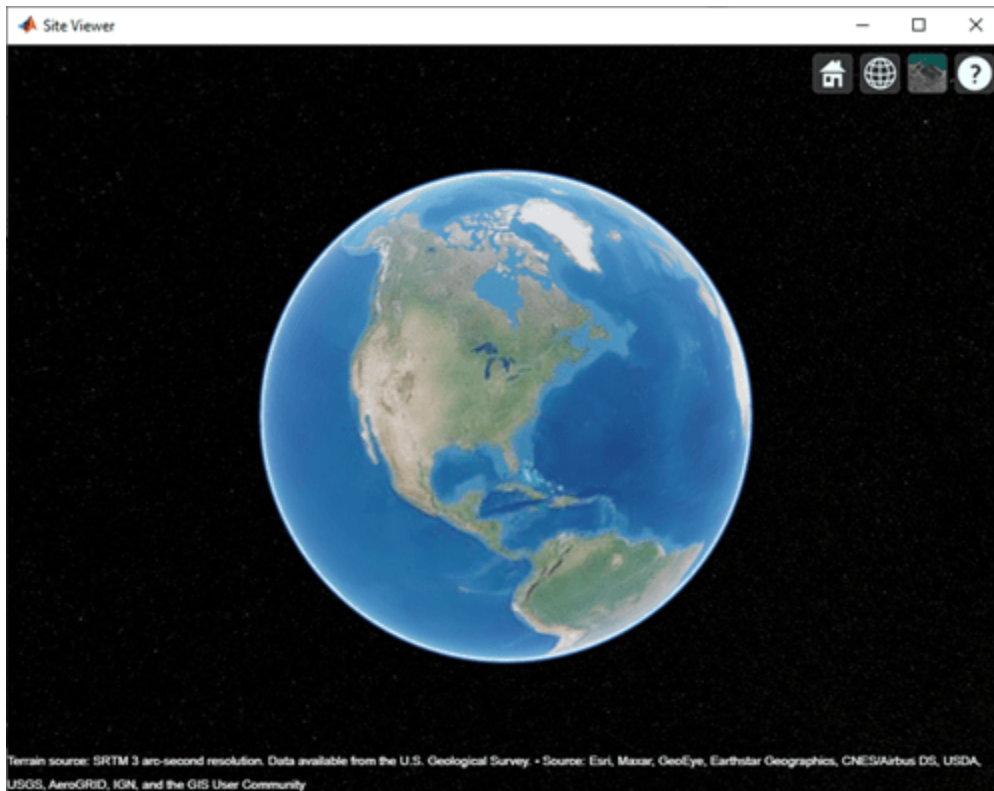

### Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
    "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.

```
mtzion = txsite("Name","Mount Zion", ...  
               "Latitude",39.74356, ...  
               "Longitude",-105.24193, ...  
               "AntennaHeight", 30);  
show(mtzion)
```

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...  
  "MaxRange", 20000, ...  
  "SignalStrengths", -100: -5)
```

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("southboulder")
```

## Input Arguments

### **terrainName** — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data, specified as a string scalar or a character vector.

Data Types: char | string

### **files** — Names of DTED files to read

string scalar | character vector | string vector | cell array of character vectors

Names of DTED files to read, specified as a string scalar, a character vector, a string vector, or a cell array of character vectors.

- To add custom terrain from one DTED file, specify `files` as a string scalar or a character vector.
- To add custom terrain from multiple DTED files, specify `files` as a string vector or a cell array of character vectors. If you specify multiple files that do not cover a complete rectangular geographic region, you must set the `FillMissing` name-value argument to `true`.

The form of each element of `files` depends on the location of the file.

- If the file is in your current folder or in a folder on the MATLAB path, then specify the name of the file, such as "myFile.dt1".
- If the file is not in the current folder or in a folder on the MATLAB path, then specify the full or relative path name, such as "C:\myfolder\myFile.dt1" or "dataDir\myFile.dt1".

Data Types: char | string | cell

### Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'FillMissing',true

### Attribution — Attribution of custom terrain data

character vector | string scalar

Attribution of custom terrain data, specified as a character vector or a string scalar. The attribution is displayed on the Site Viewer map. By default, the value is empty.

Data Types: char | string

### FillMissing — Fill data of missing files with value 0

false (default) | true

Fill data of missing files with value 0, specified as true or false. Missing file values are required to complete a rectangular geographic region with the input files.

Data Types: logical

### WriteLocation — Name of folder to write extracted terrain files to

character vector | string scalar

Name of folder to write extracted terrain files to, specified as a character vector or a string scalar. The folder must exist and have write permissions. By default, addCustomTerrain writes extracted terrain files to a temporary folder that it generates using the tempname function.

Data Types: char | string

## Tips

- You can find and download DTED files by using EarthExplorer, a data portal provided by the US Geological Survey (USGS). From the list of data sets, search for DTED files by selecting **Digital Elevation, SRTM**, and then **SRTM 1 Arc-Second Global** and **SRTM Void Filled**.

## angle

Angle between sites

### Syntax

```
[az,el] = angle(site1,site2)
[az,el] = angle(site1,site2,path)
[az,el] = angle( ____,Name,Value)
```

### Description

`[az,el] = angle(site1,site2)` returns the azimuth and elevation angles between `site1` and `site2`.

`[az,el] = angle(site1,site2,path)` returns the angles using a specified path type, either a Euclidean or great circle path.

`[az,el] = angle( ____,Name,Value)` returns the azimuth and elevation angles with additional options specified by name-value arguments.

### Examples

#### Angle Between Sites

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx)
```

```
az = 14.0142
```

```
el = -0.2816
```

Get the azimuth angle between sites in degrees clockwise from north.

```
azFromEast = angle(tx,rx); % Unit: degrees counter-clockwise from east
azFromNorth = -azFromEast + 90 % Convert angle to clockwise from north
```

```
azFromNorth = 75.9858
```

#### Angle Between Sites When Path is Great Circle

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx,'greatcircle')
```

```
az = 14.0635
```

```
el = 0
```

## Input Arguments

### site1,site2 — Transmitter or receiver site

txsite object | rxsite object

Transmitter or receiver site, specified as a txsite or rxsite object. You can use array inputs to specify multiple sites.

### path — Measurement path type

'euclidean' | 'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean' — Use the shortest path through space connecting the antenna center positions of the sites.
- 'greatcircle' — Use the shortest path on the surface of the earth connecting the latitude and longitude locations of the sites. This path uses a spherical Earth model.

Data Types: char

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Map','siteviewer1'

### Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A <code>siteviewer</code> object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>• The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A <code>siteviewer</code> object.</li> <li>• The name of an STL file.</li> <li>• A <code>triangulation</code> object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

## Output Arguments

### az — Azimuth angle between sites

*M*-by-*N* arrays

Azimuth angle between `site1` and `site2`, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in `site1` and *N* is the number of sites in `site2`. The azimuth angle is expressed in degrees counter-clockwise from the east (for geographic sites), or from the global x-axis around the global z-axis (for Cartesian sites), ranging from -180 to 180 degrees.

### e1 — Elevation angle between sites

*M*-by-*N* arrays

Elevation angle between `site1` and `site2`, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in `site2` and *N* is the number of sites in `site1`. The elevation angle is expressed in degrees from the horizontal (or X-Y) plane, ranging from -90 to 90 degrees.

When you specify the path type as 'greatcircle', the elevation angle is always zero.

## Version History

Introduced in R2019b

### See Also

`distance`

# clearMap

Clear plots

## Syntax

```
clearMap(viewer)
```

## Description

`clearMap(viewer)` removes all plots from the specified Site Viewer.

## Examples

### Clear Transmitter Site From Site Viewer

Create a Site Viewer that uses the "streets" basemap. Display a transmitter site.

```
viewer = siteviewer("Basemap", "streets");
tx = txsite;
show(tx)
```

Clear the map.

```
clearMap(viewer)
```

# close

Close Site Viewer

## Syntax

```
close(viewer)
```

## Description

`close(viewer)` closes the Site Viewer window and deletes the handle.

## Examples

### Compare Coverage Maps

Launch two Site Viewer windows. One Site Viewer window uses the terrain model and the other window does not use the terrain model.

```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");  
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```

Create a transmitter site.

```
tx = txsite;
```

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx,"Map",viewer1)
```

The map without terrain uses the free-space model by default.

```
coverage(tx, "Map", viewer2)
```

## Input Arguments

**viewer** — Map viewer for visualizing transmitter or receiver sites

siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a siteviewer object.<sup>2</sup>

## Version History

Introduced in R2019b

## See Also

clearMap | siteviewer

<sup>2</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## contour

Display contour map of RF propagation data in Site Viewer

### Syntax

```
contour(pd)  
contour( ____,Name,Value)
```

### Description

`contour(pd)` creates a filled contour plot in the current Site Viewer. Contours are colored according to data values of corresponding locations.

`contour( ____,Name,Value)` creates a filled contour map with additional options specified by name-value pair arguments.

### Examples

#### Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];  
lats = [42.3467,42.3598,42.3763];  
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name",names,...  
            "Latitude",lats,...  
            "Longitude",lons, ...  
            "TransmitterFrequency",2.5e9);  
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

## Input Arguments

### pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Type', 'power'

### DataVariableName — Data variable to contour map

DataVariableName (default) | character vector | string scalar

Data variable to contour map, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object pd.

Data Types: char | string

### Type — Type of value to plot

'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the 'Type' column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	''
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: char | string

### Levels — Data value levels to plot

numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and numeric vector. Each level is displayed as a different colored, filled contour on the map. The colors are selected using `Colors` if specified, or else `Colormap` and `ColorLimits`. Data points with values below the minimum level are not included in the plot.

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: double

### Colors — Colors of data points

*M*-by-3 array of RGB | array of strings | cell array of character vectors

Colors of the filled contours, specified as the comma-separated pair consisting of 'Colors' and an *M*-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in `Levels` for coloring the corresponding points. Colors cannot be used with `Colormap` and `ColorLimits`.

Data Types: double | char | string

### Colormap — Color map for coloring points

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap' and a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors. `Colormap` cannot be used with `Colors`.

Data Types: double | char | string

### ColorLimits — Color limits for color map

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. `ColorLimits` cannot be used with `Colors`.

Data Types: double

**Transparency — Transparency of contour map**`0.4 (default) | numeric scalar in the range of [0,1]`

Transparency of the contour plot, specified as a numeric scalar in the range [0,1], where 0 is completely transparent and 1 is completely opaque.

Data Types: `double`

**ShowLegend — Show color legend on map**`true (default) | false`

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: `logical`

**LegendTitle — Title of color legend**`character vector | string scalar`

Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: `string | char`

**Map — Map for surface data**`siteviewer object`

Map for surface data, specified as the comma-separated pair consisting of 'Map' and a `siteviewer` object.<sup>3</sup> The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: `char | string`

## Version History

Introduced in R2020a

**See Also**`plot | interp | getDataVariable`

---

<sup>3</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## coverage

Display or compute coverage map

### Syntax

```
coverage(txs)
coverage(txs,propmodel)
coverage(txs,rx)
coverage(txs,rx,propmodel)
coverage( ___,Name,Value, ___ )
pd = coverage(txs, ___ )
```

### Description

`coverage(txs)` displays the coverage map for the specified transmitter site in the current Site Viewer. Each colored contour of the map defines an area where the corresponding signal strength is transmitted to the mobile receiver.

---

**Note** This function only supports antenna sites with `CoordinateSystem` property set to "geographic".

---

`coverage(txs,propmodel)` displays the coverage map based on the specified propagation model. The default propagation model is "longley-ricc" when terrain is in use and "freospace" when terrain is not used.

`coverage(txs,rx)` displays the coverage map based on the receiver site properties.

`coverage(txs,rx,propmodel)` displays the coverage map based on the receiver site properties and specified propagation model.

`coverage( ___,Name,Value, ___ )` displays the coverage map using additional options specified by the `Name,Value` pairs.

`pd = coverage(txs, ___ )` returns computed coverage data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

### Examples

#### Coverage Map of Transmitter

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Show the coverage map.

coverage(tx)

### Coverage Map Using Transmitter and Receiver

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Create a receiver site at Fenway Park with an antenna height of 1.2 m and system loss of 10 dB.

```
rx = rxsite('Name','Fenway Park', ...
           'Latitude', 42.3467, ...
           'Longitude', -71.0972, 'AntennaHeight', 1.2, 'SystemLoss', 10);
```

Calculate the coverage area of the transmitter using a close-in propagation model.

```
coverage(tx, rx, 'PropagationModel', 'closein')
```

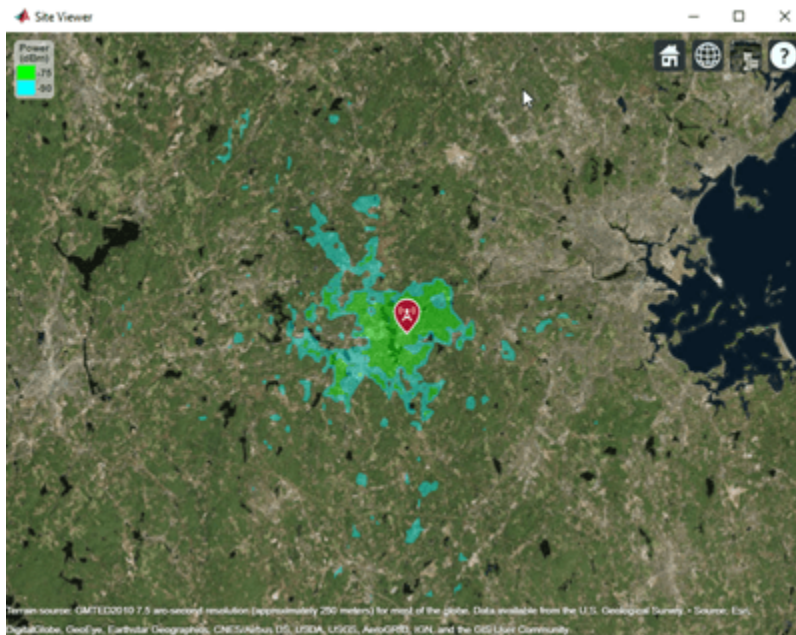

### Coverage Map for Strong and Weak Signals

Define strong and weak signal strengths with corresponding colors.

```
strongSignal = -75;
strongSignalColor = "green";
weakSignal = -90;
weakSignalColor = "cyan";
```

Create a transmitter site and display the coverage map.

```
tx = txsite('Name','MathWorks', ...
    'Latitude',42.3001, ...
    'Longitude',-71.3503);
coverage(tx, ...
    'SignalStrengths',[strongSignal,weakSignal], ...
    'Colors', [strongSignalColor,weakSignalColor])
```

### Combined Coverage Map of Multiple Transmitters

Define the names and the locations of sites around Boston.

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];
lats = [42.3467, 42.3598, 42.3763];
lons = [-71.0972, -71.0545, -71.0611];
```

Create the transmitter site array.

```
txs = txsite('Name', names, ...
            'Latitude', lats, ...
            'Longitude', lons, ...
            'TransmitterFrequency', 2.5e9);
```

Display the combined coverage map for multiple signal strengths, using close-in propagation model.

```
coverage(txs, 'close-in', 'SignalStrengths', -100:5:-60)
```

### Coverage Map Using Longley-Rice and Ray Tracing Method

Launch Site Viewer using buildings in Chicago. For more information about the osm file, see [1] on page 4-208.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite("Latitude",41.8800, ...  
           "Longitude",-87.6295, ...  
           "TransmitterFrequency",2.5e9);  
show(tx)
```

### Coverage Map Using Longley-Rice Propagation Model

Create a coverage map of the city using the Longley-Rice propagation model.

```
coverage(tx, "SignalStrengths", -100:-5, "MaxRange", 250, "Resolution", 1)
```

Longley-Rice models over-the-rooftops propagation along vertical slices and obstructions tend to dominate the coverage region.

### Coverage Map Using Ray Tracing Propagation Model and Image Method

Create a ray tracing propagation model, which MATLAB® represents using a `RayTracing` object. Configure the model to use the image method and to find propagation paths with up to 1 surface reflection.

```
pmImage = propagationModel("raytracing", "Method", "image", ...
    "MaxNumReflections", 1);
```

Create a coverage map of the city using the transmitter site and the ray tracing propagation model.

```
coverage(tx, pmImage, "SignalStrengths", -100:-5, ...
    "MaxRange", 250, "Resolution", 2)
```

This coverage map shows new regions that are in service due to reflected propagation paths.

### Coverage Map Using Ray Tracing Propagation Model and SBR Method

Create another ray tracing propagation model. This time, configure the model to use the shooting and bouncing rays (SBR) method and to find propagation paths with up to 2 surface reflections. The SBR method is generally faster than the image method.

```
pmSBR = propagationModel("raytracing", "Method", "sbr", ...
    "MaxNumReflections", 2);
```

Create an updated coverage map of the city.

```
coverage(tx, pmSBR, "SignalStrengths", -100:-5, ...
    "MaxRange", 250, "Resolution", 2)
```

This coverage map shows new regions that are in service due to the additional reflected propagation paths.

### Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### txs — Transmitter sites

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to "geographic".

### rx — Receiver site

`rxsite` object

Receiver site, specified as a `rxsite` object.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to "geographic".

**propmodel** — Propagation model to use for path loss calculations

"longley-ric" (default) | "freospace" | "close-in" | "rain" | "gas" | "fog" | "raytracing" | propagation model created using propagationModel

Propagation model to use for the path loss calculations, specified as one of these options:

- "freospace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-ric" — Longley-Rice propagation model
- "tirem" — TIREM™ propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the propagationModel function. For example, you can create a ray tracing propagation model that uses the image method by specifying propagationModel("raytracing", "Method", "image").

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-ric" when you use a terrain.</li> <li>• "freospace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freospace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-ric" and "tirem", are only supported for sites with a CoordinateSystem value of "geographic".

You can also specify the propagation model by using the PropagationModel name-value pair argument.

**Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: "Type", "power"

**Type** — Type of signal strength to compute

"power" (default) | "efield"

Type of signal strength to compute, specified as one of these options:

- "power" — The signal strengths in SignalStrengths is in power units (dBm) of the signal at the mobile receiver input.
- "efield"— The signal strength in SignalStrengths is in electric field strength units (dBuV/m) of signal wave incident on the antenna.

Data Types: char | string

**SignalStrengths — Signal strengths to display on coverage map**

numeric vector

Signal strengths to display on coverage map, specified as a numeric vector.

Each strength uses different colored filled contour on the map. The default value is -100 dBm if Type is "power" and 40 dBuV/m if Type is "efield".

Data Types: double

**PropagationModel — Propagation model to use for path loss calculations**

"freespace" | "close-in" | "rain" | "gas" | "fog" | "longley-rice" | "raytracing" | propagation model created using propagationModel

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-rice" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the propagationModel function. For example, you can create a ray tracing propagation model that uses the image method by specifying propagationModel("raytracing", "Method", "image").

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-rice" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-rice" and "tirem", are only supported for sites with a CoordinateSystem value of "geographic".

Data Types: char | string

### **MaxRange — Maximum range of coverage map from each transmitter site**

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the type of propagation model.

Type of Propagation Model	MaxRange
Atmospheric or empirical	Range of minimum value in SignalStrengths.
Terrain	30 km or distance to the furthest building.
Ray tracing	500 m

For more information about the types of propagation models, see “Choose a Propagation Model”.

Data Types: double

### **Resolution — Resolution of coverage map**

"auto" (default) | numeric scalar

Resolution of coverage map, specified as "auto" or a numeric scalar in meters.

The resolution of "auto" computes the maximum value scaled to MaxRange. Decreasing the resolution increases the quality of the coverage map and the time required to create it.

Data Types: char | string | double

### **ReceiverGain — Mobile receiver gain**

2.1 (default) | numeric scalar

Mobile receiver gain, specified as a numeric scalar in dB. The receiver gain value includes the mobile receiver antenna gain and system loss.

The receiver gain computes received signal strength when Type is "power".

If receiver site argument rx is passed to coverage, the default value is the maximum gain of the receiver antenna with the system loss subtracted. Otherwise the default value is 2.1.

Data Types: char | string | double

### **ReceiverAntennaHeight — Mobile receiver antenna height above ground elevation**

1 (default) | numeric scalar

Mobile receiver antenna height above ground elevation, specified as a numeric scalar in meters.

If receiver site argument rx is passed to coverage, the default value is the AntennaHeight of the receiver. Otherwise the default value is 1.

Data Types: double

### **Colors — Colors of filled contours on coverage map**

M-by-3 array of RGB triplets | array of strings | cell array of character vectors

Colors of filled contours on coverage map, specified as one of these options:

- An  $M$ -by-3 array of RGB triplets whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ ; for example,  $[0.4 \ 0.6 \ 0.7]$ .
- An array of strings such as `["red" "green" "blue"]` or `["r" "g" "b"]`.
- A cell array of character vectors such as `{'red', 'green', 'blue'}` or `{'r', 'g', 'b'}`.

Colors are assigned element-wise to `SignalStrengths` values for coloring the corresponding filled contours.

Colors cannot be used with `ColorLimits` or `ColorMap`.

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

Data Types: `char` | `string` | `double`

### **ColorLimits — Color limits for colormap**

two-element vector

Color limits for colormap, specified as a two-element vector of type `[min max]`.

The color limits indicate the signal level values that map to the first and last colors on the colormap.

The default value is `[-120 -5]` if the `Type` is "power" and `[20 135]` if `Type` is "efield".

`ColorLimits` cannot be used with `Colors`.

Data Types: `double`

### **ColorMap — Colormap filled contours for coverage map**

"jet" (default) | predefined color map |  $M$ -by-3 array of RGB triplets

Colormap filled contours on coverage map, specified as a predefined colormap or  $M$ -by-3 array of RGB triplets, where  $M$  defines individual colors.

`ColorMap` cannot be used with `Colors`.

Data Types: `char` | `string` | `double`

### **ShowLegend — Show signal strength color legend on map**

`true` (default) | `false`

Show signal strength color legend on map, specified as `true` or `false`.

Data Types: `logical`

### Transparency — Transparency of coverage map

0.4 (default) | numeric scalar

Transparency of coverage map, specified as a numeric scalar in the range 0 to 1. 0 is transparent and 1 is opaque.

Data Types: `double`

### Map — Map for visualization of surface data

`siteviewer` object

Map for visualization of surface data, specified as a `siteviewer` object.<sup>4</sup>

Data Types: `char` | `string`

## Output Arguments

### pd — Coverage data

`propagationData` object

Coverage data, returned as a `propagationData` object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the `propagationData` is "Coverage Data".

## Limitations

When you specify a `RayTracing` object as input to the `coverage` function, the value of the `MaxNumDiffractions` property must be 0 or 1.

## Version History

### Introduced in R2019b

### R2023a: Ray tracing models discard paths based on path loss

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as "raytracing" or a `RayTracing` object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `coverage` function can return different values in R2023a compared to previous releases. To avoid discarding paths based on relative path loss thresholds, create a `RayTracing` object (by using the `propagationModel` function) and set its `MaxRelativePathLoss` property to `Inf`. Then, use the object as input to the `coverage` function.

### R2022b: Ray tracing functions consider multipath interference

*Behavior changed in R2022b*

<sup>4</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

When calculating received power using ray tracing models, the `coverage` function now incorporates multipath interference by using a phasor sum. In previous releases, the function used a power sum. As a result, the calculations in R2022b are more accurate than in previous releases.

### **R2021b: "raytracing" propagation models use SBR method**

*Behavior changed in R2021b*

Starting in R2021b, when you use the `coverage` function and specify the `propmodel` argument or `PropagationModel` name-value argument as `"raytracing"`, the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `coverage` function uses the image method and calculates up to one reflection.

To display or compute coverage maps using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `coverage` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel("raytracing", "Method", "image");  
coverage(txs, pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-270.

# distance

Distance between sites

## Syntax

```
d = distance(site1,site2)
d = distance(site1,site2,path)
d = distance( ____,Name,Value)
```

## Description

`d = distance(site1,site2)` returns the distance in meters between `site1` and `site2`.

`d = distance(site1,site2,path)` returns the distance using a specified path type, either a Euclidean or great circle path.

`d = distance( ____,Name,Value)` returns the distance with additional options specified by name-value arguments.

## Examples

### Distance Between Transmitter and Receiver Site

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the Euclidean distance in km between the sites.

```
dme = distance(tx,rx)
```

```
dme = 2.1504e+04
```

```
dkm = dme / 1000
```

```
dkm = 21.5037
```

Get the great circle distance between the two sites.

```
dmg = distance(tx,rx,'greatcircle')
```

```
dmg = 2.1451e+04
```

## Input Arguments

**site1,site2** — Transmitter or receiver site

txsite object | rxsite object

Transmitter or receiver site, specified as a `txsite` or `rxsite` object. You can use array inputs to specify multiple sites.

**path — Measurement path type**

'euclidean' | 'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean' — Use the shortest path through space that connects the antenna center positions of the sites.
- 'greatcircle' — Use the shortest path on the surface of the earth that connects the latitude and longitude locations of the sites. This path uses a spherical Earth model.

Data Types: char

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Map', 'siteviewer1'

**Map — Map for visualization or surface data**

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A <code>siteviewer</code> object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>• The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A <code>siteviewer</code> object.</li> <li>• The name of an STL file.</li> <li>• A <code>triangulation</code> object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

## Output Arguments

### **d** — Distance between sites

*M*-by-*N* numeric array

Distance between sites, returned as an *M*-by-*N* numeric array in meters, where *M* is the number of sites in `site2` and *N* is the number of sites in `site1`.

## Version History

Introduced in R2019b

### See Also

`angle`

## elevation

Elevation of site

### Syntax

```
z = elevation(site)
z = elevation( ____,Name,Value)
```

### Description

`z = elevation(site)` returns the ground or building surface elevation of antenna site in meters. Elevation is measured relative to mean sea level using earth gravitational model, EGM-96. If the site coincides with a building, elevation is measured at the top of the building. Otherwise, elevation is measured at the ground.

This function only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

`z = elevation( ____,Name,Value)` returns the ground elevation of the antenna in meters with additional options specified by name-value arguments.

### Examples

#### Elevation at Mount Washington

Compute and display the elevation at Mount Washington in meters.

```
mtwash = txsite('Name','Mt Washington','Latitude',44.2706, ...
               'Longitude',-71.3033);
z = elevation(mtwash)

z = 1.8704e+03
```

### Input Arguments

#### site — Transmitter or receiver site

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Map', 'siteviewer1'

### Map — Map for visualization or surface data

siteviewer object | string scalar | character vector

Map for visualization or surface data, specified as one of the following:

- A `siteviewer` object.<sup>5</sup>
- A terrain name if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`.

The default value is:

- The current `siteviewer` object or a new `siteviewer` object if none are open.
- 'gmted2010' if called with an output.

Data Types: char | string

## Output Arguments

### z — Ground or building surface elevation of antenna site

*M*-by-1 matrix

Ground or building surface elevation of the antenna site, returned as an *M*-by-1 matrix with each element unit in meters. *M* is the number of sites in `site`.

## Version History

Introduced in R2019b

## See Also

### Functions

distance | angle

### Objects

txsite | rxsite

<sup>5</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## getDataVariable

Get data variable values

### Syntax

```
datavARIABLE = getDataVariable(pd)
[datavARIABLE,lat,lon] = getDataVariable(pd)
[ ___ ] = getDataVariable(pd,varname)
```

### Description

`datavARIABLE = getDataVariable(pd)` returns the values of the data points in the propagation data object. The data is processed such that the missing values are removed and duplicate location data are replaced with mean values.

`[datavARIABLE,lat,lon] = getDataVariable(pd)` returns the location coordinates of the data points in the propagation data object.

`[ ___ ] = getDataVariable(pd,varname)` returns the values of the data points corresponding to the `varname` variable.

### Examples

#### Capacity Map Using SINR Data

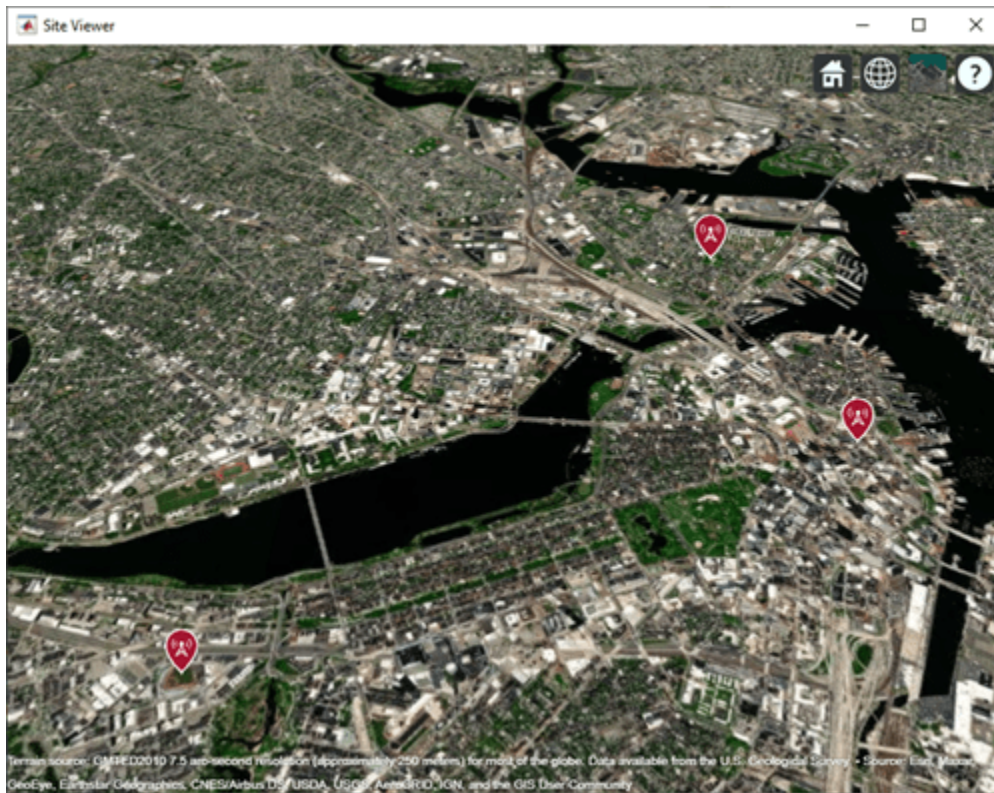

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

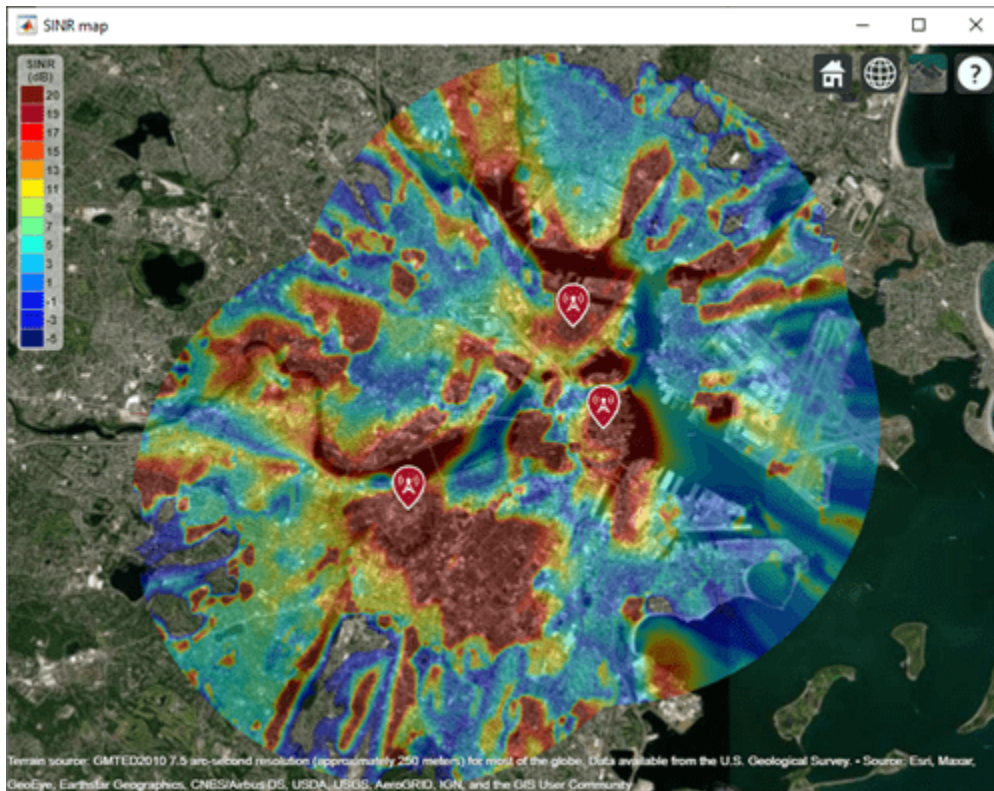

```
txs = txsite("Name",names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

## Input Arguments

### **pd** — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

### **varname** — Variable name in data table

character vector | string scalar

Variable name in the data table, specified as a character vector or a string scalar. This variable name must correspond to a variable with numeric data other than the latitude or longitude data.

## Output Arguments

### **datavalue** — Values of data points

column vector

Values of data points in the propagation data object, returned as a column vector.

### **lat** — Latitude of data points

$M$ -by-1 vector

Latitude of data points, returned as an  $M$ -by-1 vector with each element unit in degrees.

### **lon — Longitude of data points**

*M*-by-1 vector

Longitude of data points, returned as an *M*-by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range `[-180 180]`.

### **Version History**

**Introduced in R2020a**

# hide

Hide site from Site Viewer

## Syntax

```
hide(site)
hide( ____,Name,Value)
```

## Description

`hide(site)` hides the location of the specified antenna site from the current Site Viewer.

`hide( ____,Name,Value)` hides the site with additional options specified by one or more name-value pairs.

## Examples

### Show and Hide Transmitter Site

Create and show a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
show(tx)
```

Hide the transmitter site.

```
hide(tx)
```

### Show and Hide Sites with Cartesian Coordinates

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters. Then, visualize the sites.

```
tx = txsite('cartesian', ...  
           'AntennaPosition', [-1.46; -1.42; 2.1]);  
rx = rxsite('cartesian', ...  
           'AntennaPosition', [0.3; 0.3; 0.85]);
```

```
show(tx)  
show(rx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Hide the sites.

```
hide(tx)  
hide(rx)
```

## Input Arguments

### **site** — Transmitter or receiver site

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Map', 'siteviewer1'

### **Map** — Map for visualization of surface data

siteviewer object

Map for visualization of surface data, specified as a siteviewer object.<sup>6</sup>

Data Types: char | string

## Version History

**Introduced in R2019b**

### **See Also**

# interp

Interpolate RF propagation data

## Syntax

```
interpvalue = interp(pd,lat,lon)
interpvalue = interp(pd,Name,Value)
```

## Description

`interpvalue = interp(pd,lat,lon)` returns interpolated values from the propagation data for each query point specified in latitude and longitude vectors. The interpolation is performed using a scattered data interpolation method. Values corresponding to query points outside the data region are assigned a NaN.

`interpvalue = interp(pd,Name,Value)` returns interpolated values with additional options specified by name-value pair arguments.

## Examples

### Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
```

```
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);  
[lons,lats] = meshgrid(lonv,latv);  
lats = lats(:);  
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

```
v1 = interp(pd1,lats,lons);  
v2 = interp(pd2,lats,lons);  
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");  
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;  
contour(pd,"Levels",sensitivity:-5,"Type","power")
```

### Input Arguments

#### **pd** — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

**lat — Latitude coordinate values**

vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84. The latitude coordinates must be in the range [-90 90].

**lon — Longitude coordinate values**

vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84.

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'Method', 'linear'`

**DataVariableName — Data variable to interpolate**

character vector | string scalar

Data variable to interpolate, specified as the comma-separated pair consisting of `'DataVariableName'` and a character vector or string scalar corresponding to a variable name in the data table used to create the `propagationData` container object. The default value is the `DataVariableName` property in the `propagationData`.

Data Types: `char` | `string`

**Method — Method used to interpolate data**`'natural'` (default) | `'nearest'` | `'linear'`

Method used to interpolate data, specified as the comma separated-pair consisting `'Method'` and one of the following:

- `'natural'` - Natural neighbor interpolation
- `'linear'` - Linear interpolation
- `'nearest'` - Nearest neighbor interpolation

Data Types: `char` | `string`

**Output Arguments****interpvalue — Interpolated values from propagation data**

numeric vector

Interpolated values from the propagation data for each query point specified in latitude and longitude vectors, returned as a numeric vector.

## **Version History**

**Introduced in R2020a**

# link

Display or compute communication link status

## Syntax

```
link(rx,tx)
link(rx,tx,propmodel)
link( ____,Name,Value)
status = link( ____)
```

## Description

`link(rx,tx)` displays a one-way point-to-point communication link between a receiver site and transmitter site in the current Site Viewer. The plot is color coded to identify the link success status.

`link(rx,tx,propmodel)` displays the communication link based on the specified propagation model.

`link( ____,Name,Value)` displays a communication link using additional options specified by `Name,Value` pairs.

`status = link( ____)` returns the success status of the communication link as `true` or `false`.

## Examples

### Communication Link Between Geographic Transmitter and Receiver

Create a transmitter site.

```
tx = txsite("Name","MathWorks", ...
           "Latitude",42.3001, ...
           "Longitude",-71.3503);
```

Create a receiver site with a sensitivity defined in dBm.

```
rx = rxsite("Name","Boston", ...
           "Latitude",42.3601, ...
           "Longitude",-71.0589, ...
           "ReceiverSensitivity",-90);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx,tx)
```

### Communication Link Between Cartesian Transmitter and Receiver

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters.

```
tx = txsite('cartesian', ...
    'AntennaPosition', [-1.46; -1.42; 2.1]);
rx = rxsite('cartesian', ...
    'AntennaPosition', [0.3; 0.3; 0.85]);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx, tx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

## Input Arguments

### **rx** — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

### **tx** — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

### **propmodel** — Propagation model to use for path loss calculations

"longley-rice" (default) | "freespace" | "close-in" | "rain" | "gas" | "fog" | "raytracing" | propagation model created using `propagationModel`

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-rice" — Longley-Rice propagation model
- "tirem" — TIREM propagation model

- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the `propagationModel` function. For example, you can create a ray tracing propagation model that uses the image method by specifying `propagationModel("raytracing", "Method", "image")`.

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-ric" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-ric" and "tirem", are only supported for sites with a `CoordinateSystem` value of "geographic".

You can also specify the propagation model by using the `PropagationModel` name-value pair argument.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: "Type", "power"

### PropagationModel — Propagation model to use for path loss calculations

"freespace" | "close-in" | "rain" | "gas" | "fog" | "longley-ric" | "raytracing" | propagation model created using `propagationModel`

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-ric" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.

- A propagation model created using the `propagationModel` function. For example, you can create a ray tracing propagation model that uses the image method by specifying `propagationModel("raytracing", "Method", "image")`.

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-rice" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-rice" and "tirem", are only supported for sites with a `CoordinateSystem` value of "geographic".

Data Types: char | string

#### SuccessColor — Color of successful links

"green" (default) | RGB triplet | character vector | string scalar

Color of successful links, specified as one of these options:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A character vector such as "red" or "r".
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

Data Types: char | string | double

#### FailColor — Color of unsuccessful links

"red" (default) | RGB triplet | character vector | string scalar

Color of unsuccessful links, specified as one of these options:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].
- A character vector such as "red" or "r".
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

Data Types: char | string | double

### Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A siteviewer object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using addCustomTerrain.</li> </ul>	<ul style="list-style-type: none"> <li>• The current siteviewer object or a new siteviewer object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A siteviewer object.</li> <li>• The name of an STL file.</li> <li>• A triangulation object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

## Output Arguments

### status — Success status of communication link

M-by-N array

Success status of communication links, returned as an  $M$ -by- $N$  arrays.  $M$  is the number of transmitter sites and  $N$  is the number of receiver sites.

## Version History

### Introduced in R2019b

#### **R2023a: Ray tracing models discard paths based on path loss**

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as "raytracing" or a `RayTracing` object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `link` function can return different values in R2023a compared to previous releases. To avoid discarding paths based on relative path loss thresholds, create a `RayTracing` object (by using the `propagationModel` function) and set its `MaxRelativePathLoss` property to `Inf`. Then, use the object as input to the `link` function.

#### **R2022b: Ray tracing functions consider multipath interference**

*Behavior changed in R2022b*

When calculating received power using ray tracing models, the `link` function now incorporates multipath interference by using a phasor sum. In previous releases, the function used a power sum. As a result, the calculations in R2022b are more accurate than in previous releases.

#### **R2021b: "raytracing" propagation models use SBR method**

*Behavior changed in R2021b*

Starting in R2021b, when you use the `link` function and specify the `propmodel` argument or `PropagationModel` name-value argument as "raytracing", the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `link` function uses the image method and calculates up to one reflection.

To display or compute communication link status using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `link` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel("raytracing", "Method", "image");  
link(rx,tx,pm)
```

For information about the SBR and image methods, see "Choose a Propagation Model".

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see "Default modeling method is shooting and bouncing rays method" on page 4-270.

## location

Coordinates at distance and angle from site

### Syntax

```
sitelocation = location(site)
[lat,lon] = location(site)
[ ___ ] = location(site,distance,azimuth)
```

### Description

`sitelocation = location(site)` returns the site location of the antenna.

`[lat,lon] = location(site)` returns the latitude and longitude of the antenna site.

This syntax only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

`[ ___ ] = location(site,distance,azimuth)` returns the new location achieved by moving the antenna site by the distance specified in the direction of the azimuth angle. The location is calculated by moving along a great circle path using a spherical Earth model.

This syntax only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

### Examples

#### Location of Antenna Site

Create a site 1 km north of a given site.

Create the first transmitter site.

```
tx = txsite('Name','MathWorks', ...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
```

Calculate the location 1 km north of the first site.

```
[lat,lon] = location(tx,1000,90)
```

```
lat = 42.3091
```

```
lon = -71.3504
```

Create a second transmitter site at the location specified by `lat` and `lon`.

```
tx2 = txsite('Name','Second transmitter', ...
            'Latitude',lat, ...
            'Longitude',lon);
```

Show the two transmitter sites.

```
show([tx,tx2])
```

## Input Arguments

### site — Antenna site

scalar | array

Antenna site, specified as a scalar or an array. It is either a txsite or a rxsite object. For more information, see txsite, and rxsite

---

**Note** If distance or azimuth is a vector, then site must be a scalar.

---

### distance — Distance to move antenna site

scalar | vector

Distance to move antenna site, specified as a scalar or vector in meters.

### azimuth — Azimuth angle

scalar | vector

Azimuth angle, specified as a scalar or vector in degrees. Azimuth angle is measured counterclockwise from due east.

## Output Arguments

### **siteLocation** — Location of antenna site

*M*-by-2 matrix

Location of antenna site, returned as an *M*-by-2 matrix with each element unit in degrees. *M* is the number of sites in `site`. The location value includes the latitude and longitude of the antenna site.

If the antenna site has the `CoordinateSystem` property set to 'geographic', *L* is a 1-by-2 vector in degrees latitude and longitude. The output longitude wrapped so that values are in the range [-180 180]. If `SITE` has `CoordinateSystem` set to 'cartesian', *L* is a 1-by-3 vector.

### **lat** — Latitude of one or more antenna sites

*M*-by-1 vector

Latitude of one or more antenna sites, returned as an *M*-by-1 vector with each element unit in degrees. *M* is the number of sites in `site`.

### **lon** — Longitude of one or more antenna sites

*M*-by-1 matrix

Longitude of one or more antenna sites, returned as an *M*-by-1 matrix with each element unit in degrees. *M* is the number of sites in `site`. The output is wrapped so that the values are in the range [-180 180].

## Version History

`distance` | `angle` | `txsite` | `rxsite`

# los

Display or compute line-of-sight (LOS) visibility status

## Syntax

```
los(site1,site2)
los(site1,site2,Name,Value)
vis = los(site1,site2,Name,Value)
```

## Description

`los(site1,site2)` displays the line-of-sight (LOS) visibility from site 1 to site 2 in the current Site Viewer. The plot is color coded to identify the visibility of the points along the line.

`los(site1,site2,Name,Value)` sets properties using one or more name-value pairs. For example, `los(site1,site2,'ObstructedColor','red')` displays the LOS in red to show blocked visibility.

`vis = los(site1,site2,Name,Value)` returns the status of the LOS visibility.

## Examples

### LOS from a Transmitter Site to a Receiver Site

Create a transmitter site with an antenna of height 30 m and a receiver site at ground level.

```
tx = txsite("Name","MathWorks Apple Hill",...
           "Latitude",42.3001,"Longitude",-71.3504,"AntennaHeight",30);
rx = rxsite("Name","MathWorks Lakeside", ...
           "Latitude",42.3021,"Longitude",-71.3764);
```

Plot the LOS between the two sites.

```
los(tx,rx)
```

### LOS from a Transmitter Site to Two Receiver Sites

Create a transmitter site with an antenna of height 30 m and two receiver sites with antennas at ground level.

```
tx = txsite("Name", "MathWorks Apple Hill", ...
           "Latitude", 42.3001, "Longitude", -71.3504, "AntennaHeight", 30);
```

```
names = ["Fenway Park", "Bunker Hill Monument"];
lats = [42.3467, 42.3763];
lons = [-71.0972, -71.0611];
```

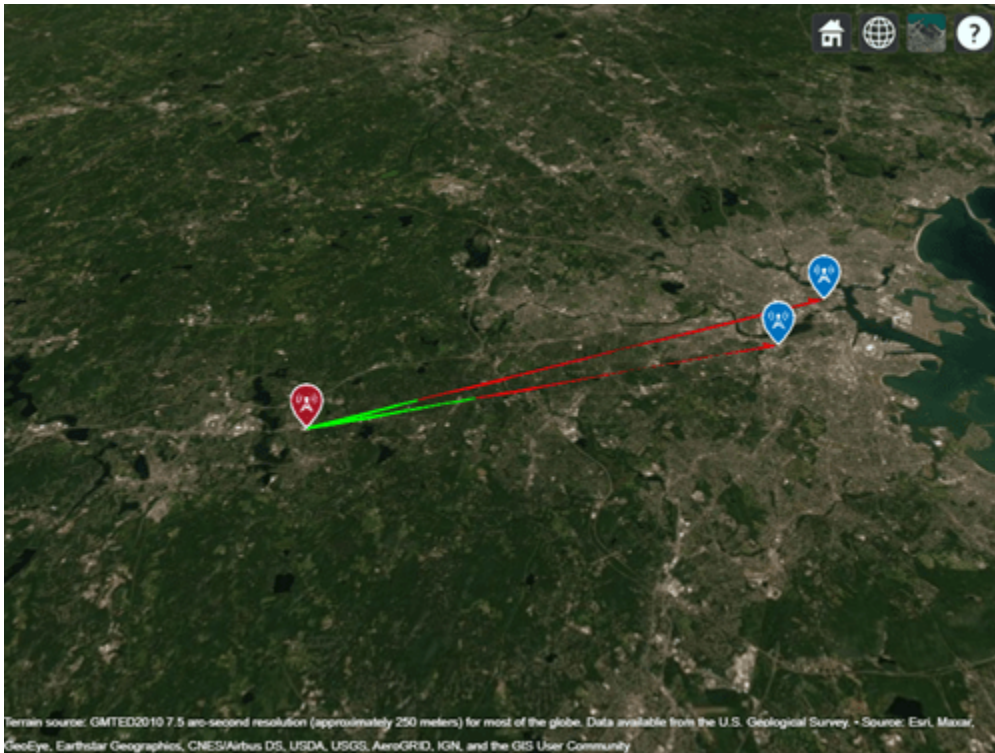

Create the receiver site array.

```
rxs = rxsite("Name", names, ...
            "Latitude", lats, ...
            "Longitude", lons);
```

Plot the LOSs to the receiver sites. The red portion of the LOS represents obstructed visibility.

```
los(tx, rxs)
```

### LOS Between Cartesian Sites

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer("SceneModel", "conferenceroom.stl");
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters.

```
tx = txsite("cartesian", ...
    "AntennaPosition", [-1.46; -1.42; 2.1]);
rx = rxsite("cartesian", ...
    "AntennaPosition", [0.3; 0.3; 0.85]);
```

Plot the LOS between the transmitter and the receiver.

```
los(rx, tx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

### Plot Propagation Rays Between Sites in Chicago

Perform ray tracing in Chicago and return the rays in `comm.Ray` objects. Then, display the rays without performing the ray tracing analysis again.

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-249.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on one building and a receiver site on another building. Show the line-of-sight path between the sites using the `los` function.

```
tx = txsite("Latitude",41.8800, ...  
           "Longitude",-87.6295, ...  
           "TransmitterFrequency",2.5e9);  
rx = rxsite("Latitude",41.881352, ...  
           "Longitude",-87.629771, ...  
           "AntennaHeight",30);  
los(tx,rx)
```

Create a ray tracing propagation model, which MATLAB® represents using a `RayTracing` object. By default, the model uses the SBR method and calculates propagation paths with up to two reflections.

```
pm = propagationModel("raytracing");
```

Perform the ray tracing analysis. The `raytrace` function returns a cell array containing the `comm.Ray` objects.

```
rays = raytrace(tx,rx,pm)
```

```
rays = 1x1 cell array
      {1x3 comm.Ray}
```

View the properties of the first ray object.

```
rays{1}(1)
```

```
ans =
  Ray with properties:

    PathSpecification: 'Locations'
   CoordinateSystem: 'Geographic'
  TransmitterLocation: [3x1 double]
   ReceiverLocation: [3x1 double]
     LineOfSight: 0
   Interactions: [1x1 struct]
      Frequency: 2.5000e+09
 PathLossSource: 'Custom'
     PathLoss: 92.7740
    PhaseShift: 1.2933
```

```

Read-only properties:
  PropagationDelay: 5.7088e-07
  PropagationDistance: 171.1462
  AngleOfDeparture: [2x1 double]
  AngleOfArrival: [2x1 double]
  NumInteractions: 1

```

Close Site Viewer.

```
close(viewer)
```

Create another Site Viewer with the same buildings, transmitter site, and receiver site. Then, display the propagation paths. Alternatively, you can plot individual paths by specifying a single ray object, for example `rays{1}(2)`.

```

siteviewer("Buildings", "chicago.osm");
show(tx)
show(rx)
plot(rays{1}, "Type", "power", ...
     "TransmitterSite", tx, "ReceiverSite", rx)

```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### site1 — Source antenna site

txsite object | rxsite object

Source antenna site, specified as a txsite object or a rxsite object. Site 1 must be a single site object.

### site2 — Target antenna site

txsite object | rxsite object | vector of txsite or rxsite objects

Target antenna site, specified as a txsite object or a rxsite object. Site 2 can be a single site object or a vector of multiple site objects.

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'ObstructedColor', 'blue'

### VisibleColor — Plot color for successful visibility

'green' (default) | RGB triplet | character vector | string scalar

Plot color for successful visibility, specified as one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A character vector such as 'red' or 'r'.
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

**ObstructedColor – Plot color for blocked visibility**

'red' (default) | RGB triplet | character vector | string scalar

Plot color for blocked visibility, specified as one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1]; for example, [0.4 0.6 0.7].
- A character vector such as 'red' or 'r'.
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
"red"	"r"	[1 0 0]	
"green"	"g"	[0 1 0]	
"blue"	"b"	[0 0 1]	
"cyan"	"c"	[0 1 1]	
"magenta"	"m"	[1 0 1]	
"yellow"	"y"	[1 1 0]	
"black"	"k"	[0 0 0]	
"white"	"w"	[1 1 1]	

**Resolution – Sampling distance between two sites**

'auto' (default) | numeric scalar

Resolution of sample locations used to compute line-of-sight visibility, specified as 'auto' or a numeric scalar expressed in meters. Resolution defines the distance between samples on the great circle path using a spherical Earth model. If Resolution is 'auto', the function computes a value based on the distance between the sites.

**Map – Map for visualization or surface data**

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A siteviewer object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using addCustomTerrain.</li> </ul>	<ul style="list-style-type: none"> <li>• The current siteviewer object or a new siteviewer object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>

Coordinate System	Valid map values	Default map value
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A siteviewer object.</li> <li>• The name of an STL file.</li> <li>• A triangulation object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

## Output Arguments

### vis — Status of LOS visibility

true or 1 | false or 0 | *n*-by-1 logical array

Status of LOS visibility, returned as logical 1 (true) or 0 (false). If there are multiple target sites, the function returns a logical array of *n*-by-1.

## Version History

Introduced in R2019b

# pathloss

**Package:** rfprop

Path loss of radio wave propagation

## Syntax

```
pl = pathloss(propmodel,rx,tx)
pl = pathloss( ____,Name,Value)
[pl,info] = pathloss( ____ )
```

## Description

`pl = pathloss(propmodel,rx,tx)` returns the path loss of radio wave propagation at the receiver site from the transmitter site.

`pl = pathloss( ____,Name,Value)` returns the path loss using additional options specified by `Name,Value` pairs.

`[pl,info] = pathloss( ____ )` returns the path loss and the information about the propagation paths.

## Examples

### Path Loss of Receiver In Heavy Rain

Specify the transmitter and the receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill', ...
           'Latitude',42.3001,'Longitude',-71.3504, ...
           'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park', ...
           'Latitude',42.3467,'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
  Rain with properties:
```

```
    RainRate: 50
         Tilt: 0
```

Calculate the pathloss at the receiver using the rain propagation model.

```
pl = pathloss(pm,rx,tx)
```

```
pl = 127.3208
```

## Input Arguments

### propmodel — Propagation model

propagation model object

Propagation model, specified as a `FreeSpace`, `Rain`, `Gas`, `Fog`, `CloseIn`, `LongleyRice`, `TIREM`, or `RayTracing` object.

Create propagation models by using the `propagationModel` function.

### rx — Receiver site

rxsite object

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

### tx — Transmitter site

txsite object

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'Map', 'none'`

### Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>A <code>siteviewer</code> object<sup>a</sup>.</li> <li>A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open.</li> <li>"gmted2010", if the function is called with an output.</li> </ul>

Coordinate System	Valid map values	Default map value
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A <code>siteviewer</code> object.</li> <li>• The name of an STL file.</li> <li>• A <code>triangulation</code> object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

## Output Arguments

### **pL** — Path loss

scalar |  $M$ -by- $N$  arrays

Path loss, returned as a scalar or  $M$ -by- $N$  cell arrays containing a row vector of path loss values in decibels.  $M$  is the number of TX sites and  $N$  is the number of RX sites.

Path loss is computed along the shortest path through space connecting the transmitter and receiver antenna centers.

For terrain propagation models, path loss is computed using terrain elevation profile that is computed at sample locations on the great circle path between the transmitter and the receiver. If `Map` is a `siteviewer` object with buildings specified, the terrain elevation is adjusted to include the height of the buildings.

### **info** — Information corresponding to each propagation path

$M$ -by- $N$  structure array |  $M$ -by- $N$  cell array containing vector of structures in each cell

Information corresponding to each propagation path, returned as a  $M$ -by- $N$  cell array containing vector of structures in each cell for ray tracing propagation models and  $M$ -by- $N$  structure array for all other propagation models. The field and values for the structures are:

- `PropagationDistance` — Total distance of propagation path returned as a double scalar in meters.
- `AngleOfDeparture` — Angle of departure of signal from transmitter site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `AngleOfArrival` — Angle of arrival of signal at receiver site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `NumReflections` — Number of reflections undergone by signal along propagation path, returned specified as 0, 1, or 2. This field and value is only for ray tracing propagation models.

Angle values in this structure are defined using the local East-North-Up coordinate system of the antenna when `CoordinateSystem` is set to `geographic`. Angle values in this structure are defined using global Cartesian coordinate system when `CoordinateSystem` is set to `cartesian`. Azimuth angle is measured either from east (when '`geographic`') or from the global x-axis around the global z-axis (when '`cartesian`'). Elevation angle is measured from the horizontal (or X-Y) plane to the x-axis of the antenna in the range -90 to 90.

## Version History

### Introduced in R2019b

#### **R2023a: Ray tracing models discard paths based on path loss**

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as a `RayTracing` object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `pathloss` function can return different values in R2023a compared to previous releases. To avoid discarding propagation paths based on relative path loss thresholds, set the `MaxRelativePathLoss` property of the ray tracing object to `Inf`.

#### **R2022b: Ray tracing models using SBR method find paths with exact geometric accuracy**

*Behavior changed in R2022b*

Ray tracing models that find propagation paths by using the shooting and bouncing rays (SBR) method correct the results so that the geometric accuracy of each path is exact, using single-precision floating-point computations. In previous releases, the paths have approximate geometric accuracy.

As a result, when you use a ray tracing model as input to the `pathloss` function, the function can return different results than in previous releases.

`propagationModel` | `range`

# plot

Display RF propagation data in Site Viewer

## Syntax

```
plot(pd)
plot( ____,Name,Value)
```

## Description

`plot(pd)` displays propagation data in the current Site Viewer. Each data point is displayed as a circular marker that is colored according to the corresponding value.

`plot( ____,Name,Value)` displays the propagation data with additional options specified by name-value pair arguments.

## Examples

### Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the `osm` file, see [1] on page 4-259.

```
viewer = siteviewer("Basemap","streets_dark",...
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
           "Longitude",-74.0114,...
           "AntennaHeight",80);
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
            linspace(40.71416, 40.715505, 25), ...
            linspace(40.715505, 40.7133, 25), ...
            linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
             linspace(-74.00627, -74.0092, 25), ...
             linspace(-74.0092, -74.0110, 25), ...
             linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a propagationData object to hold computed signal strength data.

```
tbl = table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
```

Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'Type', 'power'

### DataVariableName — Data variable to plot

pd.DataVariableName (default) | character vector | string scalar

Data variable to plot, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create

the propagation data container object `pd`. The default value is dynamic and corresponds to the `DataVariableName` property of the `propagationData` object.

Data Types: `char` | `string`

#### Type — Type of value to plot

'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the Type column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	' '
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: `char` | `string`

#### Levels — Data value levels to plot

numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and a numeric vector. The propagation data is binned according to `Levels`. The data in each bin is color coded according to the corresponding level. The colors are selected using `Colors` if specified, or else `Colormap` and `ColorLimits`. Data points with values below the minimum level are not included in the plot.

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: `double`

#### Colors — Colors of data points

$M$ -by-3 array of RGB | array of strings | cell array of character vectors

Colors of the data points, specified as the comma-separated pair consisting of 'Colors' and an  $M$ -by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in `Levels` for coloring the corresponding points. Colors cannot be used with `Colormap` and `ColorLimits`.

Data Types: `double` | `char` | `string`

#### Colormap — Color map for coloring points

'jet(256)' (default) | predefined colormap name |  $M$ -by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap' and a predefined colormap name or an  $M$ -by-3 array of RGB (red, blue, green) triplets that define  $M$  individual colors. `Colormap` cannot be used with `Colors`.

Data Types: `double` | `char` | `string`

**ColorLimits — Color limits for color map**

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. ColorLimits cannot be used with Colors.

Data Types: double

**MarkerSize — Size of data markers**

10 (default) | positive numeric scalar

Size of data markers plotted on the map, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric scalar in pixels.

Data Types: double

**ShowLegend — Show color legend on map**

true (default) | false

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: logical

**LegendTitle — Title of color legend**

character vector | string scalar

Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: string | char

**Map — Map for surface data**

siteviewer object

Map for surface data, specified as the comma-separated pair consisting of 'Map' and a siteviewer object.<sup>7</sup> The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: char | string

## Version History

**Introduced in R2020a**

<sup>7</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## location

Coordinates of RF propagation data

### Syntax

```
datalocation = location(pd)
[lat,lon] = location(pd)
```

### Description

`datalocation = location(pd)` returns the location coordinates of the data points in the propagation data object.

`[lat,lon] = location(pd)` returns the latitude and longitude of the propagation data object

### Examples

#### Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1), "MaxRange",maxr);
pd2 = coverage(txs(2), "MaxRange",maxr);
pd3 = coverage(txs(3), "MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;
contour(pd,"Levels",sensitivity:-5,"Type","power")
```

## Input Arguments

### **pd** — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

## Output Arguments

### **dataLocation** — Location coordinates of data points

$M$ -by-2 matrix

Location of antenna site, returned as an  $M$ -by-2 matrix with each element unit in degrees.  $M$  is the number of rows in the data table with valid latitude and longitude values. Duplicate locations are not removed.

**lat — Latitude of data points**

$M$ -by-1 vector

Latitude of data points, returned as an  $M$ -by-1 vector with each element unit in degrees.

**lon — Longitude of data points**

$M$ -by-1 vector

Longitude of data points, returned as an  $M$ -by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range  $[-180\ 180]$ .

## Version History

**Introduced in R2020a**

# propagationModel

Create RF propagation model

## Syntax

```
pm = propagationModel(modelname)
pm = propagationModel( ____,Name,Value)
```

## Description

`pm = propagationModel(modelname)` creates an RF propagation model for the specified model.

`pm = propagationModel( ____,Name,Value)` specifies options using name-value arguments. For example, `pm = propagationModel("rain","RainRate",96)` creates a rain propagation model with a rain rate of 96 mm/h.

## Examples

### Signal Strength of Receiver in Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for a heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
    Rain with properties:
```

```
    RainRate: 50
    Tilt: 0
```

Calculate the signal strength at the receiver using the rain propagation model.

```
ss = sigstrength(rx,tx,pm)
```

```
ss = -87.1559
```

### Longley-Rice Propagation Model

Create a default transmitter site.

```
tx = txsite;
```

Create a Longley-Rice propagation model by using the `propagationModel` function.

```
pm = propagationModel("longley-rice", "TimeVariabilityTolerance", 0.7)
```

```
pm =
```

```
LongleyRice with properties:
```

```
    AntennaPolarization: 'horizontal'  
    GroundConductivity: 0.0050  
    GroundPermittivity: 15  
    AtmosphericRefractivity: 301  
    ClimateZone: 'continental-temperate'  
    TimeVariabilityTolerance: 0.7000  
    SituationVariabilityTolerance: 0.5000
```

Find the coverage of the transmitter site by using the defined propagation model.

```
coverage(tx, "PropagationModel", pm)
```

## Input Arguments

### modelName — Name of propagation model

"freespace" | "rain" | "gas" | "fog" | "close-in" | "longley-ric" | "tirem" | "raytracing"

Name of propagation model, specified as one of these options. Each option creates a different type of object.

Option	Description	Object
"freespace"	Free space propagation model.	FreeSpace
"rain"	Rain propagation model. For more information, see [3].	Rain
"gas"	Gas propagation model. For more information, see [6].	Gas
"fog"	Fog propagation model. For more information, see [2].	Fog
"close-in"	<p>Close-in propagation model typically used in urban macro-cell scenarios. For more information, see [1].</p> <hr/> <p><b>Note</b> The close-in model implements a statistical path loss model and can be configured for different scenarios. The default values correspond to an urban macro-cell scenario in a non-line-of-sight (NLOS) environment.</p>	CloseIn

Option	Description	Object
<p>"longley-rice"</p>	<p>Longley-Rice propagation model. This model is also known as Irregular Terrain Model (ITM). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. For more information and list of limitations, see [4].</p> <hr/> <p><b>Note</b> The Longley-Rice model implements the point-to-point mode of the model, which uses terrain data to predict the loss between two points.</p>	<p>LongleyRice</p>
<p>"tirem"</p>	<p>Terrain Integrated Rough Earth Model™ (TIREM). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings.</p> <p>Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption.</p> <p>This model needs access to an external TIREM library. The actual model is valid from 1 MHz to 1000 GHz, but with Antenna Toolbox elements and arrays, the frequency range is limited to 200 GHz.</p>	<p>TIREM</p>

Option	Description	Object
"raytracing"	<p>A multipath propagation model that uses ray tracing analysis to compute propagation paths and corresponding path losses. Path loss is calculated from free-space loss, reflection and diffraction loss due to interactions with materials, and antenna polarization loss.</p> <p>You can perform ray tracing analysis using the shooting and bouncing rays (SBR) method or the image method. Specify a method using the Method name-value argument.</p> <ul style="list-style-type: none"> <li>• The SBR method includes effects from surface reflections and edge diffractions but does not include effects from corner diffraction, refraction, or rough-surface diffuse scattering.</li> <li>• The image method considers only surface reflections.</li> </ul> <p>Both ray tracing methods are reasonable for a frequency range of 100 MHz to 100 GHz. For information about differences between the image and SBR methods, see "Choose a Propagation Model".</p> <p>Use the <code>raytrace</code> function to compute and plot the propagation paths between the sites.</p>	RayTracing

### Dependencies

Specifying "tirem" requires Antenna Toolbox.

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `propagationModel("rain","RainRate",50)` sets the rate of rainfall in the rain propagation model to 50 millimeters per hour.

Each type of propagation model object supports a different set of properties. For a full list of the properties and their descriptions for a propagation model type, see the associated object page.

Type of Propagation Model	Object Page
"freespace"	FreeSpace
"rain"	Rain
"gas"	Gas
"fog"	Fog
"close-in"	CloseIn
"longley-rice"	LongleyRice
"tirem"	TIREM
"raytracing"	RayTracing

## Output Arguments

### pm — Propagation model

FreeSpace object | Rain object | Gas object | Fog object | CloseIn object | ...

Propagation model, returned as a FreeSpace, Rain, Gas, Fog, CloseIn, LongleyRice, TIREM, or RayTracing object.

## Version History

### Introduced in R2019b

### R2023a: `propagationModel("raytracing-image-method")` syntax has been removed

Errors starting in R2023a

The `propagationModel("raytracing-image-method")` syntax has been removed.

Use the `propagationModel("raytracing")` syntax instead, which uses the shooting and bouncing rays (SBR) method by default. To use the image method, specify the `Method` name-value argument as "image", for example `propagationModel("raytracing",Method="image")`.

### R2021b: Default modeling method is shooting and bouncing rays method

Behavior changed in R2021b

Starting in R2021b, when you create a propagation model using the syntax `propagationModel("raytracing")`, MATLAB returns a RayTracing model with the `Method` value set to "sbr" and two reflections (instead of "image" and one reflection as in previous releases).

To create ray tracing propagation models that use the image method, use the syntax `propagationModel("raytracing","Method","image")`.

## R2022a: propagationModel("raytracing-image-method") syntax will be removed in a future release

Warns starting in R2022a

The propagationModel("raytracing-image-method") syntax issues a warning that it will be removed in a future release.

### Functions

sigstrength | coverage | link | sinr | range | los | pathloss | rangeangle | raytrace

**Topics**

“Choose a Propagation Model”

## range

**Package:** rfprop

Range of radio wave propagation

### Syntax

```
r = range(propmodel,tx,pl)
```

### Description

`r = range(propmodel,tx,pl)` returns the range of radio wave propagation from the transmitter site.

### Examples

#### Range of Transmitter In Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504, ...
           'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park',...
           'Latitude',42.3467, ...
           'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
  Rain with properties:
```

```
    RainRate: 50
         Tilt: 0
```

Calculate the range of transmitter using the rain propagation model and a path loss of 127 dB.

```
r = range(pm,tx,127)
```

```
r = 2.0747e+04
```

### Input Arguments

**propmodel** — Propagation model

propagation model object

Propagation model, specified as a propagation model object. Use the `propagationModel` function.

Data Types: `object`

### **tx — Transmitter site**

`txsite` object

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

Data Types: `char`

### **pL — Path loss**

scalar

Path loss, specified as a scalar in decibels.

Data Types: `double`

## **Output Arguments**

### **r — range**

scalar |  $M$ -by-1 arrays

Range, returned as a scalar or  $M$ -by-1 array with each element in meters.  $M$  is the number of TX sites.

Range is the maximum distance for which the path loss does not exceed the value of the specified `pL`.

## **Version History**

**Introduced in R2019b**

### **See Also**

`propagationModel` | `pathloss`

# raytrace

Display or compute RF propagation rays

## Syntax

```
raytrace(tx,rx)
raytrace(tx,rx,propmodel)
raytrace( ____,Name,Value)
rays = raytrace( ____ )
```

## Description

The `raytrace` function plots or computes propagation paths by using ray tracing with surface geometry defined by the 'Map' property. The function color-codes each propagation path according to the received power (dBm) or path loss (dB) from the transmitter site to the receiver site. The ray tracing analysis includes surface reflections and edge diffractions, but does not include effects from corner diffraction, refraction, or diffuse scattering. This function supports frequencies from 100 MHz to 100 GHz. For more information, see "Choose a Propagation Model".

`raytrace(tx,rx)` displays the propagation paths from the transmitter site `tx` to the receiver site `rx` in the current Site Viewer. By default, the function uses the shooting and bouncing rays (SBR) method, finds paths with up to two reflections and zero diffractions, and discards paths that are more than 40 dB weaker than the strongest path.

`raytrace(tx,rx,propmodel)` finds propagation paths using the ray tracing propagation model `propmodel`. Ray tracing propagation models enable you to specify properties such as the maximum number of reflections and diffractions, path loss thresholds, and building and terrain materials. Create a ray tracing propagation model by using the `propagationModel` function.

`raytrace( ____,Name,Value)` specifies options using one or more name-value arguments, in addition to any combination of inputs from the previous syntaxes.

`rays = raytrace( ____ )` returns the propagation paths in `rays`.

## Examples

### Obstructed and Reflected Paths Using Ray Tracing

Show reflected propagation paths in Chicago using a ray tracing propagation model.

Launch Site Viewer with buildings in Chicago. For more information about the `osm` file, see [1] on page 4-277.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site and a receiver site near two different buildings.

```
tx = txsite("Latitude",41.8800,"Longitude",-87.6295, ...
    "TransmitterFrequency",2.5e9);
```

```
show(tx)
rx = rxsite("Latitude",41.8813452,"Longitude",-87.629771, ...
  "AntennaHeight",30);
show(rx)
```

Show the obstruction to the line-of-sight path.

```
los(tx,rx)
```

Display propagation paths with reflections. By default, the `raytrace` function uses the SBR method and calculates propagation paths with up to two reflections.

```
raytrace(tx,rx)
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Signal Strength Using Ray Tracing Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-280.

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
```

Create a receiver site near another building.

```
rx = rxsite("Latitude",41.881352, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
```

Create a ray tracing propagation model, which MATLAB® represents using a RayTracing object. By default, the propagation model uses the SBR method and finds propagation paths with up to two surface reflections.

```
pm = propagationModel("raytracing");
```

Calculate the signal strength using the receiver site, the transmitter site, and the propagation model.

```
ssTwoReflections = sigstrength(rx,tx,pm)
```

```
ssTwoReflections = -54.3015
```

Plot the propagation paths.

```
raytrace(tx,rx,pm)
```

Change the RayTracing object to find paths with up to 5 reflections. Then, recalculate the signal strength.

```
pm.MaxNumReflections = 5;
ssFiveReflections = sigstrength(rx,tx,pm)
```

```
ssFiveReflections = -53.3889
```

By default, RayTracing objects assume that building and terrain materials are concrete. Change the building and terrain material types to model perfect electrical conductors.

```
pm.BuildingsMaterial = "perfect-reflector";
ssPerfect = sigstrength(rx,tx,pm)
```

```
ssPerfect = -39.6711
```

Plot the propagation paths for the updated propagation model.

```
raytrace(tx,rx,pm)
```

### Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Path Loss Due to Material Reflection and Atmosphere

Launch Site Viewer with buildings in Hong Kong. For more information about the osm file, see [1] on page 4-284.

```
viewer = siteviewer("Buildings", "hongkong.osm");
```

Create transmitter and receiver sites that model a small cell scenario in a dense urban environment.

```
tx = txsite("Name","Small cell transmitter", ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaHeight",10, ...
    "TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Name","Small cell receiver", ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaHeight",1);
```

Create a ray tracing propagation model, which MATLAB represents using a RayTracing object. Configure the model to use a low average number of degrees between launched rays, to find paths with up to 5 path reflections, and to use building and terrain material types that model perfect electrical conductors. By default, the model uses the SBR method.

```
pm = propagationModel("raytracing", ...
    "MaxNumReflections",5, ...
    "AngularSeparation","low", ...
    "BuildingsMaterial","perfect-reflector", ...
    "TerrainMaterial","perfect-reflector");
```

Visualize the propagation paths and calculate the corresponding path losses.

```
raytrace(tx,rx,pm,"Type","pathloss")
raysPerfect = raytrace(tx,rx,pm,"Type","pathloss");
plPerfect = [raysPerfect{1}.PathLoss]
```

```
plPerfect = 1x13
```

```
104.2656 103.5699 112.0092 109.3137 111.2840 111.9979 112.4416 108.1505 111.2825 111.1
```

Set the building and terrain material types to glass and concrete, respectively. Then, revisualize the propagation paths and recalculate the corresponding path losses. The model finds one fewer path because, by default, the model discards paths that are more than 40 decibels weaker than the strongest path. The first path loss value does not change because it corresponds to the line-of-sight propagation path.

```
pm.BuildingsMaterial = "glass";
pm.TerrainMaterial = "concrete";
```

```
raytrace(tx,rx,pm,"Type","pathloss")
raysMtrls = raytrace(tx,rx,pm,"Type","pathloss");
plMtrls = [raysMtrls{1}.PathLoss]
```

```
plMtrls = 1x12
```

```
104.2656 106.1290 119.2409 121.2488 122.4103 121.5566 126.9462 124.1624 122.8190 127.1
```

Incorporate atmospheric loss by adding rain and gas propagation models to the ray tracing model. Then, revisualize the propagation paths and recalculate the corresponding path losses.

```
pm = pm + propagationModel("rain") + propagationModel("gas");
```

```
raytrace(tx, rx, pm, "Type", "pathloss")
```

```
raysAtmospheric = raytrace(tx, rx, pm, "Type", "pathloss");
```

```
plAtmospheric = [raysAtmospheric{1}.PathLoss]
```

```
plAtmospheric = 1x12
```

```
105.3245 107.1887 121.8261 123.1442 124.9972 124.1457 129.6641 126.0587 125.4094 130.1
```

### Appendix

### Visualize Ray Tracing in Conference Room

This example shows how to:

- Scale an STL file so that the model uses units of meters.
- View the scaled model in Site Viewer.
- Use ray tracing to calculate and display propagation paths from a transmitter to a receiver.

While Cartesian `txsite` and `rxsite` objects require position coordinates in meters, STL files might use other units. If your STL file does not use meters, you must scale the model before importing it into Site Viewer.

Read an STL file as a `triangulation` object. The file models a small conference room with one table and four chairs.

```
TR = stlread("conferenceroom.stl");
```

Scale the coordinates and create a new `triangulation` object. For this example, assume that the conversion factor from the STL units to meters is 0.9.

```

scale = 0.9;
scaledPts = TR.Points * scale;
TR_scaled = triangulation(TR.ConnectivityList,scaledPts);

```

View the new triangulation object using Site Viewer. Alternatively, you can save the new triangulation object as an STL file by using the `stlwrite` function.

```
viewer = siteviewer("SceneModel",TR_scaled);
```

Create and display a transmitter site close to the wall and a receiver site under the table. Specify the position using Cartesian coordinates in meters.

```

tx = txsite("cartesian", ...
    "AntennaPosition",[-1.25; -1.25; 1.9], ...
    "TransmitterFrequency",2.8e9);
show(tx,"ShowAntennaHeight",false)

rx = rxsite("cartesian", ...
    "AntennaPosition",[0.3; 0.2; 0.5]);
show(rx,"ShowAntennaHeight",false)

```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Create a ray tracing propagation model for Cartesian coordinates, which MATLAB represents using a `RayTracing` object. Calculate rays that have up to 1 reflection and 1 diffraction. Set the surface material to wood. By default, the model uses the SBR method.

```
pm = propagationModel("raytracing", ...  
    "CoordinateSystem","cartesian", ...  
    "MaxNumReflections",1, ...  
    "MaxNumDiffractions",1, ...  
    "SurfaceMaterial","wood");
```

Calculate the propagation paths and return the result as a cell array of `comm.Ray` objects. Extract and plot the rays.

```
r = raytrace(tx,rx,pm);  
r = r{1};  
plot(r)
```

View information about a ray by clicking on it.

## Input Arguments

### **tx — Transmitter site**

`txsite object` | array of `txsite` objects

Transmitter site, specified as a `txsite` object or an array of `txsite` objects. If you specify an array, then the function plots propagation paths from each transmitter to each receiver site.

### **rx — Receiver site**

`rxsite object` | array of `rxsite` objects

Receiver site, specified as an `rxsite` object or an array of `rxsite` objects. If you specify an array, then the function plots propagation paths from each transmitter to each receiver site.

### **propmodel — Ray tracing propagation model**

"raytracing" (default) | `RayTracing` object

Ray tracing propagation model, specified as "raytracing" or as a `RayTracing` object. The default is "raytracing", which uses the SBR method, finds paths with up to two reflections and zero diffractions, and discards paths that are more than 40 dB weaker than the strongest path.

Create a `RayTracing` object by using the `propagationModel` function. `RayTracing` objects enable you to specify properties such as the ray tracing method, the maximum number of reflections and diffractions, path loss thresholds, and building and terrain materials.

For information about the differences between ray tracing methods, see "Choose a Propagation Model".

Data Types: char | string

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `raytrace(tx,rx,Type="pathloss")` color-codes paths based on path loss.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `raytrace(tx,rx,"Type","pathloss")` color-codes paths based on path loss.

### Type — Type of quantity to plot

"power" (default) | "pathloss"

Type of quantity to plot, specified as one of these options:

- "power" — Color-code paths based on the received power in dBm.
- "pathloss" — Color-code paths based on path loss in dB.

The function uses a modified version of the Friis transmission equation to calculate received power (in logarithmic units):

$$P_{rx} = P_{tx} + G_{tx} + G_{rx} - L - L_{tx} - L_{rx}$$

where:

- $P_{rx}$  is the received power at the receiver.
- $P_{tx}$  is the transmit power specified by the `TransmitterPower` property of the transmitter site.
- $G_{tx}$  is the absolute antenna gain of the transmitter site in the direction of the angle-of-departure (AoD).
- $G_{rx}$  is the absolute antenna gain of the receiver site in the direction of the angle-of-arrival (AoA).
- $L$  is the path loss between the transmitter site and the receiver site.
- $L_{tx}$  is the system loss specified by the `SystemLoss` property of the transmitter site.
- $L_{rx}$  is the system loss specified by the `SystemLoss` property of the receiver site.

Data Types: char | string

### PropagationModel — Type of propagation model for ray tracing analysis

"raytracing" (default) | RayTracing object

Propagation model, specified as "raytracing" or as a `RayTracing` object. The default is "raytracing", which uses the SBR method, finds paths with up to two reflections and zero diffractions, and discards paths that are more than 40 dB weaker than the strongest path.

Create a `RayTracing` object by using the `propagationModel` function. `RayTracing` objects enable you to specify properties such as the ray tracing method, the maximum number of reflections and diffractions, path loss thresholds, and building and terrain materials.

For information about the differences between ray tracing methods, see "Choose a Propagation Model".

Data Types: char | string

### ColorLimits — Color limits for colormap

two-element numeric row vector

Color limits for the colormap, specified as a two-element numeric row vector of the form [min max].

The units and the default value depend on the value of Type:

- "power"- Units are in dBm, and the default value is [-120 -5].
- "pathloss"- Units are in dB, and the default value is [45 160].

The color limits indicate the values that map to the first and last colors in the colormap. The function does not plot propagation paths with values that are below the minimum color limit.

Data Types: double

### Colormap — Colormap for coloring propagation paths

"jet" (default) | colormap name | *M*-by-3 array of RGB

Colormap for coloring the propagation paths, specified as a colormap name or as an *M*-by-3 array of RGB triplets that define *M* individual colors. For more information about colormap names, see `colormap`.

Data Types: char | string | double

### ShowLegend — Show color legend in Site Viewer

true or 1 (default) | false or 0

Show color legend in Site Viewer, specified as a numeric or logical 1 (true) or 0 (false).

### Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A <code>siteviewer</code> object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>• The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>

Coordinate System	Valid map values	Default map value
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A <code>siteviewer</code> object.</li> <li>• The name of an STL file.</li> <li>• A <code>triangulation</code> object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

## Output Arguments

### rays — Ray configuration

*M*-by-*N* cell array of `comm.Ray` objects

Ray configuration, returned as a *M*-by-*N* cell array of `comm.Ray` objects, where *M* is the number of transmitter sites and *N* is the number of receiver sites. Each cell element is a row vector of `comm.Ray` objects that represent the propagation paths (rays) found between the corresponding transmitter site and receiver site.

Within each row vector, the function sorts the `comm.Ray` objects alphabetically by the first interaction type. When the first interaction type for multiple rays is the same, the function sorts according to the second interaction type and repeats this behavior for succeeding repeated interaction types. When multiple `comm.Ray` objects have the same number and types of interactions in the same order, the function sorts the objects by increasing propagation distance. If a line-of-sight path exists, the function includes it as the first element.

## Version History

Introduced in R2019b

### R2023a: Ray tracing models discard paths based on path loss

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as "raytracing" or a `RayTracing` object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `raytrace` function can return different values in R2023a compared to previous releases. To avoid discarding paths based on relative path loss thresholds, create a `RayTracing` object (by using the `propagationModel` function) and set its `MaxRelativePathLoss` property to `Inf`. Then, use the object as input to the `raytrace` function.

### R2023a: Ray tracing with SBR method calculates paths using increased precision

*Behavior changed in R2023a*

When you find propagation paths by using the `raytrace` function with a ray tracing model that uses the shooting and bouncing rays (SBR) method, MATLAB calculates the results using double-precision floating-point computations. In previous releases, the function used single-precision floating-point computations.

As a result, the raytrace function can return different comm.Ray objects in R2023a compared to previous releases.

### **R2023a: NumReflections name-value argument has been removed**

*Errors starting in R2023a*

The NumReflections name-value argument has been removed.

Instead, create a propagation model by using the propagationModel function and specify the MaxNumReflections name-value argument. Then, use the raytrace function with the propagation model as an input. This code shows the recommended workflow.

```
pm = propagationModel("raytracing",MaxNumReflections=3);  
rays = raytrace(tx,rx,pm);
```

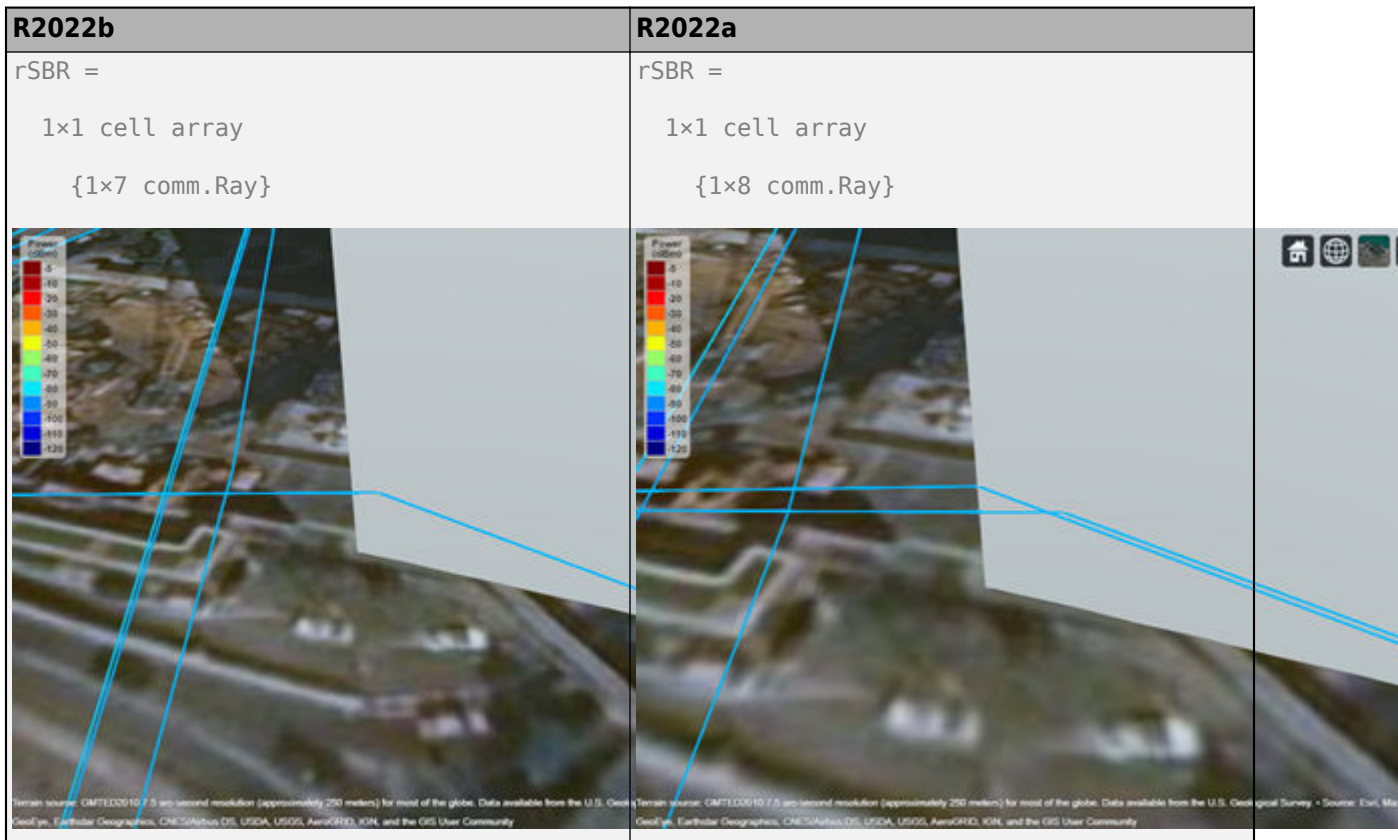

### **R2022b: SBR method finds paths with exact geometric accuracy**

*Behavior changed in R2022b*

When you find propagation paths using the SBR method, MATLAB corrects the results so that the geometric accuracy of each path is exact, using single-precision floating-point computations. In previous releases, the paths have approximate geometric accuracy.

For example, this code finds propagation paths between a transmitter and receiver by using the default SBR method and returns the paths as comm.Ray objects. In R2022b, the raytrace function finds seven propagation paths. In earlier releases, the function approximates eight propagation paths, one of which is a duplicate path.

```
viewer = siteviewer(Buildings="hongkong.osm");  
  
tx = txsite(Latitude=22.2789,Longitude=114.1625,AntennaHeight=10, ...  
    TransmitterPower=5,TransmitterFrequency=28e9);  
rx = rxsite(Latitude=22.2799,Longitude=114.1617,AntennaHeight=1);  
  
rSBR = raytrace(tx,rx)  
raytrace(tx,rx)
```

Paths calculated using the SBR method in R2022b more closely align with paths calculated using the image method. The image method finds all possible paths with exact geometric accuracy. For example, this code uses the image method to find propagation paths between the same transmitter and receiver.

```
viewer = siteviewer(Buildings="hongkong.osm");

tx = txsite(Latitude=22.2789,Longitude=114.1625, ...
    AntennaHeight=10,TransmitterPower=5, ...
    TransmitterFrequency=28e9);
rx = rxsite(Latitude=22.2799,Longitude=114.1617, ...
    AntennaHeight=1);

pm = propagationModel("raytracing",Method="image",MaxNumReflections=2);

rImage = raytrace(tx,rx,pm)

rImage =
1x1 cell array
{1x7 comm.Ray}
```

In this case, the SBR method finds the same number of propagation paths as the image method. In general, the SBR method finds a subset of the paths found by the image method. When both the image and SBR methods find the same path, the points along the path are the same within a tolerance of machine precision for single-precision floating-point values.

This code compares the path losses, within a tolerance of  $0.0001$ , calculated by the SBR and image methods.

```
abs([rSBR{1}.PathLoss] - [rImage{1}.PathLoss]) < 0.0001
```

```
ans =
```

```
1×7 logical array
```

```
1 1 1 1 1 1 1
```

The path losses are the same within the specified tolerance.

As a result, the `raytrace` function can return different results in R2022b compared to previous releases.

- The function can return a different number of `comm.Ray` objects because it discards invalid or duplicate paths.
- The function can return different `comm.Ray` objects because it calculates exact paths rather than approximate paths.

### **R2021b: raytrace function uses SBR method**

*Behavior changed in R2021b*

Starting in R2021b, the `raytrace` function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections by default. In previous releases, the `raytrace` function uses the image method and calculates up to one reflection.

To display or compute RF propagation rays using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `raytrace` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing', 'Method', 'image');
raytrace(tx, rx, pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-270.

### **R2022a: NumReflections name-value argument will be removed**

*Warns starting in R2022a*

The `NumReflections` name-value argument issues a warning that it will be removed in a future release.

# removeCustomTerrain

Remove custom terrain data

## Syntax

```
removeCustomTerrain(terrainName)
```

## Description

`removeCustomTerrain(terrainName)` removes the custom terrain data specified by the user-defined `terrainName`. You can use this function to remove terrain data that is no longer needed. The terrain data to be removed must have been previously added using `addCustomTerrain`.

## Examples

### Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";  
attribution = "SRTM 3 arc-second resolution. Data available " + ...  
             "from the U.S. Geological Survey.";  
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.

```
mtzion = txsite("Name","Mount Zion", ...  
              "Latitude",39.74356, ...  
              "Longitude",-105.24193, ...  
              "AntennaHeight", 30);  
show(mtzion)
```

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...  
         "MaxRange", 20000, ...  
         "SignalStrengths", -100: -5)
```

Remove the custom terrain.

```
close(viewer)  
removeCustomTerrain("southboulder")
```

### Input Arguments

**terrainName** — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data previously added using `addCustomTerrain`, specified as a string scalar or a character vector.

Data Types: `char` | `string`

### Version History

Introduced in R2019b

### See Also

`addCustomTerrain` | `siteviewer`

# add

**Package:** rfprop

Add propagation models

## Syntax

```
pmc = add(propmodel1,propmodel2)
```

## Description

`pmc = add(propmodel1,propmodel2)` adds propagation model objects `propmodel1` and `propmodel2` and returns a composite propagation model object `pmc` which contains `propmodel1` and `propmodel2`.

---

## Note

- The syntax `propmodel1+propmodel2` can be used in place of `add`.
  - A composite propagation model cannot contain more than one propagation model object of the same class.
  - A composite propagation model cannot contain more than one propagation model object which includes effects of free-space loss.
- 

## Examples

### Signal Strength Over Terrain Using Composite Propagation Model

Specify the transmitter and the receiver sites.

```
tx = txsite("Name","Fenway Park", ...
           "Latitude",42.3467, ...
           "Longitude",-71.0972, ...
           "TransmitterFrequency",6e9);
rx = rxsite("Name","Bunker Hill Monument", ...
           "Latitude",42.3763, ...
           "Longitude",-71.0611);
```

Calculate signal strength using default Longley-Rice model.

```
ss1 = sigstrength(rx,tx)
```

```
ss1 = -80.9353
```

Create composite propagation model with Longley-Rice and specific atmospheric propagation models.

```
pm = propagationModel("longley-rice") + ...
    propagationModel("gas") + propagationModel("rain");
```

Calculate signal strength using composite propagation model.

```
ss2 = sigstrength(rx,tx,pm)
```

```
ss2 = -81.2259
```

### Input Arguments

#### **propmodel1 — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: char | string

#### **propmodel2 — Propagation model**

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: char | string

### Output Arguments

#### **pmc — Composite propagation model**

composite propagationModel function object

Composite propagation model, composite `propagationModel` function object

The path loss computed by `pmc` is the sum of path losses computed by `propmodel1` and `propmodel2`. If either `propmodel1` or `propmodel2` is a ray tracing model, then `pmc` is also a ray tracing model where path losses from rain, gas, or fog models in the composite are added to the path loss computed for each propagation path.

### Version History

Introduced in R2020a

# pattern

Display antenna radiation pattern in Site Viewer

## Syntax

```
pattern(tx)
pattern(rx, frequency)
pattern( ____, Name, Value)
```

## Description

`pattern(tx)` displays the 3-D antenna radiation pattern for the transmitter site `txsite` in the current Site Viewer. Signal gain value (dBi) in a particular direction determines the color of the pattern.

`pattern(rx, frequency)` displays the 3-D radiation pattern for the receiver site `rxsite` for the specified frequency.

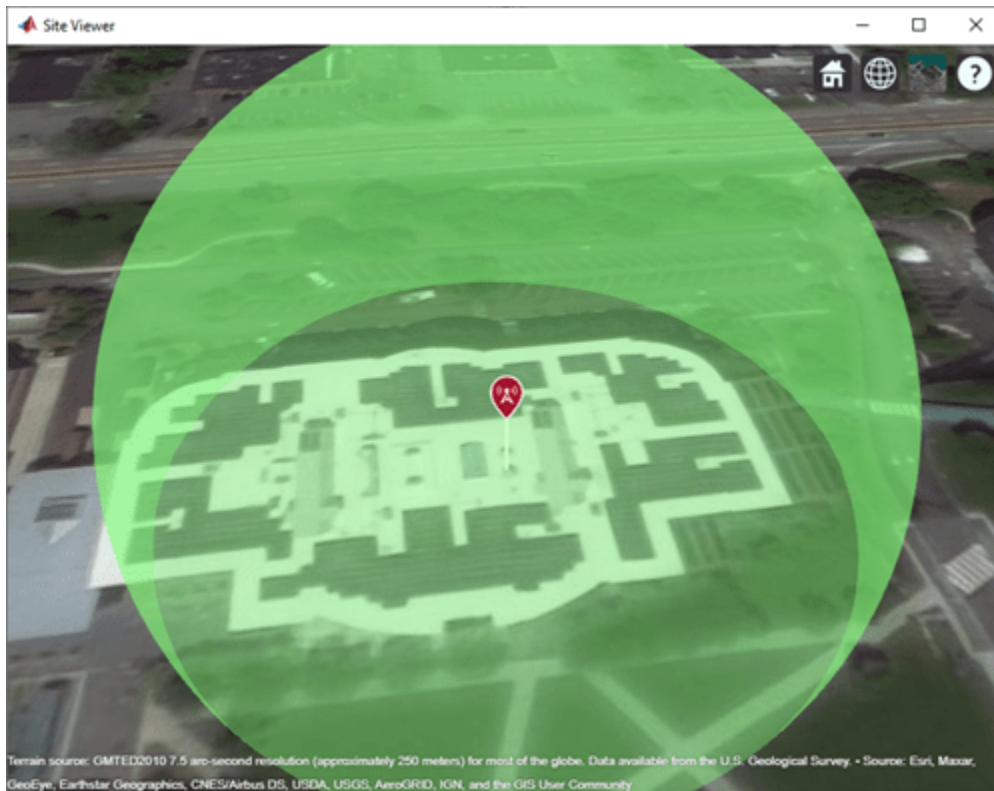

`pattern( ____, Name, Value)` displays the 3-D radiation pattern with additional options specified by name-value pair arguments.

## Examples

### Single Transmitter Site Pattern

Define and visualize the radiation pattern of a single transmitter site.

```
tx = txsite;
pattern(tx)
```

### Pattern for Cartesian Transmitter

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site that uses a three-element uniform linear array (ULA) with an element spacing of 0.05 meters. Specify the position using Cartesian coordinates in meters.

```
cfgArray = arrayConfig("Size", [3 1], "ElementSpacing", 0.05);
tx = txsite("cartesian", ...
    "AntennaPosition", [0; 0; 2.1], ...
    "Antenna", cfgArray);
```

Display the antenna pattern. Specify the size of the pattern plot as 0.4 meters.

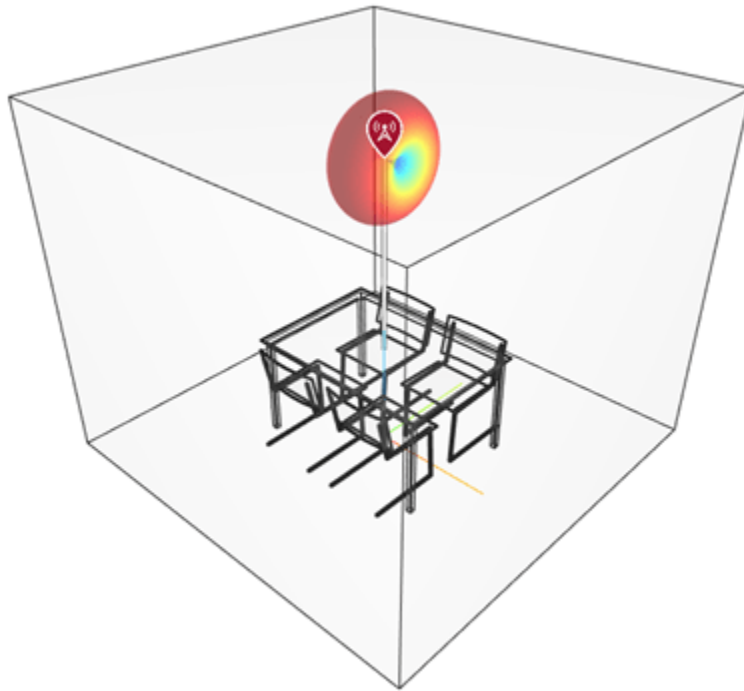

```
pattern(tx, "Transparency", 0.6, "Size", 0.4)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Tilt the antenna by updating the `AntennaAngle` property of the transmitter. Display the updated pattern.

```
tx.AntennaAngle = [0 90];  
pattern(tx, "Transparency", 0.6, "Size", 0.4)
```

## Input Arguments

### **tx — Transmitter site**

`txsite` object

Transmitter site, specified as a `txsite` object.

### **rx — Receiver site**

`rxsite` object

Receiver site, specified as a `rxsite` object.

### **frequency — Frequency to calculate radiation pattern**

positive scalar

Frequency to calculate radiation pattern, specified as a positive scalar.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'Size',2`

### **Size — Size of pattern plot**

`'auto'` (default) | numerical scalar

Size of the pattern plot, specified as a numerical scalar in meters. This parameter represents the distance between the antenna position and the point on the plot with the highest gain.

The default value depends on the `CoordinateSystem` property of the `siteviewer` object. When `CoordinateSystem` is 'geographic', the default size is 50 meters. When `CoordinateSystem` is 'cartesian', the default size is approximately 1/6 of the scene model size.

Data Types: double

### Transparency — Transparency of pattern plot

0.4 (default) | real number in the range of [0,1]

Transparency of the pattern plot, specified as a real number in the range of [0,1], where 0 is completely transparent and 1 is completely opaque.

Data Types: double

### Colormap — Colormap for coloring of pattern plot

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for coloring of the pattern plot, specified as a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors.

Data Types: double

### Resolution — Resolution of 3-D pattern

'high' (default) | 'low' | 'medium'

Resolution of 3-D map, specified as 'low', 'medium', or 'high'. This property controls the visual quality and the time taken to plot the pattern where the value of 'low' corresponds to the fastest and the least detailed pattern.

Data Types: double

### Map — Map for visualization of surface data

siteviewer object

Map for visualization of surface data, specified as a `siteviewer` object.<sup>8</sup>

Data Types: char | string

## Version History

Introduced in R2019b

## show

Show site in Site Viewer

### Syntax

```
show(site)
show(site,Name,Value)
```

### Description

`show(site)` displays the location of the specified transmitter or receiver site using a marker in the current Site Viewer.

`show(site,Name,Value)` displays `site` with additional options specified by one or more name-value arguments.

### Examples

#### Default Receiver Site

Create and show the default receiver site.

```
rx = rxsite
rx =
    rxsite with properties:
        Name: 'Site 2'
        Latitude: 42.3021
        Longitude: -71.3764
        Antenna: 'isotropic'
        AntennaAngle: 0
        AntennaHeight: 1
        SystemLoss: 0
        ReceiverSensitivity: -100

show(rx)
```

### Show and Hide Transmitter Site

Create and show a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...  
           'Latitude',42.3001, ...  
           'Longitude',-71.3504);  
show(tx)
```

Hide the transmitter site.

hide(tx)

## Show and Hide Sites with Cartesian Coordinates

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters. Then, visualize the sites.

```
tx = txsite('cartesian', ...  
           'AntennaPosition', [-1.46; -1.42; 2.1]);  
rx = rxsite('cartesian', ...  
           'AntennaPosition', [0.3; 0.3; 0.85]);
```

```
show(tx)  
show(rx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Hide the sites.

```
hide(tx)  
hide(rx)
```

## Input Arguments

### **site — Transmitter or receiver site**

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'ClusterMarkers', true`

### **Icon — Image file**

character vector

Image file, specified as a character vector.

Data Types: char

### **IconSize — Width and height of icon**

36-by-36 (default) | 1-by-2 vector of positive numeric values

Width and height of the icon, specified as a 1-by-2 vector of positive numeric values in pixels.

**IconAlignment — Vertical position of icon relative to site**`'top' (default) | 'center' | 'bottom'`

Vertical position of icon relative to site, specified as:

- `'bottom'` - Aligns the icon below the site antenna position.
- `'center'` - Aligns the center of the icon to the site antenna position.
- `'top'` - Aligns the icon above the site antenna position.

**ClusterMarkers — Combine nearby markers into groups or clusters**`true | false`

Combine nearby markers into groups or clusters, specified as true or false.

Data Types: `char`

**Map — Map for visualization of surface data**`siteviewer object`

Map for visualization of surface data, specified as a `siteviewer` object.<sup>9</sup>

Data Types: `char` | `string`

**ShowAntennaHeight — Option to show line from site to surface**`true or 1 (default) | false or 0`

Option to show a white line from the site down to the nearest surface, specified as numeric or logical `1` (true) or `0` (false).

Data Types: `logical`

## Version History

**Introduced in R2019b**

`hide`

<sup>9</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## sigstrength

Received signal strength

### Syntax

```
ss = sigstrength(rx,tx)
ss = sigstrength(rx,tx,propmodel)
ss = sigstrength( ____,Name,Value)
```

### Description

`ss = sigstrength(rx,tx)` returns the signal strength in power units (dBm) at the receiver site due to the transmitter site.

`ss = sigstrength(rx,tx,propmodel)` returns the signal strength at the receiver site using the specified propagation model. Specifying a propagation model is the same as specifying the `PropagationModel` name-value argument.

`ss = sigstrength( ____,Name,Value)` specifies options using name-value arguments, in addition to any combination of arguments from the previous syntaxes. For example, `"Type","efield"` returns the signal strength in electric field strength units (dB $\mu$ V/m).

### Examples

#### Received Power and Link Margin at Receiver

Create a transmitter site.

```
tx = txsite('Name','Fenway Park', ...
           'Latitude', 42.3467, ...
           'Longitude', -71.0972);
```

Create a receiver site with sensitivity defined (in dBm).

```
rx = rxsite('Name','Bunker Hill Monument', ...
           'Latitude', 42.3763, ...
           'Longitude', -71.0611, ...
           'ReceiverSensitivity', -90);
```

Calculate the received power and link margin. Link margin is the difference between the receiver's sensitivity and the received power.

```
ss = sigstrength(rx,tx)
ss = -71.1414
margin = abs(rx.ReceiverSensitivity - ss)
margin = 18.8586
```

## Signal Strength Using Ray Tracing Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-315.

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
```

Create a receiver site near another building.

```
rx = rxsite("Latitude",41.881352, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
```

Create a ray tracing propagation model, which MATLAB® represents using a RayTracing object. By default, the propagation model uses the SBR method and finds propagation paths with up to two surface reflections.

```
pm = propagationModel("raytracing");
```

Calculate the signal strength using the receiver site, the transmitter site, and the propagation model.

```
ssTwoReflections = sigstrength(rx,tx,pm)
```

```
ssTwoReflections = -54.3015
```

Plot the propagation paths.

```
raytrace(tx, rx, pm)
```

Change the RayTracing object to find paths with up to 5 reflections. Then, recalculate the signal strength.

```
pm.MaxNumReflections = 5;  
ssFiveReflections = sigstrength(rx, tx, pm)
```

```
ssFiveReflections = -53.3889
```

By default, RayTracing objects assume that building and terrain materials are concrete. Change the building and terrain material types to model perfect electrical conductors.

```
pm.BuildingsMaterial = "perfect-reflector";  
ssPerfect = sigstrength(rx, tx, pm)
```

```
ssPerfect = -39.6711
```

Plot the propagation paths for the updated propagation model.

```
raytrace(tx, rx, pm)
```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

## Input Arguments

### **rx — Receiver site**

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

### **tx — Transmitter site**

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

### **propmodel — Propagation model to use for path loss calculations**

"longley-rice" (default) | "freespace" | "close-in" | "rain" | "gas" | "fog" | "raytracing" | propagation model created using `propagationModel`

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model

- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-rice" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the `propagationModel` function. For example, you can create a ray tracing propagation model that uses the image method by specifying `propagationModel("raytracing","Method","image")`.

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-rice" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-rice" and "tirem", are only supported for sites with a `CoordinateSystem` value of "geographic".

You can also specify the propagation model by using the `PropagationModel` name-value pair argument.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: "Type", "power"

### Type — Type of signal strength to compute

"power" (default) | "efield"

Type of signal strength to compute, specified as one of these options:

- "power" — The signal strength is in power units (dBm) of the signal at the mobile receiver input.
- "efield" — The signal strength is in electric field strength units (dBµV/m) of signal wave incident on the antenna.

Data Types: char | string

**PropagationModel — Propagation model to use for path loss calculations**

"freespace" | "close-in" | "rain" | "gas" | "fog" | "longley-rice" | "raytracing" | propagation model created using propagationModel

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-rice" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the propagationModel function. For example, you can create a ray tracing propagation model that uses the image method by specifying propagationModel("raytracing", "Method", "image").

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-rice" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-rice" and "tirem", are only supported for sites with a CoordinateSystem value of "geographic".

Data Types: char | string

**Map — Map for visualization or surface data**

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A siteviewer object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>• The current siteviewer object or a new siteviewer object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A siteviewer object.</li> <li>• The name of an STL file.</li> <li>• A triangulation object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

## Output Arguments

### **ss** — Signal strength

*M*-by-*N* array

Signal strength, returned as *M*-by-*N* array, where *M* is the number of transmitter sites and *N* is the number of receiver sites.

The units of `ss` depend on the value of the `Type` name-value argument.

- When you specify `Type` as "power", then `ss` is in power units (dBm) of the signal at the mobile receiver input.
- When you specify `Type` as "efield", then `ss` is in electric field strength units (dBμV/m) of signal wave incident on the antenna.

## Version History

### Introduced in R2019b

#### **R2023a: Ray tracing models discard paths based on path loss**

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as "raytracing" or a `RayTracing` object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `sigstrength` function can return different values in R2023a compared to previous releases. To avoid discarding paths based on relative path loss thresholds, create a `RayTracing` object (by using the `propagationModel` function) and set its `MaxRelativePathLoss` property to `Inf`. Then, use the object as input to the `sigstrength` function.

**R2022b: Ray tracing functions consider multipath interference***Behavior changed in R2022b*

When calculating received power using ray tracing models, the `sigstrength` function now considers multipath interference by using a phasor sum. In previous releases, the function used a power sum. As a result, the calculations in R2022b are more accurate than in previous releases.

**R2021b: "raytracing" propagation models use SBR method***Behavior changed in R2021b*

Starting in R2021b, when you use the `sigstrength` function and specify the `propmodel` argument or `PropagationModel` name-value argument as "raytracing", the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `sigstrength` function uses the image method and calculates up to one reflection.

To calculate received signal strength using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `sigstrength` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel("raytracing", "Method", "image");  
ss = sigstrength(rx,tx,pm)
```

For information about the SBR and image methods, see "Choose a Propagation Model".

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see "Default modeling method is shooting and bouncing rays method" on page 4-270.

[link](#) | [sinr](#) | [propagationModel](#)

## sinr

Display or compute signal-to-interference-plus-noise (SINR) ratio

### Syntax

```
sinr(txs)
sinr(txs,propmodel)
sinr( ____,Name,Value)
pd = sinr(txs, ____)
r = sinr(rxs,txs, ____)
```

### Description

`sinr(txs)` displays the signal-to-interference-plus-noise ratio (SINR) for transmitter sites `txs` in the current Site Viewer. The map contours are generated using SINR values computed for receiver site locations on the map. For each location, the signal source is the transmitter site in `TXS` with the greatest signal strength. The remaining transmitter sites in `txs` with the same transmitter frequency act as sources of interference. If `txs` is scalar or there are no sources of interference the resultant map displays signal-to-noise ratio (SNR).

This function only supports plotting for antenna sites with a `CoordinateSystem` property value of "geographic".

`sinr(txs,propmodel)` displays the SINR map with the propagation model set to the value in `propmodel`.

`sinr( ____,Name,Value)` sets properties using one or more name-value pairs, in addition to the input arguments in previous syntaxes. For example, `sinr(txs,"MaxRange",8000)` sets the range from the site location at 8000 meters to include in the SINR map region.

`pd = sinr(txs, ____)` returns computed SINR data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

`r = sinr(rxs,txs, ____)` returns the `sinr` in dB computed at the receiver sites due to the transmitter sites.

### Examples

#### SINR Map for Multiple Transmitters

Define names and location of sites in Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

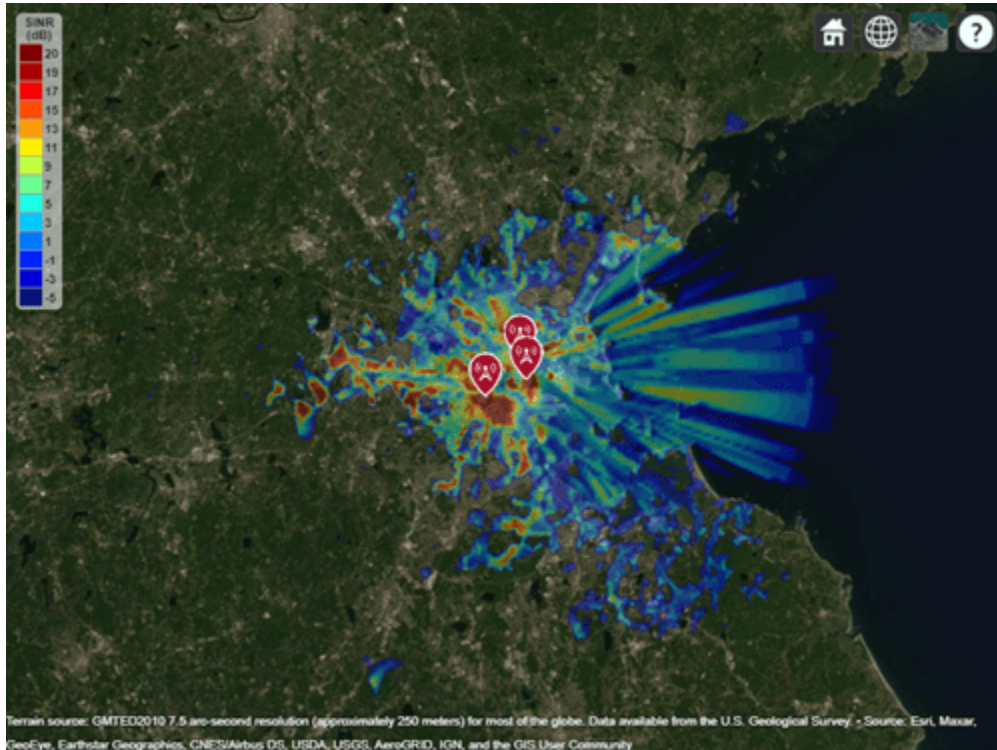

Create a transmitter site array.

```
txs = txsite("Name", names,...
            "Latitude",lats,...
```

```
"Longitude",lons, ...
"TransmitterFrequency",2.5e9);
```

Display the SINR map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sinr(txs)
```

## Input Arguments

### **txs — Transmitter sites**

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when CoordinateSystem property is set to "geographic".

### **rxs — Receiver sites**

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when CoordinateSystem property is set to "geographic".

### **propmodel — Propagation model to use for path loss calculations**

"longley-ric" (default) | "freespace" | "close-in" | "rain" | "gas" | "fog" |  
"raytracing" | propagation model created using propagationModel

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-rice" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the `propagationModel` function. For example, you can create a ray tracing propagation model that uses the image method by specifying `propagationModel("raytracing","Method","image")`.

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-rice" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when Map is set to none.</li> <li>• "raytracing" when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-rice" and "tirem", are only supported for sites with a `CoordinateSystem` value of "geographic".

You can also specify the propagation model by using the `PropagationModel` name-value pair argument.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: "MaxRange", 8000

### General

#### SignalSource — Signal source of interest

"strongest" (default) | transmitter site object

Signal source of interest, specified as the comma-separated pair consisting of `SignalSource` and "strongest" or as a transmitter site object. When the signal source of interest is "strongest", the

transmitter with the greatest signal strength is chosen as the signal source of interest for that location. When computing `sinr`, `SignalSource` can be a `txsite` array with equal number of elements `rxs` where each transmitter site element defines the signal source for the corresponding receiver site.

### PropagationModel — Propagation model to use for path loss calculations

"freespace" | "close-in" | "rain" | "gas" | "fog" | "longley-ric" | "raytracing" | propagation model created using `propagationModel`

Propagation model to use for the path loss calculations, specified as one of these options:

- "freespace" — Free space propagation model
- "rain" — Rain propagation model
- "gas" — Gas propagation model
- "fog" — Fog propagation model
- "close-in" — Close-in propagation model
- "longley-ric" — Longley-Rice propagation model
- "tirem" — TIREM propagation model
- "raytracing" — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method. When you specify a ray tracing model as input, the function incorporates multipath interference by using a phasor sum.
- A propagation model created using the `propagationModel` function. For example, you can create a ray tracing propagation model that uses the image method by specifying `propagationModel("raytracing","Method","image")`.

The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
"geographic"	<ul style="list-style-type: none"> <li>• "longley-ric" when you use a terrain.</li> <li>• "freespace" when you do not use a terrain.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "freespace" when <code>Map</code> is set to none.</li> <li>• "raytracing" when <code>Map</code> is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.</li> </ul>

Terrain propagation models, including "longley-ric" and "tirem", are only supported for sites with a `CoordinateSystem` value of "geographic".

Data Types: char | string

### ReceiverNoisePower — Total noise power at receiver

-107 (default) | scalar

Total noise power at receiver, specified as a scalar in dBm. The default value assumes that the receiver bandwidth is 1 MHz and receiver noise figure is 7 dB.

$$N = -174 + 10 \cdot \log(B) + F$$

where,

- $N$  = Receiver noise in dBm
- $B$  = Receiver bandwidth in Hz
- $F$  = Noise figure in dB

**ReceiverGain — Receiver gain**

2.1 (default) | scalar

Mobile receiver gain, specified as a scalar in dB. The receiver gain values include the antenna gain and the system loss. If you call the function using an output argument, the default value is computed using `rxs`.

**ReceiverAntennaHeight — Receiver antenna height**

1 (default) | scalar

Receiver antenna height above the ground, specified as a scalar in meters. If you call the function using an output argument, the default value is computed using `rxs`.

**Map — Map for visualization or surface data**

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
"geographic"	<ul style="list-style-type: none"> <li>• A <code>siteviewer</code> object<sup>a</sup>.</li> <li>• A terrain name, if the function is called with an output argument. Valid terrain names are "none", "gmted2010", or the name of the custom terrain data added using <code>addCustomTerrain</code>.</li> </ul>	<ul style="list-style-type: none"> <li>• The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open.</li> <li>• "gmted2010", if the function is called with an output.</li> </ul>
"cartesian"	<ul style="list-style-type: none"> <li>• "none".</li> <li>• A <code>siteviewer</code> object.</li> <li>• The name of an STL file.</li> <li>• A <code>triangulation</code> object.</li> </ul>	<ul style="list-style-type: none"> <li>• "none".</li> </ul>

<sup>a</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

**For Plotting SINR**

**Values — Values of SINR for display**

[-5:20] (default) | numeric vector

Values of SINR for display, specified as a numeric vector. Each value is displayed as a different colored, filled on the contour map. The contour colors are derived using `ColorMap` and `ColorLimits`.

**MaxRange — Maximum range of coverage map from each transmitter site**

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the type of propagation model.

Type of Propagation Model	MaxRange
Atmospheric or empirical	30 km
Terrain	30 km or distance to the furthest building.
Ray tracing	500 m

For more information about the types of propagation models, see “Choose a Propagation Model”.

Data Types: double

**Resolution — Resolution of receiver site locations used to compute SINR values**

"auto" (default) | numeric scalar

Resolution of receiver site locations used to compute SINR values, specified as "auto" or a numeric scalar in meters. The resolution defines the maximum distance between the locations. If the resolution is "auto", sinr computes a value scaled to MaxRange. Decreasing the resolution increases the quality of the SINR map and the time required to create it.

**Colormap — Colormap for coloring filled contours**"jet" (default) |  $M$ -by-3 array of RGB triplets

Colormap for coloring filled contours, specified as an  $M$ -by-3 array of RGB triplets, where  $M$  is the number of individual colors.

**ColorLimits — Color limits for color maps**

[-5 20] (default) | two-element vector

Color limits for color maps, specified as a two-element vector of the form [min max]. The color limits indicate the SINR values that map to the first and last colors in the colormap.

**ShowLegend — Show signal strength color legend on map**

"true" (default) | "false"

Show signal strength color legend on map, specified as "true" or "false".

**Transparency — Transparency of SINR map**

0.4 (default) | numeric scalar

Transparency of SINR map, specified as a numeric scalar in the range [0, 1]. If the value is zero, the map is completely transparent. If the value is one, the map is completely opaque.

**Output Arguments****r — Signal to interference plus noise ratio at the receiver**

numeric vector (default)

Signal to interference plus noise ratio at the receiver due to the transmitter sites, returned as a numeric vector. The vector length is equal to the number of receiver sites.

Data Types: double

### **pd — SINR data**

propagationData object

SINR data, returned as a propagationData object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the propagationData is "SINR Data".

## **Limitations**

When you specify a RayTracing object as input to the `sinr` function, the value of the `MaxNumDiffractions` property must be 0 or 1.

## **Version History**

### **Introduced in R2019b**

#### **R2023a: Ray tracing models discard paths based on path loss**

*Behavior changed in R2023a*

Ray tracing propagation models discard propagation paths based on path loss thresholds. By default, when you specify the `propmodel` input argument as "raytracing" or a RayTracing object, the propagation model discards paths that are more than 40 dB weaker than the strongest path.

As a result, the `sinr` function can return different values in R2023a compared to previous releases. To avoid discarding paths based on relative path loss thresholds, create a RayTracing object (by using the `propagationModel` function) and set its `MaxRelativePathLoss` property to `Inf`. Then, use the object as input to the `sinr` function.

#### **R2022b: Ray tracing functions consider multipath interference**

*Behavior changed in R2022b*

When calculating received power using ray tracing models, the `sinr` function now incorporates multipath interference by using a phasor sum. In previous releases, the function used a power sum. As a result, the calculations in R2022b are more accurate than in previous releases.

#### **R2021b: "raytracing" propagation models use SBR method**

*Behavior changed in R2021b*

Starting in R2021b, when you use the `sinr` function and specify the `propmodel` argument or `PropagationModel` name-value argument as "raytracing", the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `sinr` function uses the image method and calculates up to one reflection.

To display or compute the SINR using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `sinr` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel("raytracing", "Method", "image");  
sinr(txs, pm)
```

For information about the SBR and image methods, see "Choose a Propagation Model".

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-270.

## plot (rays), plot

**Package:** comm

Display RF propagation rays in Site Viewer

### Syntax

```
plot(rays)
plot(rays, Name, Value)
```

### Description

`plot(rays)` plots the propagation paths for ray objects in the Site Viewer map.

`plot(rays, Name, Value)` plots the propagation paths for ray objects in the Site Viewer map with additional options specified by one or more name-value pair arguments.

### Examples

#### Plot Propagation Rays Between Sites in Chicago

Perform ray tracing in Chicago and return the rays in `comm.Ray` objects. Then, display the rays without performing the ray tracing analysis again.

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-331.

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site on one building and a receiver site on another building. Show the line-of-sight path between the sites using the `los` function.

```
tx = txsite("Latitude",41.8800, ...  
           "Longitude",-87.6295, ...  
           "TransmitterFrequency",2.5e9);  
rx = rxsite("Latitude",41.881352, ...  
           "Longitude",-87.629771, ...  
           "AntennaHeight",30);  
los(tx,rx)
```

Create a ray tracing propagation model, which MATLAB® represents using a `RayTracing` object. By default, the model uses the SBR method and calculates propagation paths with up to two reflections.

```
pm = propagationModel("raytracing");
```

Perform the ray tracing analysis. The `raytrace` function returns a cell array containing the `comm.Ray` objects.

```
rays = raytrace(tx,rx,pm)
```

```
rays = 1x1 cell array
      {1x3 comm.Ray}
```

View the properties of the first ray object.

```
rays{1}(1)
```

```
ans =
  Ray with properties:

    PathSpecification: 'Locations'
    CoordinateSystem: 'Geographic'
    TransmitterLocation: [3x1 double]
    ReceiverLocation: [3x1 double]
    LineOfSight: 0
    Interactions: [1x1 struct]
      Frequency: 2.5000e+09
    PathLossSource: 'Custom'
      PathLoss: 92.7740
      PhaseShift: 1.2933
```

```

Read-only properties:
  PropagationDelay: 5.7088e-07
  PropagationDistance: 171.1462
  AngleOfDeparture: [2x1 double]
  AngleOfArrival: [2x1 double]
  NumInteractions: 1

```

Close Site Viewer.

```
close(viewer)
```

Create another Site Viewer with the same buildings, transmitter site, and receiver site. Then, display the propagation paths. Alternatively, you can plot individual paths by specifying a single ray object, for example `rays{1}(2)`.

```

siteviewer("Buildings", "chicago.osm");
show(tx)
show(rx)
plot(rays{1}, "Type", "power", ...
     "TransmitterSite", tx, "ReceiverSite", rx)

```

## Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

### Input Arguments

#### **rays — Ray configuration object**

`comm.Ray` object

Ray configuration, specified as one `comm.Ray` object or a vector of `comm.Ray` objects. Each object must have the `PathSpecification` property set to "Locations".

Data Types: `comm.Ray`

#### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `plot(rays, "Type", "pathloss", "ColorLimits", [-100 0])` adds the propagation path specified in `rays` to the current Site Viewer and adjusts the default color limits.

#### **Type — Quantity type to plot**

"pathloss" (default) | "power"

Quantity type to plot, specified as "pathloss" or "power". Based on the value specified for `Type`, the color applied along the path maps to the path loss in dB or the power in dBm of the signal along the path.

Data Types: `char` | `string`

#### **TransmitterSite — Transmitter site**

`txsite` object

Transmitter site, specified as a `txsite` object.

#### **Dependencies**

Applies only when `Type` is set to "power".

Data Types: `char`

#### **ReceiverSite — Receiver site**

`rxsite` object

Receiver site, specified as an `rxsite` object.

#### **Dependencies**

Applies only when `Type` is set to "power".

Data Types: `char`

#### **ColorLimits — Colormap color limits**

[-120 -5] or [45 160] (default) | 1-by-2 numeric vector

Color limits for colormap, specified as a 1-by-2 numeric vector,  $[min, max]$ , where  $min$  represents the lower saturation limit and  $max$  represents the upper saturation limit. The default is  $[-120 -5]$  when Type is set to 'power' and  $[45 160]$  when Type is set to 'pathloss'.

Data Types: double

### **Colormap — Colormap applied to propagation path**

'jet' (default) |  $M$ -by-3 numeric array

Colormap applied to propagation path, specified as an  $M$ -by-3 numeric array of RGB (red,green,blue) triplets that define  $M$  individual colors.

Data Types: double | char | string

### **ShowLegend — Show color legend on map**

true (default) | false

Show color legend on map, specified as true or false.

Data Types: logical

### **Map — Map for visualization and surface data**

siteviewer object

Map for visualization and surface data, specified as a siteviewer object.<sup>10</sup> The default is the current siteviewer object, or if no Site Viewer is open a new siteviewer object opens.

Data Types: siteviewer object

## **Version History**

Introduced in R2020a

<sup>10</sup> Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

## hasdata

**Package:** matlab.io.datastore

Determine if data is available to read from TDMS datastore

### Syntax

```
tf = hasdata(tdmsds)
```

### Description

`tf = hasdata(tdmsds)` returns logical 1 (true) if there is data available to read from the TDMS datastore specified by `tdmsds`. Otherwise, it returns logical 0 (false).

### Examples

#### Check TDMS Datastore for Readable Data

In a while-loop, use `hasdata` to determine if there is any more data to read at the current location.

```
tdmsds = tdmsDatastore(tdmsDatastore("C:\data\tdms"));  
while hasdata(tdmsds)  
    m = read(tdmsds);  
    ;  
end
```

### Input Arguments

#### **tdmsds** — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

### Output Arguments

#### **tf** — Indicator of data to read

1 | 0

Indicator of data to read, returned as a logical 1 (true) or 0 (false).

### Limitations

- TDMS functions are supported on Windows platforms only.

## Version History

Introduced in R2022a

## See Also

### Functions

tdmsDatastore | read | reset

## preview

**Package:** matlab.io.datastore

Read first 8 records from TDMS datastore

### Syntax

```
data = preview(tdmsds)
```

### Description

`data = preview(tdmsds)` returns the first 8 records from TDMS datastore `tdmsds`, without changing the current read position in the datastore.

### Examples

#### Examine Preview of TDMS Datastore

```
tdmsds = tdmsds = tdmsDatastore("C:\data\tdms");  
data = preview(tdmsds)
```

```
data =
```

```
1x3 cell array
```

```
{8x2 table} {8x2 table} {8x2 table}
```

```
data{3}
```

```
ans =
```

```
8x2 table
```

### Input Arguments

#### **tdmsds** — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

## Output Arguments

### **data** — Start of TDMS datastore records

cell array of tables

Start of TDMS datastore records, returned as a cell array of tables from the TDMS data.

## Limitations

- TDMS functions are supported on Windows platforms only.

## Version History

Introduced in R2022a

## See Also

### Functions

tdmsDatastore | read | readall | hasdata

## read

**Package:** matlab.io.datastore

Read data in TDMS datastore

### Syntax

```
data = read(tdmsds)
[data,info] = read(tdmsds)
```

### Description

`data = read(tdmsds)` reads data from the files in the TDMS datastore `tdmsds`, and returns a cell array of tables or timetables. Each element of the cell array corresponds to a channel group in the datastore file `data`.

The `read` function returns a subset of data from the datastore. The size of the subset is determined by the `ReadSize` property of the datastore object. On the first call, `read` starts reading from the beginning of the datastore, and subsequent calls continue reading from the endpoint of the previous call. Use `reset` to read from the beginning again.

The function returns a cell array of tables or a cell array of timetables, depending on the value of the `tdmsds.RowTimes` property. See “Read TDMS-File Data into Timetables” on page 4-338.

`[data,info] = read(tdmsds)` also returns the output argument `info`, with information and metadata about the extracted data.

### Examples

#### Read Datastore by Files

Read data from a TDMS datastore one file at a time. Set the read size and read the first data set.

```
tdmsds = tdmsDatastore("C:\data\tdms",ReadSize="file");
data1 = read(tdmsds);
```

Read the second file and view information about the data.

```
[data2,info2] = read(tdmsds);
info2

info2 =
    struct with fields:
        Filename: "C:\data\tdms\Turbine_002.tdms"
        FileSize: 172098
        Offset: 0
```

## Read TDMS-File Data into Timetables

By providing a vector of durations, you can read TDMS-file data into timetables.

Define a vector of 1000 elements of 1 ms duration. Set up the datastore object to read 1000 records (ReadSize) and return a timetable (RowTimes).

```
durvec = milliseconds(1:1000);
tdmsds = tdmsDatastore("C:\data\tdms", ReadSize=1000, RowTimes=durvec)
```

```
tdmsds =
```

```
TDMSDatastore with properties:
```

```
Files: ["C:\data\tdms\Turbine_001.tdms" "C:\data\tdms\Turbine_002.tdms"
ChannelList: [6x8 table]
SelectedChannelGroup: [0x0 string]
SelectedChannels: [0x0 string]
RowTimes: [0.001 sec 0.002 sec 0.003 sec 0.004 sec 0.005 sec 0.006 sec 0.007 sec 0.008 sec]
ReadSize: 1000
```

Read 1000 records from the datastore into timetables.

```
dd = read(tdmsds)
```

```
dd =
```

```
1x3 cell array
```

```
{1000x2 timetable} {1000x2 timetable} {1000x2 timetable}
```

View part of one of the timetables.

```
dd{1}
```

```
ans =
```

```
1000x2 timetable
```

Display all 1000 rows.

### Input Arguments

#### **tdmsds** — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

### Output Arguments

#### **data** — Output data

cell array of tables

Output data, returned as a cell array of tables from the TDMS records.

#### **info** — Information about data

structure array

Information about the data source file, returned as a structure with the following fields:

Filename  
FileSize  
Offset

The `offset` field indicates the position of the data in the file.

### Limitations

- TDMS functions are supported on Windows platforms only.

## Version History

Introduced in R2022a

### See Also

#### Functions

`tdmsDatastore` | `reset` | `preview` | `readall` | `hasdata`

# readall

**Package:** matlab.io.datastore

Read all data in TDMS datastore

## Syntax

```
data = readall(tdmsds)
```

## Description

`data = readall(tdmsds)` reads all the data in the datastore specified by `tdmsds`, and returns a cell array of tables or timetables. Each element of the cell array corresponds to a channel group in the datastore file data.

The function returns a cell array of tables or a cell array of timetables, depending on the value of the `tdms.RowTimes` property. See `tdmsDatastore`.

After the `readall` function returns all the data, it resets `tdmsds` to point to the beginning of the datastore.

## Examples

### Read All the Data in a Datastore

Read all the data from a multiple file TDMS datastore into an array of tables.

Set up datastore and read all its data.

```
tdmsds = tdmsDatastore("C:\data\tdms");
data = readall(td)
```

```
data =
```

```
1x3 cell array
    {9936x2 table}    {9936x2 table}    {9936x2 table}
```

View part of the data.

```

-12.011	4.5218

### Input Arguments

#### **tdmsds** — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

### Output Arguments

#### **data** — Output data

cell array of tables

Output data, returned as a cell array of tables from all TDMS-files in the datastore.

### Limitations

- TDMS functions are supported on Windows platforms only.

### Version History

Introduced in R2022a

### See Also

#### Functions

`tdmsDatastore` | `read` | `preview`

# reset

**Package:** matlab.io.datastore

Reset TDMS datastore to initial state

## Syntax

```
reset(tdmsds)
```

## Description

`reset(tdmsds)` resets the TDMS datastore specified by `tdmsds` to its initial read state, where no data has been read from it. Resetting allows you to reread from the same datastore.

## Examples

### Reset TDMS Datastore

Reset a TDMS datastore so that you can read from it again.

```
tdmsds = tdmsDatastore("C:\data\tdms");  
data = read(tdmsds);  
:  
reset(tdmsds);  
data = read(tdmsds);
```

## Input Arguments

### **tdmsds** — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

## Limitations

- TDMS functions are supported on Windows platforms only.

## Version History

Introduced in R2022a

# Blocks

---

## AGC

Adaptively adjust gain for constant signal-level output

### Libraries:

Communications Toolbox / RF Impairments Correction

## Description

The automatic gain controller (AGC) block adaptively adjusts its gain to achieve a constant signal level at the output.

This icon shows the AGC block with the optional Px port.

## Ports

### Input

**In** — Input signal  
column vector

Input signal, specified as a column vector.

Data Types: `single` | `double` | `int` | `uint`

### Output

**y** — Output signal  
 $N_S$ -element column vector

Output signal, returned as an  $N_S$ -element column vector.  $N_S$  is the length of the input signal. The output signal is the same data type as the input signal.

**Px** — Power level estimate  
 $N_S$ -element column vector

Power level estimate, returned as an  $N_S$ -element column vector.  $N_S$  is the length of the input signal. You can use `powerLevel` as an energy detector output.

### Dependencies

To enable this port, select the **Enable output of estimated input power** parameter.

## Parameters

**Step size** — Step size for gain updates

0.01 | positive scalar

Step size for gain updates, specified as a positive scalar. Increasing the step size enables the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level after reaching steady-state operation. For more information, see “AGC Performance Criteria” on page 5-5.

**Desired output power (W)** — Target output power level

1 | positive scalar

Target output power level, specified as a positive scalar. The power level is measured in watts referenced to 1 ohm.

**Averaging length** — Length of averaging window

100 | positive integer

Length of the averaging window in samples, specified as a positive integer. For more information on how the averaging length influences the variance of the AGC output signal in steady-state operation and the execution speed, see “Tips” on page 5-5.

**Maximum power gain (dB)** — Maximum power gain

60 (default) | positive scalar

Maximum power gain in decibels, specified as a positive scalar. Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use this property to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal. For an example, see “Compare AGC Performance for Different Maximum Gains”.

**Enable output of estimated input power** — Option to output estimated input power

off (default) | on

Select this check box to provide an output port, Px, that returns an estimate of the input signal power.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run, specified as Interpreted execution or Code generation.

- **Interpreted execution** — Simulate the model by using the MATLAB interpreter. This option requires less startup time, but the speed of subsequent simulations is slower than with the Code generation option. In this mode, you can debug the source code of the block.
- **Code generation** — Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The model reuses the C code for subsequent

simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than with the Interpreted execution option.

## More About

### Logarithmic-Loop AGC

The AGC implementation uses a logarithmic feedback loop. As this figure of the logarithmic-loop AGC algorithm shows, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.

The logarithmic-loop AGC performs well for a variety of signal types, including amplitude modulation. The “AGC Detector” on page 5-5 is applied to the input signal, which improves convergence times, but increases signal power variation at the detector input. Large signal variation at the detector input is acceptable for floating-point systems.

Mathematically, the algorithm is summarized as

$$\begin{aligned}
 y(n) &= x(n) \cdot \exp(g(n-1)), \\
 z(n) &= D(x(n)) \cdot \exp(2g(n-1)), \\
 e(n) &= A - \ln(z(n)), \text{ and} \\
 g(n) &= g(n-1) + K \cdot e(n),
 \end{aligned}$$

where:

- $x$  is the input signal.
- $y$  is the output signal.
- $g$  is the loop gain.
- $D(\bullet)$  is the detector function.
- $z$  is the detector output.
- $A$  is the reference value.
- $e$  is the error signal.
- $K$  is the step size.

### AGC Detector

The AGC detector output,  $z$ , computes a square law detector given by

$$z(m) = \frac{1}{N} \sum_{n=mN}^{(m+1)N-1} |y(n)|^2,$$

where  $N$  is the update period. The square law detector produces an output proportional to the square of the input signal  $y$ .

### AGC Performance Criteria

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

- Attack time — The duration taken for the AGC to respond to an increase in the input amplitude
- Decay time — The duration taken for the AGC to respond to a decrease in the input amplitude
- Gain pumping — The variation in the gain value during steady-state operation

### Tips

- This block is designed for streaming applications.
- If the signal amplitude does not change within the frame, you can simulate an ideal AGC by calculating the average gain desired for a frame of samples. Then, apply the gain to each sample in the frame.
- If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC during steady-state operation. You can increase the averaging length to avoid frequent gain adjustments. An increase in averaging length reduces execution speed.

# A-Law Compressor

Implement A-law compressor for source coding

## Library

Source Coding

## Description

The A-Law Compressor block implements an A-law compressor for the input signal. The formula for the A-law compressor is

$$y = \begin{cases} \frac{A|x|}{1 + \log A} \operatorname{sgn}(x) & \text{for } 0 \leq |x| \leq \frac{V}{A} \\ \frac{V(1 + \log(A|x|/V))}{1 + \log A} \operatorname{sgn}(x) & \text{for } \frac{V}{A} < |x| \leq V \end{cases}$$

where  $A$  is the A-law parameter of the compressor,  $V$  is the peak signal magnitude for  $x$ ,  $\log$  is the natural logarithm, and  $\operatorname{sgn}$  is the sign function.

The most commonly used  $A$  value is 87.6.

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### A value

The A-law parameter of the compressor.

### Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

## Supported Data Type

Port	Supported Data Types
In	• double
Out	• double

# A-Law Expander

Implement A-law expander for source coding

## Library

Source Coding

## Description

The A-Law Expander block recovers data that the A-Law Compressor block compressed. The formula for the A-law expander, shown below, is the inverse of the compressor function.

$$x = \begin{cases} \frac{y(1 + \log A)}{A} & \text{for } 0 \leq |y| \leq \frac{V}{1 + \log A} \\ \exp(|y|(1 + \log A)/V - 1) \frac{V}{A} \operatorname{sgn}(y) & \text{for } \frac{V}{1 + \log A} < |y| \leq V \end{cases}$$

The input can have any shape or frame status. This block processes each vector element independently.

## Parameters

### A value

The A-law parameter of the compressor.

### Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Match these parameters to the ones in the corresponding A-Law Compressor block.

# Algebraic Deinterleaver

Restore ordering of input symbols using algebraically derived permutation

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Deinterleaver block restores the original ordering of a sequence that was interleaved using the Algebraic Interleaver block. In typical usage, the parameters in the two blocks have the same values.

The **Number of elements** parameter,  $N$ , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it; these are described on the reference page for the Algebraic Interleaver block.

## Parameters

### Type

The type of permutation table that the block uses for deinterleaving. Choices are `Takeshita-Costello` and `Welch-Costas`.

### Number of elements

The number of elements,  $N$ , in the input vector.

### Multiplicative factor

The factor the block uses to compute the corresponding interleaver's cycle vector. This field appears only when you set **Type** to `Takeshita-Costello`.

### Cyclic shift

The amount by which the block shifts indices when creating the corresponding interleaver's permutation table. This field appears only when you set **Type** to `Takeshita-Costello`.

### Primitive element

An element of order  $N$  in the finite field  $GF(N+1)$ . This field appears only if **Type** is set to `Welch-Costas`.

### **Blocks**

General Block Deinterleaver | Algebraic Interleaver

# Algebraic Interleaver

Reorder input symbols using algebraically derived permutation table

## Library

Block sublibrary of Interleaving

## Description

The Algebraic Interleaver block rearranges the elements of its input vector using a permutation that is algebraically derived. The **Number of elements** parameter,  $N$ , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and `fixed-point`. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it:

- If you set **Type** to `Welch-Costas`, then  $N + 1$  must be prime. The **Primitive element** parameter is an integer,  $A$ , between 1 and  $N$  that represents a primitive element of the finite field  $\text{GF}(N + 1)$ . This means that every nonzero element of  $\text{GF}(N + 1)$  can be expressed as  $A$  raised to some integer power.

In a Welch-Costas interleaver, the permutation maps the integer  $k$  to  $\text{mod}(A^k, N + 1) - 1$ .

- If you set **Type** to `Takeshita-Costello`, then  $N$  must be  $2^m$  for some integer  $m$ . The **Multiplicative factor** parameter,  $k$ , must be an odd integer less than  $N$ . The **Cyclic shift** parameter,  $h$ , must be a nonnegative integer less than  $N$ .

A Takeshita-Costello interleaver uses a length- $N$  *cycle vector* whose  $n$ th element is

$$c(n) = \text{mod}\left(k \cdot \frac{n \cdot (n - 1)}{2}, N\right) + 1, n$$

for integers  $n$  between 1 and  $N$ . The intermediate permutation function is obtained by using the following relationship:

$$\Pi(c(n)) = c(n + 1)$$

where

$$n = 1:N$$

The interleaver's actual permutation vector is the result of cyclically shifting the elements of the permutation vector,  $\pi$ , by the **Cyclic shift** parameter,  $h$ .

## Parameters

### Type

The type of permutation table that the block uses for interleaving.

### Number of elements

The number of elements,  $N$ , in the input vector.

### Multiplicative factor

The factor used to compute the interleaver's cycle vector. This field appears only if **Type** is set to **Takeshita-Costello**.

### Cyclic shift

The amount by which the block shifts indices when creating the permutation table. This field appears only if **Type** is set to **Takeshita-Costello**.

### Primitive element

An element of order  $N$  in the finite field  $GF(N+1)$ . This field appears only if **Type** is set to **Welch-Costas**.

# Amplifier

(To be removed) Complex baseband model of amplifier with noise and nonlinearities

---

**Note** will be removed in a future release. Use Memoryless Nonlinearity instead. For information on updating your code, see “Version History”.

---

## Libraries:

Communications Toolbox / RF Impairments and Components

## Description

The Amplifier block generates a complex baseband model of an amplifier with thermal noise. This block provides four nonlinearity models and three options to specify noise representation.

## Ports

### Input

**Port\_1** — Input baseband signal

real scalar | real column | complex scalar | complex column

Input baseband signal, specified as a real scalar, real column, complex scalar, or complex column.

Data Types: double | single

### Output

**Port\_1** — Output baseband signal

real scalar | real column | complex scalar | complex column

Output baseband signal, specified as a real scalar, real column, complex scalar, or complex column. The output port mimics the properties of the input port. For example, if the input baseband signal is specified as a real scalar with a data type double, then the output baseband signal is also specified as a real signal with the data type double.

Data Types: double | single

## Parameters

### Main Tab

**Model** — Amplifier nonlinearity model

Cubic polynomial (default) | AM/AM - AM/PM | Modified Rapp | Saleh

Specify the amplifier nonlinearity model as one of the following:

- Cubic polynomial
- AM/AM - AM/PM
- Modified Rapp
- Saleh

For more information, see “Nonlinearity Models in Idealized Amplifier Block” (RF Blockset).

**Linear power gain (dB)** — Linear gain of amplifier  
0 (default) | real scalar

Linear gain, specified as a scalar in dB.

**Type of Non-Linearity** — Third - order nonlinearity type  
IIP3 (default) | OIP3 | IP1dB | OP1dB | IPSat | OPSat

Third order nonlinearity type, specified as IIP3, OIP3, IP1dB, OP1dB, IPSat, or OPSat.

**IIP3 (dBm)** — Input third-order intercept point  
Inf (default) | real positive number

Input third-order intercept point, specified as a real positive number in dBm.

#### Dependencies

To enable this parameter, set **Model** to Cubic polynomial and **Type of Non-Linearity** to IIP3.

**OIP3 (dBm)** — Output third-order intercept point  
Inf (default) | real positive number

Output third-order intercept point, specified as a real positive number in dBm.

#### Dependencies

To enable this parameter, set **Model** to Cubic polynomial and **Type of Non-Linearity** to OIP3.

**IP1dB (dBm)** — Input 1 dB compression point  
Inf (default) | real positive number

Input 1 dB compression point, specified as a real positive number in dBm.

#### Dependencies

To enable this parameter, set **Model** to Cubic polynomial and **Type of Non-Linearity** to IP1dB.

**OP1dB (dBm)** — Output 1 dB compression point  
Inf (default) | real positive number

Output 1 dB compression point, specified as a real positive number in dBm.

#### Dependencies

To enable this parameter, set **Model** to Cubic polynomial and **Type of Non-Linearity** to OP1dB.

**IPSat (dBm)** — Input saturation point  
Inf (default) | real positive number

Input saturation point, specified as a real positive number in dBm.

**Dependencies**

To enable this parameter, set **Model** to `Cubic polynomial` and **Type of Non-Linearity** to `IPsat`.

**OPsat (dBm)** — Output saturation point

`Inf` (default) | real positive number

Output saturation point, specified as a positive real number in dBm.

**Dependencies**

To enable this parameter, set **Model** to `Cubic polynomial` and **Type of Non-Linearity** to `OPsat`.

**Reference load (ohm)** — Reference load

`1` (default) | positive scalar

Reference load value in ohms, specified as a positive scalar. This value is used to convert between the voltage levels and the signal and noise power levels.

**Tunable:** Yes

**Simulate using** — Specify type of simulation to run

`Code generation` (default) | `Interpreted execution`

- `Code generation` - Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time, but the speed of the subsequent simulations is faster than `Interpreted execution`.
- `Interpreted execution` - Simulate model using the MATLAB interpreter. This option shortens startup time speed, but the speed of the subsequent simulations is slower than `Code generation`. In this mode, you can debug the source code of the block.

**Plot power characteristics** — Plot power characteristics

`button` (default)

This button plots the power characteristics based on the parameters specified on the **Main** tab.

For more information, see “Plot Power Characteristics” (RF Blockset).

**Lookup table (Pin(dBm), Pout(dBm), deg)** — Lookup table

[ `-25, 5, -1; -10, 20, -2; 0, 27, 5; 5, 28, 12` ] (default) | *M*-by-3 real matrix

Table lookup entries specified as a real *M*-by-3 matrix. This table expresses the model output power dBm level in matrix column 2 and the model phase change in degrees in matrix column 3 as related to the absolute value of the input signal power of matrix column 1 for the AM/AM - AM/PM model. The column 1 input power must increase monotonically.

**Dependencies**

To enable this parameter, set **Model** to `AM/AM - AM/PM`.

**Output saturation level (V)** — Output saturation level

`1` (default) | real positive number

Voltage output saturation level, specified as a real positive number in dBm.

**Dependencies**

To enable this parameter, set **Model** to Modified Rapp.

**Magnitude smoothness factor** — Magnitude smoothness factor  
2 (default) | real positive number

Magnitude smoothness factor for the Modified Rapp amplifier model AM/AM calculations, specified as a positive real number.

**Dependencies**

To enable this parameter, set **Model** to Modified Rapp.

**Phase gain (rad)** — Phase gain  
-0.45 (default) | real scalar

Phase gain for the Modified Rapp amplifier model AM/PM calculations, specified as a real scalar in radians.

**Dependencies**

To enable this parameter, set **Model** to Modified Rapp.

**Phase saturation** — Phase saturation  
0.88 (default) | real positive number

Phase saturation for the Modified Rapp amplifier model AM/PM calculations, specified as a positive real number.

**Dependencies**

To enable this parameter, set **Model** to Modified Rapp.

**Phase smoothness factor** — Phase smoothness factor  
3.43 (default) | real positive number

Phase smoothness factor for the Modified Rapp amplifier model AM/PM calculations, specified as a positive real number.

**Dependencies**

To enable this parameter, set **Model** to Modified Rapp.

**Input scaling (dB)** — Scaling factor for input signal level  
0 (default) | nonnegative real number

Scaling factor for input signal level for the Saleh amplifier model, specified as a nonnegative real number in dB.

**Dependencies**

To enable this parameter, set **Model** to Saleh.

**AM / AM parameters [alpha beta]** — AM/AM conversion parameters  
[ 2.1587, 1.1517 ] (default) | two-element vector

AM/AM two-tuple conversion parameters for Saleh amplifier model, specified as a two-element vector of nonnegative real numbers.

#### Dependencies

To enable this parameter, set **Model** to Saleh.

**AM / PM parameters [alpha beta]** — AM/PM conversion parameters  
[ 4.0033, 9.1040 ] (default) | two-element vector

AM/PM two-tuple conversion parameters for Saleh amplifier model, specified as a two-element vector of nonnegative real numbers.

#### Dependencies

To enable this parameter, set **Model** to Saleh.

**Output scaling (dB)** — Scaling factor for output signal level  
0 (default) | nonnegative real number

Scaling factor for output signal level for Saleh amplifier model, specified as nonnegative real number in dB.

#### Dependencies

To enable this parameter, set **Model** to Saleh.

#### Noise Tab

**Include Noise** — Add noise to system  
off (default) | on

Select this parameter to add system noise to the input signal. Once you select this parameter, the parameters associated with the **Noise** tab are displayed.

**Specify noise type** — Noise representation  
Noise temperature (default) | Noise figure | Noise factor

Noise descriptive type, specified as Noise temperature, Noise figure, or Noise factor.

For more information, see “Thermal Noise Simulations in Idealized Amplifier Block” (RF Blockset).

#### Dependencies

To enable this parameter, select **Include Noise**.

**Noise temperature (K)** — Noise temperature to model noises in amplifier  
290 (default) | nonnegative real number

Noise temperature to model noise in the amplifier, specified as a nonnegative real number in degrees (K).

#### Dependencies

To enable this parameter, select **Include Noise** and set **Specify noise type** to Noise temperature.

**Noise figure (dB)** — Noise figure to model noise in amplifier  
 $10 * \log_{10}( 2 )$  (default) | nonnegative real number

Noise figure to model noise in the amplifier, specified as a nonnegative real number in dB.

#### Dependencies

To enable this parameter, select **Include Noise** and set **Specify noise type** to `Noise figure`.

**Noise factor** — Noise factor to model noise in amplifier  
2 (default) | positive integer scalar greater than or equal to 1

Noise factor to model noise in the amplifier, specified as a positive integer scalar greater than or equal to 1.

#### Dependencies

To enable this parameter, select **Include Noise** and set **Specify noise type** to `Noise factor`.

**Seed source** — Source of initial seed  
`Auto` (default) | `User specified`

Source of initial seed used to prepare the Gaussian random number noise generator, specified as one of the following:

- `Auto` - When **Seed source** is set to `Auto`, seeds for each amplifier instance are generated using a random number generator. The reset method of the instance has no effect.
- `User specified` - When **Seed source** is set to `User specified`, the value provided in the **Seed** is used to initialize the random number generator and the reset method resets the random number generator using the **Seed** property value.

**Seed** — Seed for random number generator  
67987 (default) | nonnegative integer

Seed for the random number generator, specified as a nonnegative integer less than  $2^{32}$ . Use this value to initialize the random number generator.

#### Dependencies

To enable this parameter, click **Include Noise** check box and choose `User specified` in the **Seed source** parameter.

## Version History

**Introduced in R2020a**

**R2023a: To be removed**

*Warns starting in R2023a*

The Amplifier block will be removed in a future release. To compute model amplifier characteristics, use the Memoryless Nonlinearity block instead.

- For models that use Amplifier with **Include Noise** not selected, the block is automatically replaced with the Memoryless Nonlinearity block.

- For models that use Amplifier with **Include Noise** selected, run Upgrade Advisor (Simulink) and the block will be replaced by a Receiver Thermal Noise block plus a Memoryless Nonlinearity block.

### **R2022b: Reference load parameter added to the block**

You can now specify load resistance in ohms using the Reference Load parameter.

### Input Signals and Output Signals

The input  $L(u)$  represents the sequence of log-likelihoods of encoder input bits, while the input  $L(c)$  represents the sequence of log-likelihoods of code bits. The outputs  $L(u)$  and  $L(c)$  are updated versions of these sequences, based on information about the encoder.

If the convolutional code uses an alphabet of  $2^n$  possible symbols, this block's  $L(c)$  vectors have length  $Q*n$  for some positive integer  $Q$ . Similarly, if the decoded data uses an alphabet of  $2^k$  possible output symbols, then this block's  $L(u)$  vectors have length  $Q*k$ .

This block accepts a column vector input signal with any positive integer for  $Q$ .

If you only need the input  $L(c)$  and output  $L(u)$ , you can attach a Simulink Ground block to the input  $L(u)$  and a Simulink Terminator block to the output  $L(c)$ .

This block accepts `single` and `double` data types. Both inputs, however, must be of the same type. The output data type is the same as the input data type.

### Specifying the Encoder

To define the convolutional encoder that produced the coded input, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name as the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

To indicate how the encoder treats the trellis at the beginning and end of each frame, set the **Termination method** parameter to either `Truncated` or `Terminated`. The `Truncated` option indicates that the encoder resets to the all-zeros state at the beginning of each frame. The `Terminated` option indicates that the encoder forces the trellis to end each frame in the all-zeros state. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Truncated` (reset every frame), use the `Truncated` option in this block. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Terminate trellis by appending bits`, use the `Terminated` option in this block.

### Specifying Details of the Algorithm

You can control part of the decoding algorithm using the **Algorithm** parameter. The `True APP` option implements a posteriori probability decoding as per equations 20–23 in section V of [1]. To gain speed, both the `Max*` and `Max` options approximate expressions like

$$\log \sum_i \exp(a_i)$$

by other quantities. The `Max` option uses  $\max(a_i)$  as the approximation, while the `Max*` option uses  $\max(a_i)$  plus a correction term given by  $\ln(1 + \exp(-|a_{i-1} - a_i|))$  [3].

The `Max*` option enables the **Scaling bits** parameter in the dialog box. This parameter is the number of bits by which the block scales the data it processes internally (multiplies the input by  $(2^{\text{numScalingBits}})$  and divides the pre-output by the same factor). Use this parameter to avoid losing precision during the computations.

## Parameters

### Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

### Termination method

Either `Truncated` or `Terminated`. This parameter indicates how the convolutional encoder treats the trellis at the beginning and end of frames.

### Algorithm

Either `True APP`, `Max*`, or `Max`.

### Number of scaling bits

An integer between 0 and 8 that indicates by how many bits the decoder scales data in order to avoid losing precision. This field is active only when **Algorithm** is set to `Max*`.

### Disable L(c) output port

Select this check box to disable the secondary block output, L(c).

# AWGN Channel

Add white Gaussian noise to input signal

**Libraries:**  
Communications Toolbox / Channels

## Description

The AWGN Channel block adds white Gaussian noise to the input signal. It inherits the sample time from the input signal.

## Examples

### LLR vs. Hard Decision Demodulation in Simulink

This model shows the improvement in BER performance when using log-likelihood ratio (LLR) instead of hard decision demodulation in a convolutionally coded communication link.

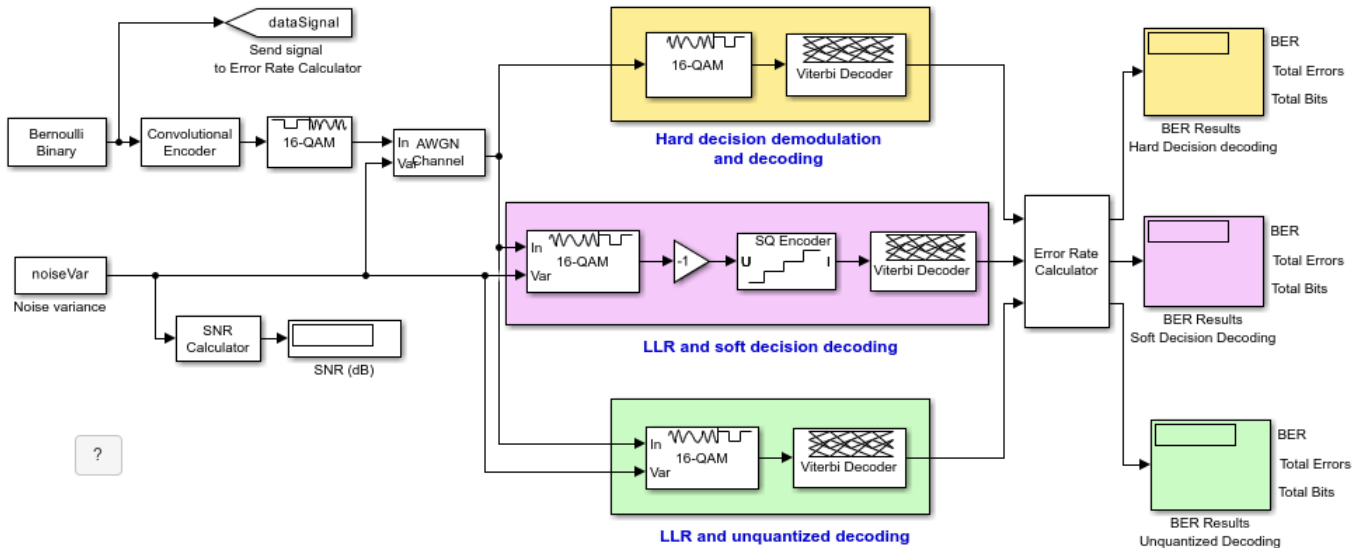

For a MATLAB® version of this example, see “Log-Likelihood Ratio (LLR) Demodulation”.

### System Setup

This example model simulates a convolutionally coded communication system having one transmitter, an AWGN channel and three receivers. The convolutional encoder has a code rate of 1/2. The system employs a 16-QAM modulation. The modulated signal passes through an additive white Gaussian noise channel. The top receiver performs hard decision demodulation in conjunction with a Viterbi decoder that is set up to perform hard decision decoding. The second receiver has the demodulator configured to compute log-likelihood ratios (LLRs) that are then quantized using a 3-bit quantizer. It is well known that the quantization levels are dependent on noise variance for optimum performance [2]. The exact boundaries of the quantizer are empirically determined here. A Viterbi decoder that is set up for soft decision decoding processes these quantized values. The LLR values computed by the demodulator are multiplied by -1 to map them to the right quantizer index for use with Viterbi Decoder. To compute the LLR, the demodulator must be given the variance of noise as seen at its input. The third receiver includes a demodulator that computes LLRs which are processed by a Viterbi decoder that is set up in unquantized mode. The BER performance of each receiver is computed and displayed.
