## Filter Builder

Design filters starting with frequency and magnitude specifications (`filterBuilder`)

### Description

The **Filter Builder** app provides a graphical user interface to design filters using the `fdesign` object. The first step is to choose the filter response. Based on the response you choose, the algorithm, constraints, and the design parameter settings appear on the **Main** tab of the user interface. You can further specify the precision and data types in the **Data Types** tab. The **Code Generation** tab contains options for various implementations of the completed filter design. Once you specify all the filter parameters and the design algorithm, you can visualize the filter response by clicking on the **View Filter Response** button. When you click on this button, **FVTool** opens to display the magnitude response of the filter. When you have achieved the desired filter response through iterations of design and analysis, click **OK**. When you click **OK**, the app exports the filter object to the base workspace. If you select the **Use a System object to implement filter** check box in the user interface, the app exports a filter System object™. For more information on the design process using the **Filter Builder** app, see “Filter Builder Design Process”. For details on each of the response methods and settings of all the associated parameters, see `filterBuilder`.

## Open the Filter Builder App

- MATLAB® Toolstrip: On the **Apps** tab, under **Signal Processing and Communications**, click the  app icon.
- MATLAB command prompt: Enter `filterBuilder`.

- MATLAB command prompt: Enter `filterBuilder(obj)`, where `obj` is an existing filter object. For example, if `obj` is a bandpass filter, `filterBuilder(obj)` opens the bandpass filter design dialog. The `obj` object must have been created using `filterBuilder` or using `fdesign`.
- MATLAB command prompt: Enter `filterBuilder('response')` to replace *response* with a supported response method. MATLAB opens a filter design dialog that corresponds to the specified response. For details on the supported response methods, see `filterBuilder`.

# Logic Analyzer

Visualize, measure, and analyze transitions and states over time

## Description

The **Logic Analyzer** is a tool for visualizing and inspecting signals and states in your Simulink® model. Using the **Logic Analyzer**, you can:

- Debug and analyze models
- Trace and correlate many signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

**For keyboard shortcuts, click [More](#).**

### Keyboard Shortcuts

| Actions                      | Description                   | Applicable When                         |
|------------------------------|-------------------------------|---|
| <b>Ctrl+X</b>                | Cut                           | Wave is selected                        |
| <b>Ctrl+C</b>                | Copy                          | Wave is selected                        |
| <b>Ctrl+V</b>                | Paste                         | Wave is selected                        |
| <b>Delete</b>                | Delete                        | Wave is selected                        |
| <b>Ctrl+-</b>                | Zoom out                      | Always                                  |
| <b>Shift+Ctrl+-</b>          | Zoom out around active cursor | Always                                  |
| <b>Ctrl++</b>                | Zoom in                       | Always                                  |
| <b>Shift+Ctrl++</b>          | Zoom in around active cursor  | Always                                  |
| <b>Shift+Ctrl+C</b>          | Move display to active cursor | When cursor is not in the display range |
| <b>Space</b>                 | Zoom out full                 | Always                                  |
| <b>Tab, Right Arrow</b>      | Next transition               | Digital format wave is selected         |
| <b>Shift+Tab, Left Arrow</b> | Previous transition           | Digital format wave is selected         |
| <b>Ctrl+A</b>                | Select all waves              | Always                                  |
| <b>Up Arrow</b>              | Select wave above selected    | Wave is selected                        |
| <b>Down Arrow</b>            | Select wave below selection   | Wave is selected                        |
| <b>Ctrl+Up Arrow</b>         | Move selected waves up        | Wave is selected                        |
| <b>Ctrl+Down Arrow</b>       | Move selected waves down      | Wave is selected                        |
| <b>Escape</b>                | Unselect all signals          | Wave is selected                        |
| <b>Page Up</b>               | Scroll up                     | Always                                  |
| <b>Page Down</b>             | Scroll down                   | Always                                  |

## Open the Logic Analyzer App

On the Simulink toolstrip Simulation tab, click the **Logic Analyzer** app button. If the button is not displayed, expand the review results app gallery. Your most recent choice for data visualization is saved across Simulink sessions.

To visualize referenced models, you must open the Logic Analyzer from the referenced model. You should see the name of the referenced model in the Logic Analyzer toolbar.

## Examples

### Select Signals to Analyze

The **Logic Analyzer** supports several methods for selecting data to visualize.

- Select a signal in your model. When you select a signal, an ellipsis appears above the signal line. Hover over the ellipsis to view options and then select the **Enable Data Logging** option.

- Right-click a signal in your model to open an options dialog box. Select the **Log Selected Signals** option.

- Use any method to select multiple signal lines in your model. For example, use **Shift**+click to select multiple lines individually or **CTRL+A** to select all lines at once. Then, on the **Signal** tab, select the **Log Signals** button.

To visualize data in the Logic Analyzer, you must enable signal logging for the model. (Logging is on by default.) To enable signal logging, open **Model Settings** from the toolstrip, navigate to the **Data Import/Export** pane, and select **Signal logging**.

When you open the **Logic Analyzer**, all signals marked for logging are listed. You can add and delete waves from your **Logic Analyzer** while it is open. Adding and deleting signals does not disable logging, only removes the signal from the Logic Analyzer.

### Modify Individual Wave Settings

Open the **Logic Analyzer** and select a wave by double-clicking the wave name. Then from the **Wave** tab, set parameters specific to the individual wave you selected. Any setting made on individual signals supersedes the global setting. To return individual wave parameters to the global settings, click **Reset**.

The screenshot shows the Logic Analyzer interface with the **WAVE** tab selected. The **PROPERTIES** section includes:

- Name: Discrete-time signal
- Height: 12
- Radix: (dropdown menu)
- Font Size: 10
- Format: Digital
- Wave Color: (color selector)

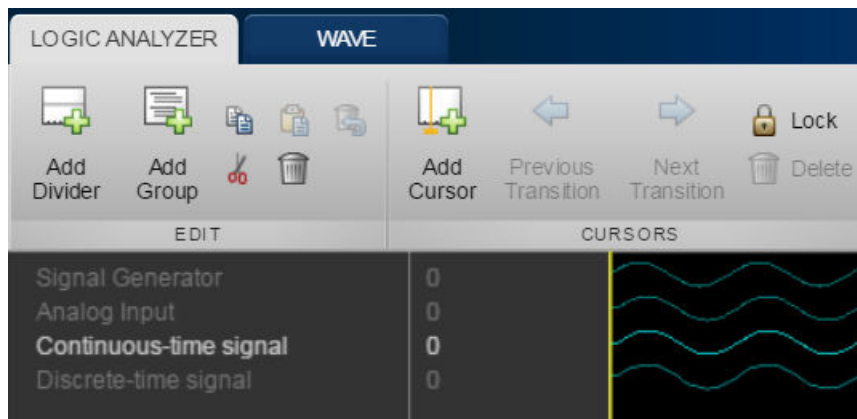

The **ACTIONS** section includes:

- Move: (up/down arrows)
- Reset: (refresh icon)
- Delete: (trash icon)

The main display area shows a signal waveform with a cursor. The signal is a discrete-time signal with values 0, 1, 0, 1, 0, 1, 0, 1, 0, 1. The cursor is positioned at 0 us. The time axis is marked with 7340800 us, 7341000 us, and 7341200 us.

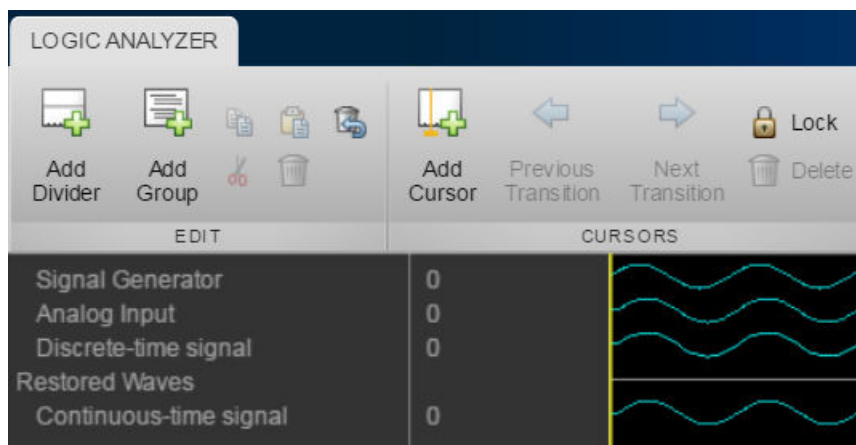

### Delete and Restore Waves

- 1 Open the **Logic Analyzer** and select a wave by clicking the wave name.

- 2 From the **Logic Analyzer** toolbar, click . The wave is removed from the **Logic Analyzer**.
- 3 To restore the wave, from the **Logic Analyzer** toolbar, click .

A divider named **Restored Waves** is added to the bottom of your channels, with all deleted waves placed below it.

## Add Trigger

- 1 Open the **Logic Analyzer** and select the **Trigger** tab.

- 2 To attach a signal to the trigger, select **Attach Signals**, then select the signal you want to trigger on. You can attach up to 20 signals to the trigger. Each signal can have only one triggering condition.
- 3 By default, the trigger looks for rising edges in the attached signals. You can set the trigger to look for rising or falling edges, bit sequences, or a comparison value. To change the triggering conditions, select **Set Conditions**.

If you add multiple signals to the trigger, control the trigger logic using the **Operator** option:

- AND - match all conditions.
  - OR - match any condition.
- 4 To control how many samples you see before triggering, set the **Display Samples** option. For example, if you set this option to 500, the **Logic Analyzer** tries to give you 500 samples before the trigger. Depending on the simulation, the **Logic Analyzer** may show more or fewer than 500 samples before the trigger. However, if the trigger is found before the 500th sample, the Logic Analyzer still shows the trigger.
  - 5 Control the trigger mode using **Display Mode**.
    - Once - The **Logic Analyzer** marks only the first location matching the trigger conditions and stops showing updates to the Logic Analyzer. If you want to reset the trigger, select **Rearm Trigger**. Relative to the current simulation time, the **Logic Analyzer** shows the next matching trigger event.
    - Auto - The **Logic Analyzer** marks every location matching the trigger conditions.
  - 6 Before running the simulation, select **Enable Trigger**. A blue cursor appears as time 0. Then, run the simulation. When a trigger is found, the **Logic Analyzer** marks the location with a locked blue cursor.

### Choose Visible Instance of Multi-Reference Model Block

The **Logic Analyzer** can stream only a single instance of a multi-instance Model block. If the same model is opened across different windows, those models will share the same Logic Analyzer. This example shows how to select an instance of a multi-instance Model block for logging on the **Logic Analyzer**.

Open the `multipleModelInstances` model.

```
open_system('multipleModelInstances')
```

Copyright 2016 The MathWorks, Inc.

The model contains three instances of the `referencedModel` model.

Double-click any of the Model blocks to open the model referenced by all three Model blocks.

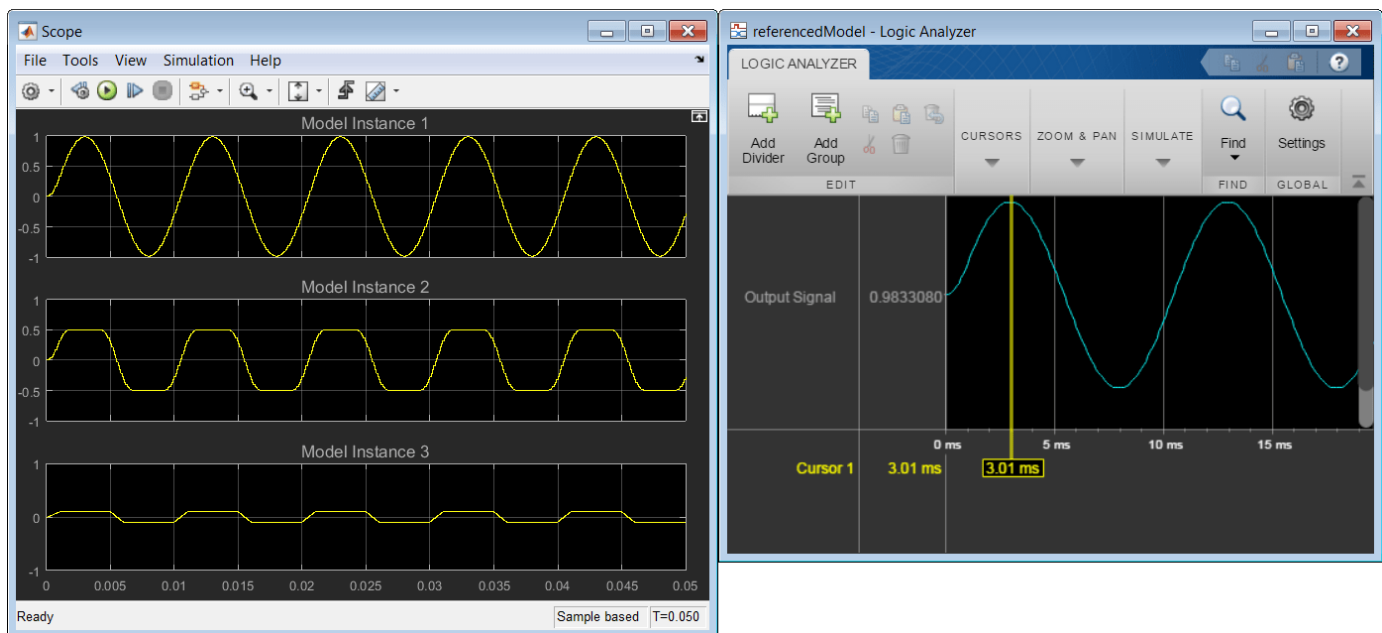

```
open_system('referencedModel')
```

Copyright 2016 The MathWorks, Inc.

Open the Logic Analyzer in the referenced model by double-clicking the logging symbol next to the MovingAverage block. You should see `referencedModel - [multipleModelInstances]` in the toolbar of the Logic Analyzer.

From the Logic Analyzer window, run the model. By running the simulation from a referenced version of `referencedModel`, Simulink runs the top model (`multipleModelInstances`) and referenced models (`referencedModel`). The **Logic Analyzer** displays a single instance of a multi-instance Model block.

When you run a simulation, the logic analyzer runs the model listed in the Logic Analyzer toolbar. If this model is a referenced model, the toolbar also lists the top model and you will see results from

running the top model. To view results from the referenced model in isolation, you must open the referenced model as a top model.

To switch between instances, from the Simulink Editor menu, on the Simulation tab open the Prepare gallery and select **Normal Mode Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**. Select **Model Instance 3** and then click **OK**.

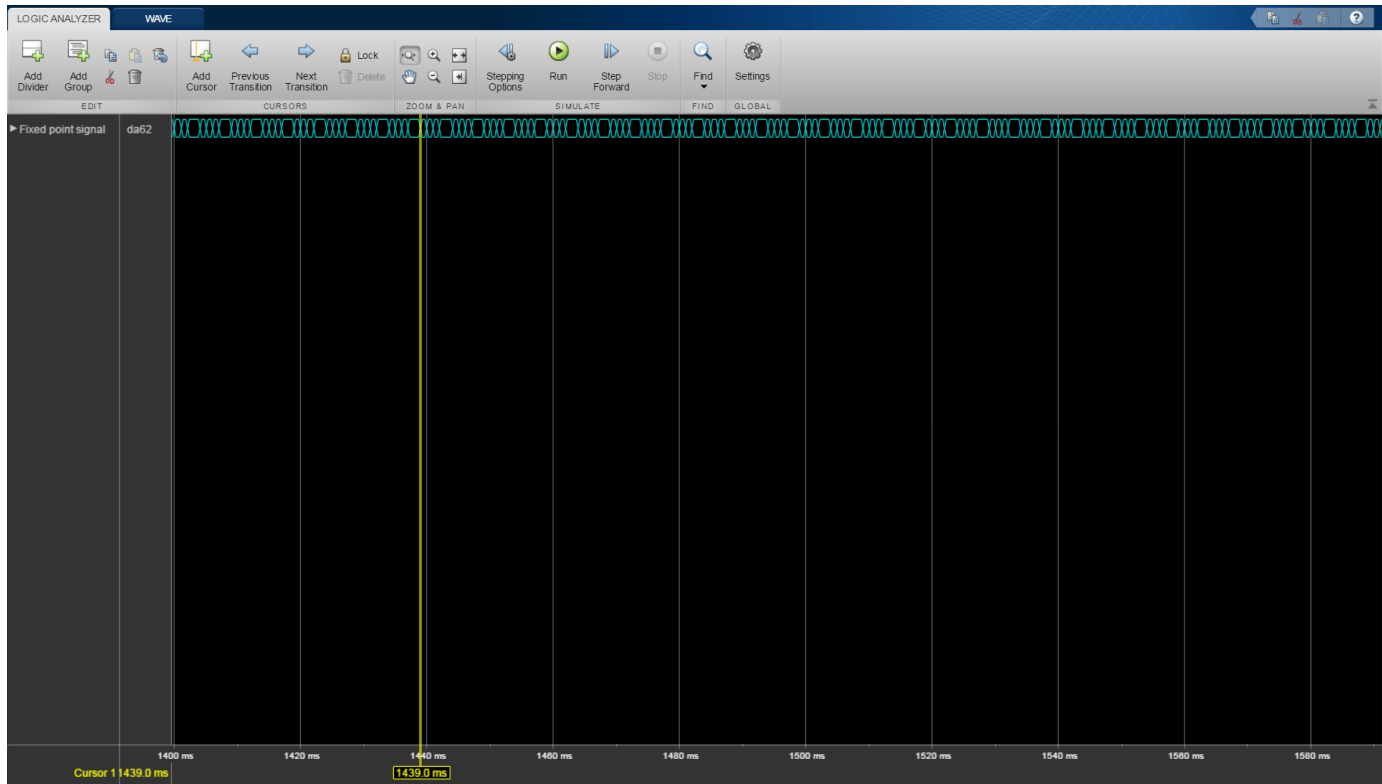

Run the `multipleModelInstances` model again. The **Logic Analyzer** displays `Model Instance 3` data.

## View Bit-Expanded Wave and Reverse Display Order of Bits

The **Logic Analyzer** enables you to bit-expand fixed-point and integer waves.

- 1 In the **Logic Analyzer**, click the arrow next to a fixed-point or integer wave to view the bits.

The least significant bit and the most significant bit are marked with **lsb** and **msb** next to the wave names.

# 1 Apps

- 2 Click Settings, and then select **Display Least Significant bit first** to reverse the order of the displayed bits.

### Add Triggers to Verify Write Operation

- 1 Open the Programmable FIR Filter model (dspprogfirhdl).

- 2 Open the **Logic Analyzer** and select the **Trigger** tab.
- 3 To add a trigger, in the toolstrip, select **Attach Signals** and attach the write enable `Write En` signal. An icon appears in front of the signal name to indicate it is attached to a trigger. The icon changes depending on the type of trigger.
- 4 Select **Set Conditions** and change the trigger condition for the `Write En` signal to **Falling Edge**. The trigger will show when the write enable signal was sent.
- 5 Attach the `Write Done` signal to the trigger. Keep the trigger condition for this signal as the default, **Rising Edge**. Now, the trigger will also show when the write was completed.

If you open the **Set Conditions** drop down, you see an **Operator** field. This field appears when multiple signals are attached to the trigger. Change the operator to **OR** so that the trigger will show instances where a write was started or completed.

- 6 Set the **Display Mode** to Auto. With this setting, the **Logic Analyzer** marks all locations where the trigger conditions are met.
- 7 Select **Enable Trigger** and run the simulation.

Each time the trigger conditions are met, the **Logic Analyzer** marks the time with a locked blue cursor. At each marked location, `Write En` is 0 and `Write Done` is 1. If you examine each location marked by a trigger, you can verify that each time a write is sent, it is also completed.

- “Inspect and Measure Transitions Using the Logic Analyzer”
- “Visualizing Multiple Signals Using Logic Analyzer”
- “Partly Serial Systolic FIR Filter Implementation” (DSP HDL Toolbox)
- “Fully Parallel Systolic FIR Filter Implementation” (DSP HDL Toolbox)
- “Configure Logic Analyzer”
- “Programmable FIR Filter for FPGA” (HDL Coder)
- “Log Simulation Output for States and Data” (Stateflow)
- “View Stateflow States in the Logic Analyzer” (Stateflow)

## Limitations

### Logging Settings

- If you enable the configuration parameter **Log Dataset data to file**, you cannot stream logged data to the **Logic Analyzer**.
- Signals marked for logging using `Simulink.sdi.markSignalForStreaming` or visualized with a Dashboard Scope do not appear on the **Logic Analyzer**.
- You cannot visualize Data Store Memory block signals in the **Logic Analyzer** if you set the **Log data store data** parameter to on.

## Input Signal Limitations

- Signals marked for logging for the **Logic Analyzer** must have fewer than 8000 samples per simulation step.
- The **Logic Analyzer** does not support frame-based processing.
- For 64-bit integers and fixed-point numbers greater than 53 bits, if the numbers are greater than the maximum value of double precision, the transitions between numbers might not display correctly.
- You may see performance degradation in the **Logic Analyzer** for large matrices (greater than 500 elements) and buses with more than 1000 signals.
- The **Logic Analyzer** does not support Stateflow data output.

## Graphical Settings

- While the simulation is running, you cannot zoom, pan, or modify the trigger.
- To visualize constant signals, in the settings, you must set the **Format** to **Digital**. Constants marked for logging are visualized as a continuous transition.

## Supported Simulation Modes

| Mode                        | Supported | Notes and Limitations   |
|-----------------------------|-----------|---|
| Normal                      | Yes       |   |
| Accelerator                 | Yes       | You cannot use the <b>Logic Analyzer</b> to visualize signals in Model blocks with <b>Simulation mode</b> set to Accelerator.   |
| Rapid Accelerator           | Yes       | Data is not available in the <b>Logic Analyzer</b> during simulation.<br><br>If you simulate a model with the simulation mode set to rapid accelerator, after simulation the following signals cannot be visualized in the <b>Logic Analyzer</b> : <ul style="list-style-type: none"> <li>• Multi-instance model reference signals</li> <li>• Nonvirtual bus signals</li> </ul> |
| Processor-in-the-loop (PIL) | No        |   |
| Software-in-the-loop (SIL)  | No        |   |
| External                    | No        |   |

For more information about these modes, see “How Acceleration Modes Work” (Simulink).

# Allpass Filter

Single-section or multiple-section allpass filter

## Libraries:

DSP System Toolbox / Filtering / Filter Implementations

## Description

The Allpass Filter block filters each channel of the input signal independently using a single-section or multiple-section (cascaded) allpass filter. You can implement the allpass filter using a minimum multiplier, wave digital filter, or a lattice structure.

In minimum multiplier form, the block uses the minimum number of required multipliers,  $n$ , with  $2n$  delay units and  $2n$  adders. In wave digital filter form, the block uses only  $n$  multipliers and  $n$  delay units, at the expense of  $3n$  adders. The lattice structure uses  $2n$  multipliers,  $n$  delay units, and  $2n$  adders. For more details on these structures, see “Algorithms” on page 2-7.

## Input/Output Ports

### Input

**x** — Input data

column vector | row vector | matrix

Input data that is passed into the allpass filter. The block accepts real-valued or complex-valued multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$  and  $n \geq 1$ . The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

This port is unnamed until you set **Internal allpass structure** to Minimum multiplier or Lattice, and select the **Specify coefficients from input port** parameter.

Data Types: single | double

**coeffs** — Allpass filter coefficients

column vector | row vector | matrix

This port inputs the coefficients of the allpass filter. When you set **Internal allpass structure** to Minimum multiplier, the **coeffs** port accepts matrices of size  $N$ -by-1 or  $N$ -by-2. When you set **Internal allpass structure** to Lattice, the **coeffs** port accepts an  $N$ -by-1 column vector or an 1-by- $N$  row vector.

### Dependencies

This port appears when you set **Internal allpass structure** to Minimum multiplier or Lattice, and select the **Specify coefficients from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

## Output

**Port\_1** — Output of the allpass filter  
column vector | row vector | matrix

The size of the filtered output matches the size of the input.

Data Types: single | double

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Internal allpass structure** — Filter structure

Minimum multiplier (default) | Wave Digital Filter | Lattice

- **Minimum multiplier** — This structure uses the minimum number of required multipliers,  $n$ , with  $2n$  delay units and  $2n$  adders. The coefficients to this structure are specified through the **Allpass polynomial coefficients** parameter.
- **Wave Digital Filter** — The structure uses  $n$  multipliers and  $n$  delay units, at the expense of  $3n$  adders. The coefficients to this structure are specified through the **Wave Digital Filter allpass coefficients** parameter.
- **Lattice** — The structure uses  $2n$  multipliers,  $n$  delay units, and  $2n$  adders. The coefficients to this structure are specified through the **Lattice allpass coefficients** parameter.

For more details on these structures, see “Algorithms” on page 2-7.

**Specify coefficients from input port** — Flag to specify allpass polynomial coefficients

off (default) | on

When you select this check box and set **Internal allpass structure** to **Minimum multiplier**, the allpass polynomial coefficients are input through the **coeffs** port. When you clear this check box, the allpass polynomial coefficients are specified on the block dialog through the **Allpass polynomial coefficients** parameter.

When you select this check box and set **Internal allpass structure** to **Lattice**, the lattice allpass coefficients are input through the **coeffs** port. When you clear this check box, the lattice allpass coefficients are specified on the block dialog through the **Lattice allpass coefficients** parameter.

## Dependencies

This parameter applies when you set **Internal allpass structure** to **Minimum multiplier** or **Lattice**.

**Allpass polynomial coefficients** — Coefficients in minimum multiplier form

$[-2^{(-1/2)}, 1/2]$  (default) |  $N$ -by-1 matrix |  $N$ -by-2 matrix

Specify the real allpass polynomial filter coefficients in minimum multiplier form as an  $N$ -by-1 matrix or an  $N$ -by-2 matrix.

- $N$ -by-1 matrix — The block realizes  $N$  first-order allpass sections.

- $N$ -by-2 matrix — The block realizes  $N$  second-order allpass sections.

The default value,  $[-2^{(-1/2)}, 1/2]$ , defines a stable second-order allpass filter with poles and zeros at  $\pm\pi/3$  in the  $z$ -plane.

Tunable: Yes

#### Dependencies

To enable this parameter, set **Internal allpass structure** to Minimum multiplier and clear the **Specify coefficients from input port** parameter.

**Wave Digital Filter allpass coefficients** — Coefficients in wave digital filter form  
 $[1/2, -2^{(1/2)}/3]$  (default) |  $N$ -by-1 matrix |  $N$ -by-2 matrix

Specify the real allpass filter coefficients in wave digital filter form. The coefficients can be  $N$ -by-1 matrix for  $N$  first-order allpass sections and  $N$ -by-2 matrix for  $N$  second-order allpass sections. The default value,  $[1/2, -2^{(1/2)}/3]$ , is a transformed version of the default value of allpass polynomial coefficients. This value is computed using `allpass2wdf(Allpass polynomial coefficients)`. These coefficients define the same stable second-order allpass filter as when the allpass structure is set to Minimum multiplier.

Tunable: Yes

#### Dependencies

To enable this parameter, set **Internal allpass structure** to Wave Digital Filter.

**Indicate if last section is first order** — Is last section first order  
 off (default) | on

- on — When you set select this check box, the last section is considered first order. Also, the second element of the last row of the  $N$ -by-2 matrix is ignored.
- off — When you do not select this check box, the last section is considered second-order.

#### Dependencies

To enable this parameter, set **Internal allpass structure** to Minimum multiplier or Wave Digital Filter.

**Lattice allpass coefficients** — Coefficients in lattice form  
 $[-2^{(1/2)}/3, 1/2]$  (default) |  $N$ -by-1 column vector | 1-by- $N$  row vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. The default value,  $[-2^{(1/2)}/3, 1/2]$ , is a transformed and transposed version of the default value of the allpass polynomial coefficients. This value is computed using `transpose(tf2latc(1, [1 A]))`, where  $A$  is the value specified in **Allpass polynomial coefficients**.

Tunable: Yes

#### Dependencies

To enable this parameter, set **Internal allpass structure** to Lattice and clear the **Specify coefficients from input port** parameter.

**View Filter Response** — Visualize filter response  
button

Opens the Filter Visualization Tool, `fvtool`, and displays the magnitude response of the allpass filter. The response is based on the parameters. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

To view the magnitude response and phase response simultaneously, click the **Magnitude and Phase responses** button on the toolbar.

In this example, the magnitude response is flat and the phase response varies with frequencies. This varying phase response has applications in phase equalization, notch filtering, and multirate filtering. You can realize a lowpass filter using a parallel combination of two allpass filters that have 180 degrees of phase shift with respect to each other.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

$c$  is allpass polynomial coefficients vector. The order,  $n$ , of the transfer function is the length of vector  $c$ .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an  $N$ -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an  $N$ -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as df1, df1t, df2, df2t. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

### Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order  $n$ . It also uses  $2n$  delay units and  $2n$  adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector  $c$  in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector,  $c$ , is equal to  $[0.1 \ -0.7]$ .

### Wave Digital Filter

This structure uses  $n$  multipliers, but only  $n$  delay units, at the expense of requiring  $3n$  adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector  $w$  is equal to `allpass2wdf([0.1 -0.7])`.

## Lattice

This lattice structure uses  $2n$  multipliers,  $n$  delay units, and  $2n$  adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients `[0.1 -0.7]`.

# Allpole Filter

Model allpole filters

## Library

Filtering / Filter Implementations

dsparch4

## Description

The Allpole Filter block independently filters each channel of the input signal with the specified allpole filter. The block can implement static filters with fixed coefficients, as well as time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing).

This block supports the Simulink state logging feature. See “State” (Simulink) in the *Simulink User's Guide* for more information.

### Filter Structure Support

You can change the filter structure implemented with the Allpole Filter block by selecting one of the following from the **Filter structure** parameter:

- Direct form
- Direct form transposed
- Lattice AR

### Specifying Initial States

The Allpole Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

### Valid Initial States

| Initial Condition   | Description   |
|---|---|
| Scalar  | The block initializes all delay elements in the filter to the scalar value.   |
| Vector or matrix<br>(for applying different delay elements to each channel) | <p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel:</p> <ul style="list-style-type: none"> <li>• The vector length equals the product of the number of input channels and the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (or <code>#_of_reflection_coeffs</code> for Lattice AR).</li> <li>• The matrix must have the same number of rows as the number of delay elements in the filter, <code>#_of_filter_coeffs-1</code> (<code>#_of_reflection_coeffs</code> for Lattice AR), and must have one column for each channel of the input signal.</li> </ul> |

### Data Type Support

The Allpole Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Allpole Filter block for fixed-point signals.

#### Direct Form

You cannot specify the state data type on the block mask for this structure because the output states have the same data types as the output.

**Direct Form Transposed**

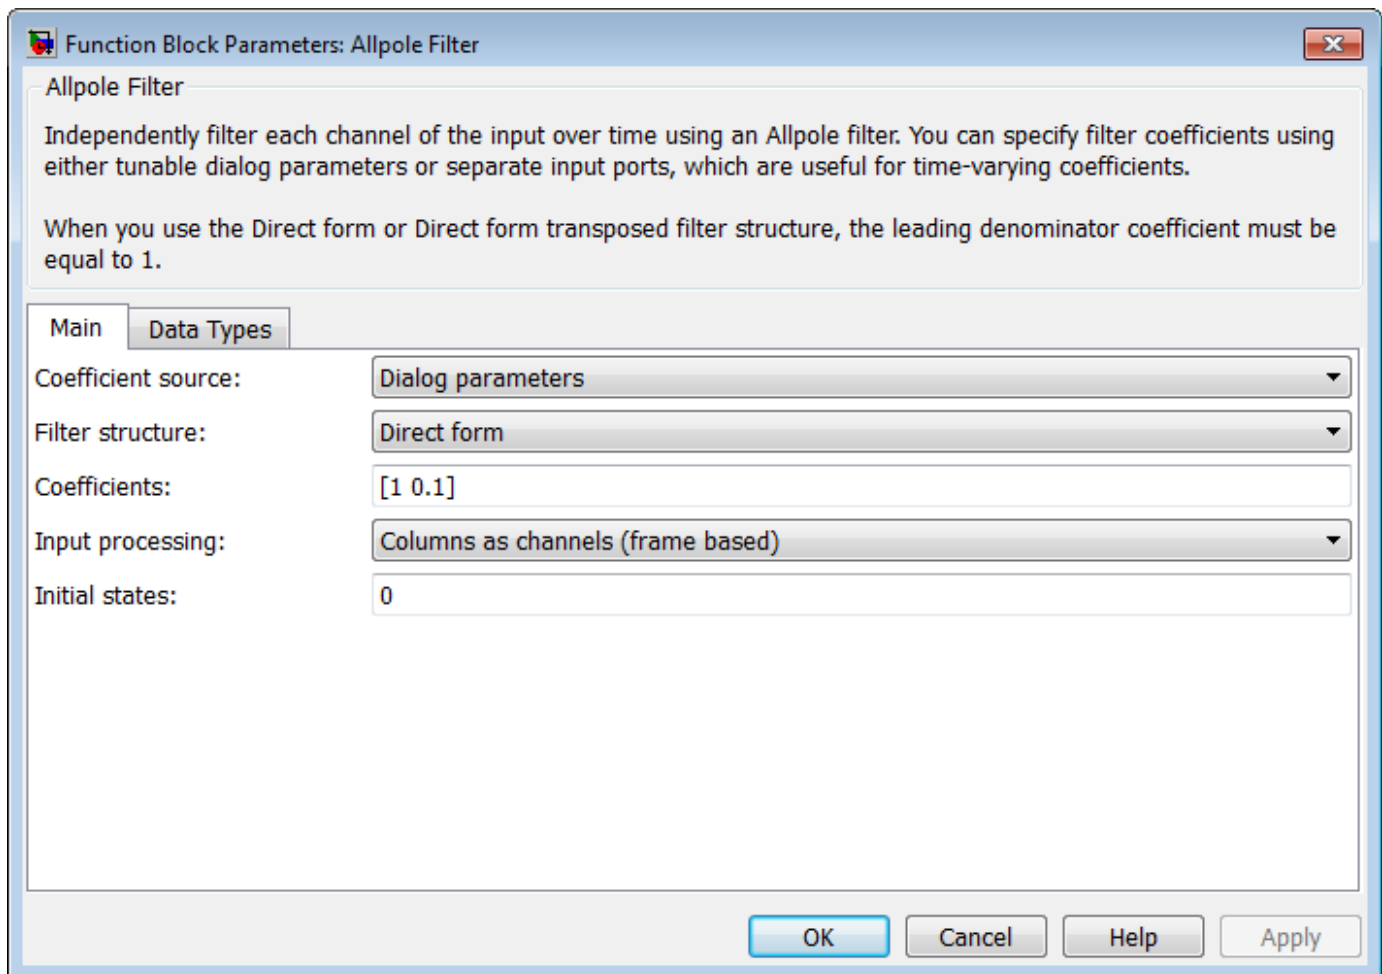

States are complex when either the inputs or the coefficients are complex.

### Coefficient source

Select whether you want to specify the filter coefficients on the block mask or through an input port.

### Filter structure

Select the filter structure you want the block to implement. You can select `Direct form`, `Direct form transposed`, or `Lattice AR`.

### Coefficients

Specify the row vector of coefficients of the filter's transfer function.

This parameter is visible only when you set the **Coefficient source** to `Dialog parameters`.

### Input processing

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as an independent channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as an independent channel (frame-based processing).

### Initial states

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 2-11.

The **Data Types** pane of the Allpole Filter block dialog box appears as follows.

### Coefficients

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficient** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

**Coefficients minimum**

Specify the minimum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

**Coefficients maximum**

Specify the maximum value that a filter coefficient should have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

**Product output**

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

**Accumulator**

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

**State**

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`

- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

This parameter is only visible when the selected filter structure is `Lattice MA`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **State** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

### Output

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in the *Simulink User's Guide* (Simulink) for more information.

### Output minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Output maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

### Integer rounding mode

Specify the rounding mode for fixed-point operations.

### Saturate on integer overflow

| Action                        | Reasons for Taking This Action   | What Happens for Overflows  | Example   |
|-------------------------------|--|---|---|
| Select this check box.        | Your model has possible overflow and you want explicit saturation protection in the generated code.  | Overflows saturate to either the minimum or maximum value that the data type can represent. | An overflow associated with a signed 8-bit integer can saturate to -128 or 127. |
| Do not select this check box. | You want to optimize efficiency of your generated code.<br><br>You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors" (Simulink). | Overflows wrap to the appropriate value that is representable by the data type.             | The number 130 does not fit in a signed 8-bit integer and wraps to -126.        |

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

### Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Signed fixed point
- 8-, 16-, and 32-bit signed integers

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# Analog Filter Design

Design and implement analog filters

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

The Analog Filter Design block designs and implements a Butterworth, Chebyshev type I, Chebyshev type II, elliptic, or Bessel filter in a highpass, lowpass, bandpass, or bandstop configuration.

You select the design and band configuration of the filter from the **Design method** and **Filter type** drop-down lists in the dialog box. For each combination of design method and band configuration, an appropriate set of secondary parameters is displayed. For more details, see “Design/Band Combination Table” on page 2-29.

The Analog Filter Design block uses a state-space filter representation, and applies the filter using the State-Space block in the Simulink Continuous library. All of the design methods use Signal Processing Toolbox™ functions to design the filter.

The Analog Filter Design block is built on the filter design capabilities of Signal Processing Toolbox software.

---

**Note** The Analog Filter Design block does not work with the Simulink discrete solver, which is enabled when you set the **Solver** list to **Discrete (no continuous states)** in the **Solver** pane of the **Model Configuration Parameters** dialog box. Select one of the continuous solvers (such as ode4) instead.

---

## Ports

### Input

**Port\_1** — Input signal  
scalar

Input signal to filter, specified as a sample-based, continuous-time, real-valued scalar value.

Data Types: double

### Output

**Port\_1** — Output signal  
scalar

Filtered signal, returned as a real double scalar value.

Data Types: double

## Parameters

### Design method — Filter design

Butterworth (default) | Chebyshev I | Chebyshev II | Elliptic | Bessel

The filter design methods are:

- **Butterworth** — The magnitude response of a Butterworth filter is maximally flat in the passband and monotonic overall. The Butterworth design uses the toolbox function `butter`.
- **Chebyshev I** — The magnitude response of a Chebyshev I filter is equiripple in the passband and monotonic in the stopband. The Chebyshev I design uses the toolbox function `cheby1`.
- **Chebyshev II** — The magnitude response of a Chebyshev II filter is monotonic in the passband and equiripple in the stopband. The Chebyshev II design uses the toolbox function `cheby2`.
- **Elliptic** — The magnitude response of an elliptic filter is equiripple in both the passband and the stopband. The elliptic design uses the toolbox function `ellip`.
- **Bessel** — The magnitude response of a Bessel filter is maximally flat in the passband and monotonic overall. The filter has a maximally flat linear phase response. The Bessel design uses the function `bessel`.

**Tunable:** Yes

### Filter type — Filter type

Lowpass (default) | Highpass | Bandpass | Bandstop

The type of filter to design:

- Lowpass
- Highpass
- Bandpass
- Bandstop

**Tunable:** Yes

### Filter order — Filter order

8 (default) | scalar value

The order of the filter when `Filter type` is set to:

- Lowpass
- Highpass

The order of the final filter is *twice* the value of **Filter order** when **Filter type** is set to:

- Bandpass
- Bandstop

**Passband edge frequency (rad/s)** — Passband edge frequency

30 (default) | scalar value

The passband edge frequency, in rad/s.

**Tunable:** Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Lowpass
- Highpass

**Lower passband edge frequency (rad/s)** — Lower passband edge frequency

30 (default) | scalar value

The lower passband edge frequency, specified in rad/s.

**Tunable:** Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Bandpass
- Bandstop

**Upper passband edge frequency (rad/s)** — Upper passband edge frequency

80 (default) | scalar value

The upper passband edge frequency, specified in rad/s.

**Tunable:** Yes**Dependencies**This parameter appears only when `Design method` is set to:

- Butterworth
- Chebyshev I
- Elliptic
- Bessel

and `Filter type` is set to:

- Bandpass
- Bandstop

**Stopband edge frequency (rad/s)** — Stopband edge frequency

30 (default) | scalar value

The stopband edge frequency, specified in rad/s.

**Tunable:** Yes

**Dependencies**

This parameter appears only when `Design method` is set to:

- Chebyshev II

and `Filter type` is set to:

- Lowpass
- Highpass

**Lower stopband edge frequency (rad/s)** — Lower stopband edge frequency

30 (default) | scalar value

The lower stopband edge frequency, in rad/s.

**Tunable:** Yes

**Dependencies**

This parameter appears only when `Design method` is set to:

- Chebyshev II

and `Filter type` is set to:

- Bandpass
- Bandstop

**Upper stopband edge frequency (rad/s)** — Upper stopband edge frequency

80 (default) | scalar value

The upper stopband edge frequency, specified in rad/s.

**Tunable:** Yes

**Dependencies**

This parameter appears only when `Design method` is set to:

- Chebyshev II

and `Filter type` is set to:

- Bandpass
- Bandstop

**Passband ripple in dB** — Passband ripple

2 (default) | scalar value

The passband ripple, specified in dB.

**Tunable:** Yes

**Dependencies**

This parameter appears only when `Design method` is set to:

- Chebyshev I
- Elliptic

**Stopband attenuation in dB** — Stopband attenuation

40 (default) | scalar value

The stopband attenuation, in dB.

**Tunable:** Yes

**Dependencies**

This parameter appears only when `Design method` is set to:

- Chebyshev II
- Elliptic

**Block Characteristics**

|                                 |        |
|---------------------------------|--------|
| <b>Data Types</b>               | double |
| <b>Direct Feedthrough</b>       | no     |
| <b>Multidimensional Signals</b> | no     |
| <b>Variable-Size Signals</b>    | no     |
| <b>Zero-Crossing Detection</b>  | no     |

## More About

### Design/Band Combination Table

This table lists the available parameters for each design/band combination. For lowpass and highpass band configurations, these parameters include:

- The passband edge frequency  $\Omega_p$ .
- The stopband edge frequency  $\Omega_s$
- The passband ripple  $R_p$
- The stopband attenuation  $R_s$

For bandpass and bandstop configurations, the parameters include:

- The lower and upper passband edge frequencies,  $\Omega_{p1}$  and  $\Omega_{p2}$
- The lower and upper stopband edge frequencies,  $\Omega_{s1}$  and  $\Omega_{s2}$
- The passband ripple  $R_p$
- The stopband attenuation  $R_s$

Frequency values are in rad/s, and ripple and attenuation values are in dB.

| Filter Design Type       | Lowpass                           | Highpass                          | Bandpass   | Bandstop   |
|--------------------------|-----------------------------------|-----------------------------------|--|--|
| <b>Butterworth</b>       | Order, $\Omega_p$                 | Order, $\Omega_p$                 | Order, $\Omega_{p1}$ , $\Omega_{p2}$                 | Order, $\Omega_{p1}$ , $\Omega_{p2}$                 |
| <b>Chebyshev Type I</b>  | Order, $\Omega_p$ , $R_p$         | Order, $\Omega_p$ , $R_p$         | Order, $\Omega_{p1}$ , $\Omega_{p2}$ , $R_p$         | Order, $\Omega_{p1}$ , $\Omega_{p2}$ , $R_p$         |
| <b>Chebyshev Type II</b> | Order, $\Omega_s$ , $R_s$         | Order, $\Omega_s$ , $R_s$         | Order, $\Omega_{s1}$ , $\Omega_{s2}$ , $R_s$         | Order, $\Omega_{s1}$ , $\Omega_{s2}$ , $R_s$         |
| <b>Elliptic</b>          | Order, $\Omega_p$ , $R_p$ , $R_s$ | Order, $\Omega_p$ , $R_p$ , $R_s$ | Order, $\Omega_{p1}$ , $\Omega_{p2}$ , $R_p$ , $R_s$ | Order, $\Omega_{p1}$ , $\Omega_{p2}$ , $R_p$ , $R_s$ |
| <b>Bessel</b>            | Order, $\Omega_p$                 | Order, $\Omega_p$                 | Order, $\Omega_{p1}$ , $\Omega_{p2}$                 | Order, $\Omega_{p1}$ , $\Omega_{p2}$                 |

# Analytic Signal

Compute analytic signals of discrete-time inputs

**Libraries:**  
DSP System Toolbox / Transforms

## Description

The Analytic Signal block computes the complex analytic signal  $y$  corresponding to each channel of the real input  $u$ .

$$y = u + jH\{u\},$$

where  $j = \sqrt{-1}$  and  $H\{ \}$  denotes the Hilbert transform.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-33.

## Ports

### Input

**Input** — Data input  
vector | matrix

Specify the data input  $u$  as a vector or a matrix of size  $M$ -by- $N$ .

Data Types: single | double

### Output

**Output** — Analytic signal output  
vector | matrix

Analytic signal output  $y$ , returned as a vector or a matrix.

The block computes the analytic signal for each channel. The real part of the output in each channel is a replica of the real input in that channel. The imaginary part of the output is the Hilbert transform of the input. In the frequency domain, the Fourier transform of the analytic signal doubles the positive frequency content of the original signal while zeroing out the negative frequencies and retaining the DC component.

The output has the same size and data type as the input.

Data Types: single | double

## Parameters

**Filter order (must be even)** — Filter order

100 (default) | even positive integer

Specify the order of the equiripple FIR filter as an even positive integer. The FIR filter computes the Hilbert transform of the real input signal.

**Input processing** — Method to process input signals

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input.

You can set this parameter to one of these options:

- **Columns as channels (frame based)** — The block performs frame-based processing. In this mode, the block treats an  $M$ -by- $N$  matrix input as  $N$  independent channels containing  $M$  sequential time samples. The block computes the analytic signal for each channel over time.
- **Elements as channels (sample based)** — The block performs sample-based processing. In this mode, the block treats an  $M$ -by- $N$  matrix input as  $M*N$  independent channels and computes the analytic signal for each channel (matrix element) over time.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | No              |

## More About

### Analytic Signal

The analytic signal  $x = x_r + jx_i$ , where the real part  $x_r$  is the original data and the imaginary part  $x_i$  contains the Hilbert transform. The imaginary part is a version of the original real sequence with a 90° phase shift. Sines are therefore transformed to cosines, and conversely, cosines are transformed to sines. The Hilbert-transformed series has the same amplitude and frequency content as the original sequence. The transform includes phase information that depends on the phase of the original.

The Hilbert transform is useful in calculating instantaneous attributes of a time series, especially the amplitude and the frequency. The instantaneous amplitude is the amplitude of the complex Hilbert transform. The instantaneous frequency is the time rate of change of the instantaneous phase angle. For a pure sinusoid, the instantaneous amplitude and frequency are constant. The instantaneous phase, however, is a sawtooth, reflecting how the local phase angle varies linearly over a single cycle.

## Algorithms

The algorithm computes the Hilbert transform using an equiripple FIR filter of the specified order  $n$ . The linear phase filter is designed using the Remez exchange algorithm and imposes a delay of  $n/2$  on the input samples.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The Analytic Signal block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Input processing** is set to `Columns as channels (frame based)`.
- Input signal has to be real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

# Arbitrary Response Filter

Design arbitrary response filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-38.

## Dialog Box

See “Arbitrary Response Filter Design — Main Pane” on page 5-594 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select either FIR or IIR from the drop down list, where FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

#### Order mode

Select Minimum or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to IIR, you can

specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

### Order

Enter the order for FIR filter, or the order of the numerator for the IIR filter.

### Denominator order

Select the check box and enter the denominator order. This option is enabled only if IIR is selected for **Impulse response**.

### Filter type

This option is available for FIR filters only. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

### Response Specification

#### Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

#### Specify response as

Specify the response as **Amplitudes**, **Magnitudes and phases**, **Frequency response**, or **Group delay**. **Group delay** is only available for IIR designs.

#### Frequency units

Specify frequency units as either **Normalized**, which means normalized by the input sampling frequency, or select from **Hz**, **kHz**, **MHz**, or **GHz**.

#### Input sample rate

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down list. When you select the frequency units, this option is available.

### Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down list. Two or three columns are presented for input. The first column is always **Frequencies**. The other columns are **Amplitudes**, **Magnitudes**, **Phases**, or **Frequency Response**. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Amplitudes**.

- **Frequencies, Magnitudes, and Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Magnitudes and phases**.
- **Frequencies and Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down list is **Frequency response**.

### Algorithm

#### Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

#### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

- **Window** — Replace the square brackets with the name of a window function or function handle. For example, `hamming` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{'kaiser', 3.5}` or `{@chebwin, 60}`.
- **Density factor** — Valid when the **Design method** is **Equiripple**. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade-off between the accurate approximation to the ideal filter and the time to design the filter.

- **Phase constraint** — Valid when the **Design method** is **Equiripple**, you have the DSP System Toolbox installed, and **Specify response as** is set to **Amplitudes**. Choose one of **Linear**, **Minimum**, or **Maximum**.
- **Weights** — Valid when the **Design method** is **Equiripple**. Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands.

### Filter Implementation

#### Structure

Select the structure for the filter, available for the corresponding design method.

#### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.

- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Version History

Introduced in R2009b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Arbitrary Response Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator, **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

# Array Plot

Display vectors or arrays

**Libraries:**  
DSP System Toolbox / Sinks

## Description

The Array Plot block plots vectors or arrays of data.

The Array Plot is a vector plot where data is uniformly spaced along the x-axis. To modify the spacing, change the Sample Increment property.

Measurements available:

- Data Cursors — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.

## Ports

### Input

**Port\_1** — Signal or signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals must have these characteristics:

- Fixed number of channels, but size can be variable
- Discrete, continuous, or constant sample time
- Real or complex values
- Floating- or fixed-point data type
- 2-D and nonscalar

The Array Plot block supports inputs with different frame lengths.

This block accepts fixed-point input, but converts it to `double` for display.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

## Properties

For information about how to configure the Array Plot and use the toolstrip, see “Configure Array Plot”.

### Plot

**Legend** — Display signal legend

`off` (default) | `on`

Select this option to show the legend on the plot. The names listed in the legend are taken from the `Channel Names` property.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

---

**Note** The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

---

**Tunable:** Yes

### Programmatic Use

**Block Parameter:** `ShowLegend`

**Type:** logical

**Magnitude and Phase** — Split display into magnitude and phase plots

`off` (default) | `on`

- **On** — Display magnitude and phase plots. If the signal is real, the scope plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- **Off** — Display signal plot. If the signal is complex, the scope plots the real and imaginary parts on the same y-axis.

**Tunable:** Yes

### Programmatic Use

**Block Parameter:** `PlotAsMagnitudePhase`

**Type:** logical

### Measurements

For more information about the measurements, see “Use Array Plot Measurements”.

## Settings

### Data and Axes

**X-Data Mode** — Type of x-axis spacing

**Sample increment and X-offset** (default) | **Custom**

Select the type of spacing to use between x-axis data values.

- **Sample increment and X-offset** — Use the “Sample Increment” on page 2-0 and “X-Offset” on page 2-0 values to specify x-axis data.
- **Custom** — Specify a custom spacing between data values using the “Custom X-data” on page 2-0 property.

### Programmatic Use

**Block Parameter:** XDataMode

**Type:** character vector or string scalar

**Values:** 'Sample increment and X-offset' | 'Custom'

**Sample Increment** — x-axis spacing

1 (default) | finite scalar

Specify the spacing between samples along the x-axis as a finite numeric scalar. The input signal is only y-axis data. x-axis data is set automatically based on both the **Sample Increment** and “X-Offset” on page 2-0 values.

Example: When **X-Offset** is 0 and **Sample Increment** is 1, the x-axis values are set to 0, 1, 2, 3, 4, ... .

Example: When **X-Offset** is -1 and **Sample Increment** is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ... .

**Tunable:** Yes

### Dependency

To use this property, set “X-Data Mode” on page 2-0 to **Sample increment and X-offset**.

### Programmatic Use

**Block Parameter:** SampleIncrement

**Type:** character vector or string scalar

**Values:** scalar

**X-Offset** — x-axis offset

0 (default) | scalar

Specify the offset to apply to the x-axis, as a numeric scalar. x-axis data is set automatically based on both the “Sample Increment” on page 2-0 and **X-Offset** values. The x-offset represents the first value on the x-axis.

Example: When **X-Offset** is 0 and **Sample Increment** is 1, the x-axis values are set to 0, 1, 2, 3, 4, ... .

Example: When **X-Offset** is -1 and **Sample Increment** is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ... .

**Tunable:** Yes

**Dependency**

To use this property, set “X-Data Mode” on page 2-0 to Sample increment and X-offset.

**Programmatic Use****Block Parameter:** XOffset

**Type:** character vector or string scalar

**Values:** scalar

**Custom X-data** — x-axis data values

empty vector (default) | vector with length equal to the input frame length

Specify the x-axis data values as a vector equal in length to the frame length of the inputs. If you use the default (empty vector) value, the x-axis data is uniformly spaced over the interval  $(0:L-1)$ , where  $L$  is the frame length.

Example: A custom logarithmic x-axis data scaling is `[0:log10(44100/2):1024]`

**Tunable:** Yes

**Dependency**

To use this property, set “X-Data Mode” on page 2-0 to Custom

**Programmatic Use****Block Parameter:** CustomXData

**Type:** character vector or string scalar

**Values:** scalar

**Default:** ' [] '

**X-Axis Scale** — x-axis scale

Linear (default) | Log

Select Linear or Log as the x-axis scale.

**Tunable:** Yes

**Dependency**

If **X-Offset** is a negative value, you cannot set this parameter to Log.

**Programmatic Use****Block Parameter:** XScale

**Type:** character vector or string scalar

**Y-Axis Scale** — y-axis scale

Linear (default) | Log

Select Linear or Log as the y-axis scale.

**Tunable:** Yes

**Programmatic Use****Block Parameter:** YScale

**Type:** character vector or string scalar

**Y-limits** — y-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If **Magnitude and Phase** is off, the default is `[-10,10]`. If the magnitude/phase plot is on, the default is `[0,10]`.

**Tunable:** Yes

#### **Dependencies**

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

#### **Programmatic Use**

**Block Parameter:** `YLimits`

**Type:** character vector or string scalar

**Value:** two-element numeric vector

**Plot Type** — Type of plot

`Stem` (default) | `Stairs` | `Line`

- `Stem` — Stem graph displayed as circles at the input value with vertical lines to the x-axis.
- `Line` — Line graph
- `Stairs` — Stair-step graph. A stair-step graph is made up of only horizontal and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents the change in the signal value occurring at a specific sample time.

**Tunable:** Yes

#### **Programmatic Use**

**Block Parameter:** `PlotType`

**Type:** character vector or string scalar

**Grid** — Show internal grid lines

`on` (default) | `off`

Select this option to show grid lines on the plot.

**Tunable:** Yes

#### **Programmatic Use**

**Block Parameter:** `ShowGrid`

**Type:** logical

#### **Display and Labels**

**Title** — Display name

`none` (default) | string

Specify a title for display. To use the input signal name for the title, enter %<SignalLabel>.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** Title

**Type:** character vector or string scalar

**Default:** ''

**X-Label** — x-axis label

none (default) | string

Specify the text for the scope to display below the x-axis.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** XLabel

**Type:** character vector or string scalar

**Default:** ''

**Y-Label** — Y-axis label

none (default) | string

Specify the text to display on the y-axis. To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%<SignalUnits>) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter Velocity (%<SignalUnits>).

**Tunable:** Yes

**Dependency**

If you click on **Magnitude and Phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

**Programmatic Use**

**Block Parameter:** YLabel

**Type:** character vector or string scalar

**Default:** ''

**Property Inspector Only**

**Number of input ports** — Number of input ports

1 (default) | integer between 1 and 96

The number of input ports to the block, specified as an integer between 1 and 96. To change the number of input ports, drag a new input signal line to the block and the block will auto-create new ports.

**Programmatic Use**

**Block Parameter:** NumInputPorts

**Type:** character vector or string scalar

**Values:** scalar between 1 and 96

**Open at start of simulation** — Automatically open scope at start  
on (default) | off

Select this parameter to automatically open the Array Plot window when you run the simulation.

This parameter is only available from the Property Inspector.

#### Programmatic Use

**Block Parameter:** OpenAtSimulationStart

**Type:** logical

**Channel Names** — Input channel names

[] (default) | character vector | string | array of strings or character vectors.

Input channel names, specified as a character vector, string, or array of either. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

Example: ["A","B"]

#### Dependency

To see channel names, set “Legend” on page 2-0 to true.

#### Programmatic Use

**Block Parameter:** ChannelNames

**Type:** cell array of character vectors or string array

**Maximize axes** — Maximize size of plots

Auto (default) | Off | On

- Auto — If “Title” on page 2-0 and “Y-Label” on page 2-0 properties are not specified, maximize all plots.
- On — Maximize all plots. Values in **Title** and **Y-label** are hidden.
- Off — Do not maximize plots.

Hover over the array plot to see the maximize axes button .

**Tunable:** Yes

#### Programmatic Use

**Block Parameter:** MaximizeAxes

**Type:** character vector or string scalar

**Axes scaling** — Y-axis scaling mode

OnceAtStop (default) | Manual | Auto | Updates

- OnceAtStop — Scale y-axis after the simulation is finished.
- Manual — Manually scale y-axis range with the **Scale Y-axis Limits** toolbar button.

- Auto — Scale y-axis range during and after simulation.
- Updates — Scale y-axis after the number of time steps specified in the “Number of updates” on page 2-0 text box (100 by default). Scaling occurs only once during each run.

**Tunable:** Yes

#### Programmatic Use

**Block Parameter:** AxesScaling

**Type:** character vector or string scalar

**Number of updates** — Number of updates before scaling  
10 (default) | integer

Set this property to delay auto scaling the y-axis.

**Tunable:** Yes

#### Dependency

To enable this property, set “Axes scaling” on page 2-0 to AfterNUpdates.

#### Programmatic Use

**Block Parameter:** AxesScalingNumUpdates

**Type:** character vector or string scalar

**Values:** scalar

## Block Characteristics

|                                 |   |

## Array-Vector Add

Add vector to array along specified dimension

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

## Description

The Array-Vector Add block adds the values in the specified dimension of the  $N$ -dimensional input array  $A$  to the values in the input vector  $V$ .

The length of the input  $V$  must be the same as the length of the specified dimension of  $A$ . The Array-Vector Add block adds each element of  $V$  to the corresponding element along that dimension of  $A$ .

Consider a 3-dimensional  $M$ -by- $N$ -by- $P$  input array  $A(i,j,k)$  and an  $N$ -by-1 input vector  $V$ . When the **Add along dimension** parameter is set to 2, the output of the block  $Y(i,j,k)$  is

$$Y(i, j, k) = A(i, j, k) + V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Add block is the same size as the input array,  $A$ . This block accepts real and complex floating-point and fixed-point inputs.

## Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Add block for fixed-point signals.

When you specify the vector  $V$  on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the

vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

## Parameters

### Main Tab

#### Add along dimension

Specify the dimension along which to add the input array  $A$  to the elements of vector  $V$ .

#### Vector (V) source

Specify the source of the vector,  $V$ . The vector can come from the `Input` port or from a `Dialog` parameter.

#### Vector (V)

Specify the vector,  $V$ . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

If **Accumulator** data type is `Inherit: Inherit via internal rule` and **Output** data type is `Inherit: Same as accumulator`, the value of **Rounding mode** does not affect the numerical results.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when both of these conditions are met:

- **Accumulator** is `Inherit: Inherit via internal rule`
- **Output** is `Inherit: Same as accumulator`

---

With these data type settings, the block is effectively operating in full precision mode.

---

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

### Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

---

**Note** The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog** parameter for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

---

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-49 for a diagram showing the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-49 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

### Vector (V) Data Type

#### Mode

Select how you would like to specify the data type properties of the **Vector (V)** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

#### Signedness

Specify the **Signedness** for the **Vector (V)** data type.

#### Scaling

Specify the **Scaling** for the **Vector (V)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### Word length

Specify the **Word length** for the **Vector (V)** data type.

**Fraction length**

Specify the **Fraction length** for the **Vector (V)** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, **Inherit: Inherit via internal rule**
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

**Scaling**

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Accumulator** data type.

**Fraction length**

Specify the **Fraction length** for the **Accumulator** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### **Output Data Type Assistant Parameters**

#### **Mode**

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

#### **Signedness**

Specify the **Signedness** for the **Output** data type.

#### **Scaling**

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Output** data type.

#### **Fraction length**

Specify the **Fraction length** for the **Output** data type.

#### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| A      | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| V      | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |

Array-Vector Divide | Array-Vector Multiply | Array-Vector Subtract

## Array-Vector Divide

Divide array by vector along specified dimension

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtrx3

## Description

The Array-Vector Divide block divides the values in the specified dimension of the  $N$ -dimensional input array  $A$  by the values in the input vector  $V$ .

The length of the input  $V$  must be the same as the length of the specified dimension of  $A$ . The Array-Vector Divide block divides each element of  $V$  by the corresponding element along that dimension of  $A$ .

Consider a 3-dimensional  $M$ -by- $N$ -by- $P$  input array  $A(i,j,k)$  and an  $N$ -by-1 input vector  $V$ . When the **Divide along dimension** parameter is set to 2, the output of the block  $Y(i,j,k)$  is

$$Y(i, j, k) = \frac{A(i, j, k)}{V(j)}$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Divide block is the same size as the input array,  $A$ . This block accepts real and complex floating-point and fixed-point input arrays, and real floating-point and fixed-point input vectors.

## Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Divide block for fixed-point signals.

When you specify the vector  $V$  on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

You can set the vector and output data types in the block dialog.

## Parameters

### Main Tab

#### Divide along dimension

Specify the dimension along which to divide the input array  $A$  by the elements of vector  $V$ .

#### Vector (V) source

Specify the source of the vector,  $V$ . The vector can come from the `Input` port or from a `Dialog` parameter.

#### Vector (V)

Specify the vector,  $V$ . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

### Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector,  $V$ . You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Vector (V)** data type parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

---

**Note** The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog** parameter for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

---

## Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-56 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as first input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

## Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

## Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

## Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

## Vector (V) Data Type

### Mode

Select how you would like to specify the data type properties of the **Vector (V)** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

### **Signedness**

Specify the **Signedness** for the **Vector (V)** data type.

### **Scaling**

Specify the **Scaling** for the **Vector (V)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

### **Word length**

Specify the **Word length** for the **Vector (V)** data type.

### **Fraction length**

Specify the **Fraction length** for the **Vector (V)** data type.

### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## **Output Data Type Assistant Parameters**

### **Mode**

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

**Signedness**

Specify the **Signedness** for the **Output** data type.

**Scaling**

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Output** data type.

**Fraction length**

Specify the **Fraction length** for the **Output** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Supported Data Types**

| <b>Port</b> | <b>Supported Data Types</b>  |
|-------------|--|
| A           | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| V           | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| Output      | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |

## Array-Vector Multiply

Multiply array by vector along specified dimension

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations

### Description

The Array-Vector Multiply block multiplies the values in the specified dimension of the  $N$ -dimensional input array  $A$  by the values in the input vector  $V$ .

The length of the input  $V$  must be the same as the length of the specified dimension of  $A$ . The Array-Vector Multiply block multiplies each element of  $V$  by the corresponding element along that dimension of  $A$ .

Consider a 3-dimensional  $M$ -by- $N$ -by- $P$  input array  $A(i,j,k)$  and an  $N$ -by-1 input vector  $V$ . When the **Multiply along dimension** parameter is set to 2, the output of the block  $Y(i,j,k)$  is

$$Y(i, j, k) = A(i, j, k) * V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Multiply block is the same size as the input array  $A$ . This block accepts real and complex floating-point and fixed-point inputs.

### Ports

#### Input

**A** — Array input  
vector | matrix

Specify the array input as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

**V** — Vector input  
vector

Specify the vector input as a vector.

#### Dependencies

This port appears only when you set the **Vector (V) source** parameter to Input port.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

## Output

**Port\_1** — Multiplied output

vector | matrix

Output of the Array-Vector Multiply block, returned as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

## Parameters

### Main Tab

**Multiply along dimension** — Dimension along which to multiply input array

2 (default) | positive integer

Specify the dimension along which to multiply the input array  $A$  by the elements of vector  $V$  as a positive integer.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Vector (V) source** — Source of vector

Input port (default) | Dialog parameter

Set the source of the vector  $V$  to one of these options.

- Input port — Vector comes from the input port.
- Dialog parameter — Vector comes from the dialog parameter **Vector (V)**.

**Vector (V)** — Vector parameter

[0.5 0.25] (default) | vector

Specify the vector  $V$ .

### Dependencies

This parameter appears only when you set the **Vector (V) source** parameter to Dialog parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on the **Data Types** tab. When inputs are floating point, the block ignores these settings and all internal data types are floating point.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Set the rounding mode for fixed-point operations to one of these options.

- Ceiling
- Convergent
- Floor
- Nearest
- Round
- Simplest
- Zero

For details, see rounding mode.

### **Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operations. When you clear this parameter, the block wraps the result of its fixed-point operations. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

### **Vector (V)** — Word and fraction lengths for elements of vector

Inherit: Same word length as input (default) | `fixdt(1,16,0)` | <data type expression>

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. Select this parameter as one of these options.

- **Inherit: Same word length as input** — Inherits the data type so it is the same as that of the input array *A*.
- `fixdt(1,16,0)` — Specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.
- <data type expression> — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Vector (V)** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

---

**Note** When the vector comes in through the input port of the block, the data type and scaling of its elements are inherited from the driving block.

---

### **Dependencies**

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to **Dialog** parameter.

### **Vector (V) Minimum** — Minimum value for elements of vector

[] (unspecified) (default) | scalar

Specify the minimum value for the elements of vector  $V$ . The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking. For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).
- Automatic scaling of fixed-point data types.

#### Dependencies

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to Dialog parameter.

**Vector (V) Maximum** — Maximum value for elements of vector  
[] (unspecified) (default) | scalar

Specify the maximum value for the element of vector  $V$ . The default value is [] (unspecified). Simulink uses this value to perform:

- Parameter range checking. For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).
- Automatic scaling of fixed-point data types.

#### Dependencies

This parameter appears only when you set the **Vector (V) source** parameter on the **Main** tab to Dialog parameter.

**Product output** — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input |  
fixdt([],16,0) | <data type expression>

Specify the data type of the output of a product operation in the Array-Vector Multiply block. For illustrations depicting the use of the product output data type in this block, see “Fixed Point” on page 2-67 and “Multiplication Data Types”. Set this parameter to one of these options.

- **Inherit: Inherit via internal rule** — Inherits the data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — Inherits the data type so it is the same as that of the input array  $A$ .
- **fixdt([],16,0)** — Lets you specify the fixed-point attributes of the data type.
- **<data type expression>** — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator** — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input |  
Inherit: Same as product output | fixdt([],16,0) | <data type expression>

Specify the data type of the output of an accumulation operation in the Array-Vector Multiply block. For illustrations depicting the use of the accumulator data type in this block, see “Fixed Point” on page 2-67. Set this parameter to one of these options.

- `Inherit: Inherit via internal rule` — Inherits the data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — Inherits the data type so it is the same as that of the input array *A*.
- `Inherit: Same as product output` — Inherits the data type so it is the same as the product output data type.
- `fixdt([],16,0)` — Lets you specify the fixed-point attributes of the data type.
- `<data type expression>` — Lets you specify an expression that evaluates to a valid data type.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Output — Output data type

`Inherit: Same as product output (default) | Inherit: Same as first input | Inherit: Same as first input | fixdt([],16,0) | <data type expression>`

Specify the output data type. For illustrations depicting the use of the output data type in this block, see “Fixed Point” on page 2-67. Set this parameter to one of these options.

- `Inherit: Same as first input` — Inherits the data type so it is the same as that of the input array *A*.
- `Inherit: Same as product output` — Inherits the data type so it is the same as the product output data type.
- `fixdt([],16,0)` — Lets you specify the fixed-point attributes of the data type.
- `<data type expression>` — Lets you specify an expression that evaluates to a valid data type.

For more information, see “Control Data Types of Signals” (Simulink).

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Output Minimum — Minimum value of block output

`[] (unspecified) (default) | scalar`

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).

- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value of block output

[ ] (unspecified) (default) | scalar

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |

| <b>Zero-Crossing Detection</b>  | no                                      |

## Version History

Introduced in R2007b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The following diagram shows the data types used within the Array-Vector Multiply block for fixed-point signals.

When you specify the vector  $V$  on the **Main** tab of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

You can set the vector, accumulator, product output, and output data types in the block dialog.

Array-Vector Add | Array-Vector Divide | Array-Vector Subtract

# Array-Vector Subtract

Subtract vector from array along specified dimension

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtrx3

## Description

The Array-Vector Subtract block subtracts the values in the input vector  $V$  from the values in the specified dimension of the  $N$ -dimensional input array  $A$ .

The length of the input  $V$  must be the same as the length of the specified dimension of  $A$ . The Array-Vector Subtract block subtracts each element of  $V$  from the corresponding element along that dimension of  $A$ .

Consider a 3-dimensional  $M$ -by- $N$ -by- $P$  input array  $A(i,j,k)$  and an  $N$ -by-1 input vector  $V$ . When the **Subtract along dimension** parameter is set to 2, the output of the block  $Y(i,j,k)$  is

$$Y(i, j, k) = A(i, j, k) - V(j)$$

where

$$1 \leq i \leq M$$

$$1 \leq j \leq N$$

$$1 \leq k \leq P$$

The output of the Array-Vector Subtract block is the same size as the input array,  $A$ . This block accepts real and complex floating-point and fixed-point inputs.

## Fixed-Point Data Types

The following diagram shows the data types used within the Array-Vector Subtract block for fixed-point signals.

When you specify the vector  $V$  on the **Main** pane of the block mask, you must specify the data type and scaling properties of its elements in the **Vector (V)** parameter on the **Data Types** tab. When the

vector comes in through the block port, its elements inherit their data type and scaling from the driving block.

The output of the subtractor is in the accumulator data type.

You can set the vector, accumulator, and output data types in the block dialog as discussed below.

## Parameters

### Main Tab

#### Subtract along dimension

Specify the dimension along which to subtract the elements of vector  $V$  from the input array  $A$ .

#### Vector (V) source

Specify the source of the vector,  $V$ . The vector can come from the `Input` port or from a `Dialog` parameter.

#### Vector (V)

Specify the vector,  $V$ . This parameter is visible only when you select `Dialog` parameter for the **Vector (V) source** parameter.

### Data Types

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when both of these conditions are met:

- **Accumulator** is `Inherit`: Inherit via internal rule
- **Output** is `Inherit`: Same as accumulator

With these data type settings, the block is effectively operating in full precision mode.

---

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

### Vector (V)

Use this parameter to specify the word and fraction lengths for the elements of the vector, *V*. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

---

**Note** The **Vector (V)** parameter on the **Data Types** pane is only visible when you select **Dialog parameter** for the **Vector (V) source** parameter on the **Main** pane of the block mask. When the vector comes in through the block's input port, the data type and scaling of its elements are inherited from the driving block.

---

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-69 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-69 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A rule that inherits a data type, for example, `Inherit: Same as first input`.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Minimum**

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Maximum**

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools**

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

**Vector (V) Data Type****Mode**

Select how you would like to specify the data type properties of the **Vector (V)** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

**Signedness**

Specify the **Signedness** for the **Vector (V)** data type.

**Scaling**

Specify the **Scaling** for the **Vector (V)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Vector (V)** data type.

**Fraction length**

Specify the **Fraction length** for the **Vector (V)** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

**Scaling**

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Accumulator** data type.

**Fraction length**

Specify the **Fraction length** for the **Accumulator** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### **Output Data Type Assistant Parameters**

#### **Mode**

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

#### **Signedness**

Specify the **Signedness** for the **Output** data type.

#### **Scaling**

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Output** data type.

#### **Fraction length**

Specify the **Fraction length** for the **Output** data type.

#### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| A      | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| V      | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed only)</li> <li>• 8-, 16-, and 32-bit signed integers</li> </ul> |

## Version History

Introduced in R2007b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## See Also

### Blocks

Array-Vector Add | Array-Vector Divide | Array-Vector Multiply

## Audio Device Writer

Play to sound card

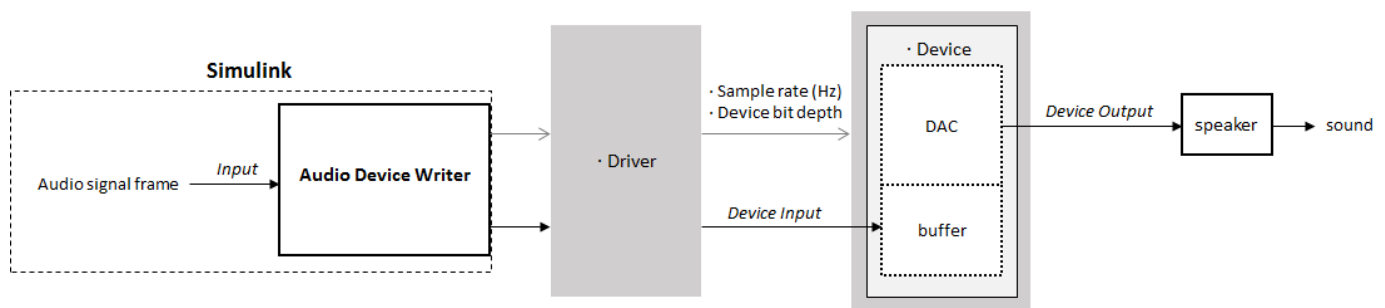

### Libraries:

Audio Toolbox / Sinks  
DSP System Toolbox / Sinks

### Description

The Audio Device Writer block writes audio samples to an audio output device.

Parameters of the Audio Device Writer block specify the driver, the device, and device attributes such as sample rate and bit depth.

### Data Flow of Audio Device Writer Block

- An audio signal frame is input to the Audio Device Writer block.
- The Audio Device Writer block uses the specified driver to pass the frame (device input) to your specified audio device buffer.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

### Ports

#### Input

**Port\_1** — Input signal

scalar | vector | matrix

If input to the Audio Device Writer block is of data type **double** or **single**, the block clips values outside the range [-1, 1]. For other data types, the allowed input range is [min, max] of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

## Output

**Port\_1** — Number of samples underrun  
scalar

This port outputs the number of samples underrun while writing a frame of data (one input matrix).

## Dependencies

To enable this port, select the **Output number of samples underrun** parameter.

Data Types: uint32

## Parameters

### Main Tab

**Driver** — Driver used to access your audio device

DirectSound (default) | ASIO | WASAPI

- ASIO drivers do not come pre-installed on Windows machines. To use the ASIO driver option, install an ASIO driver outside of MATLAB.

---

**Note** If **Driver** is set to ASIO, open the ASIO UI outside of MATLAB to set the sound card buffer size to the frame size (number of rows) input to the Audio Device Writer block. See the documentation of your ASIO driver for more information.

---

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, supply an audio stream with a sample rate supported by your audio device.

This parameter applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault **Driver** values, you must install Audio Toolbox™. If the toolbox is not installed, specifying nondefault **Driver** values returns an error.

**Device** — Device used to play audio samples

default audio device (default)

The device list is populated with devices available on your computer.

**Info** — View information about your audio output configuration

button

This button opens a dialog box that lists your selected audio driver, the full name of your audio device, and the maximum output channels for your configuration. For example:

**Inherit sample rate from input** — Specify source of input sample rate  
on (default) | off

When you select this parameter, the block inherits its sample rate from the input signal. When you clear this parameter, you specify the sample rate in **Sample rate (Hz)**.

**Sample rate (Hz)** — Sample rate used by device to play audio data  
44100 (default) | positive scalar

The possible range of **Sample rate (Hz)** depends on your audio hardware.

#### Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

#### Advanced Tab

**Device bit depth** — Data type used by device to perform digital-to-analog conversion  
16-bit integer (default) | 8-bit integer | 24-bit integer | 32-bit float

Before performing digital-to-analog conversion, the input data is cast to a data type specified by this parameter.

---

**Note** To specify a nondefault **Device bit depth**, you must install Audio Toolbox. If the toolbox is not installed, specifying a nondefault **Device bit depth** returns an error.

---

**Use default channel mapping** — Toggle channel mapping source  
on (default) | off

When you select this parameter, the block uses the default mapping between columns of the matrix input to this block and the channels of your device. When you clear this parameter, you specify the mapping in **Device output channels**.

**Device output channels** — Specify nondefault channel mapping  
[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of matrix input to the Audio Device Writer block and channels of output device, specified as a scalar or vector. For example:

If **Device output channels** is specified as 1:3, then:

- The first column of the input matrix maps to channel 1.
- The second column of the input matrix maps to channel 2.
- The third column of the input matrix maps to channel 3.

If **Device output channels** is specified as [3, 1, 2], then:

- The first column of the input matrix maps to channel 3.
- The second column of the input matrix maps to channel 1.
- The third column of the input matrix maps to channel 2.

---

**Note** To selectively map between columns of the input matrix and your sound card's output channels, you must install Audio Toolbox. If the toolbox is not installed, specifying nondefault values for **Device output channels** returns an error.

---

### Dependencies

To enable this parameter, clear the **Use default mapping between columns of input of this block and sound card's output channels** parameter.

**Output number of samples underrun** — Specify output port for number of samples underrun  
off (default) | on

When you select this parameter, an output port is added to the block. The port outputs the number of samples underrun while writing a frame of data (one input matrix).

### Block Characteristics

|                                 |  |
|---------------------------------|--|
| <b>Data Types</b>               | double   integer <sup>a</sup>   single |
| <b>Direct Feedthrough</b>       | no                                     |
| <b>Multidimensional Signals</b> | no                                     |
| <b>Variable-Size Signals</b>    | yes                                    |
| <b>Zero-Crossing Detection</b>  | no                                     |

<sup>a</sup> Supports 16- and 32-bit signed and 8-bit unsigned integers.

### Version History

Introduced in R2016a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following code generation limitations apply:

- Host computer only. Excludes Simulink Desktop Real-Time™ code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

# Audio Weighting Filter

Design audio weighting filter

## Compatibility

---

**Note** The Audio Weighting Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Weighting Filter block from Audio Toolbox instead.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “Audio Weighting Filter Design — Main Pane” on page 5-597 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View Filter Response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

**Weighting type**

The weighting type defines the frequency response of the filter. The valid weighting types for this filter are A, C, C-message, ITU-R 468-4, and ITU-T 0.41.

**Class**

The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in **FVTool** for the analysis of the filter design. The default value of this parameter is 1.

The filter class is only applicable for A weighting and C weighting filters.

**Impulse response**

Specify the impulse response type as one of IIR or FIR. For A, C, C-message, and ITU-R 468-4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.

**Frequency units**

Specify the frequency units as Hertz (Hz), kilohertz (kHz), megahertz (MHz), or gigahertz (GHz). Normalized frequency designs are not supported for audio weighting filters. The default value of this parameter is Hz.

**Input sample rate**

Specify the input sampling frequency. The units correspond to the setting of the **Frequency units** parameter.

**Algorithm****Design Method**

Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is ANSI S1.42. This is an IIR design method that follows ANSI standard S1.42-2001. For a C message filter, the only valid design method is Bell 41009, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468-4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design, the design method is IIR least p-norm. If you choose an FIR design, the design method choices are Equiripple or Frequency Sampling. For an ITU-T 0.41 weighting filter, the available FIR design methods are Equiripple or Frequency Sampling.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

**Filter Implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose a direct form, direct-form transposed, direct-form symmetric, or direct-form asymmetric structure.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

# Autocorrelation

Autocorrelation of  $N$ -D array

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Autocorrelation block computes the autocorrelation along the first dimension of an  $N$ -D input array. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the input signal is convolved with its time-reversed complex conjugate. In the frequency domain, the block computes the autocorrelation by taking the Fourier transform of the input signal, multiplying the Fourier transform with its conjugate, and computing the inverse Fourier transform of the product. In this domain, depending on the input length, the block can require fewer computations. For information on these two computation methods, see “Algorithms” on page 2-91.

You can specify the maximum lag for autocorrelation using the **Compute all non-negative lags** and **Maximum non-negative lag (less than input length)** parameters.

The block accepts fixed-point signals when you set the **Computation domain** to Time.

## Ports

### Input

**Port\_1** — Data input

vector | matrix |  $N$ -D array

Data input. The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to Time.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

### Output

**Port\_1** — Autocorrelated output

vector | matrix |  $N$ -D array

Autocorrelated output of the data input.

- When the input is an  $M$ -by- $N$  matrix,  $u$ , the output,  $y$ , is an  $(l+1)$ -by- $N$  matrix.  $l$  is the maximum positive lag for autocorrelation.
- When the input is an  $N$ -D array, the block outputs an  $N$ -D array. The size of the first dimension is  $l+1$ , and the sizes of all other dimensions match those of the input array. For example, when the input is an  $M$ -by- $N$ -by- $P$  array, the block outputs an  $(l+1)$ -by- $N$ -by- $P$  array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

### Main Tab

**Compute all non-negative lags** — Compute autocorrelation over all nonnegative lags  
on (default) | off

When you select this parameter, the Autocorrelation block computes the autocorrelation over all nonnegative lags in the range  $[0, \text{length}(\text{input}) - 1]$ . When you clear this parameter, the block computes the autocorrelation using the lags in the range  $[0, l]$ , where  $l$  is the value you specify in **Maximum non-negative lag (less than input length)**.

**Maximum non-negative lag (less than input length)** — Maximum positive lag  
1 (default) | integer greater than or equal to 0 and less than input length

Maximum positive lag for autocorrelation, specified as an integer that is greater than or equal to 0 and less than the input length.

### Dependencies

To enable this parameter, clear the **Compute all non-negative lags** parameter.

**Scaling** — Scaling of the output  
None (default) | Biased | Unbiased | Unity at zero-lag

Scaling applied to the output.

- **None** — Generates the raw autocorrelation  $y_{i,j}$  without normalization.
- **Biased** — Generates the biased estimate of the autocorrelation.

$$y_{i,j}^{biased} = \frac{y_{i,j}}{M}$$

- **Unbiased** — Generates the unbiased estimate of the autocorrelation.

$$y_{i,j}^{unbiased} = \frac{y_{i,j}}{M-i}$$

- **Unity at zero-lag** — Normalizes the estimate of the autocorrelation for each channel so that the zero-lag sum, the first element in each column, is identically 1.

$$y_{0,j} = 1$$

**Computation domain** — Domain in which the block computes the autocorrelation  
Time (default) | Frequency

- **Time** — Computes the convolutions in the time domain, which minimizes the memory usage.
- **Frequency** — Computes the autocorrelation in frequency domain. For more information, see “Algorithms” on page 2-91.

To autocorrelate fixed-point signals, set this parameter to `Time`.

### Data Types Tab

---

**Note** Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to `Time`.

---

#### **Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is `Inherit`: `Inherit via internal rule`.
- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.
- **Output** data type is `Inherit`: `Same as accumulator`.

With these data type settings, the block operates in full-precision mode.

---

#### **Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit`: `Inherit via internal rule`.
- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

---

**Product output** — Product output data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` |  
`fixdt([],16,0)`

**Product output** specifies the data type of the output of a product operation in the Autocorrelation block. For more information on the product output data type, see “Multiplication Data Types” and the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **`fixdt([],16,0)`** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit:  
`Same as product output` | `fixdt([],16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Autocorrelation block. For illustrations on how to use the accumulator data type in this block, see the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **`fixdt([],16,0)`** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the

assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output** — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

**Output** specifies the data type of the output of the Autocorrelation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the output data type to be the same as the product output data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([], 16, 0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output Minimum** — Minimum value the block can output  
[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value block can output  
[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

| <b>Variable-Size Signals</b> | No |
|------------------------------|----|

## More About

### Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence,  $x(n)$ , the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the input is a length  $N$  realization of a WSS stationary random process,  $r_x(h)$  is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where  $E\{\}$  is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

## Algorithms

### Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence,  $y$ , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- $y_{0,j}$  is the zero-lag element in the  $j$ th column of the input.
- $i$  is the index of the lag.
- $j$  is the index of the input data column.
- $*$  denotes the complex conjugate.
- $M$  is the number of elements in each column.

- $l$  is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags,  $l=M-1$ . Otherwise,  $l$  is the maximum nonnegative integer lag value specified.
- $u$  is an  $M$ -by- $N$  input matrix.

### Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

## Version History

Introduced before R2006a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

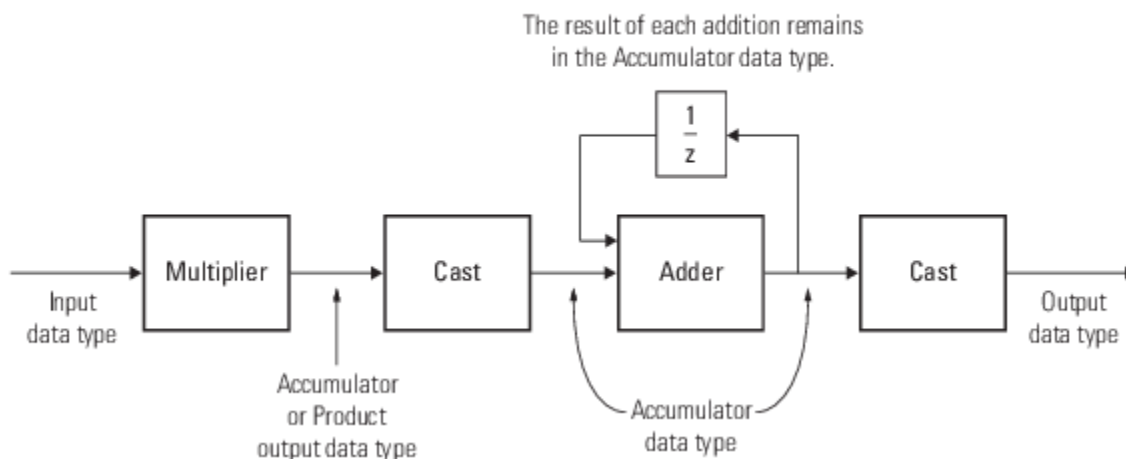

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

#### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

These diagrams show the data types that the Autocorrelation block uses for fixed-point signals (time domain only).

#### Signal flow when Scaling is "None"

### Signal flow when Scaling is other than "None"

You can set the product output, accumulator, and output data types on the **Data Types** tab of the block.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

### Blocks

Correlation

## Autocorrelation LPC

Determine coefficients of Nth-order forward linear predictors

### Libraries:

DSP System Toolbox / Estimation / Linear Prediction

## Description

The Autocorrelation LPC block determines the coefficients of an *N-step forward linear predictor* for the time-series in each length-*M* input channel, *u*, by minimizing the prediction error in the least squares sense. A linear predictor is an FIR filter that predicts the next value in a sequence from the present and past inputs. This technique has applications in filter design, speech coding, spectral analysis, and system identification.

The Autocorrelation LPC block can output the prediction error for each channel as polynomial coefficients, reflection coefficients, or both. The block can also output the prediction error power for each channel.

## Ports

### Input

#### Input 1 — Input array

unoriented vector | column vector | matrix

Specify the input *u* as an unoriented vector, column vector, or a matrix. Row vectors are not valid inputs. The block treats all *M*-by-*N* matrix inputs as *N* channels of length *M*.

Data Types: single | double

### Output

#### A — Polynomial coefficients

column vector | matrix

Polynomial coefficients generated when you set the **Output(s)** parameter to A or A and K. For each input channel, port A outputs an (*N*+1)-by-1 column vector  $a = [1 \ a_2 \ a_3 \ \dots \ a_{N+1}]^T$ , containing the coefficients of an *N*<sup>th</sup>-order moving average (MA) linear process that predicts the next value,  $\hat{u}_{M+1}$ , in the input time-series.

$$\hat{u}_{M+1} = -(a_2 u_M) - (a_3 u_{M-1}) - \dots - (a_{N+1} u_{M-N+1})$$

**Dependencies**

To enable port A, set **Output(s)** to A or A and K.

Data Types: single | double

**K** — Reflection coefficients

column vector | matrix

Reflection coefficients generated when **Output(s)** is set to K or A and K. For each input channel, port K outputs a length- $N$  column vector whose elements are the prediction error reflection coefficients.

**Dependencies**

To enable port K, set **Output(s)** to A or A and K.

Data Types: single | double

**P** — Prediction error power

vector

Prediction error power output at port P as a vector whose length is the number of input channels.

**Dependencies**

To enable port P, select the **Output prediction error power (P)** parameter.

Data Types: single | double

**Parameters****Output(s)** — Type of prediction coefficients

A (default) | A and K | K

Specify the type of prediction coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

When you set **Output(s)** to A and K, the block enables port A and K and each port outputs its respective set of prediction coefficients for each channel.

**Output prediction error power (P)** — Output prediction error power

off (default) | on

Select this parameter to enable the output port P, which outputs the output prediction error power.

**Inherit prediction order from input dimensions** — Inherit prediction order from input dimensions

off (default) | on

Select this parameter to inherit the prediction order  $N$  from the input dimensions.

**Prediction order (N)** — Prediction order

1 (default) | scalar

Specify the prediction order  $N$ . Note that  $N$  must be a scalar with a value less than the length of the input channels or the block produces an error.

### Dependencies

This parameter appears only when you do not select the **Inherit prediction order from input dimensions** parameter.

### Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

### Algorithms

The Autocorrelation LPC block computes the least squares solution to

$$\min_{i \in \mathfrak{R}^n} \|U\tilde{a} - b\|$$

where  $\|\cdot\|$  indicates the 2-norm and

$$U = \begin{bmatrix} u_1 & 0 & \cdots & 0 \\ u_2 & u_1 & \ddots & \vdots \\ \vdots & u_2 & \ddots & 0 \\ \vdots & \vdots & \ddots & u_1 \\ \vdots & \vdots & \vdots & u_2 \\ \vdots & \vdots & \vdots & \vdots \\ u_M & \vdots & \vdots & \vdots \\ 0 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & u_M \end{bmatrix}, \quad \tilde{a} = \begin{bmatrix} a_2 \\ \vdots \\ a_{n+1} \end{bmatrix}, \quad b = \begin{bmatrix} u_2 \\ u_3 \\ \vdots \\ u_M \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

Solving the least squares problem via the normal equations

$$U^*U\tilde{a} = U^*b$$

leads to the system of equations

$$\begin{bmatrix} r_1 & r_2^* & \cdots & r_n^* \\ r_2 & r_1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & r_2^* \\ r_n & \cdots & r_2 & r_1 \end{bmatrix} \begin{bmatrix} a_2 \\ a_3 \\ \vdots \\ a_{n+1} \end{bmatrix} = \begin{bmatrix} -r_2 \\ -r_3 \\ \vdots \\ -r_{n+1} \end{bmatrix}$$

where  $r = [r_1 r_2 r_3 \dots r_{n+1}]^T$  is an autocorrelation estimate for  $u$  computed using the Autocorrelation block, and \* indicates the complex conjugate transpose. The normal equations are solved in  $O(n^2)$  operations by the Levinson-Durbin block.

Note that the solution to the LPC problem is very closely related to the Yule-Walker AR method of spectral estimation. In that context, the normal equations above are referred to as the Yule-Walker AR equations.

## Backward Substitution

Solve  $UX = B$  for  $X$  when  $U$  is upper triangular matrix

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

### Description

The Backward Substitution block solves the linear system  $UX = B$  by simple backward substitution of variables, where:

- $U$  is the upper triangular  $M$ -by- $M$  matrix input to the **U** port.
- $B$  is the  $M$ -by- $N$  matrix input to the **B** port.
- $X$  is the  $M$ -by- $N$  output matrix and is the solution of the system of equations.

The block does not check the rank of the inputs. The block uses only the elements in the *upper triangle* of input  $U$  and ignores the lower elements. When you select the **Input U is unit-upper triangular** check box, the block assumes the elements on the diagonal of  $U$  are 1s. This is useful when matrix  $U$  is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the  $D$  matrix.

### Ports

#### Input

**U** — Input upper triangular matrix  
 $M$ -by- $M$  matrix

Specify the input upper triangular  $M$ -by- $M$  matrix  $U$  through this port. Inputs  $U$  and  $B$  must have the same number of rows.

When the input  $U$  is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

**B** —  $B$  matrix  
 $M$ -by- $N$  matrix |  $M$ -by-1 vector

Specify the  $B$  matrix in the  $UX = B$  equation as an  $M$ -by- $N$  matrix or an  $M$ -by-1 vector.

When you specify an  $M$ -by-1 vector, the block treats the length- $M$  vector input at port **B** as an  $M$ -by-1 matrix. Inputs  $U$  and  $B$  must have the same number of rows.

When the input  $B$  is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Output

**X** — Solution of system of equations

*M*-by-*N* matrix | *M*-by-1 matrix

The block returns the output as an *M*-by-*N* matrix or an *M*-by-1 vector. The size of the *X* matrix is same as the size of the *B* matrix.

When the inputs are fixed-point, the output matrix *X* is signed only fixed-point.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

### Main Tab

**Input U is unit-upper triangular** — Diagonal elements of input matrix have a value of 1

off (default) | on

Select this check box only when all elements on the diagonal of *U* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary division operation.

Do not select this check box if any elements on the diagonal of *U* do not have a value of 1. When you clear the **Input U is unit-upper triangular** check box, the block always performs the division operation.

**Diagonal of complex input U is real** — Diagonal elements of complex input are real

off (default) | on

Select to optimize simulation speed when the diagonal elements of complex input *U* are real.

---

**Note** When *U* is a complex fixed-point signal, you must select either **Input U is unit-upper triangular** or **Diagonal of complex input U is real**. When either of these options are selected, the block ignores any imaginary part of the diagonal of *U*.

---

### Dependencies

This parameter is visible only when **Input U is unit-upper triangular** is not selected.

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

**Product output** — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as first input | `fixdt(1,16,0)`

**Product output** specifies the data type of the output of a product operation in the Backward Substitution block. For more information on the product output data type, see “Fixed Point” on page 2-102 and “Multiplication Data Types”.

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — The block specifies the product output data type to be the same as the first input data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type

Inherit: Inherit via internal rule (default) | Inherit: Same as product output | Inherit: Same as first input | `fixdt(1,16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Backward Substitution block. For illustrations on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-102 section.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as first input** — The block specifies the accumulator data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output** — Output data type

**Inherit: Same as first input** (default) | **fixdt(1,16,0)**

**Output** specifies the data type of the output of the Backward Substitution block. For more information on the output data type, see the “Fixed Point” on page 2-102 section.

- **Inherit: Same as first input** — The block specifies the output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output Minimum** — Minimum value the block can output

**[]** (default) | **scalar**

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Output Maximum** — Maximum value block can output

**[]** (default) | **scalar**

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

**off** (default) | **on**

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

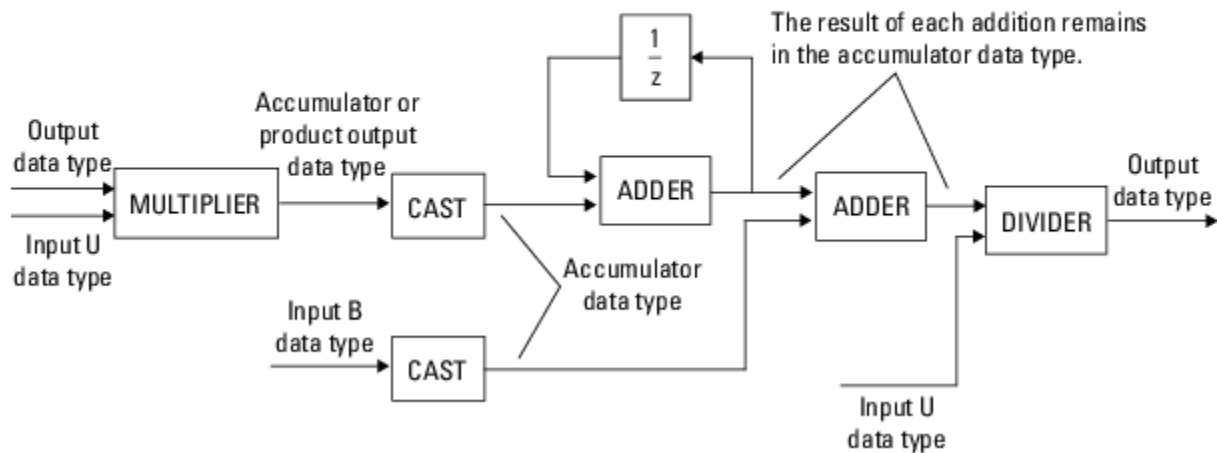

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

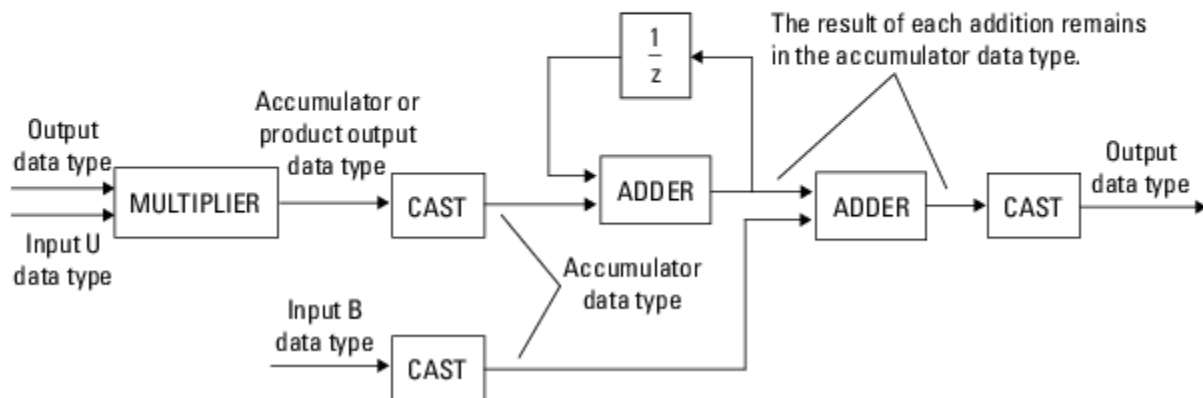

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The following diagrams show the data types used within the Backward Substitution block for fixed-point signals.

**When input  $U$  is not unit-upper triangular:**

**When input  $U$  is unit-upper triangular:**

You can set the product output, accumulator, and output data types in the block dialog box.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-113.

## Ports

### Input

**Port\_1** — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

### Output

**Port\_1** — Filtered output signal

scalar | vector | matrix

Filtered output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

## Parameters

**View Filter Response** — Open Filter Visualization Tool

button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

**Impulse response** — FIR or IIR filter

FIR (default) | IIR

Choose to implement an FIR or IIR filter.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

**Order mode** — Mode of specifying filter order

Minimum (default) | Specify

Select Minimum to have the block implement a filter with minimum order. When you select Specify, you must enter the filter order using the **Order** parameter.

---

**Tip** When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, select the **Denominator order** check box.

---

**Order** — Filter order

20 (default) | positive integer

Specify the filter order as a positive integer.

**Dependencies**

To enable this parameter, set **Order mode** to Specify.

**Denominator order** — Specify denominator order

off (default) | on

Select this check box to specify a different denominator order. When you select this check box, you can specify the denominator order as a positive integer in the resulting text box.

**Dependencies**

To enable this parameter, set the **Impulse response** to IIR and the **Order mode** to Specify.

**Filter type** — Type of filter

Single-rate (default) | Decimator | Interpolator | Sample-rate converter

Select the type of filter to implement. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

**Dependencies**

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

**Decimation Factor** — Decimation factor

2 (default) | positive integer

Specify the decimation factor as a positive integer.

**Dependencies**

To enable this parameter, set the **Filter type** to Decimator or Sample-rate converter.

**Interpolation Factor** — Interpolation factor

2 (default) | positive integer

Specify the interpolation factor as a positive integer.

**Dependencies**

To enable this parameter, set the **Filter type** to Interpolator or Sample-rate converter.

**Frequency constraints** — Frequency response constraints

Passband and stopband edges (default) | Passband edges | Half power (3dB) frequencies | Half power (3dB) frequencies and passband width | Half power (3dB) frequencies and stopband width | Cutoff (6dB) frequencies

When you set the **Order mode** to Specify, this parameter allows you to choose the filter features that the block uses to define the frequency response characteristics. Depending on the **Impulse response** you choose, you can set the **Frequency constraints** to one of:

- **Passband and stopband edges** — Specify the frequencies for the edges for the stop- and passbands.
- **Passband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequencies** — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Half power (3dB) frequencies and passband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- **Half power (3dB) frequencies and stopband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- **Cutoff (6dB) frequencies** — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point 6 dB below the passband value.

**Dependencies**

To enable this parameter, set the **Order mode** to Specify. The available **Frequency constraints** will depend on whether the **Impulse response** is FIR or IIR.

**Frequency units** — Frequency units

Normalized (0 to 1) (default) | Hz | kHz | MHz | GHz

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz.

**Input sample rate** — Input sample rate

2 (default) | positive scalar

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well.

**Dependencies**

To enable this parameter, set **Filter type** to Single-rate, Decimator, or Sample-rate converter and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

**Output sample rate** — Output sample rate

2 (default) | positive scalar

When you design an interpolator,  $F_s$  represents the sampling frequency at the filter output.

**Dependencies**

To enable this parameter, set **Filter type** to Interpolator and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

**Stopband frequency 1** — Frequency at edge of end of first stopband

0.35 (default) | positive scalar

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Passband frequency 1** — Frequency at edge of start of passband

0.45 (default) | positive scalar

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you selected for **Frequency units**.

**Passband frequency 2** — Frequency at edge of end of passband

.55 (default) | positive scalar

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Stopband frequency 2** — Frequency at edge of start of second stopband

.65 (default) | positive scalar

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Half power (3dB) frequency 1** — Lower frequency 3 dB point

.4 (default) | positive scalar

Specify the lower frequency 3 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

**Half power (3dB) frequency 2** — Higher frequency 3 dB point

.6 (default) | positive scalar

Specify the higher frequency 3 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

**Cutoff (6dB) frequency 1** — Lower frequency 6 dB point

.4 (default) | positive scalar

Specify the lower frequency 6 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

**Cutoff (6dB) frequency 2** — Higher frequency 6 dB point

.6 (default) | positive scalar

Specify the higher frequency 6 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

**Passband width** — Passband width

.15 (default) | positive scalar

Specify the width of the passband as a positive scalar, in units corresponding to the **Frequency units** parameter.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and passband width.

**Stopband width** — Width of stopband

.25 (default) | positive scalar

Specify the width of the stopband as a positive scalar, in units corresponding to the **Frequency units** parameter.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and stopband width.

**Magnitude constraints** — Magnitude constraints

Unconstrained (default) | Constrained bands | Passband ripple | Passband ripple and stopband attenuation | Stopband attenuation

Specify the magnitude constraints for the filter design.

**Dependencies**

To enable this parameter, set **Order mode** to `Specify`. The available options depend on the value of the **Frequency constraints** parameters.

**Magnitude units** — Units for magnitude specifications  
dB (default) | `Linear` | `Squared`

Specify the units for any parameter you provide in magnitude specifications:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

**Dependencies**

To enable this parameter, set **Order mode** to `Minimum`.

**Stopband attenuation 1** — Filter attenuation in first stopband  
60 (default) | real-valued positive scalar

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Passband ripple** — Allowable filter ripple in passband  
1 (default) | real-valued positive scalar

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Stopband attenuation 2** — Filter attenuation in second stopband  
60 (default) | real-valued positive scalar

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Design method** — Filter design method  
`Equiripple` (default) | `Kaiser window` | `Butterworth` | `Chebyshev type I` | `Chebyshev type II` | `Elliptic`

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually `Butterworth`, and the default FIR method is `Equiripple`.

**Scale SOS filter coefficients to reduce chance of overflow** — Scale filter coefficients  
on (default) | off

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR.

**Density factor** — Density factor  
16 (default) | positive scalar

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times `filter_order + 1`.

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable balance between the accurate approximation to the ideal filter and the time to design the filter.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

**Phase constraint** — Phase constraint  
Linear (default) | Maximum | Minimum

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

**Match exactly** — Match passband, stopband, or both  
Stopband (default) | Passband | Both

Specifies that the resulting filter design matches either the passband, stopband, or both bands.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR.

**Minimum order** — Minimum filter order  
Any (default) | Even | Odd

When you select this parameter, the design method determines and designs a minimum order filter to meet your specifications.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR and **Order mode** to Minimum.

**Structure** — Filter structure  
Direct-form FIR (default) | Direct-form FIR transposed | Direct-form symmetric FIR | Cascade minimum-multiplier allpass | Cascade wave digital filter allpass |

Direct-form I SOS | Direct-form I transposed SOS | Direct-form II SOS | Direct-form II transposed SOS

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use basic elements to enable filter customization** — Implement filter with basic Simulink blocks  
off (default) | on

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

#### Dependencies

When you select this check box, the block enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

**Optimize for unit-scale values** — Optimize unit scale values  
off (default) | on

Select this check box to scale unit gains between sections in SOS filters.

#### Dependencies

To enable this parameter, set **Impulse response** to IIR.

**Rate options** — Enforce single-rate or allow multirate processing  
Enforce single-rate processing (default) | Allow multirate processing

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

#### Dependencies

To enable this parameter, set the **Impulse response** to FIR and set **Filter type** to a multirate filter.

**Use variable names for coefficients** — Specify coefficients with MATLAB variables  
off (default) | on

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | No              |

## Version History

Introduced in R2006b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Bandpass Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Impulse response** is set to FIR.
- **Filter type** is set to Single-rate.
- **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- **Use basic elements to enable filter customization** parameter is not selected.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

# Bandstop Filter

Design bandstop filter

**Libraries:**

DSP System Toolbox / Filtering / Filter Designs

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-122.

## Ports

### Input

**Port\_1** — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

### Output

**Port\_1** — Filtered output signal

scalar | vector | matrix

Filtered output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double`

## Parameters

**View Filter Response** — Open Filter Visualization Tool

button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

**Impulse response** — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR or IIR filter.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

**Order mode** — Mode of specifying filter order

Minimum (default) | Specify

Select Minimum to have the block implement a filter with minimum order. When you select Specify, you must enter the filter order using the **Order** parameter.

---

**Tip** When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, select the **Denominator order** check box.

---

**Order** — Filter order

20 (default) | positive integer

Specify the filter order as a positive integer.

**Dependencies**

To enable this parameter, set **Order mode** to Specify.

**Denominator order** — Specify denominator order

off (default) | on

Select this check box to specify a different denominator order. When you select this check box, you can specify the denominator order as a positive integer in the resulting text box.

**Dependencies**

To enable this parameter, set the **Impulse response** to IIR and the **Order mode** to Specify.

**Filter type** — Type of filter

Single-rate (default) | Decimator | Interpolator | Sample-rate converter

Select the type of filter to implement. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

**Dependencies**

- This parameter applies only when you set **Impulse response** to FIR.
- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

**Decimation Factor** — Decimation factor

2 (default) | positive integer

Specify the decimation factor as a positive integer.

#### Dependencies

To enable this parameter, set the **Filter type** to Decimator or Sample-rate converter.

#### Interpolation Factor — Interpolation factor

2 (default) | positive integer

Specify the interpolation factor as a positive integer.

#### Dependencies

To enable this parameter, set the **Filter type** to Interpolator or Sample-rate converter.

#### Frequency constraints — Frequency response constraints

Passband and stopband edges (default) | Passband edges | Half power (3dB) frequencies | Half power (3dB) frequencies and passband width | Half power (3dB) frequencies and stopband width | Cutoff (6dB) frequencies

When you set the **Order mode** to Specify, this parameter allows you to choose the filter features that the block uses to define the frequency response characteristics. Depending on the **Impulse response** you choose, you can set the **Frequency constraints** to one of:

- **Passband and stopband edges** — Specify the frequencies for the edges for the stop- and passbands.
- **Passband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband edges** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequencies** — For IIR filters, define the filter response by specifying the locations of the 3 dB points. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Half power (3dB) frequencies and passband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband.
- **Half power (3dB) frequencies and stopband width** — For IIR filters, define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband.
- **Cutoff (6dB) frequencies** — For FIR filters, define the filter response by specifying the locations of the 6 dB points. The 6 dB point is the frequency for the point 6 dB below the passband value.

#### Dependencies

To enable this parameter, set the **Order mode** to Specify. The available **Frequency constraints** will depend on whether the **Impulse response** is FIR or IIR.

#### Frequency units — Frequency units

Normalized (0 to 1) (default) | Hz | kHz | MHz | GHz

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz.

**Input sample rate** — Input sample rate

2 (default) | positive scalar

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well.

**Dependencies**

To enable this parameter, set **Filter type** to Single-rate, Decimator, or Sample-rate converter and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

**Output sample rate** — Output sample rate

2 (default) | positive scalar

When you design an interpolator,  $F_s$  represents the sampling frequency at the filter output rather than the filter input.

**Dependencies**

To enable this parameter, set **Filter type** to Interpolator and **Frequency units** to one of the unit options (Hz, kHz, MHz, or GHz).

**Passband frequency 1** — Frequency at edge of end of first passband

0.35 (default) | positive scalar

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Stopband frequency 1** — Frequency at edge of start of stopband

0.45 (default) | positive scalar

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Stopband frequency 2** — Frequency at edge of end of stopband

0.55 (default) | positive scalar

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Passband frequency 2** — Frequency at edge of start of second passband

0.65 (default) | positive scalar

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Half power (3dB) frequency 1** — Lower frequency 3 dB point

0.4 (default) | positive scalar

Specify the lower frequency 3 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

**Half power (3dB) frequency 2** — Higher frequency 3 dB point

0.6 (default) | positive scalar

Specify the higher frequency 3 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR, **Order mode** to Specify, and **Frequency constraints** to Half power (3dB) frequencies, Half power (3dB) frequencies and passband width, or Half power (3dB) frequencies and stopband width.

**Cutoff (6dB) frequency 1** — Lower frequency 6 dB point

0.4 (default) | positive scalar

Specify the lower frequency 6 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

**Cutoff (6dB) frequency 2** — Higher frequency 6 dB point

0.6 (default) | positive scalar

Specify the higher frequency 6 dB point as a positive scalar between zero and one.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Cutoff (6dB) frequencies.

**Passband width** — Passband width

0.25 (default) | positive scalar

Specify the width of the passband as a positive scalar, in units corresponding to the **Frequency units** parameter.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and passband width.

**Stopband width** — Width of stopband

0.15 (default) | positive scalar

Specify the width of the stopband as a positive scalar, in units corresponding to the **Frequency units** parameter.

**Dependencies**

To enable this parameter, set **Frequency constraints** to Half power (3dB) frequencies and stopband width.

**Magnitude constraints** — Magnitude constraints

Unconstrained (default) | Constrained bands | Passband ripples and stopband attenuation

Specify the magnitude constraints for the filter design.

**Dependencies**

To enable this parameter, set **Order mode** to `Specify`. The available options depend on the value of the **Frequency constraints** parameter.

**Magnitude units** — Units for magnitude specifications  
dB (default) | `Linear` | `Squared`

Specify the units for any parameter you provide in magnitude specifications:

- `Linear` — Specify the magnitude in linear units.
- `dB` — Specify the magnitude in decibels (default).
- `Squared` — Specify the magnitude in squared units.

**Dependencies**

To enable this parameter, set **Order mode** to `Minimum`.

**Passband ripple 1** — Allowable filter ripple in first passband  
1 (default) | real-valued positive scalar

Specify the filter ripple allowed in the first passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Stopband attenuation** — Stopband attenuation  
60 (default) | real-valued positive scalar

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Passband ripple 2** — Allowable filter ripple in second passband  
1 (default) | real-valued positive scalar

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**. Values must be real, positive scalars. If you are specifying values in linear units, they must be smaller than 1.

**Dependencies**

To enable this parameter, set the **Order mode** to `Minimum`.

**Design method** — Filter design method  
`Equiripple` (default) | `Kaiser window` | `Butterworth` | `Chebyshev type I` | `Chebyshev type II` | `Elliptic`

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods

available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is Equiripple.

**Scale SOS filter coefficients to reduce chance of overflow** — Scale filter coefficients

on (default) | off

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR.

**Density factor** — Density factor

16 (default) | positive scalar

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (**filter order** + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable balance between the accurate approximation to the ideal filter and the time to design the filter.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

**Phase constraint** — Phase constraint

Linear (default) | Maximum | Minimum

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR and **Design method** to Equiripple.

**Minimum order** — Minimum filter order

Any (default) | Even

When you select this parameter, the design method determines and designs a minimum order filter to meet your specifications.

**Dependencies**

To enable this parameter, set **Impulse response** to FIR, **Order mode** to Minimum, and **Design method** to Kaiser window.

**Match exactly** — Match passband, stopband, or both

Stopband (default) | Passband | Both

Specifies that the resulting filter design matches either the passband, stopband, or both bands.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR.

**Structure** — Filter structure

Direct-form FIR (default) | Direct-form FIR transposed | Direct-form symmetric FIR | Cascade minimum-multiplier allpass | Cascade wave digital filter allpass | Direct-form I SOS | Direct-form I transposed SOS | Direct-form II SOS | Direct-form II transposed SOS

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use basic elements to enable filter customization** — Implement filter with basic Simulink blocks  
off (default) | on

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

**Dependencies**

When you select this check box, the block enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay of  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

**Optimize for unit scale values** — Optimize unit scale values  
off (default) | on

Select this check box to scale unit gains between sections in SOS filters.

**Dependencies**

To enable this parameter, set **Impulse response** to IIR.

**Rate options** — Enforce single-rate or allow multirate processing  
Enforce single-rate processing (default) | Allow multirate processing

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

**Dependencies**

To enable this parameter, set the **Impulse response** to FIR and set **Filter type** to a multirate filter.

**Use variable names for coefficients** — Specify coefficients with MATLAB variables  
off (default) | on

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code.

## Block Characteristics

# Binary File Reader

Read data from binary files

**Libraries:**  
DSP System Toolbox / Sources

## Description

The Binary File Reader block reads multichannel signal data from a binary file. The block reads the header that precedes the data. The **File header** parameter specifies the structure of the header. You can specify the type, size, and complexity of the data through the block parameters. You can also export the header to the base workspace by clicking on the **Export header to base workspace** button.

The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of the file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the Binary File Writer block.

## Output Ports

### Output

**data** — Binary file data  
column vector | row vector | matrix

The reader block reads the binary data from the file specified in the **File name** parameter. The data output from the block has dimensions **Samples per frame-by-Number of channels**. The block can read floating-point data and integer data. The input data can be real or complex. When the data is complex, the block reads the data as interleaved real and imaginary components. The reader assumes the default endianness of the host machine.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**EOF** — End-of-file indicator  
boolean scalar

When the block reaches the end of the file, the port outputs a 1. Otherwise, the port outputs a 0.

This port is unnamed until you select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

## Parameters

**File name** — Name of the file  
'Untitled.bin' (default) | character vector

Name of the file from which the block reads the data. If the file is not on the MATLAB path, then specify the full path for the file.

**File header** — Size of the header

`struct([])` (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this parameter to an empty structure, `struct([])`.

**Export header to base workspace** — Retrieve the header

button

To retrieve the file header, click **Export header to base workspace**. The block exports the file header to the base workspace.

**Storage data type** — Storage class of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Storage class of data in file, specified as a character vector. This parameter defines the data type of the matrix the block outputs.

**Samples per frame** — Number of samples per output frame

1024 (default) | positive integer

**Samples per frame** specifies the number of rows of the output matrix that the block outputs. The output matrix has dimensions **Samples per frame**-by-**Number of channels**. Once the end of the file is reached, the block returns zeros of the specified data type, size, and complexity.

**Data is complex** — Specify data complexity

off (default) | on

When you select this parameter, the reader treats the data as complex data. The block reads the data as interleaved real and imaginary components. Configure the block to read the data as a 2-by-2 matrix. The block reads [1 5 2 6 3 7 4 8] as [1 2; 3 4]+1j\*[5 6; 7 8]. When you do not select this parameter, the block reads the data as [1 5; 2 6].

**Number of channels** — Number of channels

1 (default) | positive integer

**Number of channels** specifies the number of columns of the output matrix that the block outputs. This parameter defines the number of consecutive interleaved data samples stored in the file for each

time instant. The size of the data is **Samples per frame-by-Number of channels**. Once the end of the file is reached, if the output matrix is not full, the block fills the matrix with zeros to make it a full-sized matrix.

**Output end-of-file indicator** — End-of-file indicator

off (default) | on

When you select this parameter, an additional output port named **EOF** appears on the block. When the block reaches the end of the file, the port outputs a 1. Otherwise, the port outputs a 0.

**Sample time (s)** — Sample time

1 (default) | nonnegative scalar

**Sample time (s)** controls the sample time at the output port of the block. This value represents  $1/F_s$ , where  $F_s$  is the sampling rate of the signal data. The Simulink sample time at the output port is **Samples per frame × Sample time (s)**.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                           |
|---------------------------------|---------------------------|
| <b>Data Types</b>               | double   integer   single |
| <b>Direct Feedthrough</b>       | no                        |
| <b>Multidimensional Signals</b> | no                        |
| <b>Variable-Size Signals</b>    | no                        |
| <b>Zero-Crossing Detection</b>  | no                        |

## Version History

# Binary File Writer

Write data to binary files

## Libraries:

DSP System Toolbox / Sinks

## Description

The Binary File Writer block writes multichannel signal data to a binary file. The block specifies the name of the file and the structure of the header that precedes the signal data. If there is no header to write, the block specifies an empty structure, `struct([])`. The first time you write to the file, the block writes the header, followed by the data. On subsequent calls, the block writes the remaining data. If the header is empty, then no header is written.

The block writes the data in a row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the block writes the data as `[1 2 4 5 8 7 9 2]`.

## Input Ports

### Input

**Port\_1** — Data to write

column vector | row vector | matrix

The writer block writes the data to the file specified in the **File name** parameter. If the **File header** structure is not empty, then the writer writes the header before writing the data. The block can write floating-point data and integer data. The input data can be real or complex. When the data is complex, the block writes the data as interleaved real and imaginary components. The writer assumes the default endianness of the host machine.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Parameters

**File name** — Name of the file

'Untitled.bin' (default) | character vector

Name of the file to which the block writes the data.

**File header** — Size of the header

`struct([])` (default) | structure

The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if **File header** is set to `struct('field1',1:10,'field2',single(1))`, the block writes a header formed by 10 double-

precision values, (1:10), followed by 1 single precision value, `single(1)`. If there is no header to write, set this parameter to an empty structure, `struct([])`.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

## Block Characteristics

|                                 |                           |
|---------------------------------|---------------------------|
| <b>Data Types</b>               | double   integer   single |
| <b>Direct Feedthrough</b>       | no                        |
| <b>Multidimensional Signals</b> | no                        |
| <b>Variable-Size Signals</b>    | no                        |
| <b>Zero-Crossing Detection</b>  | no                        |

# Biquad Filter

Model biquadratic IIR (SOS) filters

## Libraries:

DSP System Toolbox / Filtering / Filter Implementations  
 DSP System Toolbox HDL Support / Filtering

## Description

The Biquad Filter block independently filters each channel of the input signal with the specified biquadratic infinite impulse response (IIR) filter. When you specify the filter coefficients in the dialog box, the block implements static filters with fixed coefficients. When you provide the filter coefficients through an input port, you can tune the coefficients during simulation.

The Biquad Filter block supports the Simulink state logging feature. See “State” (Simulink) for more information.

## Ports

### Input

**In** — Data input  
 vector | matrix

Data input to the block, specified as a vector or a matrix. This block supports variable-size input signals, enabling you to change the input frame size (number of rows) during simulation. However, the number of channels (number of columns) must remain constant.

If the input is fixed-point, it must be signed fixed-point with binary point scaling.

This port is unnamed unless you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

**Num** — Numerator coefficients  
 matrix

Numerator coefficients of the biquad filter, specified as a 3-by- $N$  matrix, where  $N$  is the number of biquad filter sections.

If **Num** is fixed-point, it must be signed fixed-point with binary point scaling.

### Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

**Den** — Denominator coefficients  
 matrix

Denominator coefficients of the biquad filter, specified as a 2-by- $N$  matrix, where  $N$  is the number of biquad filter sections.

If **Den** is fixed-point, it must be signed fixed-point with binary point scaling.

#### Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

#### **g** — Scale values

row vector

Scale values of the biquad filter, specified as a 1-by- $(N+1)$  vector, where  $N$  is the number of biquad filter sections.

If **g** is fixed-point, it must be signed fixed-point with binary point scaling.

#### Dependencies

This port appears only when you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

#### Output

##### **Out** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix.

The output dimensions always equal the dimensions of the input signal. The output of this block numerically matches the outputs of the `dsp.BiquadFilter` System object.

If **Out** is fixed-point, it must be signed fixed-point with binary point scaling.

This port is unnamed unless you set the **Coefficient source** to `Input port(s)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Parameters

### Main Tab

#### **Coefficient source** — Mode of operation

`Dialog parameters (default)` | `Input port(s)` | `Filter object`

The Biquad Filter block can operate in three different modes:

- `Dialog parameters` — Enter information about the filter, such as structure and coefficients, in the block mask.
- `Input port(s)` — Enter information about the filter structure in the block mask using the **Filter structure** parameter. The filter coefficients come into the block through additional input ports that appear on the block icon:

- **Num** — Specify numerator coefficients.
- **Den** — Specify denominator coefficients.
- **g** — Specify scale values.

The block assumes the first denominator coefficient of each section to be 1. This configuration applies when **Coefficient source** is set to `Input port(s)` and **Scale values mode** is set to `Specify via input port (g)`.

- **Filter object** — Specify the filter using a `dsp.BiquadFilter System` object.

**Filter** — Name of filter object

BQF (default) | `dsp.BiquadFilter System` object name

Specify the name of the discrete-time filter that you want the block to implement. You must specify the filter as a `dsp.BiquadFilter System` object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

#### Dependencies

This parameter is visible only when **Coefficient source** is set to `Filter object`.

**Filter structure** — Filter structure

Direct form II transposed (default) | Direct form I | Direct form I transposed | Direct form II

Specify the filter structure.

#### Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters` or `Input port(s)`.

**SOS Matrix (Mx6)** — SOS matrix

[1 0.3 0.4 1 0.1 0.2] (default) | *M*-by-6 matrix

Specify an *M*-by-6 matrix, where *M* is the number of sections in the second-order section filter. Each row of the SOS matrix contains the numerator and denominator coefficients ( $b_{ik}$  and  $a_{ik}$ ) of the corresponding section in the filter.

$$\begin{bmatrix} b_{01} & b_{11} & b_{21} & a_{01} & a_{11} & a_{21} \\ b_{02} & b_{12} & b_{22} & a_{02} & a_{12} & a_{22} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{0M} & b_{1M} & b_{2M} & a_{0M} & a_{1M} & a_{2M} \end{bmatrix}$$

The leading denominator coefficients [ $a_{01}$   $a_{02}$  ...  $a_{0N}$ ] are treated as 1s, regardless of their actual values. No scaling is applied to the SOS matrix when **a0** is not 1.

The `ss2sos` and `tf2sos` functions convert a state-space or transfer function description of your filter into the second-order section description used by this block.

### Dependencies

This parameter is visible only when **Coefficient source** is set to Dialog parameters.

### Scale values — Scale values

1 (default) | scalar | vector

Specify scale values to be used between SOS sections. You can specify a real-valued scalar or a vector of length  $M+1$ :

- When you enter a scalar, the value specifies the gain value before the first section of the second-order filter. The rest of the gain values default to 1.
- When you enter a vector of  $M+1$  values, each value specifies a separate section of the filter. For example, the first element is the first gain value, the second element is the second gain value, and so on.

Select the **Optimize unity scale values** check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. Refer to the “Fixed-Point” on page 2-141 section for more information.

### Dependencies

This parameter is visible only when **Coefficient source** is set to Dialog parameters.

### Initial conditions — Initial conditions

0 (default) | scalar | vector

Specify the initial conditions of the filter states when **Filter structure** is set to Direct form II or Direct form II transposed.

### Direct form II

### Direct form II transposed

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions** parameter.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

**Valid Initial Conditions**

| Initial Condition   | Description  |
|---|--|
| Scalar  | The block initializes all delay elements in the filter to the scalar value.  |
| Vector or matrix<br>(for applying different delay elements to each channel) | <p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. <math>M</math> is the number of sections, and <math>N</math> is the number of input channels:</p> <ul style="list-style-type: none"> <li>The vector length must equal the number of delay elements in the filter, <math>2M</math>.</li> <li>The matrix must have the same number of rows as the number of delay elements in the filter <math>2MN</math>. The matrix must also have one column for each channel of the input signal.</li> </ul> |

**Dependencies**

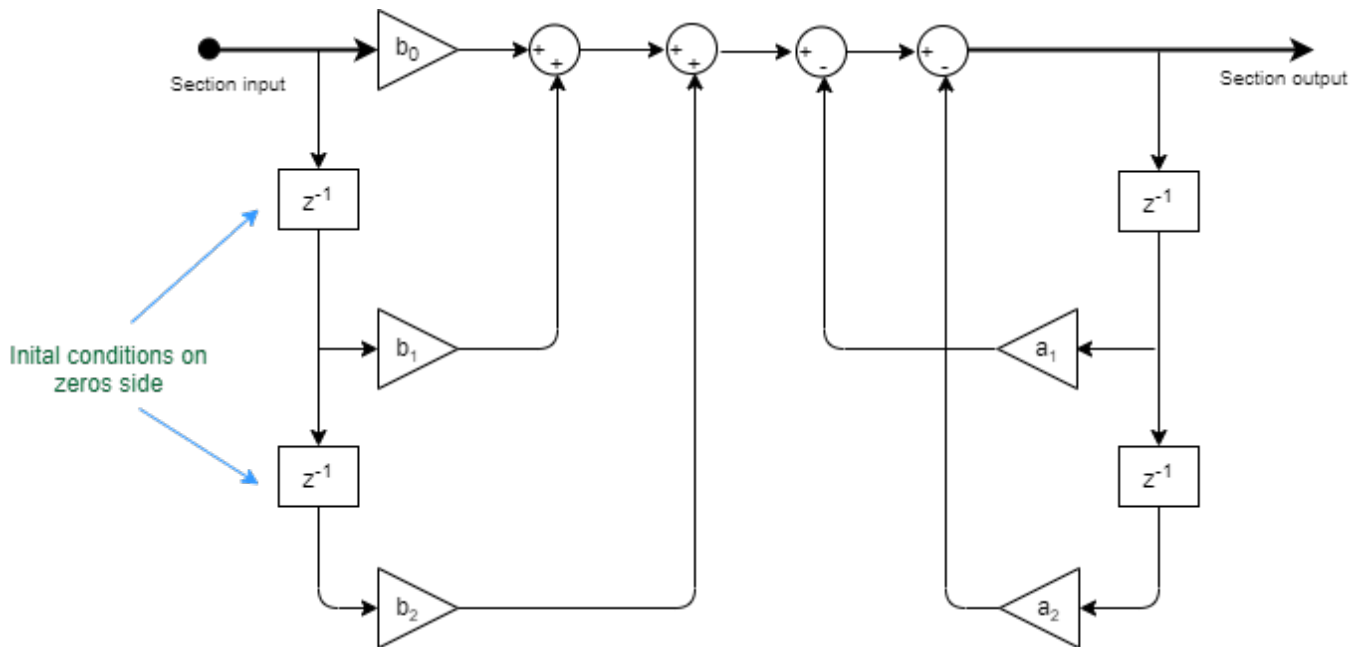

This parameter is only visible when **Coefficient source** is set to Dialog parameters or Input port(s) and the **Filter structure** is set to Direct form II or Direct form II transposed.

**Initial conditions on zeros side** — Initial conditions on zeros side

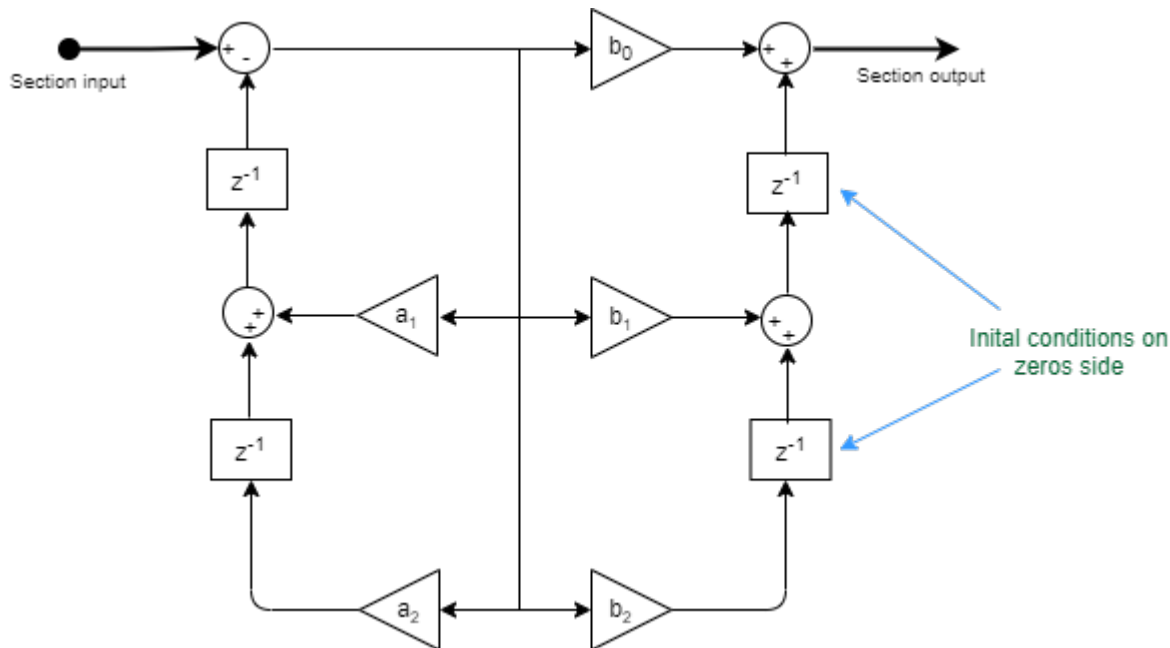

0 (default) | scalar | vector

Specify the initial conditions for the filter states on the side of the filter structure with the zeros ( $b_0, b_1, b_2, \dots$ ). This parameter applies only when **Filter structure** is set to Direct form I or Direct form I transposed.

**Direct form I**

**Direct form I transposed**

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions on zeros side** parameter.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

### Valid Initial Conditions

| Initial Condition   | Description   |
|---|---|
| Scalar  | The block initializes all delay elements in the filter to the scalar value.   |
| Vector or matrix<br>(for applying different delay elements to each channel) | <p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where <math>M</math> is the number of sections and <math>N</math> is the number of input channels:</p> <ul style="list-style-type: none"> <li>The vector length must equal the number of delay elements in the filter, <math>2M</math>.</li> <li>The matrix must have the same number of rows as the number of delay elements in the filter <math>2MN</math>. The matrix must also have one column for each channel of the input signal.</li> </ul> |

### Dependencies

This parameter is visible only when **Coefficient source** is set to Dialog parameters or Input port(s) and the **Filter structure** is set to Direct form I or Direct form I transposed.

**Initial conditions on poles side** — Initial conditions on poles side

0 (default) | scalar | vector

Specify the initial conditions for the filter states on the side of the filter structure with the poles ( $a_1$ ,  $a_2$ , ...). This parameter applies only when **Filter structure** is set to Direct form I or Direct form I transposed.

**Direct form I**

**Direct form I transposed**

The Biquad Filter block initializes the internal filter states to zero by default. To specify nonzero initial states for the filter delays, use the **Initial conditions on poles side** parameter.

To determine the number of initial conditions you must specify and how to specify them, see the following table on valid initial conditions.

## Valid Initial Conditions

| Initial Condition   | Description   |
|---|---|
| Scalar  | The block initializes all delay elements in the filter to the scalar value.   |
| Vector or matrix<br>(for applying different delay elements to each channel) | <p>Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel. Where <math>M</math> is the number of sections and <math>N</math> is the number of input channels:</p> <ul style="list-style-type: none"> <li>The vector length must equal the number of delay elements in the filter, <math>2M</math>.</li> <li>The matrix must have the same number of rows as the number of delay elements in the filter <math>2MN</math>. The matrix must also have one column for each channel of the input signal.</li> </ul> |

### Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters` or `Input port(s)` and the **Filter structure** is set to `Direct form I` or `Direct form I transposed`.

### Scale values mode — Mode to specify scale values

`Specify via input port (g)` (default) | `Assume all are unity and optimize`

Choose how to specify the scale values to use between filter sections. When you select `Specify via input port (g)`, you enter the scale values as a 2-D vector at port **g**. When you select `Assume all are unity and optimize`, all scale values are removed and treated like Simulink lines or wires.

### Dependencies

This parameter is visible only when **Coefficient source** is set to `Input port(s)`.

### Action when the a0 values of the SOS matrix are not one — Action when a0 values of SOS matrix are not one

`Warning` (default) | `None` | `Error`

Specify the action the block should perform when the SOS matrix  $a_{0j}$  values do not equal one. The action can be `Warning`, `Error`, or `None`.

When you choose `None`, the leading coefficients  $a_{0j}$  are treated as 1's, regardless of their actual values. No scaling is applied on the SOS matrix when **a0** is not 1.

### Dependencies

This parameter is visible only when **Coefficient source** is set to `Dialog parameters`.

### Optimize unity scale values — Optimize unity scale values

`on` (default) | `off`

Select this check box to optimize your simulation when one or more scale values equal 1. Selecting this option removes the unity gains so that the values are treated like Simulink lines or wires. In some fixed-point cases when there are unity scale values, selecting this parameter also omits certain casts. See the “Fixed-Point” on page 2-141 section for more information.

**Dependencies**

This parameter is visible only when **Coefficient source** is set to `Dialog` parameters.

**Input processing** — Input processing

`Columns as channels (frame based) (default)` | `Elements as channels (sample based)`

Specify how the block should process the input. If the input is an  $M$ -by- $N$  matrix, you can set this parameter to:

- `Columns as channels (frame based) (default)` — The block treats each column as a separate channel. In this mode, the block creates  $M$  instances of the same filter, each with its own independent state buffer. Each of the  $M$  filters process  $N$  input samples at every Simulink time step.
- `Elements as channels (sample based)` — The block treats each element as a separate channel. In this mode, the block creates  $MN$  instances of the same filter, each with its own independent state buffer. Each filter processes one input sample at every Simulink time step.

**View Filter Response** — View filter response

button

This button opens the Filter Visualization Tool (**FVTool**) and displays the filter response of the filter specified in the dialog.

---

**Note** When you make changes to the filter parameters on the block dialog, you must click the **Apply** button before using the **View Filter Response** button.

---

**Data Types Tab**

---

**Note** This tab appears only when you set **Coefficient source** to either `Dialog` parameters or `Input port(s)`. When the **Coefficient source** is set to `Filter object`, the data types specified in the filter object properties are used by the block.

---

**Rounding mode** — Rounding mode

`Floor (default)` | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations.

For more details, see rounding mode. The filter coefficients do not obey this parameter; instead, they always round to `Nearest`.

**Saturate on integer overflow** — Method of overflow action

`off (default)` | `on`

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

The filter coefficients are always saturated and do not obey this parameter.

#### **Section input** — Section input data type

Same as `input` (default) | `Binary point scaling`

Choose how you specify the word and fraction lengths of the fixed-point data type going into each section of a biquadratic filter. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the section input data type in this block. When you select:

- `Same as input` — Word length and fraction length characteristics of the **Section input** data type match those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section input, in bits.

#### **Section output** — Section output data type

Same as `section input` (default) | `Binary point scaling`

Choose how you specify the word and fraction lengths of the fixed-point data type coming out of each section of a biquadratic filter. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the section output data type in this block. When you select:

- `Same as section input` — Word length and fraction length characteristics of the **Section output** data type match with those of the input to the block.
- `Binary point scaling` — Enter the word and fraction lengths of the section output, in bits.

#### **Multiplicand** — Multiplicand data type

Same as `output` (default) | `Binary point scaling`

Choose how you specify the word and fraction lengths of the multiplicand data type of a `Direct form I transposed` filter structure. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the multiplicand data type in this block.

When you select:

- `Same as output` — Word length and fraction length characteristics of the **Multiplicand** data type match with those of the output of the block.
- `Binary point scaling` — Enter the word length and the fraction length of the multiplicand, in bits.

#### **Dependencies**

This parameter is visible only when the **Filter structure** parameter is set to `Direct form I transposed`.

#### **Coefficients** — Coefficients data type

Same word length as `input` (default) | `Specify word length` | `Binary point scaling`

Choose how you specify the word and fraction lengths of the filter coefficients (numerator, denominator, and scale value) when **Coefficient source** is set to `Dialog parameters`. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the coefficient data types in this block. When you select:

- `Same word length as input` — Word length of the filter coefficients matches that of the input to the block. In this mode, the block automatically sets the fraction length of the coefficients to the binary point-only scaling that provides the best precision possible given the value and word length of the coefficients.

- **Specify word length** — Enter the word length of the coefficients, in bits. In this mode, the block automatically sets the fraction length of the coefficients to the binary point-only scaling that provides the best precision possible given the value and word length of the coefficients.
- **Binary point scaling** — Enter the word length and the fraction length of the coefficients, in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.

The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; instead, they are always saturated and rounded to Nearest.

### Dependencies

This parameter is visible only when **Coefficient source** is set to **Dialog parameters**.

### Product output — Product output data type

Same as input (default) | Inherit via internal rule | Binary point scaling

Specify how to designate the product output word and fraction lengths. See “Multiplication Data Types” and the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the product output data type in this block. When you select:

- **Same as input** — Product output word length and fraction length characteristics match those of the input to the block.
- **Inherit via internal rule** — Product output word length and fraction lengths are computed based on full-precision rules. These rules prevent quantization from occurring within the block. Bits are added, as needed, so that no roundoff or overflow occurs. For more details, see “Inherit via Internal Rule”.
- **Binary point scaling** — Enter the word length and the fraction length of the product output, in bits. If applicable, enter separate fraction lengths for the numerator and denominator product output data type.

### Accumulator — Accumulator data type

Same as product output (default) | Same as input | Binary point scaling

Specify how to designate the accumulator word and fraction lengths. See “Multiplication Data Types” and the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the accumulator data type in this block. When you select:

- **Same as input** — Accumulator word and fraction length characteristics match those of the input to the block.
- **Same as product output** — Accumulator word and fraction length characteristics match those of the product output.
- **Binary point scaling** — Enter the word length and the fraction length of the accumulator, in bits. If applicable, enter separate fraction lengths for the numerator and denominator accumulator data type.

### States — States data type

Same as accumulator (default) | Same as input | Binary point scaling

Specify how to designate the state word and fraction lengths when **Coefficient source** is set to **Dialog parameters**. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the state data type in this block.

When you select:

- Same as `input` — State word and fraction length characteristics match those of the input to the block.
- Same as `accumulator` — State word and fraction length characteristics match those of the accumulator.
- `Binary point scaling` — Enter the word length and the fraction length of the state, in bits. If applicable, enter separate fraction lengths for the numerator and denominator state data type.

### Dependencies

This parameter is visible only when **Filter structure** is set to `Direct form II` or `Direct form II transposed`.

### Output — Output data type

Same as `accumulator` (default) | Same as `input` | `Binary point scaling`

Choose how you specify the output word length and fraction length. See the “Fixed-Point” on page 2-141 section for illustrations depicting the use of the output data type in this block. When you select:

- Same as `input` — Output word and fraction length characteristics match those of the input to the block.
- Same as `accumulator` — Output word and fraction length characteristics match those of the accumulator.
- `Binary point scaling` — Enter the word length and the fraction length of the output, in bits.

**Lock data type settings against changes by the fixed-point tools** — Lock data type settings `off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

## Version History

Introduced in R2008b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For an HDL-optimized biquad filter architecture with hardware-friendly control signals, use the Biquad Filter block. The DSP HDL Toolbox™ block simulates the latency of the HDL algorithm in Simulink. The DSP HDL Toolbox block generates a direct form II or direct form II transposed pipelined add-multiply operation that fits into the DSP block on an FPGA. It provides an optional pipelined feedback architecture that uses more multipliers but reduces the critical path and achieves higher clock rates. The DSP HDL Toolbox block does not support programmable coefficients. To perform multichannel filtering, put the DSP HDL Toolbox Biquad Filter block into a For Each subsystem.

---

HDL Coder™ provides additional configuration options that affect HDL implementation and synthesized logic.

### Programmable Filter Support

HDL Coder supports programmable filters for Biquad Filter blocks.

- 1 On the filter block mask, set **Coefficient source** to **Input port(s)**.
- 2 Connect vector signals to the **Num** and **Den** coefficient ports. Matrix input signals are not supported for HDL code generation. You must use one Biquad Filter block for each second-order section in your filter. For a filter with  $M$  second-order sections, use a series of  $M$  Biquad Filter blocks, each with an input **Num** that is a 3-by-1 vector and an input **Den** that is a 2-by-1 vector.

The following limitations apply to the HDL optimizations for a programmable Biquad Filter block:

- Fully serial and partly serial architectures are not supported. **Architecture** must be set to Fully parallel.
- Canonical signed digit (CSD) multiplier optimization is not supported. **CoeffMultipliers** must be set to multiplier.

### Multichannel Filter Support

HDL Coder supports the use of vector inputs to Biquad Filter blocks.

- 1 Connect a vector signal to the Biquad Filter block input port.
- 2 Specify **Input processing** as `Elements as channels (sample based)`.
- 3 To reduce area by sharing the filter kernel between channels, set the **StreamingFactor** parameter of the subsystem to the number of channels. See the Streaming section of “Subsystem Optimizations for Filters” (HDL Coder).

### Serial Architectures

To use block-level optimizations to reduce hardware resources, select a serial **Architecture**. Then set either `NumMultipliers` or `Folding Factor`. See “HDL Filter Properties” on page 2-149.

When you select a serial architecture, set **Filter structure** to `Direct form I` or `Direct form II`. The direct form transposed structures are not supported with serial architectures.

### AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

| Filter Structure | Pipeline Register Placement                               | Latency (Clock Cycles)                  |
|------------------|---|---|
| Any              | Pipeline registers are added between the filter sections. | NS - 1, where NS is number of sections. |

### Subsystem Optimizations

This block can participate in subsystem-level optimizations such as sharing, streaming, and pipelining. For the block to participate in subsystem-level optimizations, set **Architecture** to `Fully parallel`. See “Subsystem Optimizations for Filters” (HDL Coder).

### HDL Filter Properties

|                             |  |
|-----------------------------|--|
| <b>AddPipelineRegisters</b> | Insert a pipeline register between stages of computation in a filter. See also <code>AddPipelineRegisters</code> (HDL Coder).  |
| <b>CoeffMultipliers</b>     | Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set <b>CoeffMultipliers</b> to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also <code>CoeffMultipliers</code> (HDL Coder). |
| <b>FoldingFactor</b>        | Specify a serial implementation of an IIR SOS filter by the number of cycles it takes to generate the result. See also <code>FoldingFactor</code> (HDL Coder).   |
| <b>NumMultipliers</b>       | Specify a serial implementation of an IIR SOS filter by the number of hardware multipliers that are generated. See also <code>NumMultipliers</code> (HDL Coder).   |

For more details about HDL filter properties, see “HDL Filter Block Properties” (HDL Coder).

**HDL Block Properties**

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

**Restrictions**

- Frame input is not supported for HDL code generation. For frame-based input, use the Biquad Filter block.
- You must set **Initial conditions** to 0. HDL code generation is not supported for nonzero initial states.
- You must select **Optimize unity scale values**.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## Block LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

## Library

Filtering / Adaptive Filters

dspadpt3

## Description

The Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of filter weights occurs once for every block of samples. The block estimates the filter weights, or coefficients, needed to minimize the error,  $e(n)$ , between the output signal,  $y(n)$ , and the desired signal,  $d(n)$ . Connect the signal you want to filter to the **Input** port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the **Desired** port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The **Output** port outputs the filtered input signal. The **Error** port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS adaptive filter algorithm. This algorithm is defined by the following equations.

$$\begin{aligned}
 n &= kN + i \\
 y(n) &= \mathbf{w}^T(k-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(k) &= \mathbf{w}(k-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The weight update function for the Block LMS adaptive filter algorithm is defined as

$$f(\mathbf{u}(n), e(n), \mu) = \mu \sum_{i=0}^{N-1} \mathbf{u}^*(kN + i)e(kN + i)$$

The variables are as follows.

| Variable | Description   |
|----------|---|
| $n$      | The current time index                                      |
| $i$      | The iteration variable in each block, $0 \leq i \leq N - 1$ |
| $k$      | The block number  |
| $N$      | The block size  |

| Variable        | Description                                      |
|-----------------|--|
| $\mathbf{u}(n)$ | The vector of buffered input samples at step $n$ |
| $\mathbf{w}(n)$ | The vector of filter-tap estimates at step $n$   |
| $y(n)$          | The filtered output at step $n$                  |
| $e(n)$          | The estimation error at time $n$                 |
| $d(n)$          | The desired response at time $n$                 |
| $\mu$           | The adaptation step size                         |

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size** parameter.

The adaptation **Step-size (mu)** parameter corresponds to  $\mu$  in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor,  $0 < 1 - \mu\alpha \leq 1$ , in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k - 1) + f(\mathbf{u}(n), e(n), \mu)$$

Enter the initial filter weights as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value

When you select the **Adapt port** check box, an **Adapt** port appears on the block. When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select **None** to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Reset input is a **Rising edge** or **Falling edge** (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a **Wts** port on the block. For each iteration, the block outputs the current updated filter weights from this port.

## Parameters

### Filter length

Enter the length of the FIR filter weights vector.

### Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**.

### Specify step-size via

Select **Dialog** to enter a value for  $\mu$  in the Block parameters: LMS Filter dialog box. Select **Input port** to specify  $\mu$  using the Step-size input port.

### Step-size ( $\mu$ )

Enter the step-size. Tunable (Simulink).

**Leakage factor (0 to 1)**

Enter the leakage factor,  $0 < 1 - \mu\alpha \leq 1$ . Tunable (Simulink).

**Initial value of filter weights**

Specify the initial values of the FIR filter weights.

**Adapt port**

Select this check box to enable the Adapt input port.

**Reset port**

Select this check box to enable the Reset input port.

**Output filter weights**

Select this check box to export the filter weights from the Wts port.

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

## Buffer

Buffer input sequence to smaller or larger frame size

### Libraries:

DSP System Toolbox / Signal Management / Buffers

## Description

The Buffer block always performs frame-based processing. The block redistributes the data in each column of the input to produce an output with a different frame size. Buffering a signal to a larger frame size yields an output with a *slower* frame rate than the input. For example, consider this illustration for a scalar input.

Buffering a signal to a smaller frame size yields an output with a *faster* frame rate than the input. For example, consider this illustration of a scalar output.

The block coordinates the output *frame size* and *frame rate* of nonoverlapping buffers such that the sample period of the signal is the same at both the input and output:  $T_{so} = T_{si}$ .

This block supports triggered subsystems when the block input and output rates are the same.

## Ports

### Input

#### Port\_1 — Input signal

scalar | vector | matrix

To buffer single-channel signals, input a scalar or column vector. To buffer multichannel signals, input a row vector or matrix. To buffer single-channel signals, input a scalar or column vector of the size  $M_i$ -by-1, where  $M_i$  is the input frame size.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

## Output

**Port\_1** — Output signal  
vector | matrix

The buffered input signal returned as a vector or a matrix.

When the input is a single-channel signal:

- 1-by-1 (scalar) — Output is an  $M_o$ -by-1 vector.
- $M_i$ -by-1 (column vector) — Output is an  $M_o$ -by-1 vector.

where

- $M_i$  — Input frame size
- $M_o$  — Value of the **Output buffer size** parameter

The input frame period is  $M_i \cdot T_{si}$ , where  $T_{si}$  is the input sample period. The output frame period is  $(M_o - L)T_{si}$ , where  $L$  is the value of the **Buffer overlap** parameter and  $T_{si}$  is the input sample period. When you set the **Buffer overlap** parameter to  $M_o - 1$ , the output frame period equals the input sample period.

When the input is a multichannel signal:

- 1-by- $N$  — Output is an  $M_o$ -by- $N$  matrix.
- $M_i$ -by- $N$  — Output is an  $M_o$ -by- $N$  matrix.

where

- $N$  — Number of channels in the signal
- $M_i$  — Input frame period
- $M_o$  is the value of the **Output buffer size** parameter and can be greater or less than the input frame size,  $M_i$ . The block buffers each of the  $N$  input channels independently.

The input frame period is  $M_i \cdot T_{si}$ . The output frame period is  $(M_o - L)T_{si}$ , which equals the sequence sample period when the **Buffer overlap** is  $M_o - 1$ . Thus, the output sample period  $T_{so}$  is related to the input sample period  $T_{si}$  by

$$T_{so} = \frac{(M_o - L)T_{si}}{M_i}$$

The output has the same data type and complexity as the input

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

## Parameters

**Output buffer size (per channel)** — Buffer size  
64 (default) | positive integer

Specify the number of consecutive samples,  $M_o$ , from each channel to buffer into the output frame.

Data Types: double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Buffer overlap** — Buffer overlap

0 (default) | integer

Specify the number of samples,  $L$ , which specifies the amount of overlap or underlap in each successive output frame.

To overlap the data in the buffer, specify a value of  $L$  in the range  $0 \leq L < M_o$ , where  $M_o$  is the value of the **Output buffer size** parameter. The block takes  $L$  samples (rows) from the current output and repeats them in the next output. In cases of overlap, the block acquires  $M_o - L_{new}$  input samples before propagating the buffered data to the output.

When  $L < 0$ , you are buffering the signal with underlap. The block discards  $L$  input samples after the buffer fills and outputs the buffer with period  $(M_o - L)T_{si}$ , which is longer than in the zero-overlap case.

The output frame period is  $(M_o - L)T_{si}$ , which equals the input sequence sample period,  $T_{si}$ , when the **Buffer overlap** is  $M_o - 1$ .

Data Types: double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Initial conditions** — Initial output

0 (default) | scalar | vector | matrix

Specify the value of the block's initial output, in cases of nonzero latency, as a scalar, vector, or matrix.

For all cases of single-tasking operation (Simulink Coder) other than those listed in “Zero-Tasking Latency” on page 2-159, the Buffer block's buffer is initialized to the value(s) specified by the **Initial conditions** parameter. The block reads from this buffer to generate the first  $D$  output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the **Initial conditions** parameter depend on the **Buffer overlap**,  $L$ , and whether the input is single-channel or multichannel:

- When  $L \neq 0$ , the **Initial conditions** parameter must be a scalar.
- When  $L = 0$ , the **Initial conditions** parameter can be a scalar, or it can be a vector with either of these constraints:
  - For single-channel inputs, the **Initial conditions** parameter can be a vector of length  $M_o$  if  $M_i$  is 1, or a vector of length  $M_i$  if  $M_o$  is 1.
  - For multichannel inputs, the **Initial conditions** parameter can be a vector of length  $M_o * N$  if  $M_i$  is 1, or a vector of length  $M_i * N$  if  $M_o$  is 1.

For all multitasking operations (Simulink Coder), use the `rebuffer_delay` function to compute the exact delay in samples that the Buffer block introduces for a given combination of buffer size and buffer overlap.

For general buffering between arbitrary frame sizes, the **Initial conditions** parameter must be a scalar, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by- $N$  row vector, and the output of the block is an  $M_o$ -by- $N$  matrix, **Initial conditions** can be:

- An  $M_o$ -by- $N$  matrix
- A length- $M_o$  vector to be repeated across all columns of the initial output(s)
- A scalar to be repeated across all elements of the initial output(s)

In the special case where the output is a 1-by- $N$  row vector, which is the result of unbuffering an  $M_i$ -by- $N$  matrix, the **Initial conditions** can be:

- A vector containing  $M_i$  samples to output sequentially for each channel during the first  $M_i$  sample times
- A scalar to be repeated across all elements of the initial output(s)

For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

## More About

### Zero-Tasking Latency

*Zero-tasking latency* means that the first input sample, received at  $t = 0$ , appears as the first output sample. In the Simulink single-tasking mode (Simulink Coder), the Buffer block has zero-tasking latency for these special cases:

- Scalar input and output ( $M_o = M_i = 1$ ) with zero or negative **Buffer overlap** ( $L \leq 0$ )
- Input frame size is an integer multiple of the output frame size

$$M_i = kM_o$$

where  $k$  is an integer with zero **Buffer overlap** ( $L = 0$ ); notable cases of this include:

- Any input frame size  $M_i$  with scalar output ( $M_o = 1$ ) and zero **Buffer overlap** ( $L = 0$ )
- Equal input and output frame sizes ( $M_o = M_i$ ) with zero **Buffer overlap** ( $L = 0$ )

### Overflow and Underflow

The Buffer block cannot be used in an enabled subsystem under the following conditions:

- In a multirate, multitasking environment
- When the **Buffer overlap** parameter is set to a negative value

The Buffer block has an internal reservoir that temporarily stores data. When the Buffer block is used in an enabled subsystem, there is the possibility that the reservoir can overflow or underflow. The block implements safeguards against these occurrences.

Overflow occurs when more data enters the buffer than what it can hold. For example, consider buffering a scalar input to a frame of size three with a buffer that accepts an input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled every three seconds at  $t = 3s$ ,  $t = 6s$ , and so on, the buffer accumulates data in its internal reservoir without being able to empty it. This condition results in an overflow.

Underflow occurs when the buffer runs out of data to output. For example, again consider buffering a scalar input to a frame size of three with a buffer that accepts an input every second and outputs every three seconds. If you place this buffer inside an enabled subsystem that is disabled at  $t = 10s$ ,  $t = 11s$ ,  $t = 13s$ ,  $t = 14s$ ,  $t = 16s$ , and  $t = 17s$ , its internal reservoir becomes drained, and there is no data to output at  $t = 18s$ . This condition results in an underflow.

To protect from an overflow or an underflow, the Buffer block keeps a record of the amount of data in its internal reservoir. When the Buffer block reads data, the amount of data in its reservoir goes up. When the Buffer block outputs the data, the amount of data in its reservoir goes down. To protect from overflow, the oldest samples in the reservoir are discarded whenever the amount of data in the reservoir is larger than the actual buffer size. To protect from underflow, the most recent samples are repeated whenever an output is due and there is no data in the reservoir.

## Version History

Introduced before R2006a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Buffer block supports code generation for Simulink Real-Time™. The code generated for this target is executed concurrently. To generate this code, set the system target file of the model to `slrealtime.tlc`. The Buffer block also needs to satisfy certain conditions.

To set the system target file:

- 1 In the Simulink model window, in the **Modeling** tab, click **Model Settings**.
- 2 In the Model Settings > **Code Generation** pane, set the **System target file** to `slrealtime.tlc`.

In addition, the Buffer block must satisfy the following conditions:

- Ratio between output and input buffer size must be a pure integer, that is  $1/N$  or  $N/1$ . Ratios such as  $3/12$ ,  $1/7$ ,  $7/1$ , or  $2/4$  are all valid ratios. In the Buffer block, you can specify the appropriate output buffer size using the **Output buffer size (per channel)** parameter.
- There should be no overlap between frames. In the Buffer block, set the **Buffer overlap** parameter to 0.

## Burg AR Estimator

Compute estimate of autoregressive (AR) model parameters using Burg method

### Libraries:

DSP System Toolbox / Estimation / Parametric Estimation

## Description

The Burg AR Estimator block uses the Burg method to fit an autoregressive (AR) model to the input data by minimizing (least squares) the forward and backward prediction errors while constraining the AR parameters to satisfy the Levinson-Durbin recursion.

## Ports

### Input

#### Input — Input

column vector | unoriented vector

Specify the input data as a column vector or an unoriented vector. The block assumes that the input data is the output of an AR system driven by white noise and represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

### Output

#### A — Normalized estimate of the AR model polynomial coefficients

column vector

Normalized estimate of the AR model polynomial coefficients  $A(z)$ , returned as a column vector of length  $p+1$  in descending powers of  $z$ .

The block computes the estimate of these coefficients independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

### Dependency

To enable this port, set the **Output(s)** parameter to A or A and K.

Data Types: `single` | `double`

**K** — Reflection coefficients  
column vector

Reflection coefficients (which are a secondary result of the Levinson recursion), returned as a column vector of length  $p$ .

#### Dependency

To enable this port, set the **Output(s)** parameter to K or A and K.

Data Types: single | double

**G** — Model gain  
scalar

Gain of the estimated AR model, returned as a scalar.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: single | double

## Parameters

**Output(s)** — Output

A (default) | A and K | K

Specify whether the block outputs model coefficients (A), reflection coefficients (K), or both (A and K).

**Inherit estimation order from input dimensions** — Inherit estimation order from input dimensions

on (default) | off

When you select the **Inherit estimation order from input dimensions** parameter, the block sets the order  $p$  of the all-pole model to a value that is one less than the length of the input vector. Otherwise, the order is the value you specify in the **Estimation order** parameter.

**Estimation order** — Order of AR model

4 (default) | nonnegative integer

Specify the order of the AR model  $p$  as a nonnegative integer.

#### Dependency

To enable this parameter, clear the **Inherit estimation order from input dimensions** parameter.

## Block Characteristics

|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | No              |

## More About

### AR(p) Model

In an AR model of order  $p$ , the current output is a linear combination of the past  $p$  outputs plus a white noise input.

The weights on the  $p$  past outputs minimize the mean squared prediction error of the autoregression. If  $y(n)$  is the current value of the output and  $x(n)$  is a zero-mean white noise input, the AR( $p$ ) model is:

$$y(n) + \sum_{k=1}^p a(k)y(n-k) = x(n).$$

### Reflection Coefficients

The reflection coefficients are the partial autocorrelation coefficients scaled by -1. The reflection coefficients indicate the time dependence between  $y(n)$  and  $y(n-k)$  after subtracting the prediction based on the intervening  $k-1$  time steps.

### Compare AR Model Parameter Estimation Methods

This table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and the Yule-Walker AR Estimator blocks.

The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

|                        | <b>Burg AR Estimator</b>   | <b>Covariance AR Estimator</b>                                    | <b>Modified Covariance AR Estimator</b>   | <b>Yule-Walker AR Estimator</b>  |
|------------------------|--|---|---|--|
| <b>Characteristics</b> | Does not apply window to data  | Does not apply window to data                                     | Does not apply window to data   | Applies window to data   |
|                        | Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion | Minimizes the forward prediction error in the least squares sense | Minimizes the forward and backward prediction errors in the least squares sense | Minimizes the forward prediction error in the least squares sense (also called "autocorrelation method") |
| <b>Advantages</b>      | Always produces a stable model   |   |   | Always produces a stable model   |

|                                      | <b>Burg AR Estimator</b> | <b>Covariance AR Estimator</b>                               | <b>Modified Covariance AR Estimator</b>                      | <b>Yule-Walker AR Estimator</b>  |
|--------------------------------------|--------------------------|--|--|--|
| <b>Disadvantages</b>                 |                          | Can produce unstable models                                  | Can produce unstable models                                  | Performs relatively poorly for short data records  |
| <b>Conditions for Nonsingularity</b> |                          | Order must be less than or equal to 1/2 the input frame size | Order must be less than or equal to 2/3 the input frame size | Because of the biased estimate, the autocorrelation matrix is guaranteed to positive-definite, hence nonsingular |

## Algorithms

Burg's method estimates the reflection coefficients and uses the reflection coefficients to estimate the AR parameters recursively. You can find the recursion and lattice filter relations describing the update of the forward and backward prediction errors in [1].

## Burg Method

Power spectral density estimate using Burg method

### Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

## Description

The Burg Method block estimates the power spectral density (PSD) of the input frame using the Burg method. This method fits an autoregressive (AR) model to the signal by minimizing (least squares) the forward and backward prediction errors. The block minimizes the errors by constraining the AR parameters to satisfy the Levinson-Durbin recursion.

The block computes the spectrum from the FFT of the estimated AR model parameters.

## Ports

### Input

#### Input — Input

column vector | unoriented vector

Specify the input as a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

### Output

#### Output — Power spectral density estimate

column vector

Power spectral density estimate of the signal at  $N_{fft}$  equally spaced frequency points, returned as a column vector. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling rate of the signal.

Data Types: `single` | `double`

## Parameters

**Inherit estimation order from input dimensions** — Inherit estimation order from input dimensions

`off` (default) | `on`

When you select the **Inherit estimation order from input dimensions** parameter, the order of the all-pole model (estimation order) is one less than the input frame size. Otherwise, the **Estimation order** parameter determines the model order. The block computes the spectrum from the FFT of the estimated AR model parameters.

**Estimation order** — Order of AR model

6 (default) | nonnegative integer

Specify the estimation order of the AR model as a nonnegative integer.

**Dependencies**

To enable this parameter, clear the **Inherit estimation order from input dimensions** parameter.

**Inherit FFT length from estimation order** — Inherit FFT length from estimation order

off (default) | on

When you select this parameter, the FFT length  $N_{fft}$  is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** parameter. You can then specify the FFT length as a power of 2 using the **FFT length** parameter. The block zero-pads or wraps the input to  $N_{fft}$  before computing the FFT.

**FFT length** — FFT length

256 (default) | positive integer greater than or equal to 2

Enter the number of data points  $N_{fft}$  on which to perform the FFT as a positive integer greater than or equal to 2. When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

**Dependencies**

To enable this parameter, clear the **Inherit FFT length from input dimensions** parameter.

**Inherit sample time from input** — Inherit sample time from input

on (default) | off

When you select the **Inherit sample time from input** parameter, the block computes the frequency data from the sample period of the input signal. For the block to produce a valid output, the following conditions must hold:

- The input to the block is an original signal with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** parameter. You can then specify a sample time using the **Sample time of original time series** parameter.

**Sample time of original time series** — Sample time of original time-domain signal

1 (default) | positive scalar

Specify the sample time of the original time-domain signal as a positive scalar.

**Dependencies**

To enable this parameter, clear the **Inherit sample time from input** parameter.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the FFT length is not a power of 2, the executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of 2, you can generate standalone C and C++ code from this block.

# Channelizer

Polyphase FFT analysis filter bank

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Channelizer block separates a broadband input signal into multiple narrow subbands using an FFT-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block accepts variable-size inputs, so you can change the size of each input channel during simulation. However, the number of channels cannot change.

## Input/Output Ports

### Input

**x** — Broadband signal

*L*-by-1 column vector | *L*-by-*N* matrix

Specify the input broadband signal that the channelizer splits into multiple narrow bands.

- When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor.
- When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This port is unnamed until you set **Polyphase filter specification** to **Coefficients** and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

**coeffs** — Prototype lowpass filter coefficients

row vector

Coefficients of the prototype lowpass filter. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s, F_s]$ .

### Dependencies

This port appears when you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

### Output

**Port 1** — Multiple narrowband signals

$L/M$ -by- $M$  |  $L/M$ -by- $M$ -by- $N$  array

Multiple narrow subbands of the input broadband signal. Each narrow band signal forms a column in the output.

The dimensions of the output signal depend on the dimensions of the input signal and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

#### Fixed-Size Input Signal

| Input Signal  | Output Signal Dimensions   |
|---|--|
| $L$ -by-1 column vector, where $L$ is a multiple of $M$     | $(L/M)$ -by- $M$   |
| $L$ -by-1 column vector, where $L$ is not a multiple of $M$ | $\text{ceil}(L/M)$ -by- $M$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.          |
| $L$ -by- $N$ matrix, where $L$ is a multiple of $M$         | $(L/M)$ -by- $M$ -by- $N$  |
| $L$ -by- $N$ matrix, where $L$ is not a multiple of $M$     | $\text{ceil}(L/M)$ -by- $M$ -by- $N$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

This table provides more details on the dimensions of the output signal when you input a variable-size input signal.

## Variable-Size Input Signal

| Input Signal  | Output Signal Dimensions   |
|---|--|
| $L$ -by-1 column vector, where $L$ is a multiple of $M$     | $(L/M)$ -by- $M$   |
| $L$ -by-1 column vector, where $L$ is not a multiple of $M$ | $\text{ceil}(L/M)$ -by- $M$<br><b>Allow arbitrary frame length for fixed-size input signals</b> parameter setting is ignored.          |
| $L$ -by- $N$ matrix, where $L$ is a multiple of $M$         | $(L/M)$ -by- $M$ -by- $N$  |
| $L$ -by- $N$ matrix, where $L$ is not a multiple of $M$     | $\text{ceil}(L/M)$ -by- $M$ -by- $N$<br><b>Allow arbitrary frame length for fixed-size input signals</b> parameter setting is ignored. |

Data Types: single | double

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Number of frequency bands** — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands  $M$  into which the block separates the input broadband signal. This parameter indicates the FFT length and the decimation factor used by the algorithm.

**Polyphase filter specification** — Filter design parameters or coefficients

Number of taps per band and stopband attenuation (default) | Coefficients

- **Number of taps per band and stopband attenuation** — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- **Coefficients** — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter or input them through the **coeffs** port.

**DecimationFactor** — Decimation factor

8 (default) | positive integer

Decimation factor  $D$  specified as a positive integer less than or equal to the number of frequency bands  $M$ .

If the decimation factor  $D$  equals the number of frequency bands  $M$ , then the  $M/D$  ratio equals 1, and the channelizer is known as the maximally decimated channelizer.

If the  $M/D$  ratio is greater than 1, the output sample rate is different from the channel spacing, and the channelizer is known as the non-maximally decimated channelizer. If the ratio is an integer, the channelizer is known as the integer-oversampled channelizer. If the ratio is not an integer, say  $4/3$ ,

the channelizer is known as the rationally oversampled channelizer. For more details, see “Algorithm” on page 4-200.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Number of filter taps per frequency band** — Number of filter coefficients per frequency band  
12 (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by **Number of frequency bands** × **Number of filter taps per frequency band**. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

#### Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

**Stopband attenuation (dB)** — Stopband attenuation  
80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. As the stopband attenuation increases, the passband ripple decreases.

#### Dependencies

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

**Specify coefficients from input port** — Flag to specify lowpass filter coefficients  
off (default) | on

When you select this parameter, the lowpass filter coefficients are input through the **coeffs** port. When you clear this parameter, the coefficients are specified on the block dialog through the **Prototype lowpass filter coefficients** parameter.

#### Dependencies

To enable this parameter, set **Polyphase filter specification** to Coefficients.

**Prototype lowpass filter coefficients** — Coefficients of prototype lowpass filter  
`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

Coefficients of the prototype lowpass filter. The default value is the coefficients vector that `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s, F_s]$ .

**Tunable:** Yes

### Dependencies

To enable this parameter, set **Polyphase filter specification** to `Coefficients` and clear the **Specify coefficients from input port** parameter.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Block Characteristics

## More About

### Analysis Filter Bank

The generic analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal,  $x[n]$ , into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

### Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter.

The prototype lowpass filter has an impulse response of  $h[n]$ , a normalized two-sided bandwidth of  $2\pi/M$ , and a cutoff frequency of  $\pi/M$ .  $M$  is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses.  $M$  can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter corresponds to  $H_0(z)$  in the filter bank. The first branch of the filter bank contains  $H_0(z)$  followed by the decimator. The other  $M - 1$  branches contain filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k/M, \quad k = 0, 1, \dots, M - 1$$

### Using the Prototype Lowpass Filter

The transfer function of the modulated  $k$ th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of  $M$  filters.

To obtain the frequency response characteristics of the filter  $H_k(z)$ , where  $k = 1, \dots, M-1$ , uniformly shift the frequency response of the prototype filter,  $H_0(z)$ , by multiples of  $2\pi/M$ . Each subband filter,  $H_k(z)$ ,  $\{k = 1, \dots, M-1\}$ , is derived from the prototype filter.

Following is an equivalent representation of the frequency response diagram with  $\omega$  ranging from  $[-\pi, \pi]$ .

### Shift Narrow Subbands to Baseband

The frequency components in the input signal,  $x[n]$ , are translated in frequency to baseband by multiplying  $x[n]$  with the complex exponentials,  $e^{-jw_k n}$ ,  $w_k = 2\pi k/M$ ,  $k = 1, 2, \dots, M-1$ , where  $w_k = 2\pi k/M$ , and  $k = 1, 2, \dots, M-1$ . The resulting product signals are passed through the lowpass filters,  $H_0(z)$ . The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor,  $D \leq M$ , where  $M$  is the number of branches of the analysis filter bank. When  $D < M$ , the channelizer is known as oversampled or non-maximally decimated channelizer.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

Conceptual Diagram

$y_1[m], y_2[m], \dots, y_{M-1}[m]$  are narrow subband signals translated into baseband.

## Algorithms

### Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. For more details on the analysis filter bank, see Analysis Filter Bank on page 2-176.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N + 1$  is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H_0(z) = & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\
 & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\
 & \vdots \\
 & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)})
 \end{aligned}$$

$M$  is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$  are polyphase components of the prototype lowpass filter  $H_0(z)$ .

The other filters in the filter bank,  $H_k(z)$ , where  $k = 1, \dots, M-1$ , are modulated versions of this prototype filter.

You can write the transfer function of the  $k^{\text{th}}$  modulated bandpass filter as  $H_k(z) = H_0(ze^{-jw_k})$ .

Replacing  $z$  with  $ze^{jw_k}$ ,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N + 1$  is the length of the  $k^{\text{th}}$  filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all  $M$  channels in the filter bank, the transfer function  $H(z)$  is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

**Maximally decimated channelizer**

When  $D = M$ , the channelizer is known as the maximally decimated channelizer or critically sampled channelizer.

Here is the multirate noble identity for decimation, assuming that  $D = M$ .

For example, consider the first branch of the filter bank that contains the lowpass filter.

Replace  $H_0(z)$  with its polyphase representation on page 2-178.

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in the following diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

For all  $M$  channels in the filter bank, the transfer function  $H(z)$  is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches  $M-1, M-2$ , all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs  $y_0[m], y_1[m], \dots, y_{M-1}[m]$ . Each branch in the channelizer effectively outputs one sample for every  $M$  samples it receives. Hence, the sample rate at the output of the channelizer is  $f_s/M$ .

### Non-maximally decimated or oversampled channelizer

When  $D < M$ , the channelizer is known as the non-maximally decimated channelizer or oversampled channelizer. In this configuration, the output sample rate is different from the channel spacing. The non-maximally decimated channelizers offer increased design freedom, but at the expense of increasing computational cost.

If the ratio  $M/D$  equals an integer that is greater than 1 and is less than or equal to  $M-1$ , the channelizer is known as integer-oversampled channelizer. If the ratio  $M/D$  is not an integer, then the channelizer is known as rationally-oversampled channelizer.

In this configuration, when the first input sample is delivered, the switch feeds this input to branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches  $D-1, D-2$ , all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs  $y_0[m], y_1[m], \dots, y_{M-1}[m]$ .

As more data keeps coming in and the switch feeds these samples to the first  $D$  addresses, the formal contents of these addresses are shifted to the next set of  $D$  addresses, and this process of data shift continues every time there is a new set of  $D$  input samples.

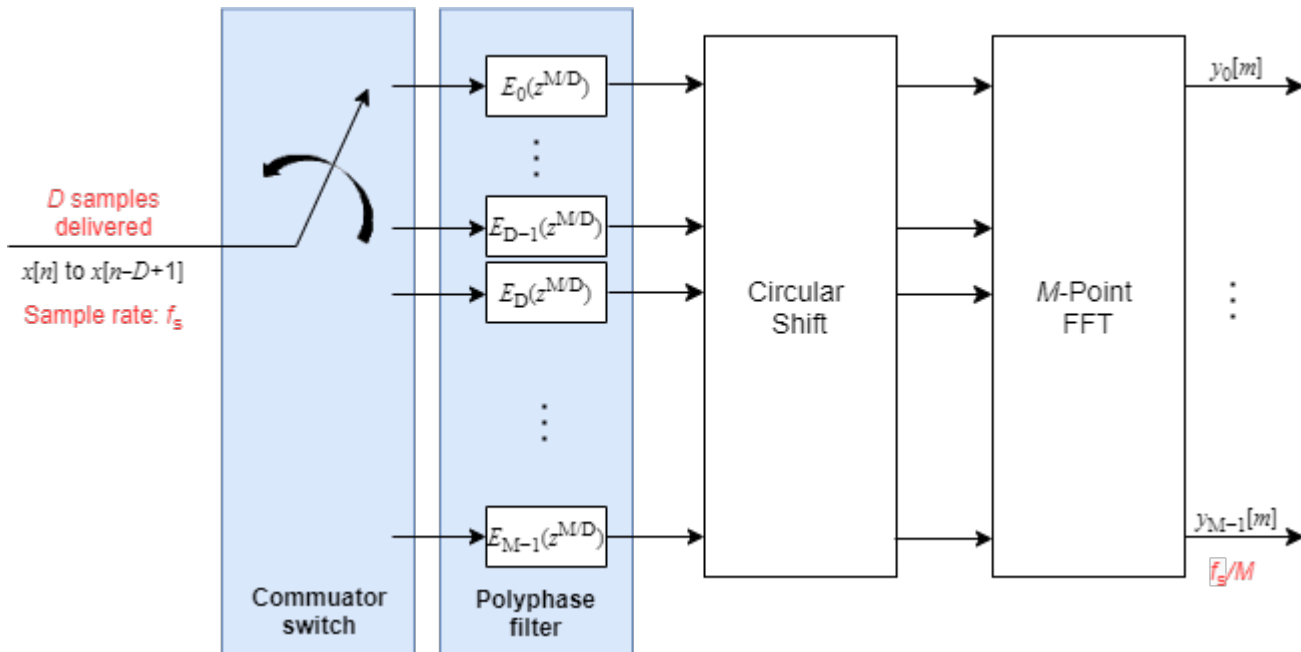

For every  $D$  input samples that are fed to the polyphase structure, the channelizer outputs  $M$  samples,  $y_0[m], y_1[m], \dots, y_{M-1}[m]$ . This process increases the output sample rate from  $f_s/M$  in the case of a maximally decimated channelizer, to  $f_s/D$  in the case of a non-maximally decimated channelizer.

For more details, see [2].

After each  $D$ -point data sequence is delivered to the partitioned  $M$ -stage polyphase filter, the outputs of the  $M$  stages are computed and conditioned for delivery to the  $M$ -point FFT. The data shifting

through the filter introduces frequency-dependent phase shift. To correct for this phase shift and alias all bands to DC, a circular shift buffer is inserted after the polyphase filters and before the  $M$ -point FFT.

With the commutator switch followed by  $M$ -stage polyphase filter, circular shift buffer, and a DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

## Version History

Introduced in R2017a

### R2022b: Support for arbitrary input frame length

Channelizer block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

The frame length is arbitrary when it is not a multiple of the decimation factor.

# Channel Synthesizer

Polyphase FFT synthesis filter bank

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Channel Synthesizer block merges multiple narrowband signals into a broadband signal by using an FFT-based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.

This block also accepts variable-size inputs. That is, during the simulation, you can change the size of each input channel. The number of channels cannot change.

## Input/Output Ports

### Input

**x** — Input narrowband signals  
*L*-by-*M* matrix | *L*-by-*M*-by-*N* array

Input narrowband signals, which the channel synthesizer merges to form the broadband signal. Each narrowband signal forms a column in the input signal. The number of columns in the input correspond to the number of frequency bands of the filter bank. If the input is three-dimensional, each matrix corresponds to a separate channel.

This port is unnamed until you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

**coeffs** — Prototype lowpass filter coefficients  
 row vector

Coefficients of the prototype lowpass filter. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s, F_s]$ .

### Dependencies

This port appears when you set **Polyphase filter specification** to `Coefficients` and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

### Output

**Port\_1** — Broadband signal

$L \times M$ -by-1 vector |  $L \times M$ -by- $N$  matrix

Broadband signal the channel synthesizer forms from the multiple input narrow subbands.

If the input is one of the following:

- $L$ -by- $M$  matrix — The output is a  $L \times M$ -by-1 vector.  $M$  is the number of frequency bands.
- $L$ -by- $M$ -by- $N$  matrix — The output is a  $L \times M$ -by- $N$  matrix.

Data Types: `single` | `double`

### Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Polyphase filter specification** — Filter design parameters or coefficients

Number of taps per band and stopband attenuation (default) | `Coefficients`

- Number of taps per band and stopband attenuation — Specify the filter design parameters through the **Number of filter taps per frequency band** and **Stopband attenuation (dB)** parameters. When you specify the design parameters, the filter is designed using the `designMultirateFIR` function.
- `Coefficients` — Specify the filter coefficients directly using the **Prototype lowpass filter coefficients** parameter or input them through the **coeffs** port.

**Number of filter taps per frequency band** — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients that each polyphase branch uses. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by the product of the number of frequency bands and the number of filter taps per frequency band. The number of frequency bands equals the number of columns in the input. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band, at the expense of increased computation.

### Dependencies

To enable this parameter, set **Polyphase filter specification** to `Number of taps per band and stopband attenuation`.

**Stopband attenuation (dB)** — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, in dB. This value controls the maximum amount of aliasing from one frequency band to the next. As the stopband attenuation increases, the passband ripple decreases.

**Dependencies**

To enable this parameter, set **Polyphase filter specification** to Number of taps per band and stopband attenuation.

**Specify coefficients from input port** — Flag to specify lowpass filter coefficients  
off (default) | on

When you select this check box, the lowpass filter coefficients are input through the **coeffs** port. When you clear this check box, the coefficients are specified on the block dialog through the **Prototype lowpass filter coefficients** parameter.

**Dependencies**

To enable this parameter, set **Polyspace filter specification** to Coefficients.

**Prototype lowpass filter coefficients** — Coefficients of prototype lowpass filter  
`rcosdesign(0.25,6,8,'sqrt')` (default) | row vector

This parameter specifies the coefficients of the prototype lowpass filter. The default value is the coefficients vector that `rcosdesign(0.25,6,8,'sqrt')` returns. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the block zero-pads the coefficients.

If you specify complex coefficients, the block designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s, F_s]$ .

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Polyphase filter specification** to Coefficients and clear the **Specify coefficients from input port** parameter.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

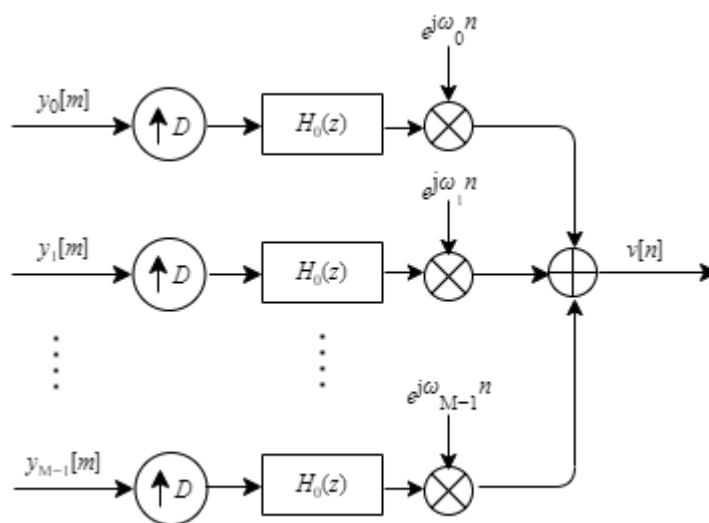

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## More About

### Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals,  $y_0[m]$ ,  $y_1[m]$ , ...,  $y_{M-1}[m]$  into a single broadband signal,  $v[n]$ . The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around  $w_k$ .

Conceptual Diagram

### Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of  $h[n]$ , a normalized two-sided bandwidth of  $2\pi/M$ , and a cutoff frequency of  $\pi/M$ .  $M$  is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses.  $M$  can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other  $M - 1$  branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by  $e^{jw_k n}$ ,  $w_k = 2\pi k/M$ ,  $k = 0, 1, \dots, M - 1$ .

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal,  $v[n]$ .

## Algorithms

### Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N + 1$  is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\ & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)}) \end{aligned}$$

$M$  is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$  are polyphase components of the prototype lowpass filter,  $H_0(z)$ .

The other filters in the filter bank,  $H_k(z)$ , where  $k = 1, \dots, M - 1$ , are modulated versions of this prototype filter.

You can write the transfer function of the  $k$ th modulated bandpass filter as  $H_k(z) = H_0(ze^{jw_k})$ .

Replacing  $z$  with  $ze^{jw_k}$ ,

$$H_k(z) = h_0 + h_1e^{jw_k}z^{-1} + h_2e^{j2w_k}z^{-2} \dots + h_Ne^{jNw_k}z^{-N}$$

$N + 1$  is the length of the  $k$ th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

For all  $M$  channels in the filter bank, the MIMO transfer function,  $H(z)$ , is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ \vdots & & & & \\ 1 & e^{jw_M-1} & e^{j2w_M-1} & \dots & e^{j(M-1)w_M-1} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that  $D = M$ :

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace  $H_0(z)$  with its polyphase representation.

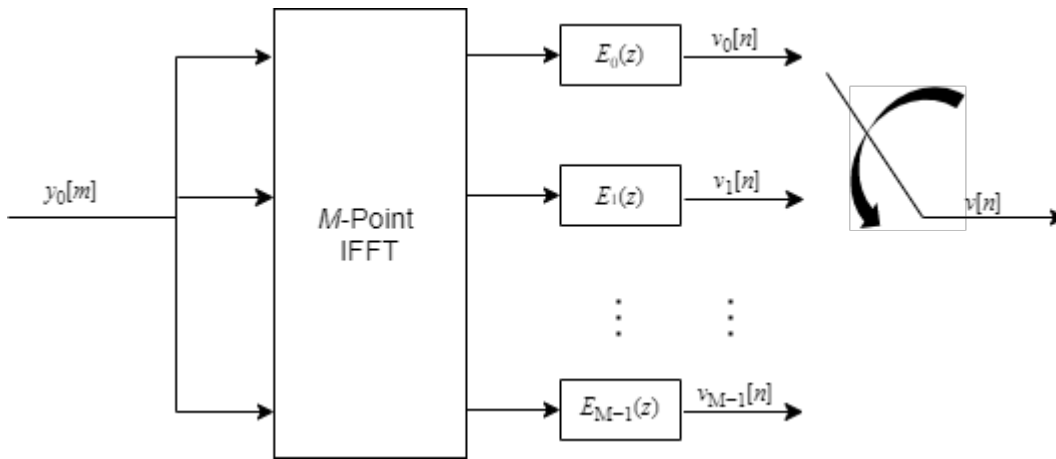

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the  $M$  channels in the filter bank, the MIMO transfer function,  $H(z)$ , is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

## Check Signal Attributes

Error when input signal does or does not match selected attributes exactly

### Libraries:

DSP System Toolbox / Signal Management / Signal Attributes

### Description

The Check Signal Attributes block terminates the simulation with an error when the input characteristics differ from the characteristics you specify in the block parameters.

The Check Signal Attributes block can test for up to five different signal attributes. When you select **Ignore** for any parameter, the block does not check the signal for the corresponding attribute. For example, when you set **Complexity** to **Ignore**, neither real nor complex inputs cause the block to generate an error.

### Ports

#### Input

**Input** — Input signal

scalar | vector | matrix | N-D array

Input signal to be checked, specified as a scalar, vector, matrix, or N-D array. The input can be any real- or complex-valued signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

#### Output

**Output** — Output signal

scalar | vector | matrix | N-D array

Output signal, returned as a scalar, vector, matrix, or N-D array, with the same values as the input signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

### Parameters

**Error when input** — Generate error when input

Does not match attributes exactly (default) | Matches attributes exactly

Specify whether the block generates an error when the input *does* or *does not* possess *all* of the required attributes.

When you set this parameter to **Does not match attributes exactly**, the block generates an error when the input fails to match *any* of the specified attributes. Only signals that possess *all* of the specified attributes propagate to the output unaltered and do not cause the block to generate an error.

When you set this parameter to **Matches attributes exactly**, the block generates an error only when the input possesses *all* specified attributes. Signals that do not possess *all* of the specified attributes propagate to the output unaltered, and do not cause the block to generate an error.

### **Complexity** — Specify complexity

Ignore (default) | Real | Complex

Specify the complexity for which you want to check the input as **Real** or **Complex**. You can display this information in a model by attaching a Probe block with **Probe complex signal** selected. Alternatively, in the **Debug** tab, select **Information Overlays > Port Data Type**.

When you set this parameter to **Ignore**, the block does not check the complexity of the input.

### **Dimensionality** — Dimensionality check

Ignore (default) | Is... | Is not...

Specify whether you want to check the input for compliance or noncompliance with the attributes in the subordinate **Dimensions** parameter. When you set this parameter to **Ignore**, the block does not check the dimensionality of the input.

### **Dimensions** — Specify dimensions

1-D (default) | 2-D | Scalar (1-D or 2-D) | Vector (1-D or 2-D) | Vector (1-D or 2-D) or scalar | Row vector (2-D) | Row vector (2-D) or scalar | Column vector (2-D) | Column vector (2-D) or scalar | Full matrix (2-D) | Square matrix (2-D)

Specify the dimensions for which you want to check the input.

Check the dimensionality of the input for compliance or noncompliance with the attributes in this parameter. See the following table.  $M$  and  $N$  are positive integers unless otherwise indicated.

| <b>Dimensions</b>      | <b>Is...</b>  | <b>Is not...</b>  |
|------------------------|---|---|
| 1-D                    | 1-D vector,<br>1-D scalar   | $M$ -by- $N$ matrix,<br>1-by- $N$ matrix (row vector),<br>$M$ -by-1 matrix (column vector),<br>1-by-1 matrix (2-D scalar) |
| 2-D                    | $M$ -by- $N$ matrix,<br>1-by- $N$ matrix (row vector),<br>$M$ -by-1 matrix (column vector),<br>1-by-1 matrix (2-D scalar) | 1-D vector,<br>1-D scalar   |
| Scalar<br>(1-D or 2-D) | 1-D scalar,<br>1-by-1 matrix (2-D scalar)   | 1-D vector with length > 1,<br>$M$ -by- $N$ matrix with $M > 1$ and/or $N > 1$  |

| Column Vector<br>(2-D) | $M$ -by-1 matrix (column vector), 1-by-1<br>matrix (2-D scalar)<br>Column vector (2-D) or scalar   | 1-D vector,<br>1-D scalar,<br>$M$ -by- $N$ matrix with $N > 1$  |
| Full matrix            | $M$ -by- $N$ matrix with $M > 1$ and $N > 1$   | 1-D vector,<br>1-D scalar,<br>1-by- $N$ matrix (row vector),<br>$M$ -by-1 matrix (column vector),<br>1-by-1 matrix (2-D scalar) |
| Square matrix          | $M$ -by- $N$ matrix with $M = N$ ,<br>1-D scalar,<br>1-by-1 matrix (2-D scalar)  | $M$ -by- $N$ matrix with $M \neq N$ ,<br>1-D vector,<br>1-by- $N$ matrix (row vector),<br>$M$ -by-1 matrix (column vector)      |

In the **Debug** tab, when you select **Information Overlays > Signal Dimensions**, Simulink displays the size of a 1-D vector signal as an unbracketed integer, and displays the dimension of a 2-D signal as a pair of bracketed integers, [MxN]. Simulink *does not display* any size information for a 1-D or 2-D scalar signal. You can also display dimension information for a signal in a model by attaching a Probe block with **Probe signal dimensions** selected.

### Dependencies

To enable this parameter, set **Dimensionality** to **Is...** or **Is not...**

### Data type — Data type check

Ignore (default) | **Is...** | **Is not...**

Specify whether you want to check the input for compliance **Is...** or noncompliance **Is not...** with the attributes in the subordinate **General data type** parameter. When you set this parameter to **Ignore**, the block does not check the input data type.

See the following table. You can individually select any of the specific data types listed in the (**Is...**) column from the subordinate **Specific data type** parameter.

| General Data Type | Is...   | Is not...  |
|-------------------|---------|--|
| Boolean           | boolean | single, double, uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated |

| General Data Type         | Is...   | Is not...   |
|---------------------------|---|---|
| Enumerated                | A user-defined enumerated data type. See "Data Types" (Simulink) .                | boolean, single, double, uint8, int8, uint16, int16, uint32, int32, fixed point |
| Floating point            | single, double  | boolean, uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated     |
| Floating point or Boolean | single, double, boolean   | uint8, int8, uint16, int16, uint32, int32, fixed point, enumerated              |
| Fixed point               | fixed point, uint8, int8, uint16, int16, uint32, int32                            | boolean, single, double, enumerated   |
| Integer                   | Signed integer<br>int8, int16, int32<br>Unsigned integer<br>uint8, uint16, uint32 | boolean, single, double, fixed point, enumerated                                |

To display data type information, in the **Debug** tab, select **Information Overlays > Port Data Type**.

#### General data type — General data type check

Boolean (default) | Enumerated | Floating-point | Floating-point or boolean | Fixed-point | Integer

Specify the general data type for which you want to check the input.

#### Dependencies

To enable this parameter, set **Data type** to **Is...** or **Is not...**

#### Specific floating-point — Specific floating-point check

Any floating-point (default) | Double precision | Single precision

Specify the floating-point data type for which you want to check the input.

#### Dependencies

To enable this parameter, set **General data type** to **Floating-point** or **Floating-point or boolean**.

#### Specific fixed-point — Specific fixed-point check

Any fixed-point (default) | Signed fixed-point | Unsigned fixed-point

Specify the fixed-point data type for which you want to check the input.

#### Dependencies

To enable this parameter, set **General data type** to **Fixed-point**.

**Specific integer** — Specific integer check

Any integer (default) | Signed integer | Unsigned integer | int8 | int16 | int32 | uint8 | uint16 | uint32

Specify the integer data type for which you want to check the input.

**Dependencies**

To enable this parameter, set **General data type** to Integer.

**Sample time** — Sample time check

Ignore (default) | Discrete | Continuous

Specify the sample time for which you want to check the input as **Discrete** or **Continuous**. When you set this parameter to **Ignore**, the block does not check the sample time of the input.

The block checks whether the signal is discrete time or continuous time. In the **Debug** tab, when you select **Information Overlays > Colors**, Simulink displays continuous-time signal lines in black or grey and discrete-time signal lines in colors corresponding to the relative rate.

When you attach a Probe block with **Probe sample time** enabled to a continuous-time signal, the block icon displays  $T_s: [0 \ T_o]$ , where  $T_o$  is the sample time offset. Valid values of  $T_o$  for continuous-time signals are 0 and 1. When  $T_o$  is 0, updates occur at every major and minor time step. When  $T_o$  is 1, updates occur only at major time steps and the sample time is *fixed in minor time step*.

When you attach a Probe block with **Probe sample time** enabled to a discrete-time signal, the block icon displays  $T_s: [T_s \ T_o]$  for sample-based signals, and  $T_f: [T_f \ T_o]$  for frame-based signals.  $T_s$  and  $T_f$  are the positive sample period and frame period, respectively.  $T_o$  is the offset, such that  $0 \leq \text{offset} < \text{period}$ . Frame-based signals are almost always discrete time.

**Block Characteristics**

|                                 |  |
|---------------------------------|--|
| <b>Data Types</b>               | Boolean   double   enumerated   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no   |
| <b>Multidimensional Signals</b> | no   |
| <b>Variable-Size Signals</b>    | yes  |
| <b>Zero-Crossing Detection</b>  | no   |

# Chirp

Generate swept-frequency cosine (chirp) signal

**Libraries:**  
DSP System Toolbox / Sources

## Description

The Chirp block outputs a swept-frequency cosine (chirp) signal with unity amplitude and continuous phase. To specify the desired output chirp signal, you must define its instantaneous frequency function, also known as the output frequency sweep. The frequency sweep can be linear, quadratic, or logarithmic, and repeats once every **Sweep time** by default. For a description of the algorithms used by the Chirp block, see “Algorithms” on page 2-202.

## Ports

### Output

**Port\_1** — Swept-frequency cosine (chirp) signal  
scalar | vector

Swept-frequency cosine (chirp) signal. In **Linear**, **Logarithmic**, and **Quadratic** modes (set by the **Frequency sweep** parameter), the block outputs a swept-frequency cosine with instantaneous frequency values specified by the frequency and time parameters. In **Swept cosine** mode, the block outputs a swept-frequency cosine with a linear instantaneous output frequency that may differ from the one specified by the frequency and time parameters.

For more information about how the block computes the output, see “Algorithms” on page 2-202.

Data Types: `single` | `double`

## Parameters

**Frequency sweep** — Type of frequency sweep

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

The type of output instantaneous frequency sweep,  $f_i(t)$ : **Linear**, **Logarithmic**, **Quadratic**, or **Swept cosine**. For more information, see “Shaping the Frequency Sweep” on page 2-201 and “Algorithms” on page 2-202.

### Limitations

When you want a linearly swept chirp signal, we recommend that you use a **Linear** frequency sweep. Though a **Swept cosine** frequency sweep also yields a linearly swept chirp signal, the output might have unexpected frequency content.

- The swept cosine sweep value at the **Target time** is not necessarily the **Target frequency**. This is because the user-specified sweep is not the actual frequency sweep of the swept cosine output, as

noted in “Output Computation Method for Swept Cosine Frequency Sweep” on page 2-204. See the table Instantaneous Frequency Sweep Values for the actual value of the swept cosine sweep at the **Target time**.

- In **Swept cosine** mode, do not set the parameters so that  $1/T_{sw}$  is much greater than the values of the **Initial frequency** and **Target frequency** parameters. In such cases, the actual frequency content of the swept cosine sweep might be closer to  $1/T_{sw}$ , far exceeding the **Initial frequency** and **Target frequency** parameter values.

**Sweep mode** — Sweep mode

Unidirectional (default) | Bidirectional

The **Sweep mode** parameter determines whether your sweep is unidirectional or bidirectional, which affects the shape of your output frequency sweep (see “Shaping the Frequency Sweep” on page 2-201). The following table describes the characteristics of unidirectional and bidirectional sweeps.

| Sweep Mode Parameter Settings | Sweep Characteristics  |
|-------------------------------|--|
| Unidirectional                | <ul style="list-style-type: none"> <li>• Lasts for one <b>Sweep time</b>, <math>T_{sw}</math></li> <li>• Repeats once every <math>T_{sw}</math></li> </ul>   |
| Bidirectional                 | <ul style="list-style-type: none"> <li>• Lasts for twice the <b>Sweep time</b>, <math>2T_{sw}</math></li> <li>• Repeats once every <math>2T_{sw}</math></li> <li>• First half is identical to its unidirectional counterpart.</li> <li>• Second half is a mirror image of the first half.</li> </ul> |

The following diagram illustrates a linear sweep in both sweep modes. For information on setting the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 2-202.

**Unidirectional Linear Sweep**

**Bidirectional Linear Sweep**

**Initial frequency (Hz)** — Initial frequency

1000 (default) | scalar

For Linear, Quadratic, and Swept cosine sweeps, the initial frequency,  $f_0$ , of the output chirp signal. You can specify the **Initial frequency (Hz)** as a scalar, greater than or equal to zero. For Logarithmic sweeps, **Initial frequency** is one less than the actual initial frequency of the sweep.

Also, when the sweep is **Logarithmic**, you must set the **Initial frequency** to be less than the **Target frequency**.

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-202.

**Tunable:** Yes

**Target frequency (Hz)** — Target frequency

4000 (default) | scalar

For **Linear**, **Quadratic**, and **Logarithmic** sweeps, the instantaneous frequency,  $f_i(t_g)$ , of the output at the **Target time**,  $t_g$ . You can specify the **Target frequency (Hz)** as a scalar, greater than or equal to zero. For a **Swept cosine** sweep, **Target frequency** is the instantaneous frequency of the output at half the **Target time**,  $t_g/2$ . When **Frequency sweep** is **Logarithmic**, you must set the **Target frequency** to be greater than the **Initial frequency**.

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-202.

**Tunable:** Yes

**Target time (s)** — Target time of sweep

1 (default) | scalar

For **Linear**, **Quadratic**, and **Logarithmic** sweeps, the time,  $t_g$ , at which the sweep reaches the **Target frequency**,  $f_i(t_g)$ . For a **Swept cosine** sweep, **Target time** is the time at which the sweep reaches  $2f_i(t_g) - f_0$ . **Target time** must be a scalar that is greater than or equal to zero, and less than or equal to **Sweep time**,  $T_{sw} \geq t_g$ .

For more information, see “Setting Instantaneous Frequency Sweep Values” on page 2-202.

**Tunable:** Yes

**Sweep time (s)** — Sweep time

1 (default) | scalar

In **Unidirectional Sweep mode**, the **Sweep time**,  $T_{sw}$ , is the period of the output frequency sweep. In **Bidirectional Sweep mode**, the **Sweep time** is half the period of the output frequency sweep. **Sweep time** must be a scalar that is greater than or equal to **Target time**,  $T_{sw} \geq t_g$ .

**Tunable:** Yes

**Initial phase (rad)** — Initial phase of cosine output

0 (default) | scalar

The phase,  $\phi_0$ , of the cosine output at  $t=0$ ;  $y_{chirp}(t) = \cos(\phi_0)$ . You can specify the **Initial phase (rad)** as a scalar that is greater than or equal to zero.

**Tunable:** Yes

**Sample time** — Output sample period

1/8000 (default) | positive scalar

The sample period,  $T_s$ , of the output. The output frame period is  $M_o T_s$ , where  $M_o$  is the number of samples per frame.

**Samples per frame** — Samples per frame

1 (default) | positive integer

The number of samples,  $M_o$ , to buffer into each output frame, specified as a positive integer scalar.

**Output data type** — Output data type

Double (default) | Single

The data type of the output, specified as single precision or double precision.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

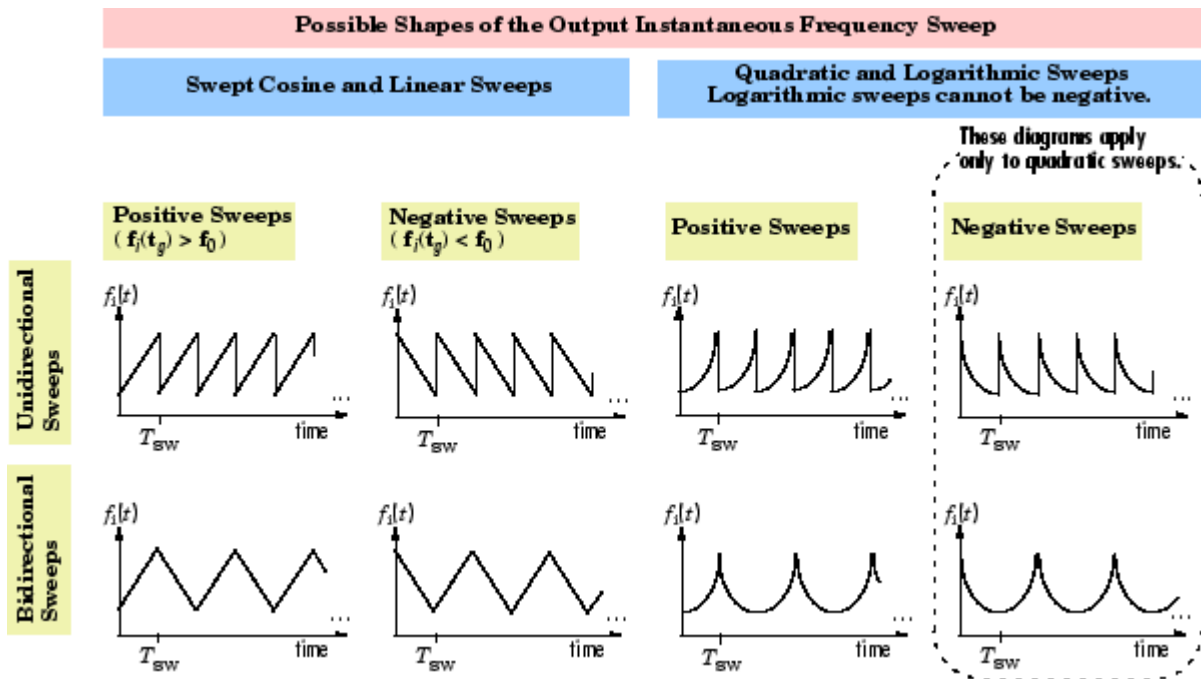

## More About

### Shaping the Frequency Sweep

You control the basic shape of the output instantaneous frequency sweep,  $f_i(t)$ , using the **Frequency sweep** and **Sweep mode** parameters.

| Parameters for Setting Sweep Shape | Possible Setting                                   | Parameter Description   |
|------------------------------------|--|---|
| <b>Frequency sweep</b>             | Linear<br>Quadratic<br>Logarithmic<br>Swept cosine | Determines whether the sweep frequencies vary linearly, quadratically, or logarithmically. Linear and swept cosine sweeps both vary linearly. |
| <b>Sweep mode</b>                  | Unidirectional<br>Bidirectional                    | Determines whether the sweep is unidirectional or bidirectional. For details, see "Sweep mode" on page 2-0                                    |

The following diagram illustrates the possible shapes of the frequency sweep that you can obtain by setting the **Frequency sweep** and **Sweep mode** parameters.

For information on how to set the frequency values in your sweep, see “Setting Instantaneous Frequency Sweep Values” on page 2-202.

### Setting Instantaneous Frequency Sweep Values

Set the following parameters to tune the frequency values of your output frequency sweep.

- **Initial frequency** (Hz),  $f_0$
- **Target frequency** (Hz),  $f_i(t_g)$
- **Target time** (seconds),  $t_g$

The following table summarizes the sweep values at specific times for all **Frequency sweep** settings. For information on the formulas used to compute sweep values at other times, see “Algorithms” on page 2-202.

### Instantaneous Frequency Sweep Values

| Frequency Sweep     | Sweep Value at $t = 0$ | Sweep Value at $t = t_g$ | Time When Sweep Value Is Target Frequency, $f_i(t_g)$ |
|---------------------|------------------------|--------------------------|---|
| <b>Linear</b>       | $f_0$                  | $f_i(t_g)$               | $t_g$   |
| <b>Quadratic</b>    | $f_0$                  | $f_i(t_g)$               | $t_g$   |
| <b>Logarithmic</b>  | $f_0$                  | $f_i(t_g)$               | $t_g$   |
| <b>Swept cosine</b> | $f_0$                  | $2f_i(t_g) - f_0$        | $t_g/2$   |

### Algorithms

The Chirp block uses one of two formulas to compute the block output, depending on the **Frequency Sweep** parameter setting. For details, see the following sections.

## Equations for Output Computation

The following table shows the equations used by the block to compute the user-specified output frequency sweep,  $f_i(t)$ , the block output,  $y_{chirp}(t)$ , and the actual output frequency sweep,  $f_{i(actual)}(t)$ . The only time the user-specified sweep is not the actual output sweep is when the **Frequency sweep** parameter is set to Swept cosine.

**Note** The following equations apply only to unidirectional sweeps in which  $f_i(0) < f_i(t_g)$ . To derive equations for other cases, examine the following table and the diagram in “Shaping the Frequency Sweep” on page 2-201.

The table of equations used by the block contains the following variables:

- $f_i(t)$  — the user-specified frequency sweep
- $f_{i(actual)}(t)$  — the actual output frequency sweep, usually equal to  $f_i(t)$
- $y(t)$  — the Chirp block output
- $\psi(t)$  — the phase of the chirp signal, where  $\psi(0) = 0$ , and  $2\pi f_i(t)$  is the derivative of the phase

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

- $\phi_0$  — the **Initial phase** parameter value, where  $y_{chirp}(0) = \cos(\phi_0)$

## Equations for Unidirectional Positive Sweeps

| Frequency Sweep | Block Output Chirp Signal            | User-Specified Frequency Sweep, $f_i(t)$   | $\beta$                                | Actual Frequency Sweep, $f_{i(actual)}(t)$ |
|-----------------|--------------------------------------|--|--|--|
| Linear          | $y(t) = \cos(\psi(t) + \phi_0)$      | $f_i(t) = f_0 + \beta t$   | $\beta = \frac{f_i(t_g) - f_0}{t_g}$   | $f_{i(actual)}(t) = f_i(t)$                |
| Quadratic       | Same as Linear                       | $f_i(t) = f_0 + \beta t^2$   | $\beta = \frac{f_i(t_g) - f_0}{t_g^2}$ | $f_{i(actual)}(t) = f_i(t)$                |
| Logarithmic     | Same as Linear                       | $F_i(t) = f_0 \left( \frac{f_i(t_g)}{f_0} \right)^{\frac{t}{t_g}}$<br>Where $f_i(t_g) > f_0 > 0$ | N/A                                    | $f_{i(actual)}(t) = f_i(t)$                |
| Swept cosine    | $y(t) = \cos(2\pi f_i(t)t + \phi_0)$ | Same as Linear   | Same as Linear                         | $f_{i(actual)}(t) = f_i(t) + \beta t$      |

## Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps

The derivative of the phase of a chirp function gives the instantaneous frequency of the chirp function. The Chirp block uses this principle to calculate the chirp output when the **Frequency Sweep** parameter is set to Linear, Quadratic, or Logarithmic.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0)$$

Linear, quadratic, or logarithmic chirp signal with phase  $\psi(t)$

$$f_i(t) = \frac{1}{2\pi} \cdot \frac{d\psi(t)}{dt}$$

Phase derivative is instantaneous frequency

For instance, if you want a chirp signal with a linear instantaneous frequency sweep, set the **Frequency Sweep** parameter to **Linear**, and tune the linear sweep values by setting other parameters appropriately. The block outputs a chirp signal, the phase derivative of which is the specified linear sweep. This ensures that the instantaneous frequency of the output is the linear sweep you desired. For equations describing the linear, quadratic, and logarithmic sweeps, see “Equations for Output Computation” on page 2-203.

### Output Computation Method for Swept Cosine Frequency Sweep

To generate the swept cosine chirp signal, the block sets the swept cosine chirp output as follows.

$$y_{chirp}(t) = \cos(\psi(t) + \phi_0) = \cos(2\pi f_i(t)t + \phi_0)$$

Swept cosine chirp output  
(Instantaneous frequency equation, does not hold.)

The instantaneous frequency equation, shown in “Output Computation Method for Linear, Quadratic, and Logarithmic Frequency Sweeps” on page 2-203, does not hold for the swept cosine chirp, so the user-defined frequency sweep,  $f_i(t)$ , is not the actual output frequency sweep,  $f_{i(actual)}(t)$ , of the swept cosine chirp. Thus, the swept cosine output might not behave as you expect. To learn more about swept cosine chirp behavior, see “Frequency sweep” on page 2-0 described for the **Frequency sweep** parameter and “Equations for Output Computation” on page 2-203.

# Cholesky Factorization

Factor square Hermitian positive definite matrix into triangular components

## Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfacto

## Description

The Cholesky Factorization block uniquely factors the square Hermitian positive definite input matrix  $S$  as

$$S = LL^*$$

where  $L$  is a lower triangular square matrix with positive diagonal elements and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ . The block outputs a matrix with lower triangle elements from  $L$  and upper triangle elements from  $L^*$ . The output is not in the same form as the output of the MATLAB `chol` function. In order to convert the output of the Cholesky Factorization block to the MATLAB form, use the following equation:

$$R = \text{triu}(LL');$$

In order to extract the  $L$  matrix exclusively, pass the output of the Cholesky Factorization block,  $LL'$ , to the Extract Triangular Matrix block. Setting the **Extract** parameter of the Extract Triangular Matrix to **Lower** extracts the  $L$  matrix. Setting the **Extract** parameter to **Upper** extracts the  $L'$  matrix.

Here,  $LL'$  is the output of the Cholesky Factorization block. Due to roundoff error, these equations do not produce a result that is exactly the same as the MATLAB result.

**Block Output Composed of  $L$  and  $L^*$**

### Input Requirements for Valid Output

The block output is valid only when its input has the following characteristics:

- Hermitian — The block does *not* check whether the input is Hermitian; it uses only the diagonal and upper triangle of the input to compute the output.
- Real-valued diagonal entries — The block disregards any imaginary component of the input's diagonal entries.
- Positive definite — Set the block to notify you when the input is not positive definite as described in “Response to Nonpositive Definite Input” on page 2-206.

### Response to Nonpositive Definite Input

To generate a valid output, the block algorithm requires a positive definite input (see “Input Requirements for Valid Output” on page 2-206). Set the **Non-positive definite input** parameter to determine how the block responds to a nonpositive definite input:

- Ignore — Proceed with the computation and *do not* issue an alert. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- Warning — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid factorization. A partial factorization will be present in the upper left corner of the output.
- Error — Display an error dialog and terminate the simulation.

---

**Note** The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder™ code generation software.

---

### Performance Comparisons with Other Blocks

Note that  $L$  and  $L^*$  share the same diagonal in the output matrix. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

## Parameters

### Non-positive definite input

Response to nonpositive definite matrix inputs: **Ignore**, **Warning**, or **Error**. See “Response to Nonpositive Definite Input” on page 2-206.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

## Cholesky Inverse

Compute inverse of Hermitian positive definite matrix using Cholesky factorization

### Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

### Description

The Cholesky Inverse block computes the inverse of the Hermitian positive definite input matrix  $S$  by performing Cholesky factorization.

$$S^{-1} = (LL^*)^{-1}$$

$L$  is a lower triangular square matrix with positive diagonal elements and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ . Only the diagonal and upper triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded. Cholesky factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable.

### Response to Nonpositive Definite Input

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and *do not* issue an alert. The output is *not* a valid inverse.
- **Warning** — Display a warning message in the MATLAB Command Window, and continue the simulation. The output is *not* a valid inverse.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

---

### Parameters

#### Non-positive definite input

Response to nonpositive definite matrix inputs: Ignore, Warning, or Error. See “Response to Nonpositive Definite Input” on page 2-208.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (string.h) under certain conditions.

## Cholesky Solver

Solve  $SX = B$  for  $X$  when  $S$  is a square Hermitian positive definite matrix

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

### Description

The Cholesky Solver block solves the linear system  $SX = B$  by applying the Cholesky factorization to the input matrix, where:

- $S$  is an  $M$ -by- $M$  square matrix input through the **S** port. The matrix must be Hermitian positive definite.
- $B$  is an  $M$ -by- $N$  matrix input through the **B** port.
- $X$  is the  $M$ -by- $N$  output matrix and is the unique solution to the equations.

### Ports

#### Input

**S** — Input  $S$  matrix  
 $M$ -by- $M$  matrix

Specify the input  $M$ -by- $M$  square matrix  $S$  through this port. The matrix must be Hermitian positive definite. The block uses only the diagonal and upper triangle of the matrix and disregards any imaginary component in the diagonal entries. Inputs  $S$  and  $B$  must have the same number of rows.

Data Types: `single` | `double`

**B** —  $B$  matrix  
 $M$ -by- $N$  matrix |  $M$ -by-1 vector

Specify the  $B$  matrix in the  $SX = B$  equation as an  $M$ -by- $N$  matrix or an  $M$ -by-1 vector.

When you specify an  $M$ -by-1 vector, the block treats the length- $M$  unoriented vector input at port **B** as an  $M$ -by-1 matrix. Inputs  $S$  and  $B$  must have the same number of rows.

Data Types: `single` | `double`

#### Output

**X** — Solution to system of equations  
 $M$ -by- $N$  matrix |  $M$ -by-1 matrix

The block returns the output as an  $M$ -by- $N$  matrix or an  $M$ -by-1 matrix. The size of the matrix  $X$  is same as the size of the matrix  $B$ .

Data Types: `single` | `double`

## Parameters

**Non-positive definite input** — Response to nonpositive definite matrix input

Ignore (default) | Warning | Error

The input matrix  $S$  must be Hermitian positive definite.

When the input is not positive definite, the block reacts as per the behavior you specify in the **Non-positive definite input** parameter.

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- **Warning** — Proceed with the computation and display a warning message in the MATLAB command window. The output is not a valid solution.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters in the Configuration Parameters dialog box, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

---

## Block Characteristics

| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

Cholesky factorization uniquely factors the Hermitian positive definite input matrix  $S$  as

$$S = LL^*$$

where  $L$  is a lower triangular square matrix with positive diagonal elements.

The equation  $SX = B$  then becomes

$$LL^*X = B,$$

which is solved for  $X$  by substituting  $Y = L^*X$  and solving the following two triangular systems by forward and backward substitution, respectively.

$$LY = B$$

$$L^*X = Y$$

# CIC Compensator (Obsolete)

(Removed) Design CIC compensator

## Compatibility

---

**Note** The CIC Compensator block has been removed from the DSP System Toolbox block library. Existing instances of the CIC Compensator block will continue to operate. For new models, use the CIC Compensation Decimator and CIC Compensation Interpolator blocks. These blocks replace the functionality of the CIC Compensator block, when **FilterType** is set to **Decimator** and **Interpolator**, respectively.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “CIC Compensator Design — Main Pane” on page 5-608 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Compensator block allows the adder's numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

## Filter Specifications

In this group, you specify your filter format, such as the filter order mode and the filter type.

### Filter order mode

Select either `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

### Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Filter order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to `Decimator` or `Sample-rate converter`. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to `Interpolator` or `Sample-rate converter`. The default value is 2.

### Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

### Differential Delay

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

## Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

### Frequency Specifications

#### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0–1)` to enter frequencies in normalized form. This behavior is

the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

### **Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Output Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

### **Fpass**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### **Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

## **Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands.

### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

### **Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

### **Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default method is **Equi ripple**.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

**Minimum order**

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

**Match Exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select **passband** or **stopband** or **both** from the drop-down list.

**Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

**Stopband Decay**

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. The block applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

**Filter Implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, the filter uses direct-form structure.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to Elements as channels (sample based).

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

CIC Compensation Decimator | CIC Compensation Interpolator

# CIC Compensation Interpolator

Compensate for CIC filter using FIR interpolator

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The CIC Compensation Interpolator block uses an FIR polyphase interpolator as the compensation filter. CIC compensation interpolators are multirate FIR filters that you cascade with CIC interpolators to mitigate the drawbacks of the CIC filters.

CIC interpolation filters are used in areas that require high interpolation. These filters are popular in ASICs and FPGAs, since they do not have any multipliers. CIC filters have two drawbacks:

- CIC filters have a magnitude response that causes a droop in the passband region. This magnitude response is:

$$\text{abs}\left(\frac{\sin\left(M\frac{\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right)^n$$

- $M$  — Differential delay
- $n$  — Number of stages
- $\omega$  — Normalized angular frequency
- CIC filters have a wide transition region.

The compensation interpolator filters have an inverse sinc passband response to correct for the CIC droop, and they have a narrow transition width.

This block brings the capabilities of the `dsp.CICCompensationInterpolator` System object to the Simulink environment.

## Ports

### Input

**Input 1** — Data input

vector | matrix

Specify the data input as a vector or a matrix.

The block treats a  $P$ -by- $Q$  input matrix as  $Q$  independent channels, interpolating each channel over the first dimension.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

## Output

**Output 1** — Upsampled and filtered signal  
vector | matrix

Upsampled and filtered signal, returned as a vector or matrix. For a  $P$ -by- $Q$  input matrix, the output is a  $LP$ -by- $Q$  matrix, where  $L$  is the interpolation factor.

When the output is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

## Parameters

### Main Tab

**Rate change factor** — Rate-change factor of the CIC filter

2 (default) | positive integer

Specify the rate-change factor of the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase interpolator as the compensation filter.

**Number of sections** — Number of sections in the CIC filter being compensated

2 (default) | positive integer

Specify the number of sections in the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase interpolator as the compensation filter.

**Differential delay** — Differential delay of the CIC filter

1 (default) | positive integer

Specify the differential delay value used in each comb section of the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase interpolator as the compensation filter.

**Interpolation factor** — Interpolation factor of compensation filter

2 (default) | positive integer

Specify the interpolation factor  $L$  of the compensation filter as a positive integer.

**Minimum order filter design** — Design compensation filter of minimum order or of specified order

on (default) | off

When you select this check box, the block designs filter with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. When you clear this check box, the block designs filter with the order that you specify in the **Filter order** parameter.

**Filter order** — Order of compensation filter

12 (default) | positive integer

Specify the order of the compensator filter as a positive integer.

**Dependencies**

To enable this parameter, clear the **Minimum order filter design** parameter.

**Passband edge frequency (Hz)** — Passband edge frequency of compensation filter

1000000 (default) | positive real scalar

Specify the passband edge frequency of the compensation filter as a positive real scalar in Hz.

**Passband edge frequency (Hz)** must be less than  $F_s/2$ , where  $F_s$  is the output sample rate.

**Stopband edge frequency (Hz)** — Stopband edge frequency of compensation filter

4000000 (default) | positive scalar

Specify the stopband edge frequency of the compensation filter as a positive scalar in Hz. **Stopband edge frequency (Hz)** must be less than  $F_s/2$ , where  $F_s$  is the sample rate of the output signal.

**Passband ripple (dB)** — Passband ripple of compensation filter

0.1 (default) | positive scalar

Specify the filter passband ripple of the compensation filter as a positive scalar in dB.

**Stopband attenuation (dB)** — Stopband attenuation of compensation filter

60 (default) | positive scalar

Specify the stopband attenuation of the compensation filter as a positive scalar in dB.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

6000000 (default) | positive scalar

Specify the sample rate of input signal as a positive scalar in Hz.

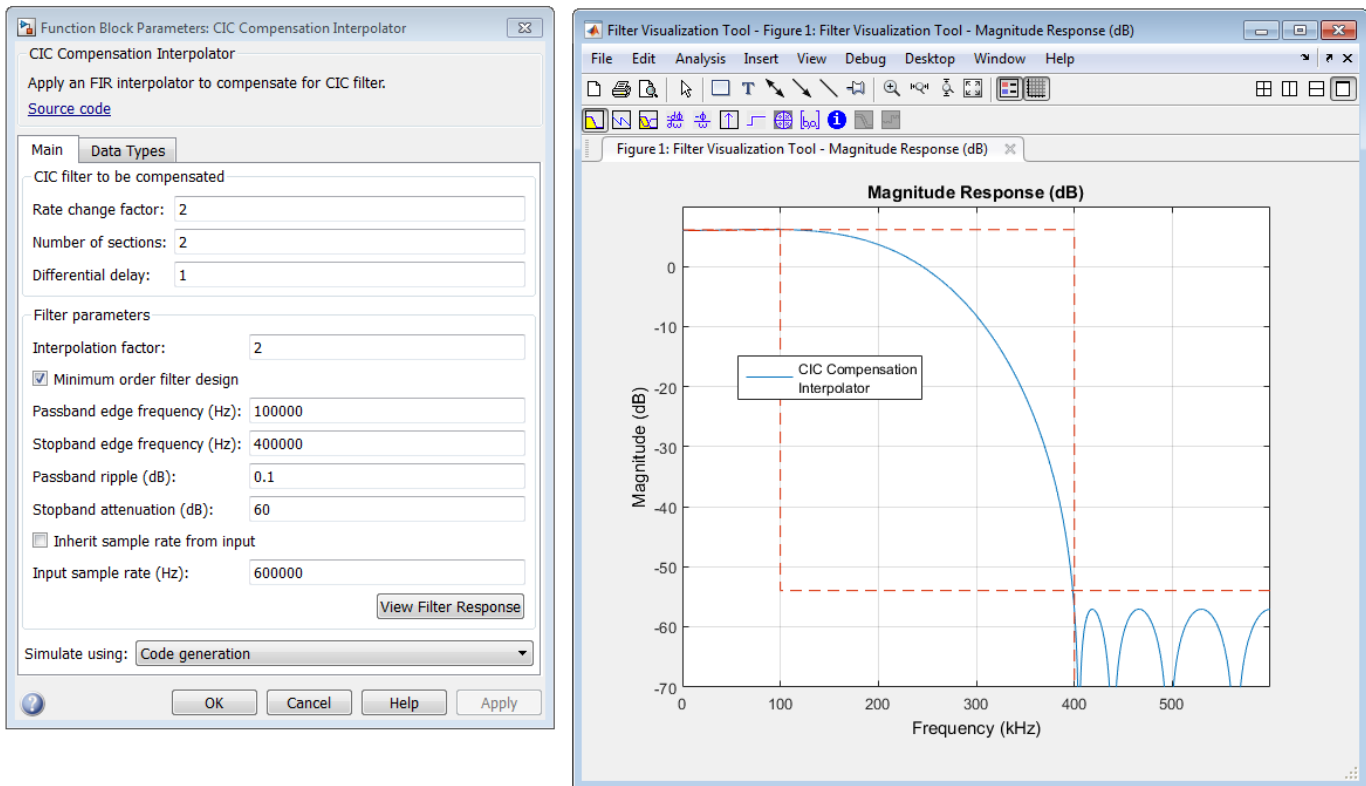

**Dependencies**

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response

button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of the CIC Compensation Interpolator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

### **Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

### **Data Types Tab**

#### **Rounding mode** — Rounding mode for output fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor.

**Coefficients** — Word and fraction lengths of coefficients

`fixdt(1,16)` (default) | `fixdt(1,16,0)`

Specify the fixed-point data type of the coefficients as one of the following:

- `fixdt(1,16)` — Signed fixed-point data type of word length 16 with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 with fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object. For example, `numerictype(fixdt([ ],16,15))`. Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the coefficients data type.

**Block Characteristics**

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | no                                      |
| <b>Zero-Crossing Detection</b>  | no                                      |

**Algorithms**

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

$R$ ,  $D$ , and  $N$  are the rate change factor, the differential delay, and the number of sections in the CIC filter, respectively.

After decimation, the CIC response has the form:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[ RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where  $\omega_p$  is the passband frequency of the CIC compensation filter.

Notice that when  $\omega/2R \ll \pi$ , the previous equation for  $H_{ciccomp}(\omega)$  can be simplified using the fact that  $\sin(x) \cong x$ :

$$H_{ciccomp}(\omega) \approx \left[ \frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[ \text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

CIC Compensation Decimator

## CIC Compensation Decimator

Compensate for CIC filter using FIR decimator

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters

### Description

The CIC Compensation Decimator block uses an FIR polyphase decimator as the compensation filter. CIC compensation decimators are multirate FIR filters that you cascade with CIC decimators to mitigate the drawbacks of the CIC filters.

CIC decimation filters are used in areas that require high decimation. These filters are popular in ASICs and FPGAs, since they do not have any multipliers. CIC filters have two drawbacks:

- CIC filters have a magnitude response that causes a droop in the passband region. This magnitude response is:

$$\text{abs}\left(\frac{\sin\left(M\frac{\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)}\right)^n$$

- $M$  — Differential delay
- $n$  — Number of stages
- $\omega$  — Normalized angular frequency
- CIC filters have a wide transition region.

The compensation decimator filters have an inverse passband response to correct for the CIC droop, and they have a narrow transition width.

This block brings the capabilities of the `dsp.CICCompensationDecimator` System object to the Simulink environment.

### Ports

#### Input

**Input 1** — Data input

vector | matrix

Specify the data input as a vector or a matrix.

The block treats a  $P$ -by- $Q$  input matrix as  $Q$  independent channels, decimating each channel over the first dimension.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal  $P$  can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during

simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Output

**Output 1** — Filtered and downsampled signal  
vector | matrix

Filtered and downsampled signal, returned as a vector or matrix.

The output signal dimensions depend on the input signal dimensions, the decimation factor of the compensator, and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal and a variable-size input signal.

| Input Signal Size | Input Signal Dimensions   | Output Signal Dimensions  |
|-------------------|---|---|
| Fixed             | $P$ -by-1 column vector, where $P$ is a multiple of the decimation factor $M$     | $(P/M)$ -by-1   |
| Fixed             | $P$ -by-1 column vector, where $P$ is not a multiple of the decimation factor $M$ | $\text{ceil}(P/M)$ -by-1 when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.    |
| Fixed             | $P$ -by- $Q$ matrix, where $P$ is a multiple of the decimation factor $M$         | $(P/M)$ -by- $Q$  |
| Fixed             | $P$ -by- $Q$ matrix, where $P$ is not a multiple of the decimation factor $M$     | $\text{ceil}(P/M)$ -by- $Q$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

| Input Signal Size | Input Signal Dimensions | Output Signal Dimensions   |
|-------------------|-------------------------|--|
| Variable          | $P$ -by- $Q$            | $\text{ceil}(P/M)$ -by- $Q$<br><br><b>Allow arbitrary frame length for fixed-size input signals</b> parameter appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the <b>Allow arbitrary frame length for fixed-size input signals</b> parameter. |

When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Parameters

### Main Tab

**Rate change factor** — Rate-change factor of the CIC filter

2 (default) | positive integer

Specify the rate-change factor of the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase decimator as the compensation filter.

**Number of sections** — Number of sections in the CIC filter

2 (default) | positive integer

Specify the number of decimator and comb sections in the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase decimator as the compensation filter.

**Differential delay** — Differential delay of the CIC filter

1 (default) | positive integer

Specify the delay value used in each comb section of the CIC filter as a positive integer. The block compensates the CIC filter using an FIR polyphase decimator as the compensation filter.

**Decimation factor** — Decimation factor of compensation filter

2 (default) | positive integer scalar

Specify the decimation factor  $M$  of the compensation filter as a positive integer. The number of input rows must be a multiple of the decimation factor.

**Minimum order filter design** — Design compensation filter of minimum order or of specified order

on (default) | off

When you select this check box, the block designs filter with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. When you clear this check box, the block designs filter with the order that you specify in the **Filter order** parameter.

By default, this check box is selected.

**Filter order** — Order of compensation filter

12 (default) | positive integer

Specify the order of the compensation filter as a positive integer.

#### Dependency

To enable this parameter, clear the **Minimum order filter design** parameter.

**Passband edge frequency (Hz)** — Passband edge frequency of compensation filter

100000 (default) | positive real scalar

Specify the passband edge frequency of the compensation filter as a positive real scalar in Hz. The value you specify in **PassbandFrequency** must be less than  $F_s/2$ , where  $F_s$  is the input sample rate.

**Stopband edge frequency (Hz)** — Stopband edge frequency of compensation filter

400000 (default) | positive real scalar

Specify the stopband edge frequency of the compensation filter as a positive real scalar in Hz. The value you specify in **StopbandFrequency** must be less than  $F_s/2$ , where  $F_s$  is the sample rate of the input signal.

#### Dependency

To enable this parameter, select the **Minimum order filter design** parameter.

**Passband ripple (dB)** — Passband ripple of compensation filter

0.1 (default) | positive real scalar

Specify the passband ripple of the compensation filter as a positive real scalar in dB.

**Stopband attenuation (dB)** — Stopband attenuation of compensation filter

60 (default) | positive real scalar

Specify the stopband attenuation of the compensation filter as a positive real scalar in dB.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you must specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

1200000 (default) | positive real scalar

Specify the sample rate of the input signal as a positive real scalar in Hz.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

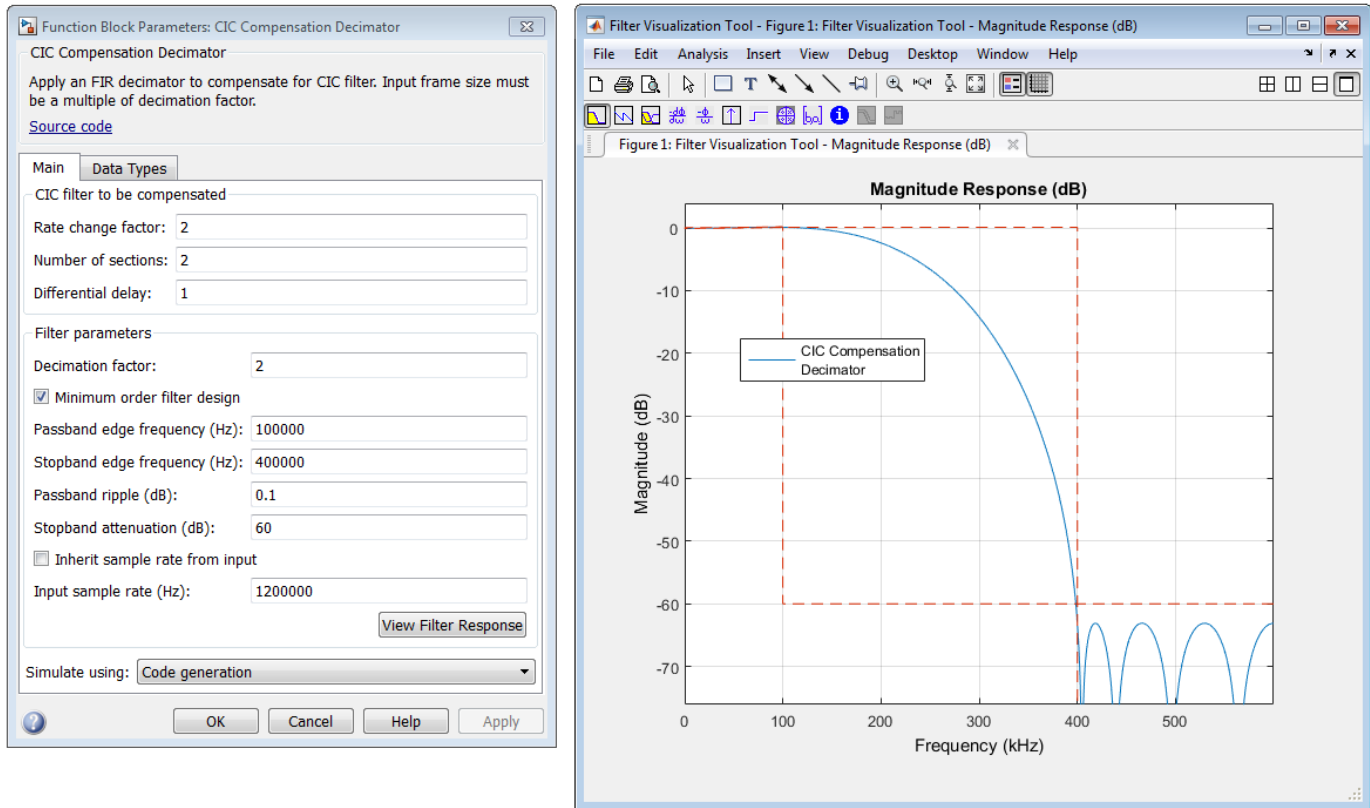

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

**View Filter Response** — View Filter Response

button (default)

Click this button to open the Filter Visualization Tool FVTool and display the magnitude and phase response of the CIC Compensation Decimator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

### Data Types Tab

**Rounding mode** — Rounding mode for output fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor.

**Coefficients** — Word and fraction lengths of coefficients

`fixdt(1,16)` (default) | `fixdt(1,16,0)`

Specify the fixed-point data type of the coefficients as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16 with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object. For example, `numerictype(fixdt([ ],16,15))`. Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the coefficients data type.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |

## Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

$R$ ,  $D$ , and  $N$  are the rate change factor, the differential delay, and the number of sections in the CIC filter, respectively.

After decimation, the CIC response has the form:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[ RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where  $\omega_p$  is the passband frequency of the CIC compensation filter.

Notice that when  $\omega/2R \ll \pi$ , the previous equation for  $H_{ciccomp}(\omega)$  can be simplified using the fact that  $\sin(x) \cong x$ :

$$H_{ciccomp}(\omega) \approx \left[ \frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[ \text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

## Version History

Introduced in R2015b

### R2023a: Support for arbitrary input frame length

This block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an input signal with an arbitrary frame length, the input frame length does not have to be a multiple of the decimation factor.

## Extended Capabilities

## CIC Decimation

Decimate signal using cascaded integrator-comb filter

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters  
 DSP System Toolbox HDL Support / Filtering

## Description

The CIC Decimation block performs a sample rate decrease (decimation) on an input signal by an integer factor. Cascaded Integrator-Comb (CIC) filters are a class of linear phase FIR filters comprised of a comb part and an integrator part.

The block supports real and complex fixed-point inputs. In its normal mode of operation, the CIC Decimation block allows the adder's numeric values to overflow and wrap around [1] [3]. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

The CIC Decimation block requires a Fixed-Point Designer™ license.

## Ports

### Input

**Port\_1** — Input signal  
 vector | matrix

Data input, specified as a vector or matrix. The number of input rows must be a multiple of the decimation factor.

If the input is fixed-point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: int8 | int16 | int32 | int64 | fixed point

### Output

**Port\_1** — CIC decimated output  
 vector | matrix

CIC decimated output, returned as a vector or a matrix. The data type of the output is determined by the settings in the block dialog. The complexity of the output matches that of the input. The number of output rows is  $(1/R) \times Num$ , where  $R$  is the decimation factor and  $Num$  is the number of input rows.

Data Types: int8 | int16 | int32 | int64 | fixed point

## Parameters

**Coefficient source** — Source of the filter information  
Dialog parameters (default) | Filter object

Source of the filter information, specified as one of the following:

- Dialog parameters — Enter information about the filter, such as **Decimation factor (R)**, **Differential delay (M)** and **Number of sections (N)**, in the block dialog.
- Filter object — Specify the filter using a `dsp.CICDecimator` System object.

Different items appear on the CIC Decimation block dialog depending on whether you select Dialog parameters or Filter object in the **Coefficient source** parameter.

**Decimation factor (R)** — Decimation factor  
2 (default) | integer

Decimation factor of the filter, specified as an integer greater than 1.

### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters.

**Differential Delay (M)** — Differential delay  
1 (default) | positive integer

Specify the differential delay of the comb part of the filter,  $M$ , as a positive integer. For more details, see “CIC Decimation Filter” on page 4-253.

### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters.

**Number of sections (N)** — Number of filter sections  
2 (default) | positive integer

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters.

**Data type specification mode** — Specify word length and fraction length of filter sections and output  
Full precision (default) | Minimum section word lengths | Specify word lengths | Binary point scaling

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output:

- **Full precision** — The word and fraction lengths of the filter sections and outputs are automatically selected for you. All word lengths (WL) are set to:

$$WL = \text{ceil}(N \times \log_2(M \times R)) + I$$

where,

- $I$  -- Input word length
- $M$  -- Differential delay
- $N$  -- Number of sections
- $R$  -- Decimation factor

All fraction lengths are set to the input fraction length.

- **Minimum section word lengths** — Specify the word length of the filter output in the **Output word length** parameter. The block automatically selects the word lengths of the filter sections and all fraction lengths such that each of the section word lengths is as small as possible. The precision of each filter section is less than in **Full precision** mode, but the range of each section is preserved.
- **Specify word lengths** — Specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The block automatically selects fraction lengths for the filter sections and output such that the range of each section is preserved when the least significant bits are discarded.
- **Binary point scaling** — Specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

#### Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters.

**Section word lengths** — Word length of filter sections

[16 16 16 16] (default) | scalar | row vector

Word lengths of filter sections, specified as a scalar or a vector of length equal to  $2N$ , where  $N$  is the number of filter sections. The section word length must be in the range [2, 128].

#### Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters and **Data type specification mode** to either **Specify word lengths** or **Binary point scaling**.

**Section fraction lengths** — Fraction lengths of filter sections

0 (default) | integer

Fraction lengths of filter sections, specified as an integer.

#### Dependencies

This parameter appears when you set **Coefficient source** to **Dialog** parameters and **Data type specification mode** to **Binary point scaling**.

**Output word length** — Word length of filter output  
32 (default) | integer

Word length of the filter output, specified as an integer in the range [2, 128].

**Dependencies**

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to any option other than Full precision.

**Output fraction length** — Fraction length of filter output  
0 (default) | integer

Fraction length of the filter output, specified as an integer.

**Dependencies**

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

**Rate options** — Rate processing rule  
Enforce single-rate processing (default) | Allow multirate processing

Specify the rate processing rule for the block:

- **Enforce single-rate processing** — The block performs frame-based processing and produces an output that has the same sample rate as the input. To decimate the signal while maintaining the input sample rate, the block decreases the output frame size. In this mode, the input column size must be a multiple of **Decimation Factor (R)**.
- **Allow multirate processing** — In this mode, the block produces an output with a sample rate that is R times slower than the input sample rate.

**Filter object** — Multirate filter object  
dsp.CICDecimator

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICDecimator System object.

You can define the System object in the block dialog or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

**Dependencies**

This parameter appears when you set **Coefficient source** to Filter object.

**View Filter Response** — View filter response  
gui button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

---

**Note** If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View Filter Response** button.

---

## Block Characteristics

|                                 |                       |

## More About

### CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC decimation filter is conceptually given by a single rate CIC filter,  $H(z)$  which is a lowpass anti-imaging filter, followed by a downsampler. The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter  $H(z)$  is factorized this way:

$$H(z) = \left[ \sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z)$$

where,

- $H_I$  is the transfer function of the integrator part of the filter containing  $N$  stages of integrators.
- $H_C$  is the transfer function of the  $N$  sections of the cascaded comb filters, each with a width of  $RM$ .
- $N$  is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part or the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.

- $R$  is the decimation factor.
- $M$  is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for decimation and moves the rate change factor,  $R$ , to follow after the  $N$  sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}.$$

For a block diagram that shows the multirate implementation, see Algorithms on page 2-239.

## Algorithms

### CIC Decimation Filter

The CIC decimation filter in More About on page 2-238 is realized as a cascade of  $N$  sections of the integrators followed by a rate change factor of  $R$ , followed by  $N$  sections of comb filters.

This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (`string.h`) under certain conditions.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For an HDL-optimized filter architecture with hardware-friendly control signals, use the CIC Decimator (DSP HDL Toolbox) block. The DSP HDL Toolbox block simulates the latency of the HDL algorithm in Simulink.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters** and **Filter object**.

### AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

| Pipeline Register Placement  | Latency (clock cycles)                                       |
|--|--|
| A pipeline register is added between the comb stages of the differentiators. | NS - 1, where NS is number of sections (at the output side). |

### HDL Filter Properties

|                             |  |
|-----------------------------|--|
| <b>AddPipelineRegisters</b> | Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder). |
|-----------------------------|--|

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

### Restrictions

- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the **Filter Structure** option Zero-latency decimator is not supported for HDL code generation. From the **Filter Structure** drop-down list, select Decimator.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

### Main Pane

See “CIC Filter Design — Main Pane” on page 5-607 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

In its normal mode of operation, the CIC Filter block allows the adder’s numbers to wrap around. The Fixed-Point infrastructure then causes warnings to appear on the command line.

### Filter Specifications

In this group, you specify your CIC filter format, such as the filter type and the differential delay.

### Filter type

Select whether your filter will be a **decimator** or an **interpolator**. Your choice determines the type of filter and the design methods and structures that are available to implement your filter.

Selecting **decimator** or **interpolator** activates the **Factor** option. When you design an interpolator, you enable the **Output sample rate** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

### Differential delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

### Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Output sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

### Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## Filter Implementation

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

## Data Types Pane

See the Data Types Pane subsection of the `filterBuilder` function reference page for more information about specifying data type parameters.

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Fixed point</li> </ul>   |

DSP System Toolbox / Filtering / Multirate Filters  
 DSP System Toolbox HDL Support / Filtering

## Description

The CIC Interpolation block performs a sample rate increase (interpolation) on an input signal by an integer factor. Cascaded integrator-comb (CIC) filters are a class of linear phase FIR filters that consist of a comb part and an integrator part.

The CIC Interpolation block requires a Fixed-Point Designer license.

## Ports

### Input

**Port 1** — Input signal  
 vector | matrix

Data input, specified as a vector or matrix. If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: int8 | int16 | int32 | int64 | fixed point

### Output

**Port 1** — CIC interpolated output  
 vector | matrix

CIC interpolated output, returned as a vector or a matrix. The data type of the output is determined by the settings in the block dialog. The complexity of the output matches that of the input. The number of output rows is  $R \times Num$ , where  $R$  is the interpolation factor and  $Num$  is the number of input rows.

Data Types: int8 | int16 | int32 | int64 | fixed point

## Parameters

**Coefficient source** — Source of filter information  
 Dialog parameters (default) | Filter object

Source of the filter information, specified as one of the following:

- Dialog parameters — Enter information about the filter, such as **Interpolation factor (R)**, **Differential delay (M)** and **Number of sections (N)**, in the block dialog.

- **Filter object** — Specify the filter using a `dsp.CICInterpolator System` object.

**Interpolation factor (R)** — Interpolation factor  
2 (default) | integer

Interpolation factor of the filter, specified as an integer greater than 1.

**Dependencies**

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

**Differential Delay (M)** — Differential delay  
1 (default) | positive integer

Specify the differential delay of the comb part of the filter,  $M$ , as a positive integer. For more details, see “CIC Interpolation Filter” on page 4-268.

**Dependencies**

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

**Number of sections (N)** — Number of filter sections  
2 (default) | positive integer

Specify the number of filter sections. The number you specify determines the number of sections in either the comb part of the filter or the integrator part of the filter. This value does not represent the total number of sections in the comb and integrator parts combined.

**Dependencies**

This parameter appears when you set **Coefficient source** to `Dialog` parameters.

**Data type specification mode** — Specify word length and fraction length of filter sections and output  
`Full precision (default) | Minimum section word lengths | Specify word lengths | Binary point scaling`

Choose how you specify the fixed-point word length and fraction length of the filter sections and/or output:

- **Full precision** — The word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths (WL) are set to:

$$WL = \text{ceil}\left(\log_2\left(\frac{(RM)^N}{R}\right)\right) + I$$

where,

- $I$  -- Input word length
- $M$  -- Differential delay
- $N$  -- Number of sections

- $R$  -- Interpolation factor

The other section word lengths are set to accommodate the bit growth, as described in Hogenauer's paper [1]. All fraction lengths are set to the input fraction length.

- **Minimum section word lengths** — Specify the word length of the filter output in the **Output word length** parameter. The word lengths of the filter sections are set in the same way as in Full precision mode.

The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section word length and the output word length.

- **Specify word lengths** — Specify the word lengths of the filter sections and output in the **Section word lengths** and **Output word length** parameters. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section word length and the output word length.
- **Binary point scaling** — Specify the word and fraction lengths of the filter sections and output in the **Section word lengths**, **Section fraction lengths**, **Output word length**, and **Output fraction length** parameters.

#### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters.

**Section word lengths** — Word length of filter sections

[16 16 16 16] (default) | scalar | row vector

Word lengths of filter sections, specified as a scalar or a vector of length equal to  $2N$ , where  $N$  is the number of filter sections. The section word length must be in the range [2, 128].

#### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to either Specify word lengths or Binary point scaling.

**Section fraction lengths** — Fraction length of filter sections

0 (default) | integer

Fraction lengths of filter sections, specified as an integer.

#### Dependencies

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

**Output word length** — Word length of filter output

32 (default) | integer

Word length of the filter output, specified as an integer in the range [2, 128].

**Dependencies**

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to any option other than Full precision.

**Output fraction length** — Fraction length of filter output  
0 (default) | integer

Fraction length of the filter output, specified as an integer.

**Dependencies**

This parameter appears when you set **Coefficient source** to Dialog parameters and **Data type specification mode** to Binary point scaling.

**Input processing** — Method of processing input  
Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. In this mode, the block always performs single-rate processing.
- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. In this mode, the input to the block must be a scalar or a vector. You can use the **Rate options** parameter to specify whether the block performs single-rate or multirate processing.

**Rate options** — Rate processing rule  
Enforce single-rate processing (default) | Allow multirate processing

Specify the rate processing rule for the block. You can select one of the following options:

- **Enforce single-rate processing** — The block maintains the sample rate of the input.
- **Allow multirate processing** — The block produces an output with a sample rate that is  $R$  times faster than the input sample rate. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

**Filter object** — Multirate filter object  
dsp.CICInterpolator System object

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a dsp.CICInterpolator System object.

You can define the System object in the block dialog or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

**Dependencies**

This parameter appears when you set **Coefficient source** to Filter object.

**View Filter Response** — View filter response button

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined in the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

**Note** If you specify a filter in the **Filter object** parameter, you must apply the filter by clicking the **Apply** button before using the **View Filter Response** button.

## Block Characteristics

|                                 |                       |
|---------------------------------|-----------------------|
| <b>Data Types</b>               | fixed point   integer |
| <b>Direct Feedthrough</b>       | no                    |
| <b>Multidimensional Signals</b> | no                    |

| <b>Zero-Crossing Detection</b>  | no                    |

## More About

### CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC interpolation filter is conceptually given by an upsampler followed by a single rate CIC filter,  $H(z)$ , which is a lowpass anti-imaging filter. The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter  $H(z)$  is factorized this way:

$$H(z) = \left[ \sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{(1 - z^{-RM})^N}{1} \cdot \frac{1}{(1 - z^{-1})^N} = H_C^N(z) \cdot H_I^N(z)$$

where,

- $H_C$  is the transfer function of the  $N$  sections of the cascaded comb filters, each with a width of  $RM$ .
- $H_I$  is the transfer function of the integrator part of the filter containing  $N$  stages of integrators.

- $N$  is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- $R$  is the interpolation factor.
- $M$  is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for interpolation and moves the rate change factor,  $R$ , to follow after the  $N$  sections of the cascaded comb filters.

The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}.$$

For a block diagram that shows the multirate implementation, see Algorithms on page 2-250.

## Algorithms

### CIC Interpolation Filter

The CIC interpolation filter in More About on page 2-249 is realized as a cascade of  $N$  sections of comb filters followed by a rate change by a factor  $R$ , followed by  $N$  sections of cascaded integrators.

This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This algorithm puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For an HDL-optimized filter architecture with hardware-friendly control signals, use the CIC Interpolator block. The DSP HDL Toolbox block simulates the latency of the HDL algorithm in Simulink.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters** and **Filter object**.

### AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

| Pipeline Register Placement  | Latency (clock cycles)                          |
|--|---|
| A pipeline register is added between the comb stages of the differentiators. | NS, the number of sections (at the input side). |

### HDL Filter Properties

|                             |  |
|-----------------------------|--|
| <b>AddPipelineRegisters</b> | Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder). |
|-----------------------------|--|

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

**Restrictions**

- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the **Filter Structure** option **Zero-latency interpolator** is not supported for HDL code generation. From the **Filter Structure** drop-down list, select **Interpolator**.
- When you use **AddPipelineRegisters**, delays in parallel paths are not automatically balanced. Manually add delays where required by your design.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# Colored Noise

Generate colored noise signal

**Libraries:**  
DSP System Toolbox / Sources

## Description

The Colored Noise block generates a colored noise signal with a power spectral density of  $1/|f|^\alpha$  over its entire frequency range. The inverse power spectral density component,  $\alpha$ , can be any value in the interval  $[-2 \ 2]$ . The type of colored noise the block generates depends on the **Noise color** option you choose in the block dialog box. When you set **Noise color** to **custom**, you can specify the power density of the noise through the **Power of inverse frequency** parameter.

## Ports

### Output

**Port\_1** — Colored noise signal  
scalar | vector | matrix

Colored noise output signal. The size and data type of the signal depend on the values of the **Number of output channels**, **Number of samples per output channel**, and **Output data type** parameters.

Data Types: single | double

## Parameters

**Noise color** — Color of the generated noise

pink (default) | white | brown | blue | purple | custom

Color of the noise the block generates. You can set this parameter to:

- **pink** — Generates pink noise. This option is equivalent to setting **Power of inverse frequency** to 1.
- **white** — Generates white noise (flat power spectral density). This option is equivalent to setting **Power of inverse frequency** to 0.
- **brown** — Generates brown noise. Also known as red or Brownian noise. This option is equivalent to setting **Power of inverse frequency** to 2.
- **blue** — Generates blue noise. Also known as azure noise. This option is equivalent to setting **Power of inverse frequency** to -1.
- **purple** — Generates violet (purple) noise. This option is equivalent to setting **Power of inverse frequency** to -2.

- **custom** — Specify the power density of the noise using the **Power of inverse frequency** parameter.

**Power of inverse frequency** — Inverse power spectral density component

1 (default) | scalar in the range [-2 2]

Inverse power spectral density component,  $\alpha$ , specified as a real-valued scalar in the interval [-2 2]. The inverse exponent defines the power spectral density of the random process by  $1/|f|^\alpha$ . The default value of this property is 1. When **Power of inverse frequency** is greater than 0, the block generates lowpass noise, with a singularity (pole) at  $f=0$ . These processes exhibit long memory. When **Power of inverse frequency** is less than 0, the block generates highpass noise with negatively correlated increments. These processes are referred to as antipersistent. In a log-log plot of power as a function of frequency, processes generated by the Colored Noise block exhibit an approximate linear relationship, with the slope equal to  $-\alpha$ .

#### Dependencies

To enable this parameter, set **Noise color** to **custom**.

**Guarantee the output is bounded (+/-1)** — Set output bounds to +1 and -1

off (default) | on

Select the parameter to make the output bounded between +1 and -1.

When you select the parameter, the internal random source that generates the noise is uniform. If **Noise color** is set to **white**, there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and -1. If **Noise color** is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain that ensures the absolute maximum output never exceeds 1.

When you do not select the parameter, the internal random source is Gaussian. The output is not bounded.

**Number of output channels** — Number of output channels

1 (default) | positive integer

Number of output channels, specified as a positive integer scalar. This parameter defines the number of columns in the generated signal.

**Output data type** — Output data type

double (default) | single

Data type of the output specified as **double** or **single**.

**Number of samples per output channel** — Samples per frame of output

1024 (default) | positive integer

Number of samples in each frame of the output signal, specified as a positive integer scalar. This parameter defines the number of rows in the generated signal.

**Output sample time (s)** — Sample time of the output

1 (default) | positive scalar

Sample time of the output signal, specified as a positive scalar in seconds.

**Initial seed** — Initial seed of random number generator

67 (default) | positive integer

Initial seed of the random number generator algorithm, specified as a real-valued positive integer scalar.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | No              |

## More About

### Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

where  $\alpha$  is a real number in the interval  $[-2,2]$  and  $L(f)$  is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to  $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10\log S(f) = -10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If  $\alpha > 0$ ,  $S(f)$  goes to infinity as the frequency,  $f$ , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If  $\alpha < 0$ , the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of  $\frac{1}{|f|^\alpha}$  processes include:

- $\alpha = 0$  — White noise, where  $L(f)$  is a constant proportional to the process variance.
- $\alpha = 1$  — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-274 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$  — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like  $\frac{1}{|f|^2}$ . Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$  — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$  — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

## Algorithms

The figure shows the overall process of generating the colored noise.

The random stream generator produces a stream of white noise that is either Gaussian or uniform in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

When  $\alpha$ , the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and -1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and -1. If  $\alpha$  is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is

enabled, a gain  $g$  is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of  $\alpha$  affects the PSD of the colored noise, see “Colored Noise Processes” on page 2-255.

When the inverse frequency power  $\alpha$  is positive, the colored noise is generated using an autoregressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$

$$a_k = (k - 1 - \frac{\alpha}{2}) \frac{a_{k-1}}{k}, \quad k = 1, 2, \dots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power  $\alpha$  is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$

$$b_k = (k - 1 + \frac{\alpha}{2}) \frac{b_{k-1}}{k}, \quad k = 1, 2, \dots, 255$$

Purple noise is generated from a first order filter,  $B = [1 \ -1]$ .

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820-822 in [2].

# Comb Filter

Design comb Filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “Comb Filter Design —Main Pane” on page 5-611 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

## Filter Specifications

In this group, you specify the type of comb filter and the number of peaks or notches.

### Comb Type

Select either **Notch** or **Peak** from the drop-down list. **Notch** creates a comb filter that attenuates a set of harmonically related frequencies. **Peak** creates a comb filter that amplifies a set of harmonically related frequencies.

### Order mode

Select either **Order** or **Number of Peaks/Notches** from the drop-down menu.

Select **Order** to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of  $2/\text{Order}$  in normalized frequency units.

Select **Number of Peaks** or **Number of Notches** to specify the number of peaks or notches and the **Shelving filter order**

### Shelving filter order

The **Shelving filter order** is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

### Frequency specifications

In this group, you specify the frequency constraints and frequency units.

#### Frequency specifications

Select either **Quality factor** or **Bandwidth**.

**Quality factor** is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the -3 dB point.

**Bandwidth** specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the -3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

#### Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input sample rate** dialog box.

#### Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Bandwidth gain** — Specify the gain at which the bandwidth is measured. The default is -3 dB.

### Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

#### Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

## Filter Implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |
| Output | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |

## Version History

Introduced in R2010a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

# Complex Bandpass Decimator

Extract a frequency subband using a one-sided (complex) bandpass decimator

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Complex Bandpass Decimator block extracts a specific subband of frequencies using a one-sided, multistage, complex bandpass decimator. The block determines the bandwidth of interest using the specified center frequency, decimator factor, and bandwidth values.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-270.

## Ports

### Input

**x** — Input data  
vector | matrix

Specify the input data as a vector or a matrix.

The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single-channel signal.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

To determine the decimation factor, click the **View Info** button.

This port is unnamed until you select the **Specify center frequency from input port** parameter.

Data Types: `single` | `double`

**Fc** — Center frequency  
real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range  $[-F_s/2, F_s/2]$ . The value of  $F_s$  depends on the **Inherit sample rate from input** parameter. When you select this parameter,  $F_s$  is the value the block inherits from the input signal. When you clear this parameter,  $F_s$  is the value you specify in the **Input sample rate (Hz)** parameter.

To enable this port, select the **Specify center frequency from input port** parameter.

Data Types: `single` | `double`

## Output

**Port\_1** — Filtered output  
vector | matrix

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the parameters on the block dialog.

The output signal dimensions depend on the input signal dimensions, the overall decimation factor of the Complex Bandpass Decimator block, and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter. You can determine the overall decimator factor  $D$  by clicking the **View Info** button in the block dialog box.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

### Fixed-Size Input Signal

| Input Signal  | Output Signal Dimensions  |
|---|---|
| $P$ -by-1 column vector, where $P$ is a multiple of the decimation factor $D$     | $(P/D)$ -by-1   |
| $P$ -by-1 column vector, where $P$ is not a multiple of the decimation factor $D$ | $\text{ceil}(P/D)$ -by-1 when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.    |
| $P$ -by- $Q$ matrix, where $P$ is a multiple of the decimation factor $D$         | $(P/D)$ -by- $Q$  |
| $P$ -by- $Q$ matrix, where $P$ is not a multiple of the decimation factor $D$     | $\text{ceil}(P/D)$ -by- $Q$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

This table gives more details on the dimensions of the output signal when you input a variable-size input signal. When you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** parameter is visible in the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

### Variable-Size Input Signal

| Input Signal | Output Signal Dimensions    |
|--------------|-----------------------------|
| $P$ -by- $Q$ | $\text{ceil}(P/D)$ -by- $Q$ |

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: single | double

## Parameters

**Filter specification** — Filter design parameters

Decimation factor (default) | Bandwidth | Decimation factor and bandwidth

Filter design parameters, specified as one of the following:

- **Decimation factor** -- The block specifies the decimation factor through the **Decimation factor** parameter. The bandwidth of interest ( $BW$ ) is computed using the following equation:

$$BW = Fs/D$$

where

- $Fs$  -- Sample rate specified through the **Input sample rate (Hz)** parameter.
- $D$  -- Decimation factor.
- **Bandwidth** -- The block specifies the bandwidth through the **Bandwidth (Hz)** parameter. The decimation factor ( $D$ ) is computed using the following equation:

$$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

where

- $Fs$  -- Sample rate specified through the **Input sample rate (Hz)** parameter.
- $BW$  -- Bandwidth of interest.
- $TW$  -- Transition width specified through the **Transition width (Hz)** parameter.
- **Decimation factor and bandwidth** -- The decimation factor and the bandwidth of interest are specified through the **Decimation factor** and **Bandwidth (Hz)** parameters.

**Decimation factor** — Decimation factor

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

### Dependencies

This parameter applies when you set **Filter specification** to either **Decimation factor** or **Decimation factor and bandwidth**.

**Bandwidth (Hz)** — Bandwidth in Hz

5000 (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

**Dependencies**

This parameter applies when you set **Filter specification** to either Bandwidth or Decimation factor and bandwidth.

Data Types: single | double

**Specify center frequency from input port** — Flag to specify center frequency  
off (default) | on

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Center frequency (Hz)** parameter.

When you select this check box, the block does not compute the filter response. To view the filter response, clear this check box, specify the center frequency on the block dialog, and click **View Filter Response** button.

**Center frequency (Hz)** — Center frequency in Hz  
0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range  $[-Fs/2, Fs/2]$ .

**Tunable:** Yes

Data Types: single | double

**Stopband attenuation (dB)** — Stopband attenuation in dB  
80 (default) | positive scalar

Stopband attenuation of the filter in dB, specified as a finite positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Passband ripple (dB)** — Passband ripple in dB  
1 (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

**Dependencies**

This parameter applies when you set **Filter specification** to either Bandwidth or Decimation factor and bandwidth.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Transition width (Hz)** — Transition width in Hz  
100 (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Reduce number of complex coefficients** — Minimize number of complex coefficients  
on (default) | off

Minimize the number of complex coefficients. When you select this parameter, the first stage of the multistage filter is bandpass (with complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.

When you clear the parameter, the input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if **Mix signal to baseband** parameter is selected and the frequency offset resulting from the decimation is nonzero.

**Mix signal to baseband** — Mix signal to baseband  
on (default) | off

Mix the signal to baseband. When you select this parameter, the block heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter. When you clear this parameter, the block skips the mixing stage.

#### Dependencies

This parameter applies when you clear the **Reduce number of complex coefficients** parameter.

**Inherit sample rate from input** — Flag to specify input sample rate  
off (default) | on

When you select this parameter, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this parameter, specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Input sample rate in Hz  
44100 (default) | real positive scalar

Sampling rate of the input signal in Hz, specified as a real positive scalar.

#### Dependencies

This parameter applies when you clear the **Inherit sample rate from input** parameter.

Data Types: single | double

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter only for fixed-size input signals and ignores it if the input data varies in size during simulation.

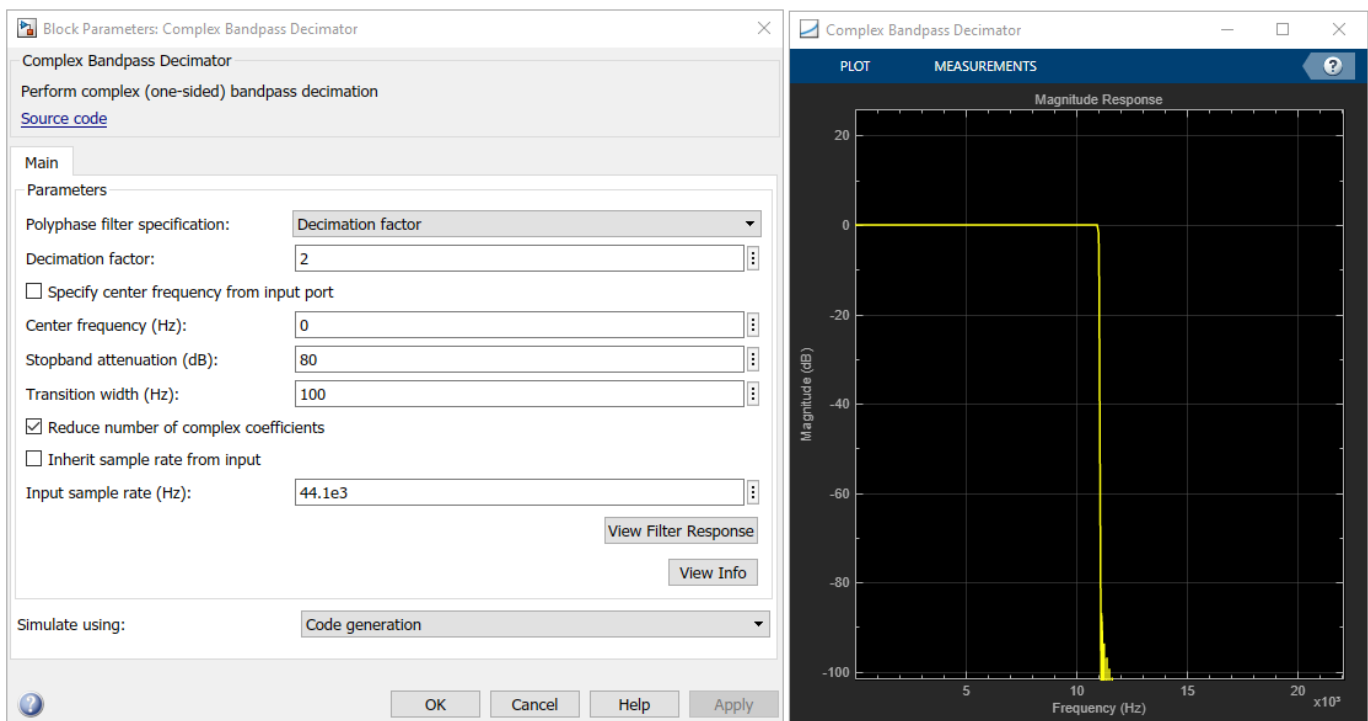

When the input signal is a variable-size signal, the signal can have an arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

**View Filter Response** — Visualize frequency response button

Click this button to open the Dynamic Filter Visualizer window and display the magnitude and phase response of the complex bandpass decimator. The response is based on the parameters you select in the block dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

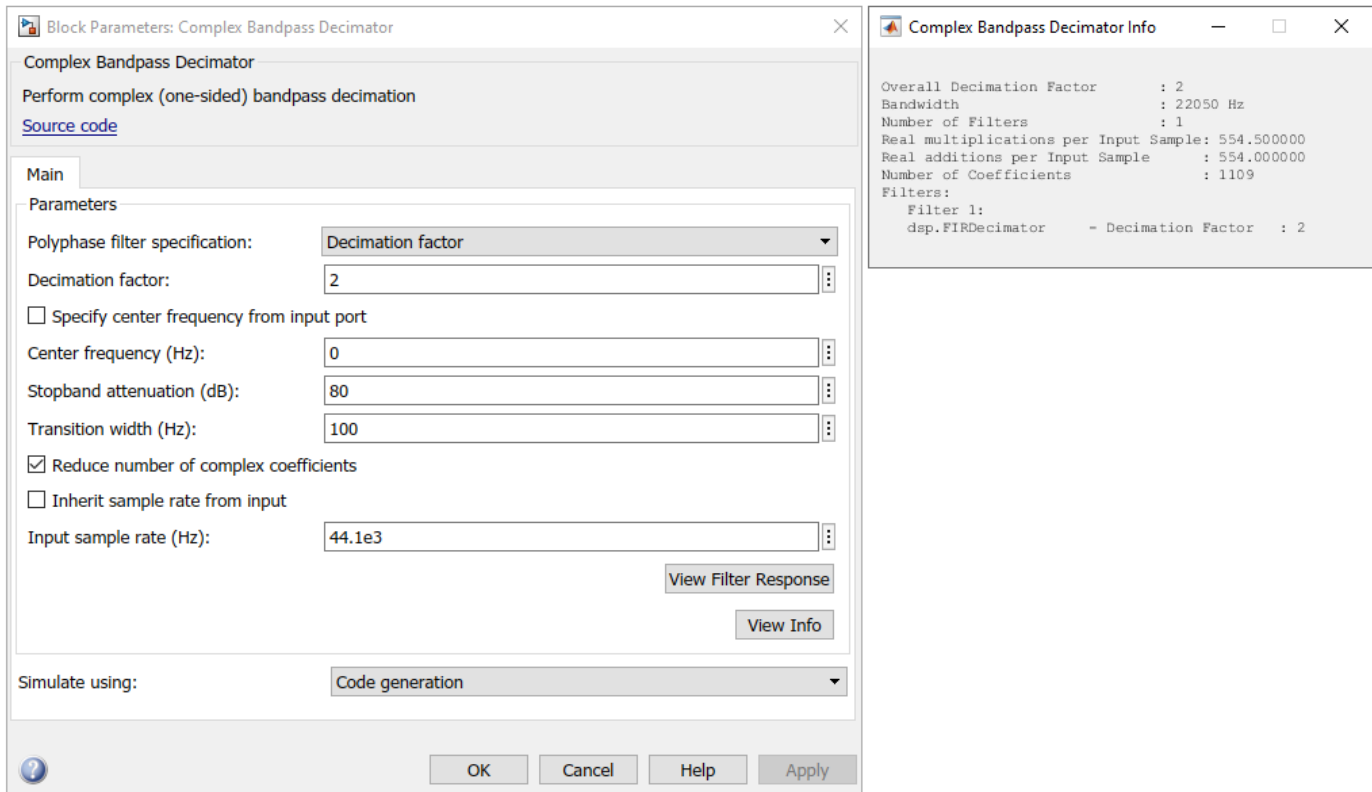

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Filter Visualizer”.

**View Info** — View filter information button

Display filter information of the Complex Bandpass Decimator block:

This button brings the functionality of the `info` analysis method into the Simulink environment.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

## Version History

**Introduced in R2018a**

### **R2023a: Support for arbitrary input frame length**

This block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an input signal with an arbitrary frame length, the input frame length does not have to be a multiple of the decimation factor and the output signal is a variable-size signal.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

The Complex Bandpass Decimator block supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is complex-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

## Complex Cepstrum

Compute complex cepstrum of input

**Libraries:**  
DSP System Toolbox / Transforms

### Description

The Complex Cepstrum block computes the complex cepstrum of the input.

### Ports

#### Input

**Input** — Input  
vector | matrix

Specify the input  $u$  as a vector or a matrix of size  $M$ -by- $N$ . The block treats each column of the input as an independent channel containing  $M$  consecutive samples. The block always processes unoriented vector inputs as a single channel, and returns the result as a length- $M$  column vector. The block does not accept complex-valued inputs.

The input is altered by the application of a linear phase term so that there is no phase discontinuity at  $\pm\pi$  radians. That is, each input channel is independently zero padded and circularly shifted to have zero phase at  $\pi$  radians.

Data Types: single | double

#### Output

**Output** — Complex cepstrum output  
vector | matrix

Complex cepstrum output, returned as an  $M_o$ -by- $N$  matrix.

When you clear the **Inherit FFT length from input port dimensions** parameter,  $M_o$  is the value you specify in the **FFT length** parameter. When you select the **Inherit FFT length from input port dimensions** parameter,  $M_o = M$ , where  $M$  is the frame size (number of rows) of the input signal.

Each output column contains the length- $M_o$  complex cepstrum of the corresponding input column.

Here is the equivalent MATLAB code for computing the complex cepstrum.

```
y = cceps(u,Mo)
```

where,

- $u$  -- Input
- $y$  -- Complex cepstrum output

- $M_o$  -- Output frame size

The output port rate is the same as the input port rate.

Data Types: `single` | `double`

## Parameters

**Inherit FFT length from input port dimensions** — Match the FFT length to the dimensions of the input port

`on` (default) | `off`

When you select this check box, the output frame size  $M_o$  matches the input frame size  $M$ .

**FFT length** — Compute FFT length

64 (default) | positive integer

The number of frequency points at which to compute the FFT, which is also the output frame size  $M_o$ .

### Dependency

To enable this parameter, clear the **Inherit FFT length from input port dimensions** parameter.

## Block Characteristics

## Constant

Generate constant value

### Libraries:

Simulink / Commonly Used Blocks  
 Simulink / Sources  
 DSP System Toolbox / Sources  
 HDL Coder / Commonly Used Blocks  
 HDL Coder / Sources

## Description

The Constant block generates a real or complex constant value signal. Use this block to provide a constant signal input. The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** check box. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

---

**Tip** To output a constant enumerated value, consider using the Enumerated Constant block instead. The Constant block provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**.

---

### Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. Using a bus object as the output data type can help simplify your model. If you use a bus object as the output data type, set the **Constant value** to  $\emptyset$  or to a MATLAB structure that matches the bus object.

### Using Structures for the Constant Value of a Bus

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as `37`. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields” (Simulink).

## Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** to Simplified. For more information, see “Underspecified initialization detection” (Simulink).

## Ports

### Output

#### Port\_1 — Constant value

scalar | vector | matrix | N-D array

Constant value, specified as a real or complex valued scalar, vector, matrix, or N-D array. By default, the Constant block outputs a signal whose dimensions, data type, and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types.

---

**Note** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For more information, see `Simulink.BusElement`.

---

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

## Parameters

### Main

#### Constant value — Constant output value

1 (default) | scalar | vector | matrix | N-D array

Specify the constant value output of the block.

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify one of these options:
  - A full MATLAB structure corresponding to the bus object
  - `0` to indicate a structure corresponding to the ground value of the bus object

For details, see “Using Bus Objects as the Output Data Type” on page 2-274.

- For nonbus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using a rounding method of nearest and overflow action of saturate.

### Programmatic Use

**Block Parameter:** Value

**Type:** character vector  
**Value:** scalar | vector | matrix | N-D array  
**Default:** '1'

### Interpret vector parameters as 1-D — Treat vectors as 1-D

on (default) | off

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N, provided the **Constant value** parameter evaluates to an N-element row or column vector.
- When you clear this check box, the block outputs a matrix of dimension 1-by-N or N-by-1, provided the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.

#### Programmatic Use

**Block Parameter:** VectorParams1D

**Type:** character vector  
**Values:** 'on' | 'off'  
**Default:** 'on'

### Sample time — Sampling interval

inf (default) | scalar | vector

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

The default value of `inf` indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” (Simulink) for more information.

#### Programmatic Use

**Block Parameter:** SampleTime

**Type:** character vector  
**Values:** scalar | vector  
**Default:** 'inf'

### Signal Attributes

#### Output minimum — Minimum output value for range checking

[] (default) | scalar

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

---

**Note** If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

---

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

---

**Note Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

#### Programmatic Use

**Block Parameter:** OutMin

**Type:** character vector

**Values:** scalar

**Default:** ' [ ] '

**Output maximum** — Maximum output value for range checking

[ ] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

---

**Note** If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

---

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see Optimize using the specified minimum and maximum values (Embedded Coder).

---

**Note Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

---

**Programmatic Use****Block Parameter:** OutMax**Type:** character vector**Values:** scalar**Default:** '[ ]'**Output data type** — Output data type

Inherit: Inherit from 'Constant value' (default) | Inherit: Inherit via back propagation | double | single | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Programmatic Use****Block Parameter:** OutDataTypeStr**Type:** character vector

**Values:** 'Inherit: Inherit from 'Constant value'' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'half' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'int64' | 'uint64' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'

**Default:** 'Inherit: Inherit from 'Constant value''**Lock output data type setting against changes by the fixed-point tools** — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

**Programmatic Use****Block Parameter:** LockScale**Type:** character vector**Values:** 'off' | 'on'**Default:** 'off'**Mode** — Category of data to specify

Inherit (default) | Built in | Fixed point | Enumerated | Bus object | Expression

Select the category of data to specify.

**Inherit**

Inheritance rules for data types. Selecting **Inherit** enables a second menu/text box to the right. Select one of the following choices:

- Inherit from 'Constant value' (default)
- Inherit via back propagation

#### Built in

Built-in data types. Selecting **Built in** enables a second menu/text box to the right. Select one of the following choices:

- double (default)
- single
- int8
- uint8
- int16
- uint16
- int32
- uint32
- boolean

#### Fixed point

Fixed-point data types.

#### Enumerated

Enumerated data types. Selecting **Enumerated** enables a second menu/text box to the right, where you can enter the class name.

#### Bus object

Bus object. Selecting **Bus** enables a **Bus object** parameter to the right, where you enter the name of a bus object that you want to use to define the structure of the bus. If you need to create or change a bus object, click **Edit** to the right of the **Bus object** field to open the Simulink Type Editor. For details, see “Create and Specify Simulink.Bus Objects” (Simulink).

#### Expression

Expressions that evaluate to data types. Selecting **Expression** enables a second menu/text box to the right, where you can enter the expression.

Do not specify a bus object as the expression.

**Data type override** — Specify data type override mode for this signal

Inherit | Off

Select the data type override mode for this signal.

- When you select **Inherit**, Simulink inherits the data type override setting from its context, that is, from the block, Simulink.Signal object or Stateflow® chart in Simulink that is using the signal.
- When you select **Off**, Simulink ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink) in the Simulink documentation.

**Dependencies**

To enable this parameter, click the **Show data type assistant** button, and set the **Mode** to **Built in** or **Fixed point**.

**Tips**

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

**Signedness** — Specify signed or unsigned

Signed (default) | Unsigned

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but unsigned data represents positive values only.

- **Signed**, specifies the fixed-point data as signed.
- **Unsigned**, specifies the fixed-point data as unsigned.

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set the **Mode** to **Fixed point**.

**Scaling** — Method for scaling fixed-point data

Best precision (default) | Binary point | Slope and bias

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specifying a Fixed-Point Data Type” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to **Fixed point**.

Setting **Scaling** to **Binary point** enables:

- **Fraction length**
- **Calculate Best-Precision Scaling**

Setting **Scaling** to **Slope and bias** enables:

- **Slope**
- **Bias**
- **Calculate Best-Precision Scaling**

**Word length** — Bit size of the word that holds the quantized integer

16 (default) | integer from 0 to 32

Specify the bit size of the word that holds the quantized integer. For more information, see “Specifying a Fixed-Point Data Type” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to `Fixed point`.

**Fraction length** — Specify fraction length for fixed-point data type

0 (default) | scalar integer

Specify fraction length for fixed-point data type as a positive or negative integer. For more information, see “Specifying a Fixed-Point Data Type” (Simulink).

**Dependencies**

To enable this parameter, set **Scaling** to `Binary point`.

**Slope** — Specify slope for the fixed-point data type

$2^0$  (default) | positive, real-valued scalar

Specify slope for the fixed-point data type. For more information, see “Specifying a Fixed-Point Data Type” (Simulink).

**Dependencies**

To enable this parameter, set **Scaling** to `Slope and bias`.

**Bias** — Specify bias for the fixed-point data type

0 (default) | real-valued scalar

Specify bias for the fixed-point data type as any real number. For more information, see “Specifying a Fixed-Point Data Type” (Simulink).

**Dependencies**

To enable this parameter, set **Scaling** to `Slope and bias`.

**Block Characteristics**

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### Tunable Parameters

You can use a tunable parameter in a Constant block intended for HDL code generation. For details, see “Generate DUT Ports for Tunable Parameters” (HDL Coder).

### HDL Architecture

| Architecture     | Parameters     | Description  |
|------------------|----------------|--|
| default Constant | None           | This implementation emits the value of the Constant block.   |
| Logic Value      | None           | By default, this implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'.   |
|                  | {'Value', 'Z'} | If the signal is in a high-impedance state, use this parameter value. This implementation emits the character 'Z' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'ZZZZ'. |
|                  | {'Value', 'X'} | If the signal is in an unknown state, use this parameter value. This implementation emits the character 'X' for each bit in the signal. For example, for a 4-bit signal, the implementation would emit 'XXXX'.       |

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

### Complex Data Support

This block supports code generation for complex signals.

### Restrictions

- The `Logic Value` implementation does not support the `double` data type. If you specify this implementation for a constant value of type `double`, a code generation error occurs.
- Delay balancing does not support a Constant block that has **Sample time** set to `inf` when the infinite sample time propagates to the device under test (DUT) output. If there is an infinite sample rate error during HDL code generation, set **Sample time** to `-1`.

### PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

## Constant Ramp

Generate ramp signal with length based on input dimensions

**Libraries:**  
DSP System Toolbox / Signal Operations

### Description

The Constant Ramp block generates the constant ramp signal

$$y = (0:L-1)*m + b$$

where  $m$  is the slope specified by the scalar **Slope** parameter, and  $b$  is the y-intercept specified by the scalar **Offset** parameter.

For an unoriented vector input,  $L$  is equal to the length of the input vector. For an N-D input array, the length  $L$  of the output ramp is equal to the length of the input in the dimension specified by the **Ramp length equals number of** or **Dimension** parameter. The output,  $y$ , is always an unoriented vector.

### Ports

#### Input

**Port\_1** — Input signal

scalar | vector | matrix | N-D array

Input signal used to generate ramp signal, specified as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

#### Output

**Port\_1** — Output signal

vector

Output signal, specified as an unoriented vector. The block determines the length of the output based on the length of the input signal, and the **Ramp length equals number of** or **Dimension** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

### Parameters

#### Main

**Ramp length equals number of** — Dimension used to determine ramp length

Rows (default) | Columns | Elements in specified dimension

Specify whether the length of the output ramp is the number of rows, number of columns, or the length of the specified dimension of the input.

**Dimension** — Dimension that determines length of output ramp

1 (default) | positive integer

Specify the one-based dimension of the input array that determines the length of the output ramp as a positive integer scalar.

#### Dependencies

To enable this parameter, set **Ramp length equals number of** to `Elements in specified dimension`.

**Slope** — Slope of the ramp

1 (default) | scalar

Specify the slope of the ramp as a real-valued double-precision scalar.

**Offset** — y-intercept of the ramp

0 (default) | scalar

Specify the scalar y-intercept of the ramp as a real-valued double-precision scalar.

#### Data Types

**Output data type** — Output data type

Inherit: Same as input (default) | Inherit: Inherit via back propagation | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | <data type conversion>

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built-in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For help setting data type parameters, display the **Data Type Assistant** by clicking the **Show data type assistant** button .

See “Control Data Types of Signals” (Simulink) for more information.

#### Data Type Assistant Parameters

**Mode** — Data type mode

Inherit (default) | Built in | Fixed point | Expression

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Same as input`
- **Built in**— Lets you specify a built-in data type, for example, `double`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Signedness** — Signedness of fixed-point data

`Signed (default) | Unsigned`

Specify whether the fixed-point data is signed or unsigned. **Signed** data can represent positive and negative values, but **Unsigned** data represents positive values only. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Word length** — Bit size of the word that holds the quantized integer

`16 (default) | integer from 2 to 128`

Specify the bit size of the word that holds the quantized integer as an integer scalar from 2 to 128. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to `Fixed point`

**Scaling** — Method for scaling fixed-point data

`Best precision (default) | Binary point`

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to `Fixed point`

**Data type override** — Data type override mode

`Inherit (default) | Off`

Select the data type override mode for this signal. You can select:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify.

**Dependencies**

To enable this parameter, set **Mode** to **Built in** or **Fixed point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Fraction length** — Fraction length for fixed-point data type

0 (default) | integer scalar

Specify the fraction length of the fixed-point data type as a positive or negative integer scalar.

**Dependencies**

To enable this parameter, set **Mode** to **Fixed point** and **Scaling** to **Binary point**.

**Block Characteristics**

|                                 |   |

## Contiguous Copy (Obsolete)

Create discontinuous input in contiguous block of memory

## Library

dspobslib

## Description

---

**Note** The Contiguous Copy block is still supported but is likely to be obsoleted in a future release.

---

The Contiguous Copy block copies the input to a contiguous block of memory, and passes this new copy to the output. The output is identical to the input, but is guaranteed to reside in a contiguous section of memory.

Because Simulink software employs an efficient copy-by-reference method for propagating data in a model, some operations produce outputs with discontinuous memory locations.

Although this does not present a problem during simulation, blocks linked to versions of DSP Blockset prior to 4.0 may require contiguous inputs for code generation with the Simulink Coder product. When such blocks are used in a model intended for code generation, they should be preceded by the Contiguous Copy block to ensure that their inputs are contiguous.

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## Version History

**Introduced in R2008b**

## Convert 1-D to 2-D

Reshape 1-D or 2-D input to 2-D matrix with specified dimensions

### Libraries:

DSP System Toolbox / Signal Management / Signal Attributes  
 DSP System Toolbox HDL Support / Signal Management

### Description

The Convert 1-D to 2-D block reshapes a length- $M_i$  1-D vector or an  $M_i$ -by- $N_i$  matrix to an  $M_o$ -by- $N_o$  matrix, where  $M_o$  is specified by the **Number of output rows** parameter and  $N_o$  is specified by the **Number of output columns** parameter.

```
y = reshape(u,Mo,No) % Equivalent MATLAB code
```

The input is reshaped *column-wise*, as shown in the two cases below. The length-6 vector and the 2-by-3 matrix are both reshaped to the same 3-by-2 output matrix.

An error is generated when  $(M_o * N_o) \neq (M_i * N_i)$ . In other words, the total number of input elements must be conserved in the output.

The output is frame based when you select the **Frame-based output** check box; otherwise, the output is sample based.

### Ports

#### Input

**Port\_1** — Input signal

vector | matrix

Input signal, specified as a 1-D vector or 2-D matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

#### Output

**Port\_1** — Output signal

matrix

Output signal, returned as a 2-D matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

## Parameters

**Number of output rows** — Number of rows in output matrix

1 (default) | positive integer

Number of rows  $M_o$  in the output matrix, specified as a positive integer.

**Number of output columns** — Number of columns in output matrix

1 (default) | positive integer

Number of columns  $N_o$  in the output matrix, specified as a positive integer.

**Frame-based output** — Option to enable frame-based output

`off` (default) | `on`

Select this parameter to create a frame-based output.

## Convert 2-D to 1-D

Convert 2-D matrix input to 1-D vector

### Libraries:

DSP System Toolbox / Signal Management / Signal Attributes

### Description

The Convert 2-D to 1-D block reshapes an  $M$ -by- $N$  matrix input to a 1-D vector that has a length of  $M*N$ .

```
y = u(:) % Equivalent MATLAB code
```

The input is reshaped column-wise for a 3-by-2 matrix.

### Ports

#### Input

**Port\_1** — Input signal

matrix

Input signal, specified as a 2-D matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

#### Output

**Port\_1** — Output signal

vector

Output signal, returned as a 1-D vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

## Convolution

Convolution of two inputs

**Libraries:**  
DSP System Toolbox / Signal Operations

### Description

The Convolution block convolves the first dimension of an  $N$ -D input array  $u$  with the first dimension of an  $N$ -D input array  $v$ . The block can also convolve a column vector with the first-dimension of an  $N$ -D input array.

The general equation for convolution is:

$$y(k) = \sum_n u(n - k)v(k)$$

Two DSP System Toolbox blocks can be used for convolving two input signals:

- Convolution
- Discrete FIR Filter

The Convolution block assumes that all elements of  $u$  and  $v$  are available at each Simulink time step and computes the entire convolution at every step.

The Discrete FIR Filter block can be used for convolving signals in situations where all elements of  $v$  is available at each time step, but  $u$  is a sequence that comes in over the life of the simulation. When you use the Discrete FIR Filter block, the convolution is computed only once.

To determine which block best fits your needs, see “Selecting the Appropriate Convolution Block” on page 2-298.

### Ports

#### Input

**Port\_1** — First input signal

scalar | vector | matrix |  $N$ -D array

First input  $u$  specified as a scalar, vector, matrix, or  $N$ -D array. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. All the input port dimensions for both the inputs, except the first dimension, must have the same value.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point  
Complex Number Support: Yes

**Port\_2** — Second input signal

scalar | vector | matrix |  $N$ -D array

Second input  $v$  specified as a scalar, vector, matrix, or  $N$ -D array. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. All the input port dimensions for both the inputs, except the first dimension, must have the same value.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`  
Complex Number Support: Yes

## Output

**Port\_1** — Output signal

scalar | vector | matrix |  $N$ -D array

Convolved signal, returned as a scalar, vector, matrix, or  $N$ -D array depending on the input signals. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex. Inputs  $u$  and  $v$  are zero when indexed outside of their valid ranges. For more details on how the convolved signal changes based on the inputs, see “More About” on page 2-298.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

## Parameters

### Main Tab

**Computation domain** — Computation domain

Time (default) | Frequency | Fastest

Set the domain in which the block computes convolutions:

- **Time** — The block computes in the time domain, which minimizes memory use.
- **Frequency** — The block computes in the frequency domain, which might require fewer computations than computing in the time domain, depending on the input length.
- **Fastest** — The block computes in the domain that minimizes the number of computations.

Fixed-point signals are only supported in the time domain. When inputting fixed-point signals, make sure you set the **Computation domain** parameter to **Time**.

### Data Types Tab

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round

- Simplest
- Zero

For more details, see Rounding Modes.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

---

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

---

**Product output** — Product output data type  
Inherit: Inherit via internal rule (default) | Inherit: Same as first input |  
fixdt([],16,0)

**Product output** specifies the data type of the output of a product operation in the Convolution block.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as first input** — The block specifies the product output data type to be the same as the first input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For more information on the product output data type, see “Multiplication Data Types” and Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Accumulator** — Data type of accumulator

Inherit: `Inherit via internal rule (default)` | Inherit: Same as first input |

Inherit: Same as product output | `fixdt([],16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Convolution block.

- `Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — The block specifies the accumulator data type to be the same as the first input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Output** — Data type of output

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as

product output | `fixdt([],16,0)`

**Output** specifies the data type of the output of the Convolution block.

- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `Inherit: Same as first input` — The block specifies the output data type to be the same as the first input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Control Data Types of Signals” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Output Minimum** — Minimum value that block can output  
[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value that block can output  
[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |

### Convoluting Two N-D Arrays

The block always computes the convolution of two N-D input arrays along the first dimension. When both inputs are N-D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when  $u$  is an  $M_u$ -by- $N$ -by- $P$  array and  $v$  is an  $M_v$ -by- $N$ -by- $P$  array, the output is an  $(M_u+M_v-1)$ -by- $N$ -by- $P$  array.

When  $u$  is a  $M_u$ -by- $N$  matrix and  $v$  is an  $M_v$ -by- $N$  matrix, the output  $y$  is a  $(M_u+M_v-1)$ -by- $N$  matrix whose  $j$ th column has these elements

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges. When both inputs are real, the output is real. When one or both inputs are complex, the output is complex.

### Convoluting a Column Vector with an N-D Array

When one input is a column vector and the other is an N-D array, the block independently convolves the vector with the first dimension of the N-D input array. For example, when  $u$  is a  $M_u$ -by-1 column vector and  $v$  is an  $M_v$ -by- $N$  matrix, the output is an  $(M_u+M_v-1)$ -by- $N$  matrix whose  $j$ th column has these elements:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

### Convoluting Two Column Vectors

The Convolution block also accepts two column vector inputs. When  $u$  and  $v$  are column vectors with lengths  $M_u$  and  $M_v$ , the Convolution block performs the vector convolution with lengths  $M_u$  and  $M_v$  such that:

$$y_i = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is a  $(M_u+M_v-1)$ -by-1 column vector.

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This diagram shows the data types used within the Convolution block for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types in the block dialog as discussed in "Parameters" on page 2-295.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on how the multiplication operation is performed, see "Multiplication Data Types".

---

**Note** When one or both of the inputs are signed fixed-point signals, all internal block data types are signed fixed point. The internal block data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

# Correlation

Cross-correlation of two inputs

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Correlation block computes the cross-correlation of two  $N$ -D input arrays along the first-dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the **Computation domain** parameter. In the time domain, the block convolves the first input signal,  $u$ , with the time-reversed complex conjugate of the second input signal,  $v$ . In the frequency domain, to compute the cross-correlation, the block:

- 1 Takes the Fourier transform of both input signals,  $U$  and  $V$ .
- 2 Multiplies  $U$  and  $V^*$ , where  $*$  denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

If you set **Computation domain** to **Fastest**, the block chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 2-306.

## Ports

### Input

**Port\_1** — First data input signal  
vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to **Time**. When one or both of the input signals are complex, the output signal is also complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Port\_2** — Second data input signal  
vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the **Computation domain** to **Time**. When one or both of the input signals are complex, the output signal is also complex.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Output

**Port\_1** — Cross-correlated output

vector | matrix |  $N$ -D array

Cross-correlated output of the two input signals.

When the inputs are  $N$ -D arrays, the object outputs an  $N$ -D array, where all the dimensions, except for the first dimension, match with the input array. For example,

- When the inputs  $u$  and  $v$  have dimensions  $M_u$ -by- $N$ -by- $P$  and  $M_v$ -by- $N$ -by- $P$ , respectively, the Correlation block outputs an  $(M_u + M_v - 1)$ -by- $N$ -by- $P$  array.
- When the inputs  $u$  and  $v$  have the dimensions  $M_u$ -by- $N$  and  $M_v$ -by- $N$ , the block outputs an  $(M_u + M_v - 1)$ -by- $N$  matrix.

If one input is a column vector and the other input is an  $N$ -D array, the Correlation block computes the cross-correlation of the vector with each column in the  $N$ -D array. For example,

- When the input  $u$  is an  $M_u$ -by-1 column vector and  $v$  is an  $M_v$ -by- $N$  matrix, the block outputs an  $(M_u + M_v - 1)$ -by- $N$  matrix.
- Similarly, when  $u$  and  $v$  are column vectors with lengths  $M_u$  and  $M_v$ , respectively, the block performs the vector cross-correlation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

### Main Tab

**Computation domain** — Domain in which the block computes the cross-correlation

Time (default) | Frequency | Fastest

- **Time** — Computes the cross-correlation in the time domain, which minimizes the memory usage.
- **Frequency** — Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 2-306.
- **Fastest** — Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this parameter to **Time**.

### Data Types Tab

---

**Note** Fixed-point signals are supported for the time domain only. To use these parameters, on the **Main** tab, set **Computation domain** to **Time**.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data type settings, the block operates in full-precision mode.

---

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

---

**Product output** — Product output data type  
Inherit: Inherit via internal rule (default) | Inherit: Same as input |  
fixdt([],16,0)

**Product output** specifies the data type of the output of a product operation in the Correlation block. For more information on the product output data type, see “Multiplication Data Types” and the ‘Fixed-Point Conversion’ section in “Extended Capabilities” on page 2-0 .

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.

- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Accumulator** — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

**Accumulator** specifies the data type of output of an accumulation operation in the Correlation block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output** — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt([],16,0)`

**Output** specifies the data type of the output of the Correlation block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as product output` — The block specifies the output data type to be the same as the product output data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output Minimum** — Minimum value block can output  
[] (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value the block can output  
[] (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

## More About

### Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length- $N$  deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes,  $x$  and  $y$ , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes,  $r_{xy}(h)$  is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where  $E\{ \}$  is the expectation operator.

## Algorithms

### Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

### Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the  $j$ th column of the output,  $y_{uv}$ , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k, j}^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- $*$  denotes the complex conjugate.
- $u$  is an  $M_u$ -by- $N$  input matrix.
- $v$  is an  $M_v$ -by- $N$  input matrix.
- $y_{u,v}$  is an  $(M_u + M_v - 1)$ -by- $N$  matrix.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

### Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The  $j$ th column of the output,  $y_{u,v}$ , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- $*$  denotes the complex conjugate.
- $u$  is an  $M_u$ -by-1 column vector.
- $v$  is an  $M_v$ -by- $N$  matrix.
- $y_{uv}$  is an  $(M_u + M_v - 1)$ -by- $N$  matrix.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

### Correlate Two Column Vectors

When the inputs are two column vectors, the  $j$ th column of the output,  $y_{uv}$ , has these elements:

$$y_{uv}(i) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i)} \quad 0 \leq i < M_v$$

$$y_{uv}(i) = y_{vu}^*(-i) \quad -M_u < i < 0$$

where:

- $*$  denotes the complex conjugate.
- $u$  is an  $M_u$ -by-1 column vector.
- $v$  is an  $M_v$ -by-1 column vector.
- $y_{uv}$  is an  $(M_u + M_v - 1)$ -by-1 column vector.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

### Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals,  $U$  and  $V$ .
- 2 Multiplies  $U$  and  $V^*$ , where  $*$  denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

### Blocks

Autocorrelation

# Counter

Count up or down through specified range of numbers

## Libraries:

DSP System Toolbox / Signal Management / Switches and Counters

## Description

The Counter block counts up or down through a specified range of numbers. The block enables the **Inc** (increment) port when you set the **Count direction** parameter to Up. When you set the **Count direction** parameter to Down, the block enables the **Dec** (decrement) port. If you set the **Count event** parameter to Free running, the block disables the **Inc** or **Dec** port and counts at a constant time interval. For all other settings of the **Count event** parameter, the block increments or decrements the counter each time a trigger event occurs at the **Inc** or **Dec** input port. When a trigger event occurs at the optional **Rst** port, the block resets the counter to its initial state.

The Counter block accepts single-channel inputs. For more information about scalar input operation, vector input operation, and free-running operation, see “Algorithms” on page 2-315.

## Ports

### Input

**Inc/Dec** — Input signal to trigger count event

scalar | vector

Input signal used to determine when the block increments or decrements the counter, specified as a real-valued scalar or vector. If the input to the **Inc** or **Dec** port is a vector, the block treats the vector as a frame. Each time a triggering event occurs at the **Inc** or **Dec** input port, the block increments or decrements the counter, respectively. You control the type of triggering event using the **Count event** parameter.

### Dependencies

The block enables the **Inc** (increment) port when you set the **Count direction** parameter to Up.

The block enables the **Dec** (decrement) port when you set the **Count direction** parameter to Down.

The block disables the **Inc/Dec** input port when you set the **Count event** parameter to Free running. In free running mode, the block counts at a constant time interval.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

**Rst** — Reset signal

scalar

Input signal used to determine when the block resets the counter, specified as a real-valued scalar. The **Rst** port must have the same port sample time as the **Inc** or **Dec** input port. Each time a

triggering event occurs at the **Rst** port, the block resets the counter to its initial value. For more information about triggering events, see “Count event” on page 2-0 .

**Dependencies**

To enable this port, select the **Reset input** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

**Max** — Maximum counter size  
scalar

Specify the maximum counter size as any unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value you specify as an input to the **Max** port.

**Dependencies**

To enable this port, set the **Counter size** parameter to `Specify via input port`.

Data Types: `uint8` | `uint16` | `uint32`

**Output**

**Cnt** — Current value of counter  
scalar | vector

Current value of the counter, specified as a scalar or vector. When you set the **Count event** parameter to `Free running`, the **Cnt** output is a  $M$ -by-1 vector containing the count value at each of  $M$  consecutive sample times, where  $M$  is the value you specify for the **Samples per output frame** parameter.

**Dependencies**

To enable this port, set the **Output** parameter to `Count` or `Count and Hit`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

**Hit** — Hit status  
scalar | vector

Hit status of the integer values you specified in the **Hit values** parameter. When a value you specify occurs in the count, the block outputs a 1 at the **Hit** port.

---

**Note** The block might output Boolean values from the **Hit** output port depending on the setting of the **Hit data type** parameter.

---

**Dependencies**

To enable this port, set the **Output** parameter to `Hit` or `Count and Hit`.

Data Types: `Boolean` | `Logical`

**Parameters**

**Count direction** — Count up or down

Up (default) | Down

Specify whether to count **Up** or **Down**. The port label on the block icon changes to **Inc** (increment) or **Dec** (decrement) based on the value of this parameter.

- When you set the **Count direction** parameter to **Up** and the counter reaches the upper limit of the counter range, the block restarts the counter at zero the next time a trigger event occurs at the **Inc** port.
- When you set the **Count direction** parameter to **Down** and the counter reaches zero, the block restarts the counter at the upper limit of the counter range the next time a trigger event occurs at the **Dec** port.

This parameter is tunable (Simulink) in Simulink normal mode.

**Tunable:** Yes

**Count event** — Type of trigger event

Rising edge (default) | Falling edge | Either edge | Non-zero sample | Free running

Specify the type of event that triggers the block to increment, decrement, or reset the counter when received at the **Inc/Dec** or **Rst** ports. You can select:

- **Rising edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port behaves in one of the following ways:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure).

- **Falling edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port behaves in one of the following ways:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure).

- **Either edge** — Triggers a count or reset operation when the input to the **Inc/Dec** or **Rst** port is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a count or reset operation at each sample time when the input to the **Inc/Dec** or **Rst** port is not zero.
- **Free running** — Disables the **Inc/Dec** port and enables the **Samples per output frame** and **Sample time** block parameters. The block increments or decrements the counter at a constant interval,  $T_s$ , which you specify using the **Sample time** parameter. For more information, see “Free-Running Operation” on page 2-316. In this mode, the block resets the counter whenever it receives a non-zero sample at the **Rst** port.

#### Dependencies

When you set this parameter to **Free running**, the block disables the **Inc/Dec** port and counts at the constant interval specified by the **Sample time** parameter.

**Counter size** — Range of integer values to count through

8 bits (default) | 16 bits | 32 bits | User defined | Specify via input port

Specify the range of integer values the block counts through. When the block counts through the entire counter range, the next time a trigger event occurs at the **Inc/Dec** port, the block resets the counter as follows:

- When you set the **Count direction** parameter to **Up** and the counter reaches the upper limit of the counter range, the block restarts the counter at zero.
- When you set the **Count direction** parameter to **Down** and the counter reaches zero, the block restarts the counter at the upper limit of the counter range.

You can set the **Counter size** parameter to one of the following options:

- **8 bits** — Specifies a counter with a range of 0 to 255.
- **16 bits** — Specifies a counter with a range of 0 to 65535.
- **32 bits** — Specifies a counter with a range of 0 to  $2^{32}-1$ .
- **User defined** — Enables the **Maximum count** parameter, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value of the **Maximum count** parameter.
- **Specify via input port** — Enables the **Max** input port, which allows you to specify the upper-count limit as any arbitrary unsigned integer that the **Count data type** can represent. The counter values range from 0 to the value you specify as an input to the **Max** port.

**Maximum count** — Maximum value of counter

255 (default) | positive integer

Specify the maximum value of the counter as any unsigned integer representable by the data type you specify for the **Counter data type** parameter. Tunable (Simulink) in Simulink normal mode.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set the **Counter size** to `User defined`.

**Initial count** — Initial value of counter

0 (default) | integer  $\geq 0$

Specify the initial value of the counter as any unsigned integer in the range defined by the **Counter size** parameter. The block uses the initial value of the counter at the start of simulation and resets the counter back to that initial value each time a trigger event occurs at the **Rst** port.

**Tunable:** Yes

**Output** — Output count value, hit value, or both

Count (default) | Hit | Count and Hit

Select the output ports to enable. You can choose to enable the `Count`, `Hit`, or `Count and Hit` ports.

**Hit values** — Count values to flag

32 (default) | scalar | vector

Specify an integer or vector of integers whose occurrence in the count should be flagged by a 1 at the (optional) **Hit** output port. This parameter appears only when you set the **Output** parameter to `Hit` or `Count and Hit`.

**Tunable:** Yes

**Reset input** — Enable Rst input port

on (default) | off

Select this check box to enable the **Rst** input port. When you enable the **Rst** port, the block resets the counter to its initial value each time a trigger event occurs at the **Rst** port. To specify the type of event that triggers a reset of the counter, set the **Count event** parameter. When you clear the **Reset input** check box, you cannot reset the counter during simulation.

**Samples per output frame** — Number of samples in each output vector

1 (default) | positive integer

Specify the number of samples,  $M$ , in each output vector as a positive integer.

**Dependencies**

To enable this parameter, set the **Count event** to Free running.

**Sample time** — Sample time in Free Running mode

1 (default) | -1 | scalar  $\geq 0$

Specify the constant interval,  $T_s$ , at which the block increments or decrements the counter when in free-running mode. You can specify a scalar that is greater than or equal to zero, or specify a value of -1 to inherit the sample time.

For example, to have the block increment the counter every 5 seconds, set the **Count direction** parameter to Up, the **Count event** parameter to Free running, and specify a value of 5 for the **Sample time** parameter. In free running mode, the sample time of the output ports is always  $MT_s$ .

**Dependencies**

To enable this parameter, set the **Count event** to Free running.

**Count data type** — Data type of Cnt port

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32

Specify the data type of the output at the **Cnt** port.

**Dependencies**

To enable this parameter, set the **Output** parameter to Count or Count and Hit.

**Hit data type** — Data type of Hit port

Logical (default) | Boolean

Specify the data type of the output at the **Hit** port.

**Dependencies**

To enable this parameter, set the **Output** parameter to Hit or set it to Count and Hit with the **Count data type** parameter set to Double.

**Block Characteristics**

## Algorithms

### Scalar Input Operation

When you set the **Count direction** parameter to Up, a trigger event at the **Inc** (increment) input port causes the block to increase the counter by one. Assuming no reset events occur, the block continues increasing the counter value when triggered, until the counter value reaches the upper-count limit. The next time a trigger event occurs at the **Inc** port, the block restarts the counter at 0 and resumes increasing the counter by one for each subsequent trigger event at the **Inc** port.

When you set the **Count direction** parameter to Down, a trigger event at the **Dec** (decrement) input port causes the block to decrease the counter by one. Assuming no reset events occur, the block continues decreasing the counter value when triggered until the counter value reaches zero. The next time a trigger event occurs at the **Dec** port, the block restarts the counter at the upper-count limit and resumes decreasing the counter by one for each subsequent trigger event at the **Dec** port.

Between triggering events, the block holds the output at its most recent value. The block resets the counter to its initial state when the trigger event specified by the **Count event** parameter occurs at the optional **Rst** input port. When the **Inc/Dec** and **Rst** ports receive trigger events simultaneously, the block first resets the counter and then increments or decrements the counter appropriately. If you do not need to reset the counter during simulation, you can disable the **Rst** port by clearing the **Reset input** check box.

The **Output** parameter allows you to specify which values the block outputs:

- **Count** enables a **Cnt** output port on the block. The **Cnt** port provides the current value of the counter as a scalar value. The **Cnt** output port has the same port sample time as the **Inc/Dec** input port.
- **Hit** enables a **Hit** output port on the block. The **Hit** port produces zeros while the value of the counter does not equal any of the integers you specify for the **Hit values** parameter. You can specify an integer or a vector of integers for the **Hit values** parameter. When the counter value does equal one or more of the values you specify for the **Hit values** parameter, the block outputs a value of 1 at the **Hit** output port. The **Hit** output port has the same port sample time as the **Inc/Dec** input port.
- **Count** and **Hit** enables both the **Cnt** and **Hit** output ports.

### Vector Input Operation

The block treats vector inputs to the **Inc/Dec** port as a frame. Vector operation is the same as scalar operation, except that the block increments or decrements the counter by the total number of trigger events contained in the **Inc/Dec** input vector. Thus, the counter may change multiple times during the processing of a single **Inc/Dec** input vector.

When the block has a **Hit** port, the block outputs a value of 1 if any of the **Hit values** match any of the counter values during the processing of the **Inc/Dec** input vector.

When a trigger event splits across two consecutive vectors, that event is counted in the vector that contains the conclusion of the event. When the **Rst** port receives a trigger event at the same time as the **Inc/Dec** port, the block first resets the counter. The block then increments or decrements the counter by the number of trigger events contained in the **Inc/Dec** input vector.

When the input to the **Inc/Dec** port is a length  $N$  vector, the port sample time of the **Inc/Dec** input port is equal to the frame period of the input, or  $N$  times the sample time of the input signal. The port sample time of the **Cnt** and **Hit** output ports equals that of the **Inc/Dec** input port.

### Free-Running Operation

The block operates in free-running mode when you select **Free running** for the **Count event** parameter.

The **Inc/Dec** input port is disabled in this mode, and the block simply increments or decrements the counter at the constant interval,  $T_s$ , which you specify using the **Sample time** parameter.

In this mode, the **Rst** port always behaves as if the **Count event** parameter were set to **Non-zero sample**. Thus, the block triggers a reset event at each sample time that the **Rst** input is not zero.

In this mode, the **Cnt** output is an  $M$ -by-1 vector containing the count value at each of  $M$  consecutive sample times, where  $M$  is the value you specify for the **Samples per output frame** parameter. The **Hit** output is an  $M$ -by-1 vector containing the hit status (0 or 1) at each of those  $M$  consecutive sample times. Both the **Cnt** and **Hit** output ports have a port sample time of  $MT_s$ .

# Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using covariance method

## Libraries:

DSP System Toolbox / Estimation / Parametric Estimation

## Description

The Covariance AR Estimator block uses the covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward prediction error in the least squares sense.

## Ports

### Input

#### Input — Input

column vector | unoriented vector

Specify the input data as a column vector or an unoriented vector. The block assumes that the input data is the output of an AR system driven by white noise and represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

### Output

#### **A** — Normalized estimate of the AR model polynomial coefficients

column vector

Normalized estimate of the AR model polynomial coefficients  $A(z)$ , returned as a column vector of length  $p+1$  in descending powers of  $z$ .

The block computes the estimate of these coefficients independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: `single` | `double`

#### **G** — Model gain

scalar

Gain of the estimated AR model, returned as a scalar.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: `single` | `double`

## Parameters

**Estimation order** — Order of AR model

4 (default) | positive integer

Specify the estimation order  $p$  of the all-pole AR model as a positive integer. To guarantee a nonsingular output, you must set  $p$  to be less than or equal to half the input vector length. Otherwise, the output can be singular.

## Block Characteristics

| <b>Multidimensional Signals</b> | No  |
| <b>Variable-Size Signals</b>    | No  |

## More About

### AR(p) Model

In an AR model of order  $p$ , the current output is a linear combination of the past  $p$  outputs plus a white noise input. The weights on the  $p$  past outputs minimize the mean squared prediction error of the autoregression.

Let  $y(n)$  be a wide-sense stationary random process that you obtain by filtering white noise of variance  $e$  with the system function  $A(z)$ . If  $P_y(e^{j\omega})$  is the power spectral density of  $y(n)$ , then

$$P_y(e^{j\omega}) = \frac{e}{|A(e^{j\omega})|^2} = \frac{e}{\left|1 + \sum_{k=1}^p a(k)e^{-j\omega k}\right|^2}.$$

Because the covariance method characterizes the input data using an all-pole model, the correct choice of the model order  $p$  is important.

### Compare AR Model Parameter Estimation Methods

This table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and the Yule-Walker AR Estimator blocks.

The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

# Covariance Method

Power spectral density estimate using covariance method

## Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

## Description

The Covariance Method block estimates the power spectral density (PSD) of the input using the covariance method. This method fits an autoregressive (AR) model to the signal by minimizing the forward prediction error in the least squares sense.

The block computes the spectrum from the FFT of the estimated AR model parameters.

## Ports

### Input

**Input** — Input

column vector | unoriented vector

Specify the input as a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

### Output

**Output** — Power spectral density estimate

column vector

Power spectral density estimate of the signal at  $N_{fft}$  equally spaced frequency points, returned as a column vector. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling rate of the signal.

Data Types: `single` | `double`

## Parameters

**Estimation order** — Order of AR model

6 (default) | positive integer

Specify the estimation order of the AR model (all-pole model) as a positive integer. The block computes the spectrum from the FFT of the estimated AR model parameters. To guarantee a nonsingular output, the value of the **Estimation order** parameter must be less than or equal to half the input vector length.

**Inherit FFT length from estimation order** — Inherit FFT length from estimation order

off (default) | on

When you select the **Inherit FFT length from estimation order** parameter, the FFT length  $N_{fft}$  is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** parameter. You can then specify a power-of-two FFT length using the **FFT length** parameter. The block zero-pads or wraps the input to  $N_{fft}$  before computing the FFT.

**FFT length** — FFT length

256 (default) | positive integer greater than or equal to 2

Enter the number of data points  $N_{fft}$  on which to perform the FFT as a positive integer greater than or equal to 2. When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

**Dependencies**

To enable this parameter, clear the **Inherit FFT length from input dimensions** parameter.

**Inherit sample time from input** — Inherit sample time from input

on (default) | off

When you select the **Inherit sample time from input** parameter, the block computes the frequency data from the sample period of the input signal. For the block to produce a valid output, the following conditions must hold:

- The input to the block is the original signal with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** parameter. You can then specify a sample time using the **Sample time of original time series** parameter.

**Sample time of original time series** — Sample time of original time-domain signal

1 (default) | positive scalar

Specify the sample time of the original time-domain signal as a positive scalar.

**Dependencies**

To enable this parameter, clear the **Inherit sample time from input** parameter.

**Block Characteristics**

|                                 |                 |

# Cross-Spectrum Estimator

Estimate cross-power spectrum density

## Library

Estimation / Power Spectrum Estimation

dspsect3

## Description

The Cross-Spectrum Estimator block outputs the frequency cross-power spectrum density of two real or complex input signals,  $x$  and  $y$ , via Welch's method of averaged modified periodograms. The input signals must be of the same size and data type.

The Cross-Spectrum Estimator block computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates, where  $N$  is the number of spectral averages defined in **Number of spectral averages**. The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box. The block computes the power spectrum based on the parameters set in the block dialog box.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

## Parameters

### Window length source

Source of the window length value. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input.
- Specify on dialog — Window length is the value specified in **Window length**.

This parameter is nontunable.

### Window length

Length of the window, in samples, used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. This parameter applies when you set **Window length source** to **Specify on dialog**. The default is 1024. This parameter is nontunable.

**Window Overlap (%)**

Percentage of overlap between successive data windows, specified as a scalar in the range [0, 100). The default is 0. This parameter is nontunable.

**Averaging method**

Specify the averaging method as `Running` or `Exponential`. In the running averaging method, the block computes an equally weighted average of a specified number of spectrum estimates defined by the **Number of spectral averages** parameter. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor.

**Number of spectral averages**

Number of spectral averages, specified as a positive integer scalar. The default is 1. The spectrum estimator computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates, where  $N$  is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to `Running`.

**Specify forgetting factor from input port**

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to `Exponential`.

**Forgetting factor**

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to `Exponential` and clear the **Specify forgetting factor from input port** parameter.

**FFT length source**

Source of the FFT length value. You can set this parameter to:

- `Auto` (default) — FFT length is set to the frame size of the input.
- `Property` — FFT length is the value specified in **FFT length**.

This parameter is nontunable.

**FFT length**

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **FFT length source** to `Property`. The default is 1024. This parameter is nontunable.

**Window function**

Window function for the cross-spectrum estimator, specified as one of `Chebyshev` | `Flat Top` | `Hamming` | `Hann` | `Kaiser` | `Rectangular`. The default is `Hann`. This parameter is nontunable.

**Sidelobe attenuation of window (dB)**

Side lobe attenuation of the window, specified as real positive scalar. This parameter applies when you set **Window function** to `Chebyshev` or `Kaiser`. The default is 60. This parameter is nontunable.

**Frequency range**

Frequency range of the cross-spectrum estimator. You can set this parameter to:

- **centered** (default) — The cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals,  $x$  and  $y$ . The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $[-\text{SampleRate}/2 \text{ SampleRate}/2]$  when the FFT length is even and  $[-\text{SampleRate}/2 \text{ SampleRate}/2]$  when FFT length is odd.
- **onesided** — The cross-spectrum estimator computes the one-sided spectrum of real input signals,  $x$  and  $y$ . When the FFT length,  $NFFT$  is even, length of the cross-spectrum estimate is  $(NFFT/2) + 1$ , and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ . When the FFT length,  $NFFT$  is odd, length of the cross-spectrum estimate is  $(NFFT + 1)/2$ , and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ .
- **twosided** — The cross-spectrum estimator computes the two-sided spectrum of complex or real input signals,  $x$  and  $y$ . The length of the cross-spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $[0 \text{ SampleRate}]$ , where  $\text{SampleRate}$  is the sample rate of the input signal.

This parameter is nontunable.

### Inherit sample rate from input

When you select this check box, the block's sample rate is computed as  $N/T_s$ , where  $N$  is the frame size of the input signal, and  $T_s$  is the sample time of the input signal. When you clear this check box, the block sample rate is the value specified in **Sample rate (Hz)**. By default, this check box is selected.

### Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

### Simulate using

Type of simulation to run. You can set this parameter to:

- **Code generation** (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

- **Interpreted execution**

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Algorithms

### Welch's Method of Averaged Modified Periodograms

Give two signal inputs,  $x$  and  $y$ :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Compute FFT of the signals,  $X$  and  $Y$ , and multiply  $X$  with  $\text{conj}(Y)$  using  $Z = X.\text{*conj}(Y)$ .
- 3 Compute the current cross power spectrum estimate by taking the moving average of the last  $N$  number of  $Z$ 's and scaling the answer by the sample rate.

For further information on the algorithms, refer to the "Averaging Method" on page 2-1343 section in Spectrum Analyzer.

# Cumulative Product

Cumulative product of channel, column, or row elements

## Library

Math Functions / Math Operations

dspmathops

## Description

The Cumulative Product block computes the cumulative product along the specified dimension of the input or across time (running product).

The input can be a vector or matrix.

### Input and Output Characteristics

#### Valid Input

The Cumulative Product block accepts vector or matrix inputs containing real or complex values.

#### Valid Reset Signal

The optional reset port, `Rst`, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the `Rst` port must be the same or slower than that of the input data signal. The sample time of the input to the `Rst` port must be a positive integer multiple of the input sample time.

### Computing the Running Product Along Channels of the Input

When you set the **Multiply input along** parameter to `Channels (running product)`, the block computes the cumulative product of the elements in each input channel. The running product of the current input takes into account the running product of all previous inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block computes the running product along each column of the current input. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block computes a running product for each element of the input across time. See the following sections for more information:

- “Computing the Running Product for Each Column of the Input” on page 2-330
- “Computing the Running Product for Each Element of the Input” on page 2-330
- “Resetting the Running Product” on page 2-331

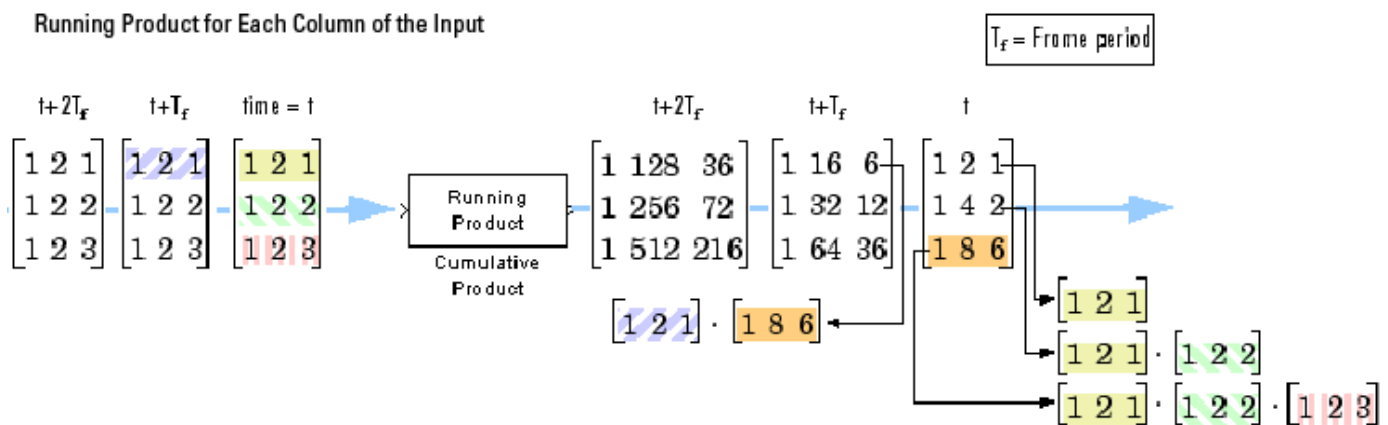

### Computing the Running Product for Each Column of the Input

When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the element-wise product of the first row of the current input (time  $t$ ), and the last row of the previous output (time  $t - T_f$ , where  $T_f$  is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an  $M$ -by- $N$  matrix input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) \cdot y_{M,j}(t - T_f)$$

### Computing the Running Product for Each Element of the Input

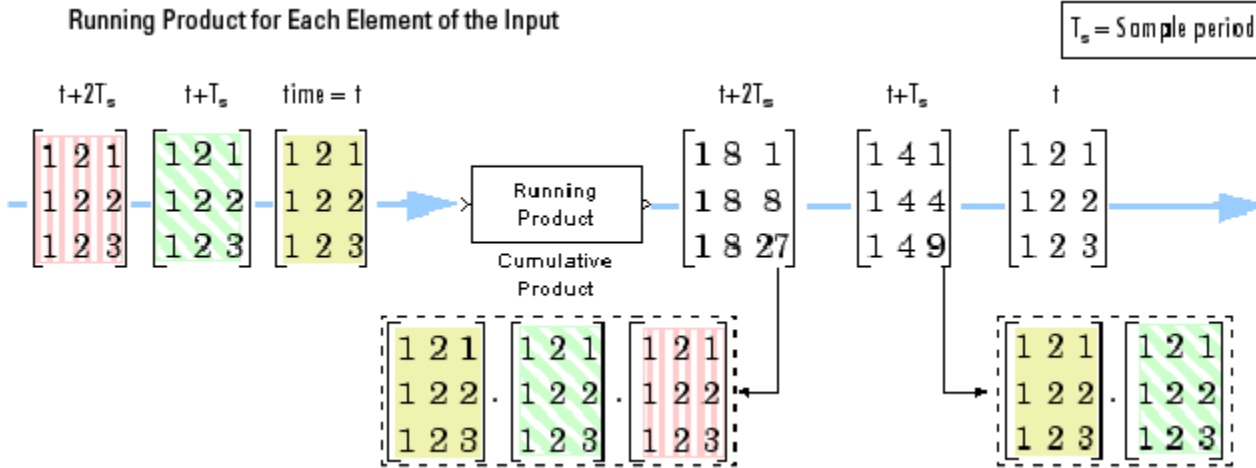

When you set the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first output is the same as the first input.
- Each subsequent output is the element-wise product of the current input (time  $t$ ) and the previous output (time  $t - T_s$ , where  $T_s$  is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an  $M$ -by- $N$  matrix input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) \cdot y_{i,j}(t - T_s) \quad \begin{matrix} 1 \leq i \leq M \\ 1 \leq j \leq N \end{matrix}$$

For convenience, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors when multiplying along channels. In such cases, the output is a length- $M$  unoriented vector.

**Resetting the Running Product**

When you are computing the running product, you can configure the block to reset the running product whenever it detects a reset event at the optional Rst port. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. The input to the Rst port can be of the Boolean data type.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

The **Reset port** parameter specifies the reset event, which can be one of the following:

- None disables the Rst port.
- Rising edge — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- Falling edge — Triggers a reset operation when the Rst input does one of the following:

- Falls from a positive value to a negative value or zero
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a Rising edge or Falling edge (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero

---

**Note** When you run simulations in Simulink MultiTasking mode, reset signals have a one-sample latency. When the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Multiplying Along Columns

When you set the **Multiply input along** parameter to **Columns**, the block computes the cumulative product of each column of the input. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u) % Equivalent MATLAB code
```

The output has the same size, dimension, data type, and complexity as the input. The  $m$ th output row is the element-wise product of the first  $m$  input rows.

Given an  $M$ -by- $N$  input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix whose  $j$ th column has elements

$$y_{i,j} = \prod_{k=1}^i u_{k,j} \quad 1 \leq i \leq M$$

When multiplying along columns, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

**Product Along Columns**

**Multiplying Along Rows**

When you set the **Multiply input along** parameter to Rows, the block computes the cumulative product of the row elements. In this mode, the current cumulative product is independent of the cumulative products of previous inputs.

```
y = cumprod(u,2) % Equivalent MATLAB code
```

The output has the same size, dimension, and data type as the input. The *n*th output column is the element-wise product of the first *n* input columns.

Given an *M*-by-*N* matrix input, *u*, the output, *y*, is an *M*-by-*N* matrix whose *i*th row has elements

$$y_{i,j} = \prod_{k=1}^j u_{i,k} \quad 1 \leq j \leq N$$

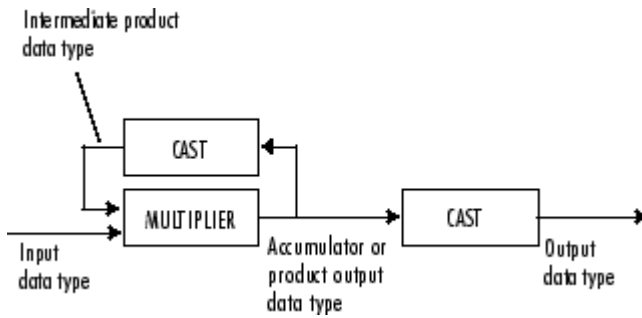

When you multiply along rows, the block treats length-*N* unoriented vector inputs as 1-by-*N* row vectors.

**Product Along Rows**

**Fixed-Point Data Types**

The following diagram shows the data types used within the Cumulative Product block for fixed-point signals.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in “Parameters” on page 2-334.

## Parameters

### Main Tab

#### Multiply input along

Specify the dimension along which to compute the cumulative product. You can choose to multiply along Channels (running product), Columns, or Rows. For more information, see the following sections:

- “Computing the Running Product Along Channels of the Input” on page 2-329
- “Multiplying Along Columns” on page 2-332
- “Multiplying Along Rows” on page 2-333

#### Input processing

Specify how the block should process the input when computing the running product along the channels of the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

This parameter is available only when you set the **Multiply input along** parameter to Channels (running product).

#### Reset port

Determines the reset event that causes the block to reset the product along channels. The rate of the input to the Rst port must be the same or slower than that of the input data signal. The sample time of the input to the Rst port must be a positive integer multiple of the input sample time. This parameter appears only when you set the **Multiply input along** parameter to Channels (running product). For more information, see “Resetting the Running Product” on page 2-331.

#### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

### Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-333, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-333 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-333 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-333 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

If both inputs are unsigned, all data types including the output data type is unsigned. If one of the inputs is signed, internal and output data types are signed.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

## Intermediate Product Data Type Assistant Parameters

### Mode

Select how you would like to specify the data type properties of the **Intermediate product** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

### Signedness

Specify the **Signedness** for the **Intermediate product** data type.

### Scaling

Specify the **Scaling** for the **Intermediate product** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

### Word length

Specify the **Word length** for the **Intermediate product** data type.

### Fraction length

Specify the **Fraction length** for the **Intermediate product** data type.

### Data type override

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Product Output Data Type Assistant Parameters

### Mode

Select how you would like to specify the data type properties of the **Product output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`

- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Product output** data type.

**Scaling**

Specify the **Scaling** for the **Product output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Product output** data type.

**Fraction length**

Specify the **Fraction length** for the **Product output** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

## Scaling

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

## Word length

Specify the **Word length** for the **Accumulator** data type.

## Fraction length

Specify the **Fraction length** for the **Accumulator** data type.

## Data type override

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Output Data Type Assistant Parameters

### Mode

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, **Inherit via internal rule**
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

### Signedness

Specify the **Signedness** for the **Output** data type.

### Scaling

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

### Word length

Specify the **Word length** for the **Output** data type.

#### Fraction length

Specify the **Fraction length** for the **Output** data type.

#### Data type override

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

| Input and Output Ports       | Supported Data Types  |
|------------------------------|---|
| Data input port, <b>In</b>   | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>                               |

`cumprod`

### Blocks

Cumulative Sum | Matrix Product

## Cumulative Sum

Cumulative sum of channel, column, or row elements

### Libraries:

DSP System Toolbox / Math Functions / Math Operations

## Description

The Cumulative Sum block computes the cumulative sum along the specified dimension of the input or across time (running sum).

## Ports

### Input

**In** — Input signal  
vector | matrix

Input, specified as a vector or as matrix inputs containing real or complex values.

This port is unnamed until you select a non-None value for the **Reset** port parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

**Rst** — Reset port  
scalar

The optional reset port, **Rst**, accepts scalar values, which can be any built-in Simulink data type including `boolean`. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time.

This port is unnamed until you select a non-None value for the **Reset** port parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean`

### Output

**Port\_1** — Output signal  
vector | matrix

Cumulative sum of input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Parameters

### Main

**Sum input along** — Dimension to sum along

Channels (running sum) (default) | Columns | Rows

Specify the dimension along which to compute the cumulative summations. You can choose to sum along Channels (running sum), Columns, or Rows. For more information, see these sections:

- “Computing the Running Sum Along Channels of the Input” on page 2-346
- “Summing Along Columns” on page 2-348
- “Summing Along Rows” on page 2-349

**Input processing** — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block processes the input when computing the running sum along the channels of the input. You can set this parameter to one of these options:

- Columns as channels (frame based) — The block treats each column of the input as a separate channel.
- Elements as channels (sample based) — The block treats each element of the input as a separate channel.

### Dependencies

This parameter is available only when you set the Sum input along parameter to Channels (running sum).

**Reset port** — Reset type

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

Determines the reset event that causes the block to reset the sum along channels. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time. For more information, see “Resetting the Running Sum” on page 2-347.

### Dependencies

This parameter is available only when you set the Sum input along parameter to Channels (running sum).

### Data Types

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings. All internal data types are floating point.

---

**Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Saturate for fixed-point operation

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Accumulator** — Data type of accumulator

Inherit: Same as first input (default) | fixdt([],16,0)

**Accumulator** specifies the data type of the output of an accumulation operation in the Cumulative Sum block. For illustrations on how to use the accumulator data type in this block, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. Click the

**Show data type assistant** button  .

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output** — Data type of output

Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)

**Output** specifies the data type of the output of the Cumulative Sum block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. Click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output Minimum** — Minimum value the block can output  
`[]` (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value block can output  
`[]` (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |

| <b>Zero-Crossing Detection</b>  | <code>no</code>   |

## More About

### Computing the Running Sum Along Channels of the Input

When you set the `Sum input along` parameter to `Channels (running sum)`, the block computes the cumulative sum of the elements in each input channel. The running sum of the current input takes into account the running sum of all previous inputs. In this mode, you must also specify a value for the `Input processing` parameter.

When you set the **Input processing** parameter to:

- `Columns as channels (frame based)` -- The block computes the running sum along each column of the current input.
- `Elements as channels (sample based)` -- The block computes a running sum for each element of the input across time.

### Computing the Running Sum for Each Column of the Input

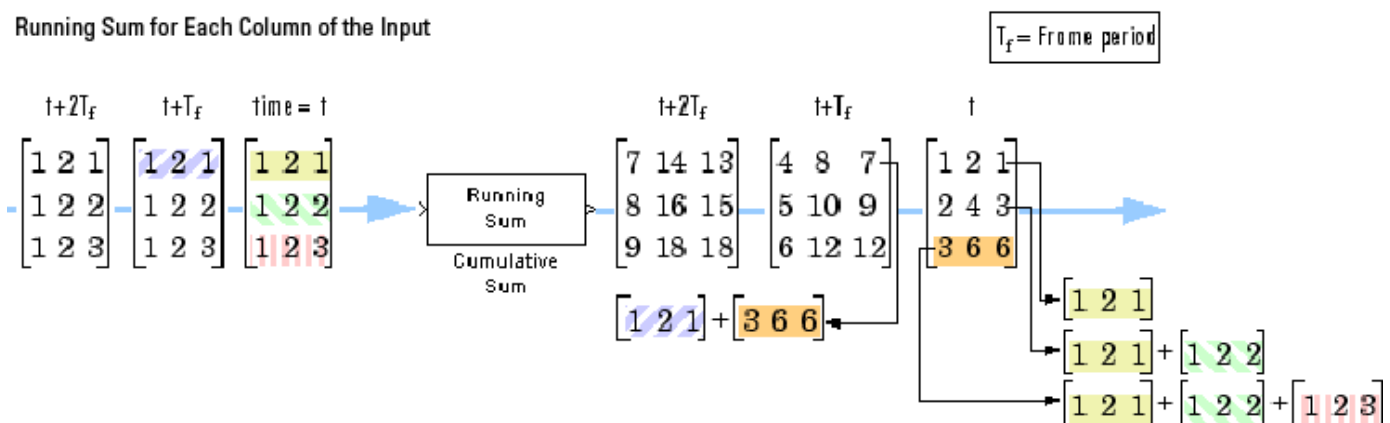

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each input column as an independent channel. As the following figure and equation illustrate, the output has the following characteristics:

- The first row of the first output is the same as the first row of the first input.
- The first row of each subsequent output is the sum of the first row of the current input (time  $t$ ), and the last row of the previous output (time  $t - T_f$ , where  $T_f$  is the frame period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an  $M$ -by- $N$  matrix input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix whose first row has elements

$$y_{1,j}(t) = u_{1,j}(t) + y_{M,j}(t - T_f)$$

Running Sum for Each Column of the Input

### Computing the Running Sum for Each Element of the Input

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input matrix as an independent channel. As the following figure and equation illustrate, the output has these characteristics:

- The first output is the same as the first input.
- Each subsequent output is the sum of the current input (time  $t$ ) and the previous output (time  $t - T_s$ , where  $T_s$  is the sample period).
- The output has the same size, dimension, data type, and complexity as the input.

Given an  $M$ -by- $N$  matrix input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix with the elements

$$y_{i,j}(t) = u_{i,j}(t) + y_{i,j}(t - T_s) \quad \begin{array}{l} 1 \leq i \leq M \\ 1 \leq j \leq N \end{array}$$

### Running Sum for Each Element of the Input

### Resetting the Running Sum

When you are computing the running sum, you can configure the block to reset the running sum whenever it detects a reset event at the optional **Rst** port. The rate of the input to the **Rst** port must be the same or slower than that of the input data signal. The sample time of the input to the **Rst** port must be a positive integer multiple of the input sample time. The reset sample time must be a positive integer multiple of the input sample time. The input to the **Rst** port can be boolean.

If a reset event occurs while the block is performing sample-based processing, the block initializes the current output to the values of the current input. If a reset event occurs while the block is performing frame-based processing, the block initializes the first row of the current output to the values in the first row of the current input.

The **Reset** port parameter specifies the reset event, which can be one of the following:

- **None** disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero

- **Either edge** — Triggers a reset operation when the **Rst** input is a **Rising edge** or **Falling edge**
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero

---

**Note** When you run simulations in the Simulink **MultiTasking** mode, reset signals have a one-sample latency. When the block detects a reset event, a one-sample delay occurs at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Summing Along Columns

When you set the `Sum` input along parameter to `Columns`, the block computes the cumulative sum of each column of the input. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

```
y = cumsum(u) % Equivalent MATLAB code
```

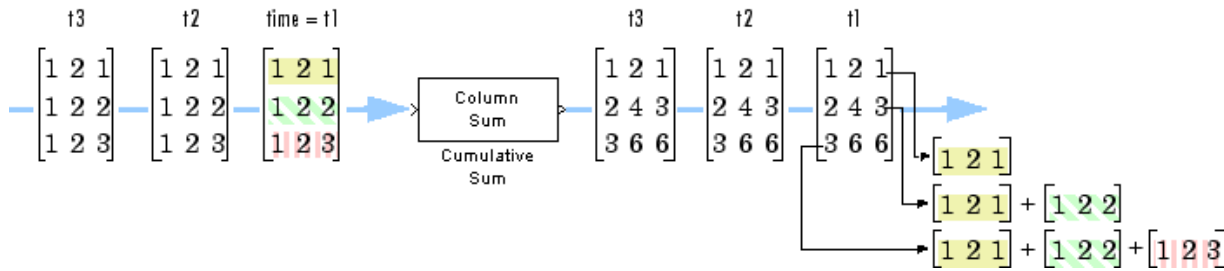

The output has the same size, dimension, data type, and complexity as the input. The  $m$ th output row is the sum of the first  $m$  input rows.

Given an  $M$ -by- $N$  input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix whose  $j$ th column has elements

$$y_{i,j} = \sum_{k=1}^j u_{k,j} \quad 1 \leq i \leq M$$

The block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors when summing along columns.

**Sum Along Columns**

**Summing Along Rows**

When you set the Sum input along parameter to Rows, the block computes the cumulative sum of the row elements. In this mode, the current cumulative sum is independent of the cumulative sums of previous inputs.

```
y = cumsum(u,2) % Equivalent MATLAB code
```

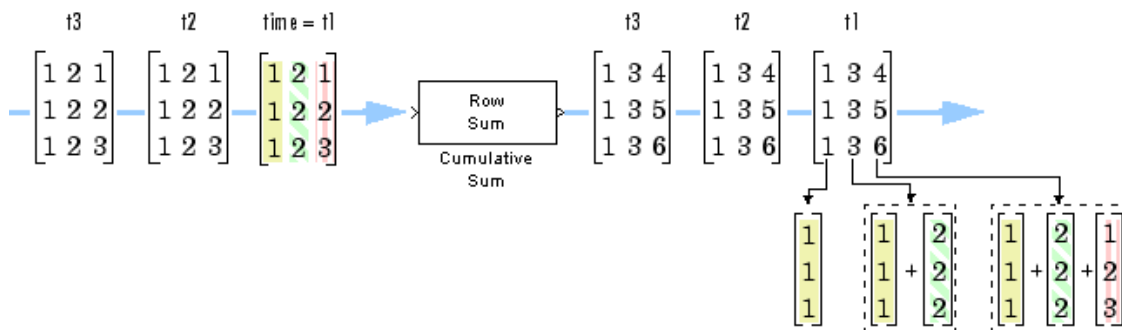

The output has the same size, dimension, and data type as the input. The  $n$ th output column is the sum of the first  $n$  input columns.

Given an  $M$ -by- $N$  input,  $u$ , the output,  $y$ , is an  $M$ -by- $N$  matrix whose  $i$ th row has elements

$$y_{i,j} = \sum_{k=1}^j u_{i,k} \quad 1 \leq j \leq N$$

When you sum along rows, the block treats length- $N$  unoriented vector inputs as 1-by- $N$  row vectors.

# Dataflow Subsystem

Subsystem whose execution domain is set to Dataflow

**Libraries:**  
DSP System Toolbox / Dataflow

## Description

The Dataflow Subsystem block is a Subsystem block preconfigured with the execution domain set to dataflow. A Dataflow Subsystem uses synchronous dataflow as a model of computation, which is data-driven and statically scheduled.

Dataflow Subsystems help to

- Improve simulation throughput with multithreaded execution

Dataflow domains leverage the multicore CPU architecture of the host computer and can improve simulation speed significantly. It automatically partitions your model and simulates the system using multiple threads. By adding latency to your system, you can further increase concurrency and improve simulation throughput of your model.

- Automatically infer signal sizes for frame-based multirate models

See “Dataflow Domain” for more information.

## Ports

### Input

**In** — Signal input to dataflow subsystem  
scalar | vector | matrix

Placing an Inport block in a subsystem adds an external input port to the block. The port label on the subsystem block is the name of the Inport block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

### Output

**Out** — Signal output from dataflow subsystem  
scalar | vector | matrix

Placing an Outport block in a subsystem adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

## Parameters

The Dataflow Subsystem block uses the same parameters as the Subsystem block. For parameter descriptions and programmatic use information, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem.

---

**Note** Dataflow subsystems cannot be atomic subsystems.

---

**Latency** — Latency of dataflow subsystem  
0 (default) | scalar integer

To increase the throughput of a system, it can be advantageous to increase the latency of the system. Specify the **Latency** value in the **Execution** tab of the Property Inspector. For more information, see “Latency”.

### Programmatic Use

**Block Parameter:** Latency

**Type:** character vector

**Values:** scalar integer

**Default:** '0'

**Automatic frame size calculation** — Automatically calculate frame sizes and insert buffers  
0 (default) | 1

When the **Automatic frame size calculation** parameter is enabled, dataflow domains automatically calculate frame sizes and insert buffers into your model, avoiding signal size propagation errors in multirate signal processing systems. For more information, see “Automatic Frame Size Calculation”.

### Programmatic Use

**Block Parameter:** AutoFrameSizeCalculation

**Type:** character vector

**Values:** 'off' | 'on'

**Default:** 'off'

## dB Conversion

Convert magnitude data to decibels (dB or dBm)

### Libraries:

DSP System Toolbox / Math Functions / Math Operations

## Description

The dB Conversion block converts a linearly scaled power or amplitude input to dB or dBm. The reference power is 1 Watt for conversions to dB and 1 mWatt for conversions to dBm. The block's **Input signal** parameter specifies whether the input is a power signal or a voltage signal, and the **Convert to** parameter controls the scaling of the output. When selected, the **Add eps to input to protect against "log(0) = -inf"** parameter adds a value of `eps` to all power and voltage inputs. When this parameter is not selected, zero-valued inputs produce `-Inf` at the output.

## Ports

### Input

**Port\_1** — Input signal

scalar | vector | matrix

Input signal to be converted, specified as a real scalar, vector, or matrix.

When the "Input signal" on page 2-0 parameter is set to:

- **Power** — The input is treated as a power signal, specified in Watts.
- **Amplitude** — The input is treated as a voltage signal, specified in Volts.

Data Types: single | double

### Output

**Port\_1** — Output signal

scalar | vector | matrix

The converted output signal, returned as a scalar, vector, or matrix. The output is the same size, and data type as the input. The output  $y$  is calculated as follows.

When the "Input signal" on page 2-0 parameter is set to **Power** and **Convert to** parameter is set to:

- **dB** — The block performs this dB conversion:  

$$y = 10 \cdot \log_{10}(u)$$
- **dBm** — The block performs this dBm conversion:  

$$y = 10 \cdot \log_{10}(u) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the input to milliwatts.

Input  $u$  is a real, nonnegative, power signal, specified in Watts.

When the **Input signal** parameter is set to **Amplitude** and **Convert to** parameter is set to:

- **dB** — The block performs this dB conversion:  

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R)$$
- **dBm** — The block performs the following dBm conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R) + 30$$

Input  $u$  is a real voltage signal, specified in Volts.

The dBm conversion is equivalent to performing the dB operation after converting the  $(\text{abs}(u)^2/R)$  result to milliwatts. The scale factor,  $R$ , is specified in Ohms.

Data Types: `single` | `double`

## Parameters

**Convert to** — Signal to convert  
 dB (default) | dBm

The logarithmic scaling to which the input is converted, **dB** or **dBm**. The reference power is 1 Watt for conversions to dB and 1 mW for conversions to dBm.

Amplitude conversions use the scale factor specified in ohms by the **Load resistance** parameter,  $R$ , to convert the voltage input to units of power (watts) before converting to dB or dBm.

When the “Input signal” on page 2-0 parameter is set to **Power** and **Convert to** parameter is set to:

- **dB** — The block performs this dB conversion:  

$$y = 10 \cdot \log_{10}(u)$$
- **dBm** — The block performs this dBm conversion:

$$y = 10 \cdot \log_{10}(u) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the input to milliwatts.

Input  $u$  is a real, nonnegative, power signal, specified in Watts.

**Input signal** is set to **Amplitude** and **Convert to** parameter is set to:

- **dB** — The block performs this dB conversion:  

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R)$$
- **dBm** — The block performs this dBm conversion:

$$y = 10 \cdot \log_{10}(\text{abs}(u)^2/R) + 30$$

The dBm conversion is equivalent to performing the dB operation after converting the  $(\text{abs}(u)^2/R)$  result to mW. The scale factor  $R$  is specified in Ohms.

Input  $u$  is a real voltage signal, specified in Volts.

**Tunable:** Yes

**Input signal** — Type of signal  
Amplitude (default) | Power

The type of input signal, Power or Amplitude.

When **Input signal** is set to:

- Power -- Input  $u$  is a real, nonnegative, power signal (units of Watts).
- Amplitude -- Input  $u$  is a real voltage signal (units of Volts).

**Load resistance (ohms)** — Scale factor  
1 (default) | positive scalar | positive integer

The scale factor  $R$ , specified in ohms. The block uses the scale factor to convert voltage input to units of power (watts) before converting to dB or dBm.

**Tunable:** Yes

#### Dependencies

To enable this parameter, set the "Input signal" on page 2-0 parameter to Amplitude.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Complex Number Support: Yes

**Add eps to input to protect against "log(0) = -inf"** — Add eps  
off (default) | on

Select this parameter to add eps to all input values (power or voltage).

**Tunable:** Yes

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|

dB Gain

## dB Gain

Apply decibel gain

## Library

Math Functions / Math Operations

dspmathops

## Description

The dB Gain block multiplies the input by the decibel values specified in the **Gain** parameter. For an  $M$ -by- $N$  input matrix  $u$  with elements  $u_{ij}$ , the **Gain** parameter can be a real  $M$ -by- $N$  matrix with elements  $g_{ij}$  to be multiplied element-wise with the input, or a real scalar.

$$y_{ij} = u_{ij}10^{(g_{ij}/k)}$$

The value of  $k$  is 10 for power signals (select **Power** as the **Input signal** parameter) and 20 for voltage signals (select **Amplitude** as the **Input signal** parameter).

The value of the equivalent linear gain

$$g_{ij}^{lin} = 10^{(g_{ij}/k)}$$

is displayed in the block icon below the dB gain value. The output is the same size as the input.

The dB Gain block supports real and complex floating-point and fixed-point data types.

### Fixed-Point Data Types

The following diagram shows the data types used within the dB Gain subsystem block for fixed-point signals.

The settings for the fixed-point parameters of the Gain block in the diagram above are as follows:

- Integer rounding mode: **Floor**
- Saturate on integer overflow — unselected
- Parameter data type mode — **Inherit via internal rule**
- Output data type mode — **Inherit via internal rule**

See the Gain reference page for more information.

## Parameters

### Gain

The dB gain to apply to the input, a scalar or a real  $M$ -by- $N$  matrix. Tunable (Simulink).

### Input signal

The type of input signal: Power or Amplitude. Tunable (Simulink).

---

**Note** This block does not support tunability in generated code.

---

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## DCT

Discrete cosine transform (DCT) of input

**Libraries:**  
DSP System Toolbox / Transforms

### Description

The DCT block computes the unitary discrete cosine transform (DCT) of the input signal  $u$ . When the input is an  $M$ -by- $N$  matrix, the block computes the DCT of each channel in the matrix.

Here is the equivalent MATLAB code.

```
y = dct(u)
```

This block supports Simulink virtual buses.

### Ports

#### Input

**Input 1** — Input signal  
vector | matrix |  $N$ -D array

Specify the input signal as a vector, matrix, or an  $N$ -D array.

For all  $N$ -D input arrays, the block computes the DCT across the first dimension. The size of the first dimension (frame size) must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input to the DCT block is an  $M$ -by- $N$  matrix, the block treats each input column as an independent channel containing  $M$  consecutive samples.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

#### Output

**Output 1** — DCT output  
vector | matrix |  $N$ -D array

The block outputs the DCT of the input signal as a vector, matrix, or an  $N$ -D array.

When the block outputs an  $M$ -by- $N$  matrix, the  $l^{\text{th}}$  column of the matrix contains the length- $M$  DCT of the corresponding input column.

$$y(k, l) = w(k) \sum_{m=1}^M u(m, l) \cos \frac{\pi(2m-1)(k-1)}{2M}, \quad k = 1, \dots, M$$

where

$$w(k) = \begin{cases} \frac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\frac{2}{M}}, & 2 \leq k \leq M \end{cases}$$

When the input is fixed-point (signed and unsigned), the output is signed fixed-point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point` | `bus`

## Parameters

### Main Tab

#### Sine and cosine computation — Sine and cosine computation

`Table lookup (default)` | `Trigonometric fcn`

Set the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`).

To compute sines and cosines, set the parameter to one of these values:

- `Table lookup` -- The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.

The block runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.

- `Trigonometric fcn` -- The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.

The block runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

### Data Types Tab

#### Rounding mode — Rounding mode

`Floor (default)` | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

#### Saturate on integer overflow — Saturate on integer overflow

`off (default)` | `on`

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

---

### Sine table — Sine table

`Inherit: Same word length as input (default) | fixd(1,16)`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters. The block always saturates and rounds off the sine table values to `Nearest`.

### Product output — Product output

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixd(1,16,0)`

Specify the product output data type. See “Fixed-Point Data Types” on page 2-364 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator — Accumulator

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixd(1,16,0)`

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-364 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output — Data type of output

Inherit: `Inherit via internal rule` (default) | `Inherit: Same as input` | `fixd(1,16,0)`

Specify the output data type. See “Fixed-Point Data Types” on page 2-364 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(DCTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output Minimum — Output minimum

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Output Maximum — Output maximum

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

## More About

### Fixed-Point Data Types

The following diagrams show the data types used within the DCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the block parameters dialog box of the DCT block.

Inputs to the DCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

**Butterfly Stage Data Types**

**Twiddle Multiplication Data Types**

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

---

**Note** When the block input is fixed point, all internal data types are signed fixed point.

---

**Input** — Input signal

scalar | vector | matrix

Specify the input signal that contains the DC component as a scalar, vector, or a matrix. When the input is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

### Output

**Output** — Output signal with no DC component

scalar | vector | matrix

Output signal with the DC component removed. When the output is fixed-point, it is signed only.

The size, data type, and complexity of the output signal are the same as that of the input signal.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

**Algorithm for estimating DC offset** — Algorithm for estimating DC offset

IIR (default) | FIR | CIC | Subtract mean

Specify the algorithm used for estimating the DC offset. Select from the following:

- IIR uses a recursive estimate based on a narrow, lowpass elliptic filter. This algorithm typically uses less memory than FIR and is more efficient.
- FIR uses a nonrecursive, moving-average estimate. This algorithm typically uses more memory than IIR and is less efficient.
- CIC uses a lowpass filter that does not employ any multipliers. If the algorithm is CIC, then fixed-point data must be input to the DC Blocker.

- **Subtract mean** computes the means of the columns of the input matrix and subtracts the means from the input. This method does not retain state between inputs. For example, if the input is `[1 2 3 4; 3 4 5 6]`, then the DC Blocker block in **Subtract mean** mode outputs `[-1 -1 -1 -1; 1 1 1 1]`.

**Normalized bandwidth of lowpass IIR or CIC filter** — Normalized bandwidth

0.001 (default) | real scalar in the range (0 1)

Specify the normalized filter bandwidth as a real scalar greater than 0 and less than 1.

**Dependencies**

The DC Blocker uses this parameter only when the estimation algorithm is set to **IIR** or **CIC**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Order of lowpass IIR elliptic filter** — Order of lowpass IIR elliptic filter

6 (default) | integer greater than 3

Specify the filter order of the lowpass IIR elliptic filter as an integer greater than 3.

**Dependencies**

The DC Blocker uses this parameter only when the estimation algorithm is set to **IIR**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Number of past input samples for FIR algorithm** — Number of past input samples for FIR algorithm

50 (default) | positive integer

Specify, as a positive integer, the number of samples to use when the estimation algorithm is set to **FIR**.

**Dependencies**

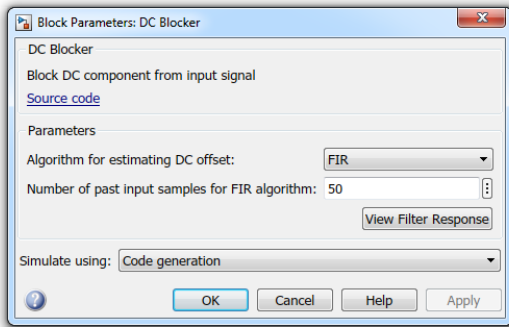

The DC Blocker uses this parameter only when the estimation algorithm is set to **FIR**.

Data Types: `single` | `double`

**View Filter Response** — Visualize frequency response  
button

Opens the `fvtool` and displays the magnitude response of the DC Blocker. The response is based on the block parameters. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

## Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

### IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

### FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as  $\text{ones}(1, \text{Length})/\text{Length}$ , where  $\text{Length}$  is the number of past input samples for FIR algorithm. The FIR filter structure is a direct form I transposed structure.

### CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3 dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})} \right|^N$$

- $B_{norm}$  is the normalized bandwidth such that  $0 < B_{norm} < 1$ .
- $M$  is the differential delay in samples.
- $N$  is the number of sections, equal to 2.

Set the differential delay,  $M$ , to the smallest integer such that  $|H(e^{j\omega})| < 1/\sqrt{2}$ . Once  $M$  is known, the gain of the CIC filter is calculated as  $M^N$ . Therefore, to precisely compensate for the filter gain, the multiplier is set to  $(1/M)^N$ .

### Subtract mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The DC Blocker block supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For a DC Blocker optimized for HDL code generation, see "High Performance DC Blocker for FPGA" (DSP HDL Toolbox). The DSP HDL Toolbox block provides an HDL-optimized algorithm with hardware-friendly control signals and simulates the latency of the HDL algorithm in Simulink.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### HDL Architecture

This block has one default HDL architecture.

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).               |

**Complex Data Support**

This block supports code generation for complex signals.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## Delay

Delay discrete-time input by specified number of samples or frames

## Compatibility

---

**Note** The Delay block from the `dspsigops` library has been replaced by the Delay block from the Discrete library in Simulink. Existing instances of the `dspsigops` Delay block will be replaced with Simulink Delay block when there is an exact match in functionality between the two blocks. For new models, use the Delay block from the Discrete library in Simulink.

---

## Library

Signal Operations

`dspsigops`

## Description

The Delay block delays a discrete-time input by the number of samples or frames specified in the **Delay units** and **Delay** parameters. The **Delay** value must be an integer value greater than or equal to zero. When you enter a value of zero for the **Delay** parameter, any initial conditions you might have entered have no effect on the output.

The Delay block allows you to set the initial conditions of the signal that is being delayed. The initial conditions must be numeric.

### Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the  $M$ -by- $N$  input matrix as an independent channel. The block delays each channel of the input as specified by the **Delay** parameter.

The **Delay** parameter can be a scalar integer by which the block equally delays all channels or a vector whose length is equal to the number of channels.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. See the “Frame-Based Processing Examples” on page 2-375 section for more information.

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the  $N$ -D input array as an independent channel. Thus, the total number

of channels in the input is equal to the product of the input dimensions. The dimension of the output is the same as that of the input.

The **Delay** parameter can be a scalar integer by which to equally delay all channels or an N-D array of the same dimensions as the input array, containing nonnegative integers that specify the number of sample intervals to delay each channel of the input.

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different within a channel. See the “Sample-Based Processing Examples” on page 2-378 section for more information.

### Resetting the Delay

The Delay block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

The reset event is specified by the **Reset port** parameter, and can be one of the following:

- **None** disables the Rst port.
- **Rising edge** triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** triggers a reset operation when the Rst input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- Either edge triggers a reset operation when the Rst input is Rising edge or Falling edge (as described earlier).
- Non-zero sample triggers a reset operation at each sample time that the Rst input is not zero.

---

**Note** When running simulations in the Simulink MultiTasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

This block supports Simulink virtual buses.

## Examples

### Frame-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be constant or varying along each channel. The next sections describe the behavior of the block for each of these four cases:

- “Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel” on page 2-375
- “Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel” on page 2-376
- “Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel” on page 2-376
- “Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel” on page 2-377

#### Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be identical and zero for the first frame:

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Clear the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to a scalar value of 0.

The output of the delay block is

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

0, the scalar initial condition value, is used across the channels and within the channels for the first frame. This frame is the output at sample time zero.

### Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be a vector of length  $N$ , where  $N \geq 1$ .  $N$  is also equal to the number of channels in your signal. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be [0 10 20] for the first frame:

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Select the **Specify different initial conditions for each channel** check box.
- 3 Clear the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [0 10 20].

The output of the delay block is

$$\begin{bmatrix} 0 & 10 & 20 \\ 0 & 10 & 20 \\ 0 & 10 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

The initial condition vector expands to create the frame that is output at sample time zero. Different initial conditions are used for each channel, but the same initial condition value is used with a channel.

### Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, the **Delay** parameter can be a scalar integer by which to equally delay all channels or a vector whose length is equal to the number of channels. All the values of this vector must be equal.

Enter the initial conditions as a vector. These values are used as the initial condition value along each of the channels to be delayed. The initial condition vector must have length equal to the value of the **Delay (frames)** parameter multiplied by the frame length. For example, if you want to delay your signal by two frames with frame length two and an initial condition value of 3, enter your initial condition vector as [3 3 3 3].

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be the same along each of the channels to be delayed:

- 1 Set the **Delay (frame)** parameter to 1.
- 2 Clear the **Specify different initial conditions for each channel** check box.
- 3 Select the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [10 20 30].

The output of the delay block is

$$\begin{bmatrix} 10 & 10 & 10 \\ 20 & 20 & 20 \\ 30 & 30 & 30 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

The initial condition vector defines the initial condition values within each of the three channels. The same initial conditions are used for each channel, but different initial condition values are used with a channel.

#### Case 4 – Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. Or, when you have a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to Columns as channels (frame based).

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix}, \dots$$

You want the initial conditions of your three-channel signal to be different for each channel and along each channel.

- 1 Set the **Delay (frames)** parameter to 1.
- 2 Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to either [10 20 30; 40 50 60; 70 80 90] or {[10 40 70]; [20 50 80]; [30 60 90]}. Each cell of the cell array represents the delay along one channel.

Regardless of whether you use a matrix or cell array, the output of the delay block is

$$\begin{bmatrix} 10 & 20 & 30 \\ 40 & 50 & 60 \\ 70 & 80 & 90 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 & 4 \\ 5 & 5 & 5 \\ 6 & 6 & 6 \end{bmatrix}, \begin{bmatrix} 7 & 7 & 7 \\ 8 & 8 & 8 \\ 9 & 9 & 9 \end{bmatrix} \dots$$

The initial condition matrix is the output at sample time zero. The elements of the initial condition cell array define the initial condition values within each channel. The first element, a

vector, represents the initial conditions within channel 1. The second element, a vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

### Sample-Based Processing Examples

There are four different choices for initial conditions. The initial conditions can be the same or different for each channel. They can also be the same or different along each channel. The next sections describe the behavior of the block for each of these four cases:

- “Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel” on page 2-378
- “Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel” on page 2-378
- “Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel” on page 2-379
- “Case 4 — Use Different Initial Conditions for Each Channel and Within a Channel” on page 2-380

#### Case 1 — Use the Same Initial Conditions for Each Channel and Within a Channel

Enter a scalar value for the initial conditions. This value is used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four-channel signal to be identical and zero for the first two samples:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Clear the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to a scalar value of 0.

The output of the delay block is

$$\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

0, the scalar initial condition value, is used for each channel and within the channels. It is the output at sample time zero and sample time one.

#### Case 2 — Use Different Initial Conditions for Each Channel and the Same Initial Conditions Within a Channel

The initial conditions must be an N-D array for N-D input. The initial conditions must have the same dimensions as the input data. These initial condition values are used as the constant initial condition value for each of the channels.

For example, suppose your input is a matrix and you set the **Input processing** parameter to `Elements as channels (sample based)`.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four-channel signal to be

$$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}$$

for the first two samples:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** check box.
- 3 Clear the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [7 9; 11 13].

The output of the delay block is

$$\begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 7 & 9 \\ 11 & 13 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

The initial condition matrix is the output at sample time zero and sample time one. Different initial conditions are used for each channel; the same initial condition value is used within a channel.

### Case 3 — Use the Same Initial Conditions for Each Channel and Different Initial Conditions Within a Channel

In this case, for N-D sample-based inputs, the initial conditions parameter must be a vector whose length is equal to the delay value, specified by the **Delay** parameter. The values in this vector are used as the initial condition values along each of the channels to be delayed.

For example, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your four channel signal to be the same along each of the channels to be delayed:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Clear the **Specify different initial conditions for each channel** check box.
- 3 Select the **Specify different initial conditions within a channel** check box.
- 4 Set the **Initial conditions** parameter to [10 20].

The output of the delay block is

$$\begin{bmatrix} 10 & 10 \\ 10 & 10 \end{bmatrix}, \begin{bmatrix} 20 & 20 \\ 20 & 20 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

The first element of the initial conditions vector is the output, for all channels, at sample time zero. The second element of the initial conditions vector is the output, for all channels, at sample

time one. The same initial conditions are used for each channel, but different initial condition values are used within a channel.

#### Case 4 – Use Different Initial Conditions for Each Channel and Within a Channel

Enter a cell array for your initial condition values. The cell array must be the same size as your input signal. Each cell of the cell array represents the delay values for one channel, and must be a vector of size equal to the delay value. If you have a vector or scalar input and a scalar delay value, you can enter the initial conditions as a matrix.

For example, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$[1 \ 1], [2 \ 2], [3 \ 3], \dots$$

You want the initial conditions of your two channel signal to be different for each channel and along each channel:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to `[10 20; 30 40]`.

The output of the delay block is

$$[10 \ 20], [30 \ 40], [1 \ 1], [2 \ 2], \dots$$

The first row of the initial conditions vector is the output at sample time zero. The second row of the initial conditions vector is the output at sample time one. Different initial conditions are used for each channel and within the channels.

In addition, suppose your input is a matrix and you set the **Input processing** parameter to **Elements as channels (sample based)**.

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}, \dots$$

You want the initial conditions of your two-channel signal to be different for each channel and along each channel:

- 1 Set the **Delay (samples)** parameter to 2.
- 2 Select the **Specify different initial conditions for each channel** and the **Specify different initial conditions within a channel** check boxes.
- 3 Set the **Initial conditions** parameter to `{[11 15] [12 16]; [13 17] [14 18]}`. The dimensions of the cell array match the dimensions of the input. Also, each element of the cell array represents the initial conditions within one channel.

The output of the delay block is

$$\begin{bmatrix} 11 & 12 \\ 13 & 14 \end{bmatrix}, \begin{bmatrix} 15 & 16 \\ 17 & 18 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, \dots$$

Each element of the cell array represents the initial conditions within a channel. The first element, a vector, represents the initial conditions within channel 1. The second element, a

vector, represents the initial conditions within channel 2, and so on. Different initial conditions are used for each channel and within the channels.

## Parameters

### Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The option **Inherit from input** (this choice will be removed - see release notes) will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Delay units

Select whether you want to delay your input by a specified number of **Samples** or **Frames**. This parameter appears only when you set the **Input processing** parameter to **Columns as channels (frame based)**.

### Delay (samples) or Delay (frames)

See “Sample-Based Processing” on page 2-373 and “Frame-Based Processing” on page 2-373 for a description of what format to use for each configuration of the block dialog.

### Specify different initial conditions for each channel

Select this check box when you want the initial conditions to vary across the channels. When you do not select this check box, the initial conditions are the same across the channels.

### Specify different initial conditions within a channel

Select this check box when you want the initial conditions to vary within the channels. When you do not select this check box, the initial conditions are the same within the channels.

### Initial conditions

Enter a scalar, vector, matrix, or cell array of initial condition values, depending on your choice for the **Specify different initial conditions for each channel** and **Specify different initial conditions within a channel** check boxes. See “Sample-Based Processing” on page 2-373 and “Frame-Based Processing” on page 2-373 for a description of what format to use for each configuration of the block dialog.

### Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 2-374.

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## **Version History**

**Introduced before R2006a**

### **Extended Capabilities**

#### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

#### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information on implementations, properties, and restrictions for HDL code generation, see the "HDL Code Generation" section of the Delay page.

# Delay Line

Rebuffer sequence of inputs

**Libraries:**

DSP System Toolbox / Signal Management / Buffers

## Description

The Delay Line block rebuffers a sequence of  $M_i$ -by- $N$  matrix inputs into a sequence of  $M_o$ -by- $N$  matrix outputs, where  $M_o$  is the output frame size you specify in the **Delay line size** parameter. Depending on whether  $M_o$  is greater than, less than, or equal to the input frame size,  $M_i$ , the output frames can be underlapped or overlapped. The block always performs frame-based processing and rebuffers each of the  $N$  input channels independently.

## Examples

### Rebuffer Signal Using Delay Line

In this example, the Delay Line block rebuffers a signal with frame size 4 to a frame size of 3 using the Delay Line block.

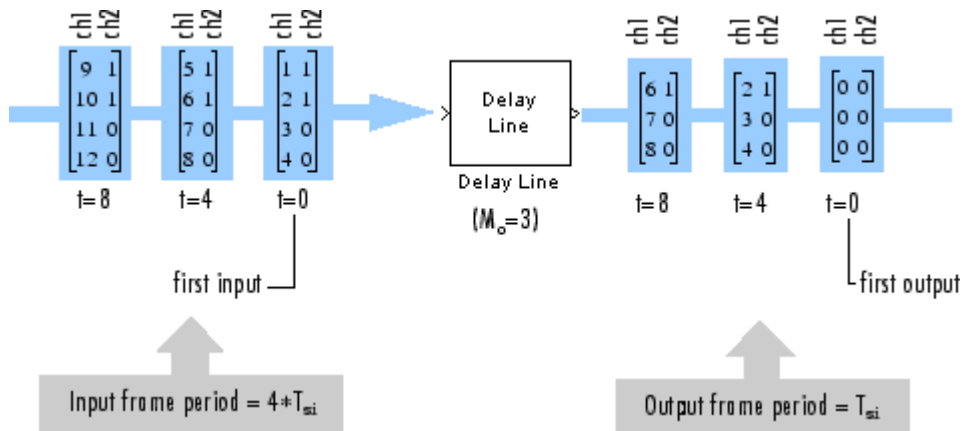

Open the model. The **Delay line size** parameter is set to 3.

Copyright 2006-2023 The MathWorks, Inc.

**Note:** This model creates workspace variables called "dsp\_examples\_A" and "dsp\_examples\_yout".

Run the model. The first output frame is all zeros because the **Initial conditions** parameter is set to zero. Because the input frame size of 4 is larger than the output frame size of 3, only the last three samples in each input frame are propagated to the corresponding output frame. The frame periods of the input and output are the same, and the output sample period is  $T_{si}(M_i/M_o)$ , or 4/3 the input sample period.

## Ports

### Input

**In** — Input signal  
vector | matrix

Specify the input signal as a vector or a matrix of size  $M_i$ -by- $N$ .

This port is unnamed until you select the **Show En\_Out port for selectively enabling output** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

**En\_Out** — Linearize the block output  
true | false

Specify whether to linearize the block output.

If the input value to the **En\_Out** port is a Boolean 1 (or true), the block linearizes the output and the output is valid. This setting allows the block to be more efficient when the tapped Delay Line output is not required at each sample time.

Note that when the input value to the **En\_Out** port is a Boolean 0 (or false), the block can give different results depending on the state of the model. The results can appear to match valid results or can be invalid, and they cannot be predicted. You should ignore the block output in all cases when the input to the **En\_Out** port is 0.

### Dependencies

To enable this port, select the **Show En\_Out port for selectively enabling output** parameter.

Data Types: Boolean

### Output

**Out** — Rebuffered output  
vector | matrix

Rebuffered output, returned as a vector or a matrix of size  $M_o$ -by- $N$ .

When  $M_o > M_i$ , the output frame overlap is the difference between the output and input frame size,  $M_o - M_i$ . When  $M_o < M_i$ , the output is underlapped and the Delay Line block discards the first  $M_i - M_o$  samples of each input frame so that only the last  $M_o$  samples are buffered into the corresponding output frame. When  $M_o = M_i$ , the output data is identical to the input data, but is delayed by the latency of the block. Due to the block latency, the outputs are always delayed by one frame, the entries of which you specify in the **Initial conditions** parameter.

The output frame period is equal to the input frame period ( $T_{fo} = T_{fi}$ ). The output sample period,  $T_{so}$ , is therefore equal to  $T_{fi}/M_o$ , or equivalently,  $T_{si}(M_i/M_o)$

In the most typical use, each output differs from the preceding output by only one sample, as illustrated below for scalar input.

Note that the first output of the block in the example above is all zeros; this is because the **Initial Conditions** parameter is set to zero.

This port is unnamed until you select the **Show En\_Out port for selectively enabling output** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

## Parameters

**Delay line size** — Delay line size

64 (default) | positive integer

Specify the number of rows  $M_o$  in output matrix as a positive integer.

**Initial conditions** — Initial conditions

0 (default) | scalar | vector | matrix

Specify the value of the block initial output as a scalar, vector, or a matrix. The Delay Line block buffer is initialized to the value specified by the **Initial conditions** parameter. The block outputs this buffer at the first simulation step ( $t=0$ ).

When the block outputs a vector, the **Initial conditions** can be a vector of the same size, or a scalar value to be repeated across all elements of the initial output. When the block outputs a matrix, the **Initial conditions** can be a matrix of the same size, a vector (of length equal to the number of matrix rows) to be repeated across all columns of the initial output, or a scalar to be repeated across all elements of the initial output.

**Allow directfeedthrough** — Allow directfeedthrough

off (default) | on

When you select this check box, the input data is not delayed by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output port of the block.

**Show En\_Out port for selectively enabling output** — Show En\_Out port for selectively enabling output

off (default) | on

When you select this check box, the **En\_Out** input port appears on the block icon. This block uses a circular buffer internally even though the output is linear. This means that for valid output, data from the circular buffer has to be linearized. The **En\_Out** port determines whether or not a valid output needs to be computed based on the value of its Boolean input. If the input value to the **En\_Out** port is 1, the block output is linearized, and thus is valid. Otherwise, the output is not linearized, and is invalid. This allows the block to be more efficient when the tapped Delay Line output is not required at each sample time.

Note that when the input value to the **En\_Out** port is 0, the block can give different results depending on the state of the model. The results can appear to match valid results or can be invalid, and they cannot be predicted. You should ignore the block output in all cases when the input to the **En\_Out** port is 0.

**Hold previous value when the output is disabled** — Hold previous value when the output is disabled

off (default) | on

Use this parameter to specify the block output at those time steps when the internal state buffer is not being linearized to output valid data.

When you do not select this check box, the block memory is free to be used by other parts of the model, and the signal on the output port is invalid. When you select this check box, the most recent valid value is held on the output port, and slightly more memory is used by the block.

#### Dependencies

To enable this parameter, select **Show En\_Out port for selectively enabling output**.

# Tunable Bandpass IIR Filter

Design IIR bandpass filter with tunable filter specifications

## Libraries:

DSP System Toolbox / Filtering / Filter Sources

## Description

Use the Tunable Bandpass IIR Filter block to design an IIR bandpass filter using the Butterworth, Chebyshev Type I and Chebyshev Type II design methods. You can tune the filter design specifications such as the filter order, 3-dB cutoff frequencies, passband ripple, and stopband attenuation while the simulation is running. When the values of these parameters change, the block redesigns the filter and outputs the numerator and denominator coefficients in the fourth-order section form.

## Examples

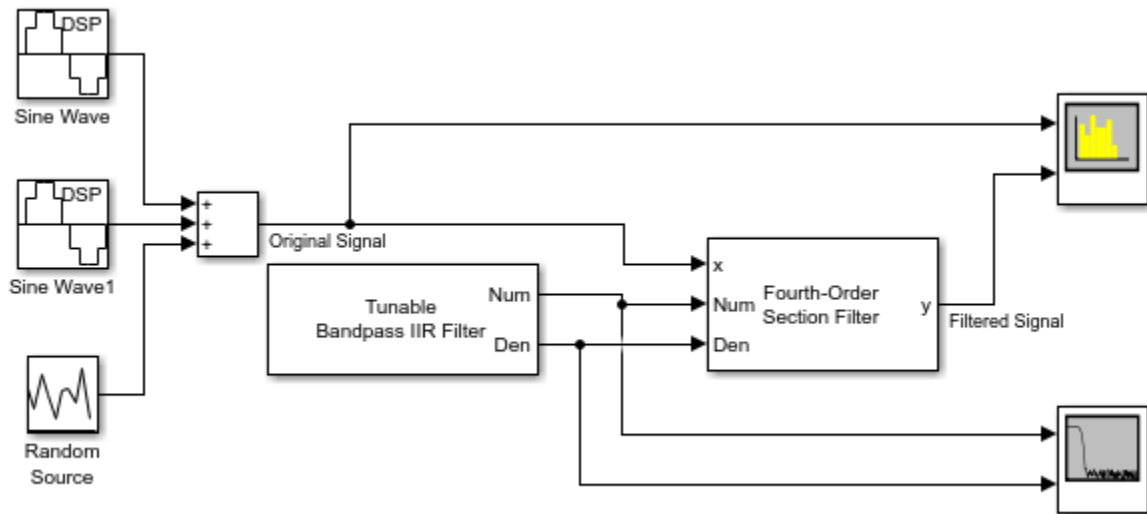

### Filter Noisy Signal Using Fourth-Order Section (FOS) Filter in Simulink

Filter a noisy sinusoidal signal using the Fourth-Order Section Filter block. The numerator and denominator coefficients of the fourth-order section filter are obtained using the Tunable Bandpass IIR Filter block. You can tune the frequency specifications of this filter during simulation.

### Open and Run the Model

The input signal is a sum of two sine waves with the frequencies of 100 Hz and 350 Hz. The sample rate is 1000 Hz and the number of samples in each frame is 1024. Add zero-mean white Gaussian noise with a variance of  $1e-4$  to the sum of the sine waves.

The Tunable Bandpass IIR Filter block designs a sixth order bandpass IIR filter with the first and second 3-dB cutoff frequencies at  $0.25 \pi$  rad/sample and  $0.75 \pi$  rad/sample, respectively. Visualize the frequency response of the filter using Filter Visualizer.

Copyright 2021-2023 The MathWorks, Inc.

Filter the noisy sinusoidal signal using the Fourth-Order Section Filter block. Visualize the original sinusoidal signal and the filtered signal using the Spectrum Analyzer.

### Tuning Frequency Specification of FOS Filter

During simulation, you can tune the frequency specifications of the FOS filter by tuning the frequency parameters in the Tunable Bandpass IIR Filter block. The filter response updates accordingly.

Change the first 3-dB cutoff frequency to  $0.65 \pi$  rad/sample in the Tunable Bandpass IIR Filter block. The first tone of the sinusoidal signal is attenuated as it no longer falls in the passband frequency of the filter.

## Ports

### Input

**N** — Filter order  
even positive integer

Specify the filter order as an even positive integer.

### Dependency

To enable this port, select the **Specify filter order from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Fc1** — First 3-dB cutoff frequency  
nonnegative scalar  $\leq$  **Fc2**

Specify the first 3-dB cutoff frequency **Fc1** of the filter in normalized frequency units as a nonnegative scalar less than or equal to the second 3-dB cutoff frequency **Fc2**.

### Dependency

To enable this port, select the **Specify first 3-dB cutoff frequency from input port** parameter.

Data Types: single | double

**Fc2** — Second 3-dB cutoff frequency  
**Fc1**  $\leq$  positive scalar  $\leq$  1

Specify the second 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar greater than or equal to **Fc1** and less than or equal to 1.

### Dependency

To enable this port, select the **Specify second 3-dB cutoff frequency from input port** parameter.

Data Types: single | double

**Ap** — Passband ripple in dB  
nonnegative scalar

Specify the passband ripple of the Chebyshev Type I filter as a nonnegative scalar in dB.

**Dependency**

To enable this port:

- Set the **Design method** parameter to Chebyshev Type I.
- Select the **Specify the passband ripple from input port** parameter.

Data Types: single | double

**Ast** — Stopband attenuation in dB  
nonnegative scalar

Specify the stopband attenuation of the Chebyshev Type II filter as a nonnegative scalar in dB.

**Dependency**

To enable this port:

- Set the **Design method** parameter to Chebyshev Type II.
- Select the **Specify the stopband attenuation from input port** parameter.

Data Types: single | double

**Output**

**Num** — Numerator coefficients  
 $P$ -by-5 matrix

Numerator coefficients **b**, returned as a  $P$ -by-5 matrix (fourth-order section form), where  $P$  is the number of filter sections.

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & b_{31} & b_{41} \\ b_{02} & b_{12} & b_{22} & b_{32} & b_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & b_{3P} & b_{4P} \end{bmatrix}$$

This equation represents the fourth-order section filter in the transfer function form.

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **a** -- Denominator coefficients matrix. For more details on how to specify this matrix, see the **Den** output port.
- $k$  -- Row index.

The maximum number of filter sections equals  $\text{ceil}(N_{max}/4)$ , where  $N_{max}$  is the value of the **Filter maximum order (must be even)** parameter.

When the actual filter order  $N$  is less than the maximum filter order  $N_{max}$ , the last  $\text{ceil}(N_{max}/4) - \text{ceil}(N/4)$  sections are trivial with coefficients  $[b_0, b_1, b_2, b_3, b_4] = [1, 0, 0, 0, 0]$ .

The data type of this port depends on the value of the **Output data type** parameter.

Data Types: `single` | `double`

**Den** — Denominator coefficients

$P$ -by-5 matrix

Denominator coefficients **a**, returned as a  $P$ -by-5 matrix (fourth-order section form), where  $P$  is the number of filter sections.

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & a_{31} & a_{41} \\ a_{02} & a_{12} & a_{22} & a_{32} & a_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & a_{3P} & a_{4P} \end{bmatrix}$$

This equation represents the fourth-order section filter in the transfer function form.

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **b** -- Numerator coefficients matrix. For more details on how to specify this matrix, see the **Num** output port.
- $k$  -- Row index.

The maximum number of filter sections equals  $\text{ceil}(N_{max}/4)$ , where  $N_{max}$  is the value of the **Filter maximum order (must be even)** parameter.

The leading denominator coefficient  $a_0$  is always 1.

When the actual filter order  $N$  is less than the maximum filter order  $N_{max}$ , the last  $\text{ceil}(N_{max}/4) - \text{ceil}(N/4)$  sections are trivial with coefficients  $[a_0, a_1, a_2, a_3, a_4] = [1, 0, 0, 0, 0]$ .

The data type of this port depends on the value of the **Output data type** parameter.

Data Types: `single` | `double`

## Parameters

**Design method** — Filter design method

Butterworth (default) | Chebyshev Type I | Chebyshev Type II

Specify the filter design method as:

- Butterworth
- Chebyshev Type I
- Chebyshev Type II

**Specify filter order from input port** — Flag to specify filter order from input port

off (default) | on

Select this parameter to specify the filter order from the input port **N**. When you clear this parameter, you can specify the filter order in the block dialog box using the **Filter order (must be even)** parameter.

**Filter order (must be even)** — Filter order

6 (default) | even positive integer

Specify the filter order as an even positive integer less than or equal to the value of the **Filter maximum order (must be even)** parameter.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify filter order from input port** parameter.

**Filter maximum order (must be even)** — Maximum order of filter

10 (default) | even positive integer

Specify the maximum order of the filter as an even positive integer. The value you specify in the **Filter order (must be even)** parameter must be less than or equal to the value you specify in the **Filter maximum order (must be even)** parameter.

**Specify first 3-dB cutoff frequency from input port** — Specify first 3-dB cutoff frequency from input port

off (default) | on

Select this parameter to specify the first 3-dB filter cutoff frequency from the input port **Fc1**. When you clear this parameter, you can specify the first 3-dB cutoff frequency in the block dialog box using the **First 3-dB cutoff frequency** parameter.

**First 3-dB cutoff frequency** — First 3-dB cutoff frequency

0.25 (default) | positive scalar

Specify the first 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar less than or equal to the second 3-dB cutoff frequency.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify first 3-dB cutoff frequency from input port** parameter.

**Specify second 3-dB cutoff frequency from input port** — Specify second 3-dB cutoff frequency from input port

off (default) | on

Select this parameter to specify the second 3-dB filter cutoff frequency from the input port **Fc2**. When you clear this parameter, you can specify the second 3-dB cut-off frequency in the block dialog box using the **Second 3-dB cutoff frequency** parameter.

**Second 3-dB cutoff frequency** — Second 3-dB cutoff frequency

0.75 (default) | positive scalar

Specify the second 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar greater than or equal to the first 3-dB cutoff frequency and less than or equal to 1.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify second 3-dB cutoff frequency from input port** parameter.

**Specify the passband ripple from input port** — Specify passband ripple from input port

off (default) | on

Select this parameter to specify passband ripple from the input port **Ap**. When you clear this parameter, you can specify the passband ripple in the block dialog box using the **Passband ripple (dB)** parameter.

**Dependency**

To enable this parameter, set the **Design method** parameter to Chebyshev Type I.

**Passband ripple (dB)** — Passband ripple in dB

1 (default) | positive scalar

Specify the passband ripple of the Chebyshev Type I filter as a positive scalar in dB.

**Tunable:** Yes

**Dependency**

To enable this parameter:

- Set the **Design method** parameter to Chebyshev Type I.
- Clear the **Specify the passband ripple from input port** parameter.

**Specify the stopband attenuation from input port** — Specify stopband attenuation from input port

off (default) | on

Select this parameter to specify stopband attenuation from the input port **Ast**. When you clear this parameter, you can specify the stopband attenuation in the block dialog box using the **Stopband attenuation (dB)** parameter.

**Dependency**

To enable this parameter, set the **Design method** parameter to Chebyshev Type II.

**Stopband attenuation (dB)** — Stopband attenuation in dB

60 (default) | positive scalar

Specify the stopband attenuation of the Chebyshev Type II filter as a positive scalar in dB.

**Tunable:** Yes

**Dependency**

To enable this parameter:

- Set the **Design method** parameter to Chebyshev Type II.
- Clear the **Specify the stopband attenuation from input port** parameter.

**Sample time** — Sample time in seconds

-1 (default) | positive scalar | Inf

Specify the sample time as -1 (inherited), Inf (constant sample time), or a positive scalar. This parameter indicates when during the simulation the block produces the output and updates its internal state. For more details, see “What Is Sample Time?” (Simulink).

**Output data type** — Data type of filter coefficients

double (default) | single

Specify the data type of the filter coefficients that the block outputs through the **Num** and **Den** ports as double or single.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

# Tunable Bandstop IIR Filter

Design IIR bandstop filter with tunable filter specifications

**Libraries:**

DSP System Toolbox / Filtering / Filter Sources

## Description

Use the Tunable Bandstop IIR Filter block to design an IIR bandstop filter using the Butterworth, Chebyshev Type I and Chebyshev Type II design methods. You can tune the filter design specifications such as the filter order, 3-dB cutoff frequencies, passband ripple, and stopband attenuation while the simulation is running. When the values of these parameters change, the block redesigns the filter and outputs the numerator and denominator coefficients in the fourth-order section form.

## Examples

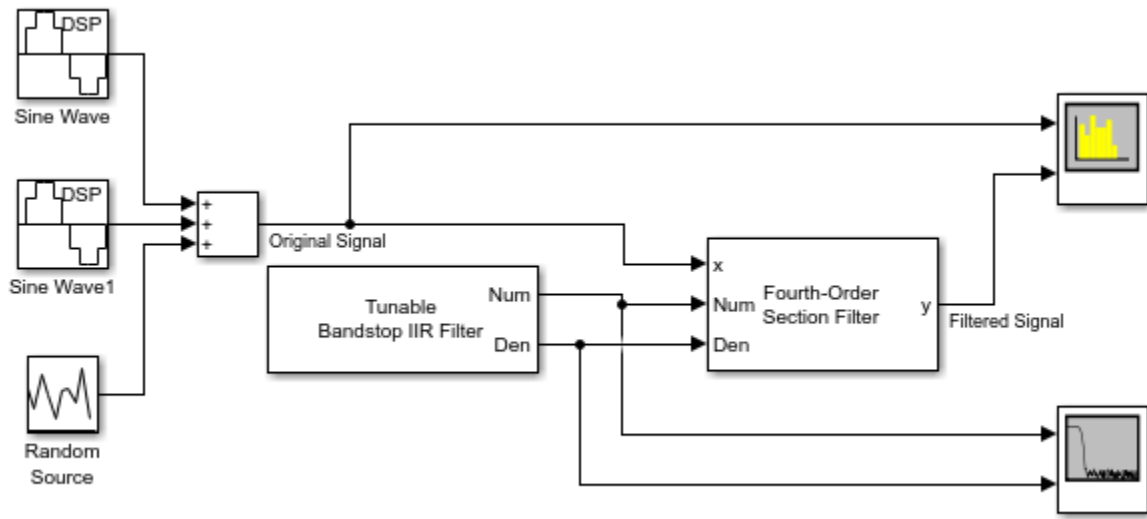

### Filter Noisy Signal Using Fourth-Order Section (FOS) Filter in Simulink

Filter a noisy sinusoidal signal using the Fourth-Order Section Filter block. The numerator and denominator coefficients of the fourth-order section filter are obtained using the Tunable Bandstop IIR Filter block. You can tune the frequency specifications of this filter during simulation.

#### Open and Run the Model

The input signal is a sum of two sine waves with the frequencies of 200 Hz and 400 Hz. The sample rate is 1000 Hz and the number of samples in each frame is 1024. Add zero-mean white Gaussian noise with a variance of  $1e-4$  to the sum of the sine waves.

The Tunable Bandstop IIR Filter block designs a sixth order bandpass IIR filter with the first and second 3-dB cutoff frequencies at  $0.2 \pi$  rad/sample and  $0.75 \pi$  rad/sample, respectively. Visualize the frequency response of the filter using Filter Visualizer.

Filter the noisy sinusoidal signal using the Fourth-Order Section Filter block. Visualize the original sinusoidal signal and the filtered signal using the Spectrum Analyzer. The first tone is attenuated as it falls in the stopband region of the filter while the second tone remains unaffected as it falls in the passband region of the filter.

### Tuning Frequency Specification of FOS Filter

During simulation, you can tune the frequency specifications of the FOS filter by tuning the frequency parameters in the Tunable Bandstop IIR Filter block. The filter response updates accordingly.

Change the first 3-dB cutoff frequency to  $0.5 \pi$  rad/sample in the Tunable Bandstop IIR Filter block. The first tone of the sinusoidal signal now falls in the passband region and is therefore unattenuated.

## Ports

### Input

**N** — Filter order  
even positive integer

Specify the filter order as an even positive integer.

### Dependency

To enable this port, select the **Specify filter order from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Fc1** — First 3-dB cutoff frequency  
nonnegative scalar  $\leq$  **Fc2**

Specify the first 3-dB cutoff frequency **Fc1** of the filter in normalized frequency units as a nonnegative scalar less than or equal to the second 3-dB cutoff frequency **Fc2**.

### Dependency

To enable this port, select the **Specify first 3-dB cutoff frequency from input port** parameter.

Data Types: `single` | `double`

**Fc2** — Second 3-dB cutoff frequency  
**Fc1**  $\leq$  positive scalar  $\leq$  1

Specify the second 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar greater than or equal to **Fc1** and less than or equal to 1.

### Dependency

To enable this port, select the **Specify second 3-dB cutoff frequency from input port** parameter.

Data Types: `single` | `double`

**Ap** — Passband ripple in dB  
nonnegative scalar

Specify the passband ripple of the Chebyshev Type I filter as a nonnegative scalar in dB.

**Dependency**

To enable this port:

- Set the **Design method** parameter to Chebyshev Type I.
- Select the **Specify the passband ripple from input port** parameter.

Data Types: single | double

**Ast** — Stopband attenuation in dB  
nonnegative scalar

Specify the stopband attenuation of the Chebyshev Type II filter as a nonnegative scalar in dB.

**Dependency**

To enable this port:

- Set the **Design method** parameter to Chebyshev Type II.
- Select the **Specify the stopband attenuation from input port** parameter.

Data Types: single | double

**Output**

**Num** — Numerator coefficients  
 $P$ -by-5 matrix

Numerator coefficients **b**, returned as a  $P$ -by-5 matrix (fourth-order section form), where  $P$  is the number of filter sections.

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & b_{31} & b_{41} \\ b_{02} & b_{12} & b_{22} & b_{32} & b_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & b_{3P} & b_{4P} \end{bmatrix}$$

This equation represents the fourth-order section filter in the transfer function form.

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **a** -- Denominator coefficients matrix. For more details on how to specify this matrix, see the **Den** output port.
- $k$  -- Row index.

The maximum number of filter sections equals  $\text{ceil}(N_{max}/4)$ , where  $N_{max}$  is the value of the **Filter maximum order (must be even)** parameter.

When the actual filter order  $N$  is less than the maximum filter order  $N_{max}$ , the last  $\text{ceil}(N_{max}/4) - \text{ceil}(N/4)$  sections are trivial with coefficients  $[b_0, b_1, b_2, b_3, b_4] = [1, 0, 0, 0, 0]$ .

The data type of this port depends on the value of the **Output data type** parameter.

Data Types: `single` | `double`

**Den** — Denominator coefficients

$P$ -by-5 matrix

Denominator coefficients **a**, returned as a  $P$ -by-5 matrix (fourth-order section form), where  $P$  is the number of filter sections.

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & a_{31} & a_{41} \\ a_{02} & a_{12} & a_{22} & a_{32} & a_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & a_{3P} & a_{4P} \end{bmatrix}$$

This equation represents the fourth-order section filter in the transfer function form.

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **b** -- Numerator coefficients matrix. For more details on how to specify this matrix, see the **Num** output port.
- $k$  -- Row index.

The maximum number of filter sections equals  $\text{ceil}(N_{max}/4)$ , where  $N_{max}$  is the value of the **Filter maximum order (must be even)** parameter.

The leading denominator coefficient  $a_0$  is always 1.

When the actual filter order  $N$  is less than the maximum filter order  $N_{max}$ , the last  $\text{ceil}(N_{max}/4) - \text{ceil}(N/4)$  sections are trivial with coefficients  $[a_0, a_1, a_2, a_3, a_4] = [1, 0, 0, 0, 0]$ .

The data type of this port depends on the value of the **Output data type** parameter.

Data Types: `single` | `double`

## Parameters

**Design method** — Filter design method

Butterworth (default) | Chebyshev Type I | Chebyshev Type II

Specify the filter design method as:

- Butterworth
- Chebyshev Type I
- Chebyshev Type II

**Specify filter order from input port** — Flag to specify filter order from input port

off (default) | on

Select this parameter to specify the filter order from the input port **N**. When you clear this parameter, you can specify the filter order in the block dialog box using the **Filter order (must be even)** parameter.

**Filter order (must be even)** — Filter order

6 (default) | even positive integer

Specify the filter order as an even positive integer less than or equal to the value of the **Filter maximum order (must be even)** parameter.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify filter order from input port** parameter.

**Filter maximum order (must be even)** — Maximum order of filter

10 (default) | even positive integer

Specify the maximum order of the filter as an even positive integer. The value you specify in the **Filter order (must be even)** parameter must be less than or equal to the value you specify in the **Filter maximum order (must be even)** parameter.

**Specify first 3-dB cutoff frequency from input port** — Specify first 3-dB cutoff frequency from input port

off (default) | on

Select this parameter to specify the first 3-dB filter cutoff frequency from the input port **Fc1**. When you clear this parameter, you can specify the first 3-dB cutoff frequency in the block dialog box using the **First 3-dB cutoff frequency** parameter.

**First 3-dB cutoff frequency** — First 3-dB cutoff frequency

0.25 (default) | positive scalar

Specify the first 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar less than or equal to the second 3-dB cutoff frequency.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify first 3-dB cutoff frequency from input port** parameter.

**Specify second 3-dB cutoff frequency from input port** — Specify second 3-dB cutoff frequency from input port

off (default) | on

Select this parameter to specify the second 3-dB filter cutoff frequency from the input port **Fc2**. When you clear this parameter, you can specify the second 3-dB cut-off frequency in the block dialog box using the **Second 3-dB cutoff frequency** parameter.

**Second 3-dB cutoff frequency** — Second 3-dB cutoff frequency

0.75 (default) | positive scalar

Specify the second 3-dB cutoff frequency of the filter in normalized frequency units as a positive scalar greater than or equal to the first 3-dB cutoff frequency and less than or equal to 1.

**Tunable:** Yes

**Dependency**

To enable this parameter, clear the **Specify second 3-dB cutoff frequency from input port** parameter.

**Specify the passband ripple from input port** — Specify passband ripple from input port

off (default) | on

Select this parameter to specify passband ripple from the input port **Ap**. When you clear this parameter, you can specify the passband ripple in the block dialog box using the **Passband ripple (dB)** parameter.

**Dependency**

To enable this parameter, set the **Design method** parameter to Chebyshev Type I.

**Passband ripple (dB)** — Passband ripple in dB

1 (default) | positive scalar

Specify the passband ripple of the Chebyshev Type I filter as a positive scalar in dB.

**Tunable:** Yes

**Dependency**

To enable this parameter:

- Set the **Design method** parameter to Chebyshev Type I.
- Clear the **Specify the passband ripple from input port** parameter.

**Specify the stopband attenuation from input port** — Specify stopband attenuation from input port

off (default) | on

Select this parameter to specify stopband attenuation from the input port **Ast**. When you clear this parameter, you can specify the stopband attenuation in the block dialog box using the **Stopband attenuation (dB)** parameter.

**Dependency**

To enable this parameter, set the **Design method** parameter to Chebyshev Type II.

**Stopband attenuation (dB)** — Stopband attenuation in dB

60 (default) | positive scalar

Specify the stopband attenuation of the Chebyshev Type II filter as a positive scalar in dB.

**Tunable:** Yes

**Dependency**

To enable this parameter:

- Set the **Design method** parameter to Chebyshev Type II.
- Clear the **Specify the stopband attenuation from input port** parameter.

**Sample time** — Sample time in seconds

-1 (default) | positive scalar | Inf

Specify the sample time as -1 (inherited), Inf (constant sample time), or a positive scalar. This parameter indicates when during the simulation the block produces the output and updates its internal state. For more details, see “What Is Sample Time?” (Simulink).

**Output data type** — Data type of filter coefficients

double (default) | single

Specify the data type of the filter coefficients that the block outputs through the **Num** and **Den** ports as double or single.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

## Detrend

Remove linear trend from vectors

**Libraries:**

DSP System Toolbox / Statistics

### Description

The Detrend block removes a linear trend from the length- $M$  input vector,  $u$ , by subtracting the straight line that best fits the data in the least squares sense.

The least squares line,  $\hat{u} = ax + b$ , is the line with parameters  $a$  and  $b$  that minimizes the quantity

$$\sum_{i=1}^M (u_i - \hat{u}_i)^2$$

for  $M$  evenly-spaced values of  $x$ , where  $u_i$  is the  $i$ th element in the input vector. The output,  $y = u - \hat{u}$ , is always an  $M$ -by-1 column vector.

### Ports

#### Input

**Input** — Input data  
vector

Input data, specified as a vector. The block removes the straight line that best fits the data in the least squares sense.

Data Types: `single` | `double`

#### Output

**Output** — Output data  
column vector

Output data, returned as a column vector. The block returns the remaining data after removing the straight line that best fits the data in the least squares sense.

Data Types: `single` | `double`

## Difference

Compute element-to-element difference along specified dimension of input

### Libraries:

DSP System Toolbox / Math Functions / Math Operations

## Description

The Difference block computes the difference between adjacent elements in rows, columns, or a specified dimension of the input array  $u$ . You can configure the block to compute the difference only within the current input, or across consecutive inputs (running difference).

## Ports

### Input

**Port\_1** — Input signal

vector | matrix |  $N$ -D array

Input signal, specified as a vector, matrix, or an  $N$ -D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Complex Number Support: Yes

### Output

**Port\_1** — Output signal

vector | matrix |  $N$ -D array

The difference between adjacent rows, columns, or a specified dimension of the input, returned as a vector, matrix, or an  $N$ -D array.

The output is the same data type and complexity as the input, but the dimension that the difference was calculated on is one less. The length of the other dimensions is unchanged.

For more details on how the output is computed, see the “Difference along” on page 2-0 parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Complex Number Support: Yes

## Parameters

### Main Tab

**Running difference** — Running difference

No (default) | Yes

Specify whether the block computes a running difference.

- **No** -- The block computes the difference between adjacent elements in the specified dimension of the current input. In this mode, the block can compute the difference along the columns, rows, or a specified dimension of the input depending on the “Difference along” on page 2-0 parameter.
- **Yes** -- The block computes the running difference along the columns of the input. See “Running Operation” on page 2-414 for more information.

**Difference along** — Difference dimension  
Columns (default) | Rows | Specified dimension

Specify whether the block computes the difference along the columns, rows, or a specified dimension of the input.

- **Columns** -- The block computes differences between adjacent elements in each column of the input. Equivalent MATLAB code is given by:

```
y = diff(u)
```

For  $M$ -by- $N$  inputs, the output is an  $(M - 1)$ -by- $N$  matrix whose  $j$ th column has these elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 1 \leq i \leq (M - 1)$$

- **Rows** -- The block computes differences between adjacent elements in each row of the input. Equivalent MATLAB code is given by:

```
y = diff(u, [], 2)
```

The output is an  $M$ -by- $(N-1)$  matrix whose  $i$ th row has the following elements:

$$y_{i,j} = u_{i,j+1} - u_{i,j} \quad 1 \leq j \leq (N - 1)$$

- **Specified dimension** -- The behavior of the block is an extension of the row-wise differencing described earlier. The block computes differences between adjacent elements along the dimension you specify in the **Dimension** parameter. Equivalent MATLAB code is given by:

```
y = diff(u, [], d)
```

where  $d$  is the dimension.

The output is an array whose length in the specified dimension is one less than that of the input, and whose lengths in other dimensions are unchanged. For example, consider an  $M$ -by- $N$ -by- $P$ -by- $R$  input array with elements  $u(i,j,k,l)$  and assume that the value of the **Dimension** parameter is 3. The output of the block is an  $M$ -by- $N$ -by- $(P-1)$ -by- $R$  array with the following elements:

$$y_{i,j,k,l} = u_{i,j,k+1,l} - u_{i,j,k,l} \quad 1 \leq k \leq (P - 1)$$

**Dimension** — One-based dimension  
1 (default) | 2 | 3

Specify the one-based dimension along which to compute element-to-element differences.

### Dependencies

To enable this parameter, select **Specified dimension** for the **Difference along** parameter.

## Data Types Tab

### Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

### Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

### Accumulator — Accumulator data type

Inherit: `Inherit via internal rule` (default) | `Inherit: Same as input` | `fixdt([],16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Difference block.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Output** — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)

**Output** specifies the data type of the output of the Difference block.

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Control Data Types of Signals” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Output Minimum** — Minimum value that block can output

[] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value that block can output

[] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |

| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Running Operation

When you set the **Running difference** parameter to Yes, the block computes the running difference along the columns of the input.

For an  $M$ -by- $N$  input matrix, the output is an  $M$ -by- $N$  matrix whose  $j$ th column has the following elements:

$$y_{i,j} = u_{i+1,j} - u_{i,j} \quad 2 \leq i \leq (M - 1)$$

In the **Running difference** mode, the first element of the output for each column is the first input element minus the last input element of the previous frame. For the first frame, the block subtracts zero from the first input element.

$$y_{1,j}(t) = u_{1,j}(t) - u_{M,j}(t - T_f)$$

## Differentiator Filter

Direct form FIR fullband differentiator filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

The Differentiator Filter block applies a fullband differentiator filter on the input signal to differentiate all its frequency components. The block uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is  $D(\omega) = j\omega$  for  $-\pi \leq \omega \leq \pi$ .

You can design the filter with minimum order or with a specifies order.

The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

This block supports variable-size input, enabling you to change the channel length during simulation. The output port properties, such as data type, complexity, and dimension, are identical to the input port properties. The block supports fixed-point operations.

This block also supports SIMD code generation. For details, see “Code Generation” on page 2-421.

## Examples

- “Group Delay Estimation in Simulink”

## Dialog Box

### Main Tab

#### Design minimum order filter

When you select this check box, the block designs a filter with the minimum order, with the passband ripple specified in **Maximum passband ripple (dB)**. When you clear this check box, specify the order of the filter in **Filter order**.

By default, this check box is selected.

#### Filter order

Filter order of the differentiator filter, specified as an odd positive scalar integer. You can specify the filter order only when **Design minimum order filter** check box is not selected. The default is 31.

#### Maximum passband ripple (dB)

Maximum ripple of the filter response in the passband, specified as a real positive scalar in dB. The default is 0.1.

#### Scale filter coefficients

When you select this check box, the filter coefficients are scaled to preserve the input dynamic range. By default, this check box is not selected.

#### View Filter Response

Opens the Filter Visualization Tool (fvtool) and displays the magnitude and phase response of the Differentiator Filter block. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

### Simulate using

Type of simulation to run. You can set this parameter to:

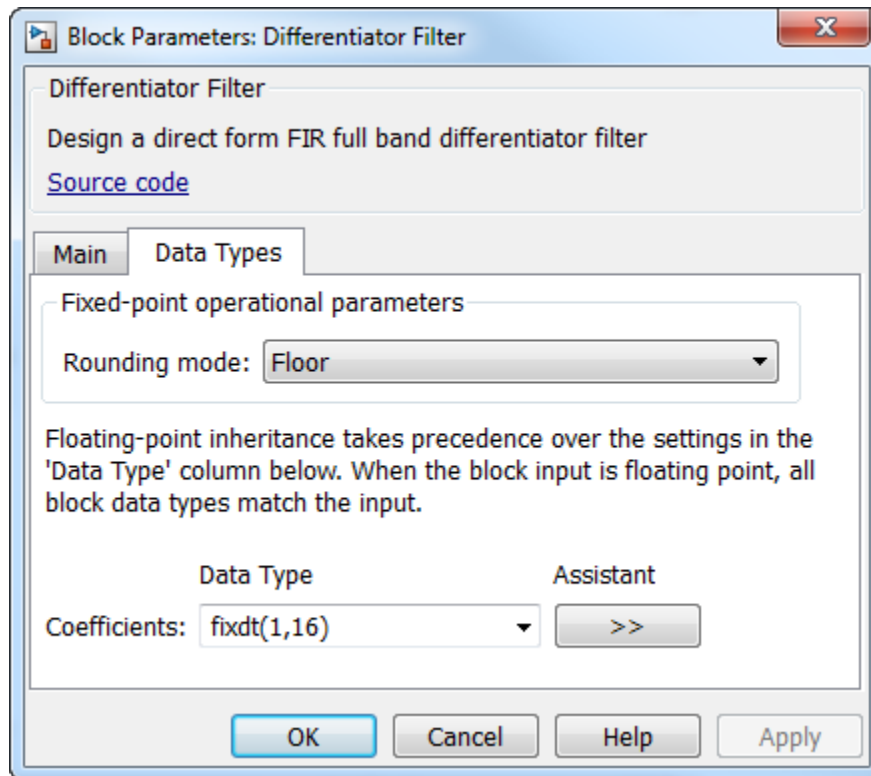

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Data Types Tab

### Rounding mode

Rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

### Coefficients

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values such that the coefficients occupy the maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16,15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the stage input parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

The word length of the output is same as the word length of the input. The fraction length of the output is computed such that the entire dynamic range of the output can be represented without

overflow. For details on how the block computes the fraction length, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed or unsigned)</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed or unsigned)</li> </ul> |

## Algorithms

### Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by  $D(\omega) = j\omega$ , defined over the Nyquist interval  $-\pi \leq \omega \leq \pi$ .

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by  $d(n) = -d(-n)$ . Hence  $d(0) = 0$ . The differentiator must have zero response at zero frequency.

### Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by  $h(n) = -h(M - 1 - n)$ , where  $M$  is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If  $M$  is odd, the real-valued frequency response of the FIR filter,  $H_r(\omega)$ , has the characteristics that  $H_r(0) = 0$  and  $H_r(\pi) = 0$ . This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because  $H_r(\pi) = 0$ . This differentiator has a linear response over the limited frequency range  $[0, 2\pi f_p]$ , where  $f_p$  is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as  $\omega$  increases from 0 to  $2\pi f_p$ .

If  $M$  is even, the real-valued frequency response of the FIR filter,  $H_r(\omega)$ , has the characteristics that  $H_r(0) = 0$  and  $H_r(\pi) \neq 0$ . This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

## Version History

Introduced in R2015b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Differentiator Filter block supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

### Dialog Box

See “Differentiator Filter Design — Main Pane” on page 5-613 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

## Filter Specifications

### Order mode

Select either **Minimum** or **Specify** (the default). Selecting **Specify** enables the **Order** option so you can enter the filter order.

### Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**. The default order is 31.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

## Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

### Frequency constraints

This option is only available when you specify the order of the filter design. Supported options are **Unconstrained** and **Passband edge and stopband edge**.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **KHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input Fs** parameter.

### Input Fs

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Fpass

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Fstop**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands. These parameters are only available for minimum-order designs.

**Magnitude constraints**

This option is only available when you specify the order of your filter design. The available **Magnitude constraints** depend on the value of the **Frequency constraints** parameter. When you set the **Frequency constraints** parameter to Unconstrained, the **Magnitude constraints** parameter must also be Unconstrained. When you set the **Frequency constraints** parameter to Passband edge and stopband edge, the **Magnitude constraints** parameter can be Unconstrained, Passband ripple, or Stopband attenuation.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Astop2**

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Wpass**

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

**Wstop**

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

**Filter Implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

**Use basic elements to enable filter customization**

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

**Input processing**

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to `Elements as channels (sample based)`.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

### Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

### Version History

Introduced in R2006b

# Digital Down-Converter

Translate digital signal from intermediate frequency (IF) band to baseband and decimate it

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Digital Down-Converter (DDC) block converts a digitized real signal centered at an intermediate frequency (IF) to a baseband complex signal centered at zero frequency. The DDC block downsamples the frequency downconverted signal using a cascade of three decimation filters. This block designs the decimation filters according to the filter parameters you set in the block dialog box.

## Ports

### Input

**Input 1** — Data input  
column vector | matrix

Specify the data input as a column vector or a matrix. The number of rows in the input signal must be a multiple of the decimation factor that you specify in the **Decimation factor** parameter.

When the input data type is `double` or `single` precision, the output data type is the same as that of the input. When the input data type is a signed integer or fixed-point type, the output data type is defined by the **Output** parameter on the **Data Types** tab.

When the input is fixed-point, it must be signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

**Osc** — Oscillator signal  
column vector | matrix

Specify the oscillator signal that the block uses to frequency down convert the input signal as a column vector or a matrix. The signal must be complex and its length must be equal to the length of the input.

When the oscillator input is fixed-point, it must be signed only.

### Dependencies

To enable this port, set the **Type of oscillator** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Output

**Output 1** — Downconverted and downsampled signal  
column vector | matrix

The block outputs the downconverted and downsampled signal as a column vector or a matrix. The length of the output is equal to the length of the input divided by the value you specify in the **Decimation factor** parameter.

When the data type of the input is `double` or `single` precision, the data type of the output is the same as that of the input. When the input data type is fixed-point type or a signed integer, the output data type is defined by the **Output** parameter on the **Data Types** tab.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Parameters

### Main Tab

**Decimation factor** — Decimation factor

100 (default) | positive integer  $\geq 2$  | vector of positive integers

Specify the decimation factor as a positive integer  $\geq 2$ , or as a 1-by-2 or 1-by-3 vector of positive integers.

When you set this parameter to a scalar value, the block applies the same decimation factor to the three decimation filtering stages.

When you set this parameter to a 1-by-2 vector, the block applies the first and second values in the vector to the first and second filtering stages, respectively, and bypasses the third stage. Both elements of **Decimation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the block applies the values in the vector to the corresponding filtering stages. The first and second elements of **Decimation factor** must be greater than 1, and the third element must be 1 or 2.

**Minimum order filter design** — Design minimum-order filter

on (default) | off

When you select this check box, the block designs filters with the minimum possible order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Number of sections of CIC decimator**, **Order of CIC compensation filter stage**, and **Order of third filter stage**. The filter designs meet the passband and stopband frequency specifications that you set in

**Two sided bandwidth of input signal (Hz), Source of stopband frequency, and Stopband frequency (Hz).** By default, this check box is selected.

**Number of sections of CIC decimator** — Number of sections in CIC decimator

3 (default) | positive integer

Specify the number of sections in the CIC decimator as a positive integer.

**Dependencies**

To enable this parameter, clear the **Minimum order filter design** parameter.

**Order of third filter stage** — Order of third filter stage

10 (default) | even positive integer

Specify the order of the third filter stage as an even positive integer. When you specify **Decimation factor** as a 1-by-2 vector, the block ignores the value in this parameter because the block bypasses the third filter stage.

**Dependencies**

To enable this parameter, clear the **Minimum order filter design** parameter.

**Source of stopband frequency** — Source of stopband frequency

Auto (default) | Property

Specify the source of the stopband frequency as Auto or Property.

When you set this parameter to Auto, the block places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate} / M/2$  Hz, where  $M$  is the total decimation factor specified in **Decimation factor**.  $\text{SampleRate}$  is computed as  $1/T_s$ , where  $T_s$  is the sample time of the input signal. The block computes the stopband frequency as  $F_{stop} = F_c + (TW / 2)$ .  $TW$  is the transition bandwidth of the cascade response, computed as  $2 \times (F_c - F_p)$ , where the passband frequency  $F_p$  equals  $\text{Bandwidth}/2$ .

When you set this parameter to Property, specify the stopband frequency in **Stopband frequency (Hz)**.

**Type of oscillator** — Type of oscillator

Sine wave (default) | NCO | Input port | None

Specify the oscillator type as one of the following:

- **Sine wave** (default) — The block performs frequency down conversion on the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function.
- **NCO** — The block performs frequency down conversion on the input signal with a complex exponential obtained using a numerically controlled oscillator (NCO).
- **Input port** — The block performs frequency down conversion on the input signal using the complex signal that you provide through the **Osc** input port.
- **None** — The block does not require the mixer stage and acts as a three-stage cascaded decimator.

**Center frequency of output signal (Hz)** — Center frequency of output signal

14e6 (default) | positive scalar

Specify the center frequency of the output signal in Hz as a double-precision positive scalar that is less than or equal to half the sample rate. The block downconverts the input signal from the passband center frequency, which you specify in **Center frequency of input signal (Hz)**, to 0 Hz.

**Dependency**

To enable this parameter, set **Type of oscillator** to Sine wave or NCO.

**Order of CIC compensation filter stage** — Order of CIC compensation filter stage

12 (default) | positive integer

Specify the order of the CIC compensation filter stage as a positive integer.

**Dependencies**

To enable this parameter, clear the **Minimum order filter design** parameter.

**Two-sided bandwidth of input signal (Hz)** — Two-sided bandwidth of input signal

200000 (default) | positive integer

Specify the two-sided bandwidth of the input signal in Hz as a positive integer. The block sets the passband frequency of the cascade of filters to half of the value you specify in this parameter. Set the value of this parameter to less than **Input sample rate/Decimation factor**. When you select the **Inherit sample rate from input** check box, set this value to less than  $((1/T_s) / \text{Decimation factor})$ , where  $T_s$  is the sample time of the input signal.

**Stopband frequency (Hz)** — Stopband frequency

150000 (default) | positive scalar

Specify the stopband frequency in Hz as a double-precision positive scalar.

**Dependencies**

To enable this parameter, set **Source of stopband frequency** to Property.

**Passband ripple of cascade response (dB)** — Passband ripple of cascade response

0.1 (default) | positive scalar

Specify the passband ripple of the cascade response in dB as a double-precision positive scalar. When you select the **Minimum order filter design**, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**.

**Dependencies**

To enable this parameter, select the **Minimum order filter design** parameter.

**Stopband attenuation of cascade response (dB)** — Stopband attenuation of cascade response

60 (default) | positive scalar

Specify the stopband attenuation of the cascade response in dB as a double-precision positive scalar. When you select the **Minimum order filter design** parameter, the block designs the filters such that the cascade response meets the stopband attenuation that you specify in this parameter.

**Dependencies**

To enable this parameter, select the **Minimum order filter design** parameter.

**Number of NCO accumulator bits** — Number of NCO accumulator bits

16 (default) | positive integer

Specify the number of NCO accumulator bits as an integer scalar in the range [1 128].

**Dependencies**

To enable this parameter, set **Type of oscillator** to NCO.

**Number of NCO quantized accumulator bits** — Number of NCO quantized accumulator bits

12 (default) | positive integer in the range [1 128]

Specify the number of NCO quantized accumulator bits as an integer scalar in the range [1 128]. This value must be less than the value you specify in **Number of NCO accumulator bits**.

**Dependencies**

To enable this parameter, set **Type of oscillator** to NCO.

**Dither control for NCO** — Dither control for NCO

on (default) | off

When you select this check box, the block applies dither to the NCO signal according to the number of dither bits you specify in **Number of NCO dither bits**. By default, this check box is selected.

**Dependencies**

To enable this parameter, set **Type of oscillator** to NCO.

**Number of NCO dither bits** — Number of NCO dither bits

4 (default) | positive integer

Specify the number of NCO dither bits as an integer scalar smaller than the number of accumulator bits in **Number of NCO accumulator bits**.

**Dependencies**

To enable this parameter, set **Type of oscillator** to NCO and select the **Dither control for NCO** parameter.

**Inherit sample rate from input** — Inherit sample rate from input

off (default) | on

When you select this check box, the block computes the sample rate as  $N/T_s$ , where  $N$  is the frame size of the input signal, and  $T_s$  is the sample time of the input signal. When you clear this check box, the block sets the sample rate to the value in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

30e6 (default) | positive scalar

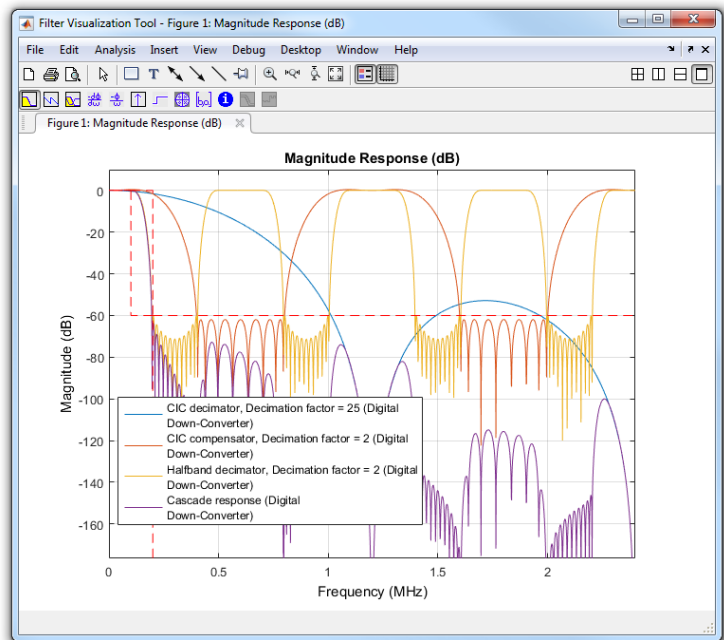

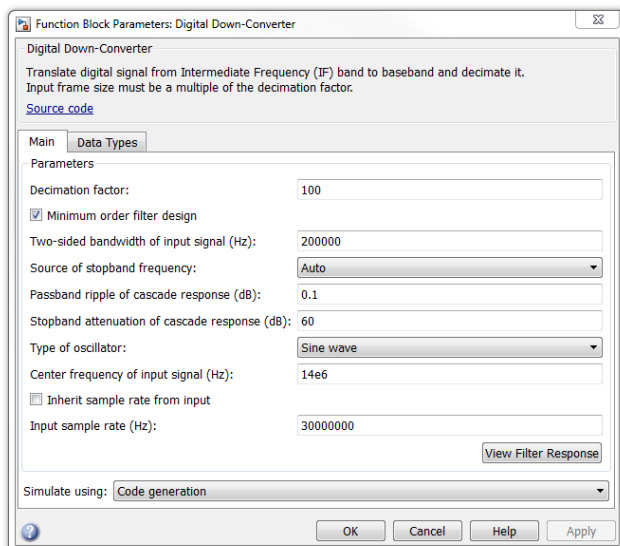

Specify the sample rate of the input signal in Hz as a positive scalar value greater than or equal to twice the value in **Center frequency of input signal (Hz)**.

### Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of each stage as well as the cascade of stages in the Digital Down-Converter. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- **Code generation** (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

- **Interpreted execution**

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Data Types Tab

### Stage input — Stage input

Inherit: Same as input (default) | `fixdt([],16,0)`

Specify the data type of the input in the first, second, and third filter stages. You can set this parameter to one of the following:

- **Inherit: Same as input** (default) — The block inherits the **Stage input** data type from the input signal.
- `fixdt([],16,0)` — The block uses the fixed-point data type with binary-point scaling. Specify the sign mode of this data type as [] or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as [] or `true`.

For help with setting the stage input parameter, you can click the **Show data type assistant** button

to display the data type assistant.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output — Output

Inherit: Same as input (default) | `fixdt([],16,0)`

Specify the data type of the block output. You can set this parameter to:

- **Inherit: Same as input** (default) — The block Inherits the output datatype from the input.
- `fixdt([],16,0)` — The block uses the fixed-point data type with binary point scaling. Specify the sign mode of this data type as [] or `true`.
- An expression that evaluates to a data type, for example, `numerictype([],16,15)`. Specify the sign mode of this data type as [] or `true`.

For help with setting the **Output** parameter, you can click the **Show data type assistant** button

to display the data type assistant.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Minimum** — Minimum

[] (default) | scalar

Specify the minimum value of the block output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Maximum** — Maximum

[] (default) | scalar

Maximum value of the block output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

**Block Characteristics**

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | no                                      |
| <b>Zero-Crossing Detection</b>  | no                                      |

**More About****Fixed Point**

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the filter input data type. In the `dsp.DigitalDownConverter` object, you can specify the filter input data type through the `FiltersInputDataType` and `CustomFiltersInputDataType` properties. In the Digital Down-Converter block, you can specify the filter input data type through the **Stage input** parameter.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse-gain and fine-gain operations.

If the normalization gain is  $G$  (where  $0 < G \leq 1$ ), then:

- $WLCic$  is the word length of the CIC decimator output and  $FLCic$  is the fraction length of the CIC decimator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved using bit shifts (coarse gain).
- $F2 = \text{fraction length specified by the filter input data type}$ .
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$ , which indicates that the remaining gain cannot be achieved with a bit shift (fine gain).

## Algorithms

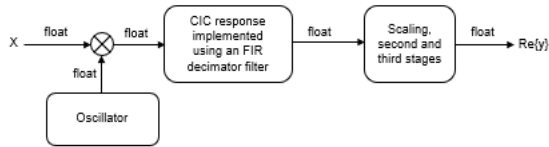

The digital down converter downconverts the input signal by multiplying it with a complex exponential that has the specified center frequency. The algorithm downsamples the frequency downconverted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. When you specify an oscillator signal through the input port, the normalization factor does not include the oscillator power factor. Depending on how you set the decimation factor, the block bypasses the third filter stage. When the input data type is double or single, the algorithm implements an  $N$ -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. The algorithm emulates a CIC filter with

an FIR filter so that you can run simulations with floating-point data. When the input data type is fixed-point, the algorithm implements a true CIC filter with actual comb and integrator sections.

This block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

For details about fixed-point operation, see “Fixed Point” on page 2-435.

## Version History

Introduced in R2015a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# Digital Up-Converter

Interpolate and translate digital signal from baseband to intermediate frequency (IF) band

**Libraries:**  
DSP System Toolbox / Signal Operations

## Description

The Digital Up-Converter (DUC) block converts a complex digital baseband signal to a real passband signal.

The DUC block upsamples the input signal using a cascade of three interpolation filters. The block frequency upconverts the upsampled signal by multiplying it by the specified center frequency of the output signal. This block designs the interpolation filters according to the filter parameters you set in the block dialog box.

## Ports

### Input

**Input 1** — Input signal  
column vector

Specify the input signal as a column vector of real or complex values.

When the input data type is `double` or `single` precision, the output data type is the same as that of the input. When the input data type is a signed integer or fixed-point, the output data type is defined by the **Output** parameter on the **Data Types** tab.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

### Output

**Output 1** — Upconverted and upsampled signal  
column vector

The block outputs the upconverted and upsampled signal as a column vector of real values. The length of the output is equal to the length of the input multiplied by the value that you specify in the **Interpolation factor** parameter.

When the input data type is `double` or `single` precision, the output data type is the same as that of the input. When the input data type is a signed integer or fixed-point, the output data type is defined by the **Output** parameter on the **Data Types** tab.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Parameters

### Main Tab

**Interpolation factor** — Interpolation factor

100 (default) | positive integer > 1 | vector of positive integers

Specify the interpolation factor as a positive integer > 1, or as a 1-by-2 or 1-by-3 vector of positive integers.

When you set this parameter to a scalar value, the block applies the same interpolation factor to the three interpolation filtering stages.

When you set this parameter to a 1-by-2 vector, the block applies the second and third values in the vector to the second and third filtering stages, respectively, and bypasses the first filter stage. Both elements of the **Interpolation factor** must be greater than 1.

When you set this parameter to a 1-by-3 vector, the block applies the values in the vector to the corresponding filtering stages. The second and third elements of **Interpolation factor** must be greater than 1, and the first element must be 1 or 2.

**Minimum order filter design** — Design minimum-order filter

on (default) | off

When you select this check box, the block designs filters with the minimum possible order that meets the requirements specified in these parameters:

- **Passband ripple of cascade response (dB)**
- **Stopband attenuation of cascade response (dB)**
- **Two sided bandwidth of input signal (Hz)**
- **Source of stopband frequency**
- **Stopband frequency (Hz)**

When you clear this check box, the block designs filters with orders that you specify in **Order of first filter stage**, **Order of CIC compensation filter stage**, and **Number of sections of CIC interpolator**. The filter designs meet the passband and stopband frequency specifications that you set in **Two sided bandwidth of input signal (Hz)**, **Source of stopband frequency**, and **Stopband frequency (Hz)**. By default, this check box is selected.

**Order of first filter stage** — Order of first filter stage

10 (default) | positive even integer

Specify the order of the first filter stage as an even positive integer. When you specify **Interpolation factor** as a 1-by-2 vector, the block ignores the value in this parameter because the block bypasses the first filter stage.

### Dependencies

To enable this parameter, clear the **Minimum order filter design** parameter.

**Number of sections of CIC interpolator** — Number of sections of CIC interpolator

3 (default) | positive integer

Specify the number of sections in the CIC interpolator as a positive integer.

**Dependencies**

This parameter appears when you clear the **Minimum order filter design** parameter.

**Source of stopband frequency** — Source of stopband frequency

Auto (default) | Property

Specify the source of the stopband frequency as Auto or Property.

When you set this parameter to *Auto*, the block places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate}/2$  Hz, and computes the stopband frequency as  $F_{stop} = F_c + TW/2$ . *SampleRate* is computed as  $1/T_s$ , where  $T_s$  is the sample time of the input signal. *TW* is the transition bandwidth of the cascade response, computed as  $2 \times (F_c - F_p)$ , and the passband frequency,  $F_p$ , equals *Bandwidth*/2.

When you set this parameter to *Property*, specify the stopband frequency in the **Stopband frequency (Hz)** parameter.

**Type of oscillator** — Type of oscillator

Sine wave (default) | NCO

Specify the oscillator type as one of the following:

- *Sine wave* (default) — The block performs frequency upconversion on the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function.
- *NCO* — The block performs frequency upconversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

**Center frequency of output signal (Hz)** — Center frequency of output signal

14e6 (default) | positive scalar

Specify the center frequency of the output signal in Hz as a double-precision positive scalar. The value of this parameter must be less than or equal to half the product of the *SampleRate* times the total interpolation factor. *SampleRate* is computed as  $1/T_s$ , where  $T_s$  is the sample time of the input signal. The block up converts the input signal so that the output spectrum centers at the frequency you specify in **Center frequency of output signal (Hz)**.

**Order of CIC compensation filter stage** — Order of CIC compensation filter stage

12 (default) | positive integer

Specify the order of the CIC compensation filter stage as a positive integer.

**Dependencies**

To enable this parameter, clear the **Minimum order filter design** parameter.

**Two sided bandwidth of input signal (Hz)** — Two sided bandwidth of input signal

200000 (default) | positive integer

Specify the two-sided bandwidth of the input signal in Hz as a positive integer. The block sets the passband frequency of the cascade of filters to half of the value you specify in this parameter.

**Stopband frequency (Hz)** — Stopband frequency

150000 (default) | positive scalar

Specify the stopband frequency in Hz as a double-precision positive scalar.

#### Dependencies

To enable this parameter, set the **Source of stopband frequency** to Property.

**Passband ripple of cascade response (dB)** — Passband ripple of cascade response

0.1 (default) | positive scalar

Specify the passband ripple of the cascade response in dB as a double-precision positive scalar. When you select the **Minimum order filter design** parameter, the block designs the filters so that the cascade response meets the passband ripple that you specify in **Passband ripple of cascade response (dB)**.

#### Dependencies

To enable this parameter, select the **Minimum order filter design** parameter.

**Stopband attenuation of cascade response (dB)** — Stopband attenuation of cascade response

60 (default) | positive scalar

Specify the stopband attenuation of the cascade response in dB as a double-precision positive scalar. When you select the **Minimum order filter design** parameter, the block designs the filters such that the cascade response meets the stopband attenuation that you specify in this parameter.

#### Dependencies

To enable this parameter, select the **Minimum order filter design** parameter.

**Number of NCO accumulator bits** — Number of NCO accumulator bits

16 (default) | positive integer

Specify the number of NCO accumulator bits as an integer scalar in the range [1 128].

#### Dependencies

To enable this parameter, set **Type of oscillator** to NCO.

**Number of NCO quantized accumulator bits** — Number of NCO quantized accumulator bits

12 (default) | positive integer

Specify the number of NCO quantized accumulator bits as an integer scalar in the range [1 128]. This value must be less than the value you specify in **Number of NCO accumulator bits**.

#### Dependencies

To enable this parameter, set **Type of oscillator** to NCO.

#### Dither control for NCO — Dither control for NCO

on (default) | off

When you select this parameter, the block applies dither to the NCO signal according to the number of dither bits you specify in **Number of NCO dither bits**.

#### Dependencies

To enable this parameter, set **Type of oscillator** to NCO.

#### Number of NCO dither bits — Number of NCO dither bits

4 (default) | positive integer

Specify the number of NCO dither bits as an integer scalar smaller than the number of accumulator bits in **Number of NCO accumulator bits**.

#### Dependencies

To enable this parameter, set **Type of oscillator** to NCO and select the **Dither control for NCO** parameter.

#### Inherit sample rate from input — Inherit sample rate from input

off (default) | on

When you select this parameter, the block computes the sample rate as  $N/T_s$ , where  $N$  is the frame size of the input signal, and  $T_s$  is the sample time of the input signal. When you clear this parameter, the block sets the sample rate to the value in **Input sample rate (Hz)**.

#### Input sample rate (Hz) — Sample rate of input signal

300e3 (default) | positive scalar

Specify the sample rate of the input signal in Hz as a positive scalar. The value of this parameter multiplied by the total interpolation factor must be greater than or equal to twice the value in **Center frequency of output signal (Hz)**.

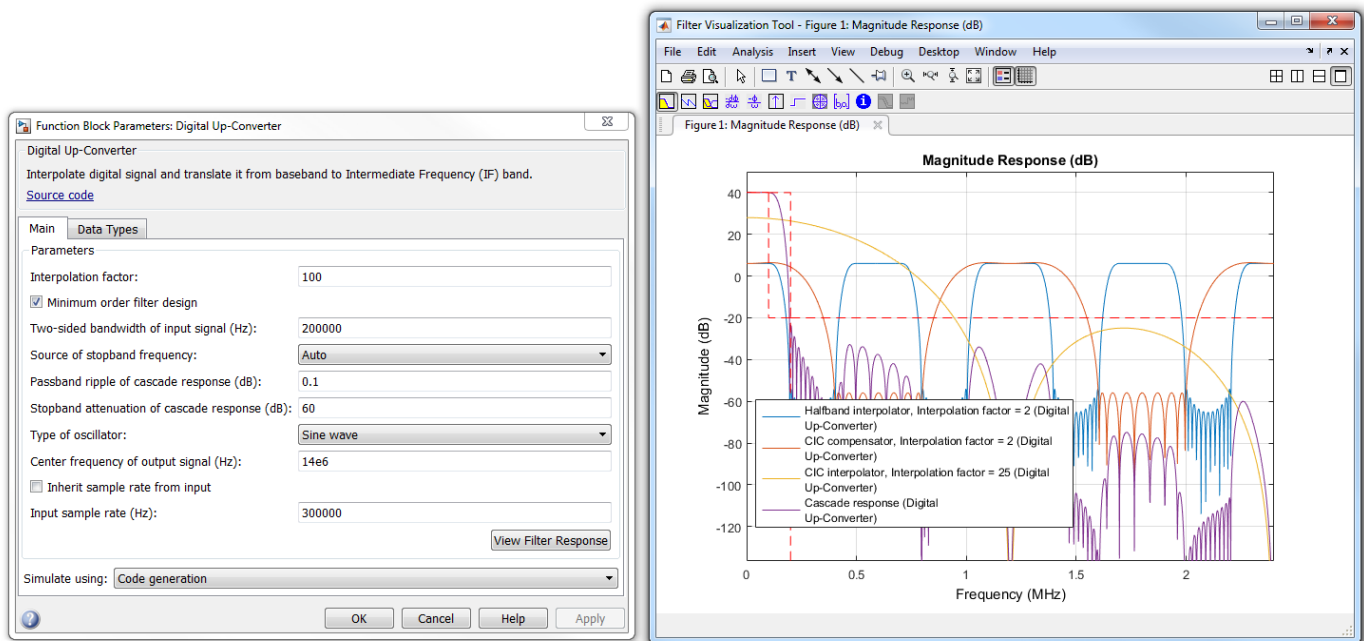

#### Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

#### View Filter Response — View Filter Response

button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of each stage as well as the cascade of stages in the Digital Up-Converter. The response is based on the values you specify in the block parameters dialog box.. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Data Types Tab

**Stage output** — Stage output

Inherit: Same as input (default) | `fixdt([],16,0)`

Specify the data type of the output in the first, second, and third filter stages. You can set this parameter to:

- Inherit: Same as input (default) — The block inherits the **Stage output** data type from the input signal.

- `fixdt([], 16, 0)` — The block uses the fixed-point data type with binary-point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

The block casts the data at the output of each filter stage according to the value you set in this parameter. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

For help with setting the stage output parameter, you can click the **Show data type assistant** button

to display the data type assistant.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output — Output

Inherit: Same as input (default) | `fixdt([], 16, 0)`

Specify the data type of the block output. You can set this parameter to:

- `Inherit: Same as input (default)` — The block Inherits the output datatype from the input.
- `fixdt([], 16, 0)` — The block uses the fixed-point data type with binary-point scaling. Specify the sign mode of this data type as `[]` or `true`.
- An expression that evaluates to a data type, for example, `numerictype([], 16, 15)`. Specify the sign mode of this data type as `[]` or `true`.

For help with setting the **Output** parameter, you can click the **Show data type assistant** button

to display the data type assistant..

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Minimum — Minimum

`[]` (default) | scalar

Specify the minimum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Maximum — Maximum

`[]` (default) | scalar

Specify the maximum value of the block output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

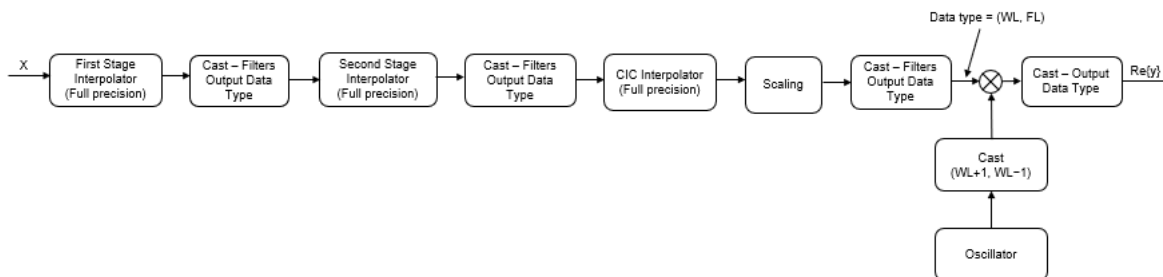

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | no                                      |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Fixed Point

The block diagram represents the DUC arithmetic with signed fixed-point inputs.

- $WL$  is the word length of the input, and  $FL$  is the fraction length of the input.
- The output of each filter is cast to the filter output data type. In the `dsp.DigitalUpConverter` object, you can specify the filter output data type through the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties. In the Digital Up-Converter block, you can specify the filter output data type through the **Stage output** parameter. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the filter output data type word length plus one. The fraction length is equal to the filter output data type word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse-gain and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The figure shows the coarse-gain and fine-gain operations.

If the normalization gain is  $G$  (where  $0 < G \leq 1$ ), then:

- $WL_{cic}$  is the word length of the CIC interpolator output, and  $FL_{cic}$  is the fraction length of the CIC interpolator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved by using bit shifts (coarse gain).
- $F2$  is the fraction length specified by the filter output data type.
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$ , which indicates that the remaining gain cannot be achieved with a bit shift (fine gain).

## Algorithms

The digital up converter upsamples the input signal using a cascade of three interpolation filters. This algorithm frequency-upconverts the upsampled signal by multiplying it with a complex exponential that has the specified center frequency. In this case, the filter cascade consists of an FIR interpolation stage, a second stage for CIC compensation, and a CIC interpolator. The block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. Depending on how you set the interpolation factor, the block bypasses the first filter stage. When the input data type is floating point, the algorithm implements an  $N$ -section CIC interpolation filter as a FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. The algorithm emulates a CIC filter with an FIR filter so that you can run simulations with floating-point data. When the input data type is a fixed-point type, the algorithm implements a true CIC filter with actual comb and integrator sections.

This block diagram represents the DUC arithmetic with floating-point inputs.

For details about fixed-point operation, see “Fixed Point” on page 2-445.

## Version History

Introduced in R2015a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## Digital Filter (Obsolete)

Filter each channel of input over time using static or time-varying digital filter implementations

## Library

Filtering / Filter Implementations

dsparch4

## Description

---

**Note** Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See “Functionality being removed or replaced for blocks and System objects”. We strongly recommend using one of Discrete FIR Filter, Discrete Filter, Biquad Filter, or Allpole Filter in new designs.

---

You can use the Digital Filter block to efficiently implement a floating-point or fixed-point filter for which you know the coefficients, or that is already defined in a `dfilt` object. The block independently filters each channel of the input signal with a specified digital IIR or FIR filter. The block can implement *static filters* with fixed coefficients, as well as *time-varying filters* with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. You must set the **Input processing** parameter to specify how the block interprets the input signal. You can select one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as an independent channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as an individual channel.

The output dimensions always match those of the input signal. The outputs of this block numerically match the outputs of the Digital Filter Design block and of the `dfilt` object.

---

**Note** The Digital Filter block has direct feedthrough, so if you connect the output of this block back to its input you get an algebraic loop. For more information on direct feedthrough and algebraic loops, see “Algebraic Loop Concepts” (Simulink).

---

## Sections of This Reference Page

- “Filter Structure Diagrams” on page 2-464
- “Supported Data Types” on page 2-491
- “See Also” on page 2-491

## Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

## Supported Filter Structures

When you select **Discrete-time filter object (DFILT)**, the following `dfilt` structures are supported:

- `dfilt.df1`
- `dfilt.df1t`
- `dfilt.df2`
- `dfilt.df2t`
- `dfilt.df1sos`
- `dfilt.df1tsos`
- `dfilt.df2sos`
- `dfilt.df2tsos`
- `dfilt.dffir`
- `dfilt.dffirt`
- `dfilt.dfsymfir`
- `dfilt.dfasymfir`
- `dfilt.latticear`
- `dfilt.latticemamin`

When you select **Dialog parameters** or **Input port(s)**, the list of filter structures offered in the **Filter structure** parameter depends on whether you set the **Transfer function type** to IIR (poles & zeros), IIR (all poles), or FIR (all zeros), as summarized in the following table.

**Note** Each structure listed in the table below supports both fixed-point and floating-point signals.

The table also shows the vector or matrix of filter coefficients you must provide for each filter structure.

### Filter Structures and Filter Coefficients

| Transfer Function Type         | Supported Filter Structures                 | Filter Coefficient Specification  |
|--------------------------------|---|---|
| <b>IIR (poles &amp; zeros)</b> | Direct form I                               | <ul style="list-style-type: none"> <li>Numerator coefficients vector [b0, b1, b2, ..., bn]</li> <li>Denominator coefficients vector [a0, a1, a2, ..., am]</li> </ul> See Special Consideration for the Leading Denominator Coefficient on page 2-450. |
|                                | Direct form I transposed                    |   |
|                                | Direct form II                              |   |
|                                | Direct form II transposed                   |   |
|                                | Biquadratic direct form I (SOS)             | <ul style="list-style-type: none"> <li>M-by-6 second-order section (SOS) matrix.</li> <li>Scale values</li> </ul>   |
|                                | Biquadratic direct form I transposed (SOS)  |   |
|                                | Biquadratic direct form II (SOS)            |   |
|                                | Biquadratic direct form II transposed (SOS) |   |
| <b>IIR (all poles)</b>         | Direct form                                 | Denominator coefficients vector [a0, a1, a2, ..., am]   |
|                                | Direct form transposed                      |   |
|                                | Lattice AR                                  | Reflection coefficients vector [k1, k2, ..., kn]  |
| <b>FIR (all zeros)</b>         | Direct form                                 | Numerator coefficients vector [b0, b1, b2, ..., bn]   |
|                                | Direct form symmetric                       |   |
|                                | Direct form antisymmetric                   |   |
|                                | Direct form transposed                      |   |
|                                | Lattice MA                                  | Reflection coefficients vector [k1, k2, ..., kn]  |

#### Special Considerations for the Leading Denominator Coefficient

In some cases, the Digital Filter block requires the leading denominator coefficient ( $a_0$ ) to be 1. This requirement applies under the following conditions:

- The Digital Filter block is operating in a fixed-point mode. The block operates in a fixed-point mode when at least one of the following statements is true:
  - The input to the Digital Filter block has a fixed-point or integer data type.

- The **Fixed-point instrumentation mode** parameter under **Analysis > Fixed Point Tool** has a setting of Minimums, maximums and overflows.
- The **Coefficient source** has a setting of Dialog or Input port(s).

---

**Note** If you are working in one of the fixed-point situations described in the previous bullet, and the **Coefficient source** is set to Input port(s), you must select the **First denominator coefficient = 1, remove a0 term in the structure** check box.

---

- The **Transfer function type** and **Filter structure** parameters are set to one of the combinations described in the following table.

| Transfer function type         | Filter structure          |
|--------------------------------|---------------------------|
| <b>IIR (poles &amp; zeros)</b> | Direct form I             |
|                                | Direct form I transposed  |
|                                | Direct form II            |
|                                | Direct form II transposed |
| <b>IIR (all poles)</b>         | Direct form               |
|                                | Direct form transposed    |

The Digital Filter block produces an error if you use it in one of these configurations and your leading denominator coefficient ( $a_0$ ) does not equal 1. To resolve the error, set your leading denominator coefficient to 1 by scaling all numerator and denominator coefficients by a factor of  $a_0$ .

### Specifying Initial Conditions

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial conditions** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial condition values you must specify, and how to specify them, see the following table on Valid Initial Conditions and Number of Delay Elements (Filter States). The **Initial conditions** parameter can take one of four forms as described in the following table.

## Valid Initial Conditions

| Initial Condition   | Examples   | Description   |
|---|--|---|
| Scalar  | 5<br><br>Each delay element for each channel is set to 5.  | The block initializes all delay elements in the filter to the scalar value.   |
| Vector<br>(for applying the same delay elements to each channel)            | For a filter with two delay elements: $[d_1 \ d_2]$<br><br>The delay elements for all channels are $d_1$ and $d_2$ .   | Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).   |
| Vector or matrix<br>(for applying different delay elements to each channel) | For a 3-channel input signal and a filter with two delay elements:<br>$[d_1 \ d_2 \ D_1 \ D_2 \ d_1 \ d_2]$ or<br>$\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ <ul style="list-style-type: none"> <li>The delay elements for channel 1 are <math>d_1</math> and <math>d_2</math>.</li> <li>The delay elements for channel 2 are <math>D_1</math> and <math>D_2</math>.</li> <li>The delay elements for channel 3 are <math>d_1</math> and <math>d_2</math>.</li> </ul> | Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: <ul style="list-style-type: none"> <li>The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).</li> <li>The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.</li> </ul> |
| Empty matrix  | $[ \ ]$<br>Each delay element for each channel is set to $\theta$ .  | The empty matrix, $[ \ ]$ , is equivalent to setting the <b>Initial conditions</b> parameter to the scalar value $\theta$ .   |

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

**Number of Delay Elements (Filter States)**

| Filter Structure   | Number of Delay Elements per Channel   |
|--|--|
| Direct form<br>Direct form transposed<br>Direct form symmetric<br>Direct form antisymmetric  | #_of_filter_coeffs-1   |
| Direct form I<br>Direct form I transposed  | <ul style="list-style-type: none"> <li>• #_of_zeros-1</li> <li>• #_of_poles-1</li> </ul> |
| Direct form II<br>Direct form II transposed  | max(#_of_zeros, #_of_poles)-1  |
| Biquadratic direct form I (SOS)<br>Biquadratic direct form I transposed (SOS)<br>Biquadratic direct form II (SOS)<br>Biquadratic direct form II transposed (SOS) | 2 * #_of_filter_sections   |
| Lattice AR<br>Lattice MA   | #_of_reflection_coeffs   |

**State Logging**

Simulink enables you to log the states in your model to the MATLAB workspace. The following table indicates which filter structures of the Digital Filter block support the Simulink state logging feature. See “State” (Simulink) for more information.

| Transfer Function Type         | Filter Structure                            | State Logging Supported |
|--------------------------------|---|-------------------------|
| <b>IIR (poles &amp; zeros)</b> | Direct form I                               | No                      |
|                                | Direct form I transposed                    | Yes                     |
|                                | Direct form II                              | No                      |
|                                | Direct form II transposed                   | Yes                     |
|                                | Biquadratic direct form I (SOS)             | Yes                     |
|                                | Biquadratic direct form I transposed (SOS)  | Yes                     |
|                                | Biquadratic direct form II (SOS)            | Yes                     |
|                                | Biquadratic direct form II transposed (SOS) | Yes                     |
| <b>IIR (all poles)</b>         | Direct form                                 | No                      |
|                                | Direct form transposed                      | Yes                     |
|                                | Lattice AR                                  | Yes                     |
| <b>FIR (all zeros)</b>         | Direct form                                 | No                      |
|                                | Direct form symmetric                       | No                      |
|                                | Direct form antisymmetric                   | No                      |
|                                | Direct form transposed                      | Yes                     |
|                                | Lattice MA                                  | Yes                     |

## Fixed-Point Data Types

All structures supported by the Digital Filter block support fixed-point data types. You can specify intermediate fixed-point data types for quantities such as the coefficients, accumulator, and product output for each filter structure. See “Filter Structure Diagrams” on page 2-464 for diagrams depicting the use of these intermediate fixed-point data types in each filter structure.

## Dialog Box

### Coefficient Source

The Digital Filter block can operate in three different modes. Select the mode in the **Coefficient source** group box.

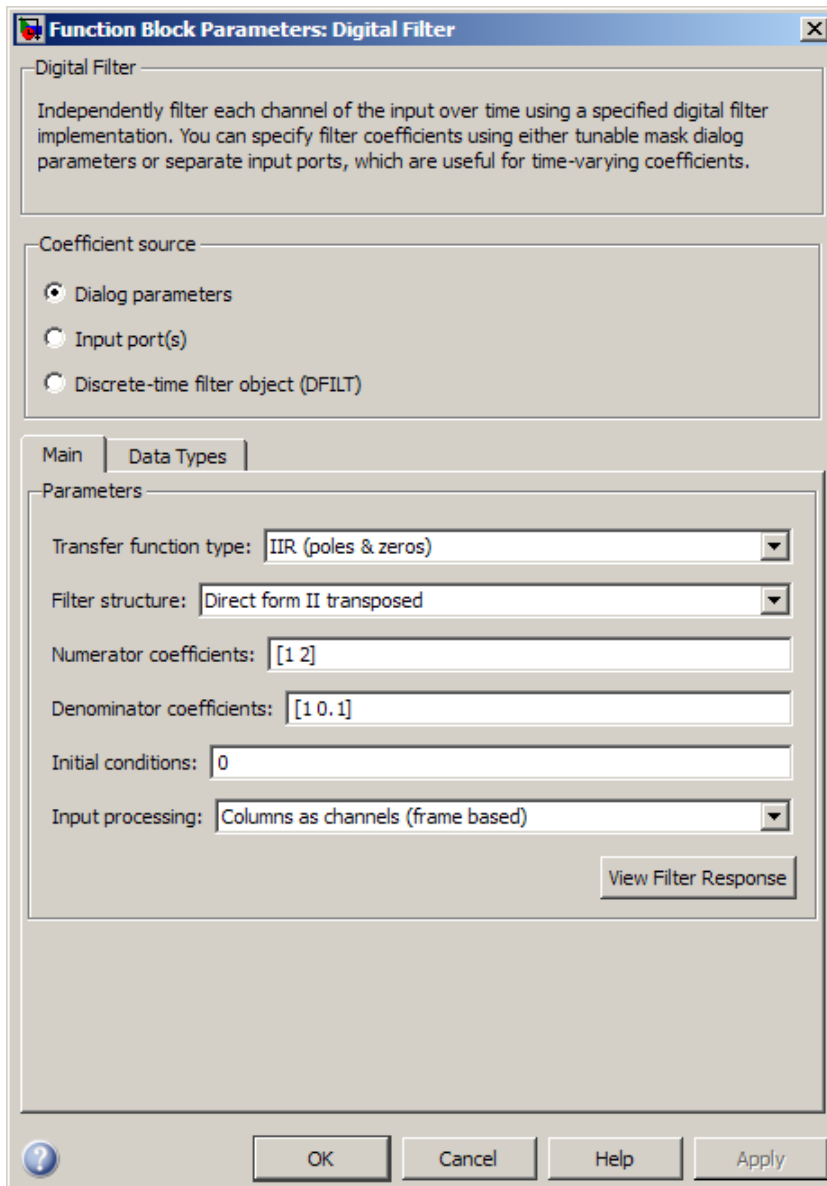

- **Dialog parameters** Enter information about the filter such as structure and coefficients in the block mask.
- **Input port(s)** Enter the filter structure in the block mask, and the filter coefficients come in through one or more block ports. This mode is useful for specifying time-varying filters.
- **Discrete-time filter object (DFILT)** Specify the filter using a `dfilt` object.

Different items appear on the Digital Filter block dialog depending on whether you select **Dialog parameters**, **Input port(s)**, or **Discrete-time filter object (DFILT)** in the **Coefficient source** group box. See the following sections for details:

- “Specify Filter Characteristics in Dialog and/or Through Input Ports” on page 2-454
- “Specify Discrete-Time Filter Object” on page 2-461

### Specify Filter Characteristics in Dialog and/or Through Input Ports

The **Main** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, as noted.

### Transfer function type

Select the type of transfer function of the filter; IIR (poles & zeros), IIR (all poles), or FIR (all zeros). See “Supported Filter Structures” on page 2-449 for more information.

### Filter structure

Select the filter structure. The selection of available structures varies depending the setting of the **Transfer function type** parameter. See “Supported Filter Structures” on page 2-449 for more information.

### Numerator coefficients

Specify the vector of numerator coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with numerator coefficients. Tunable (Simulink).

**Denominator coefficients**

Specify the vector of denominator coefficients of the filter's transfer function.

In some cases, the leading denominator coefficient ( $a_0$ ) must be 1. See *Special Consideration for the Leading Denominator Coefficient* on page 2-450 for more information.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with denominator coefficients. Tunable (Simulink).

**Reflection coefficients**

Specify the vector of reflection coefficients of the filter's transfer function.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure lends itself to specification with reflection coefficients. Tunable (Simulink).

**SOS matrix (Mx6)**

Specify an  $M$ -by-6 *SOS matrix* containing coefficients of a second-order section (SOS) filter, where  $M$  is the number of sections. You can use the `ss2sos` and `tf2sos` functions from Signal Processing Toolbox software to check whether your SOS matrix is valid.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

**Scale values**

Specify the scale values to be applied before and after each section of a biquadratic filter.

- If you specify a scalar, that value is applied before the first filter section. The rest of the scale values are set to 1.
- You can also specify a vector with  $M + 1$  elements, assigning a different value to each scale. See “Filter Structure Diagrams” on page 2-464 for diagrams depicting the use of scale values in biquadratic filter structures.

This parameter is only visible when **Dialog parameters** is selected *and* when the selected filter structure is biquadratic. Tunable (Simulink).

**First denominator coefficient = 1, remove  $a_0$  term in the structure**

Select this parameter to reduce the number of computations the block must make to produce the output by omitting the  $1 / a_0$  term in the filter structure. The block output is invalid if you select this parameter when the first denominator filter coefficient is *not* always 1 for your time-varying filter.

This parameter is only enabled when the **Input port(s)** is selected *and* when the selected filter structure lends itself to this specification.

**Coefficient update rate**

Specify how often the block updates time-varying filters; once per sample or once per frame.

This parameter appears only when the following conditions are met:

- You specify **Input port(s)** in the Coefficient source group box.
- You set the **Input processing** parameter to `Columns as channels (frame based)`.

**Initial conditions**

Specify the initial conditions of the filter states. To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-451.

### Initial conditions on zeros side

(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the zeros ( $b_0, b_1, b_2, \dots$ ); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles ( $a_k$ ) and zeros ( $b_k$ ). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-451.

### Initial conditions on poles side

(Not shown in dialog above.) Specify the initial conditions for the filter states on the side of the filter structure with the poles ( $a_0, a_1, a_2, \dots$ ); see the diagram below.

This parameter is enabled only when the filter has both poles and zeros, *and* when you select a structure such as direct form I, which has separate filter states corresponding to the poles ( $a_k$ ) and zeros ( $b_k$ ). To learn how to specify initial conditions, see “Specifying Initial Conditions” on page 2-451.

### Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the filter defined by the block. For more information on FVTool, see the Signal Processing Toolbox documentation.

**Note** If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Dialog parameters** is specified in the **Coefficient source** group box. The parameters below can appear when **Dialog parameters** or **Input port(s)** is selected, depending on the filter structure and whether the coefficients are being entered via ports or on the block mask.

### Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to Nearest.

**Overflow mode**

Select the overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

**Section I/O**

Choose how you specify the word length and the fraction length of the fixed-point data type going into and coming out of each section of a biquadratic filter. See “Filter Structure Diagrams” on page 2-464 for illustrations depicting the use of the section I/O data type in this block.

This parameter is only visible when the selected filter structure is biquadratic:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word and fraction lengths of the section input and output, in bits.
- When you select `Slope and bias scaling`, you can enter the word lengths, in bits, and the slopes of the section input and output. This block requires power-of-two slope and a bias of zero.

**Tap sum**

Choose how you specify the word length and the fraction length of the tap sum data type of a direct form symmetric or direct form antisymmetric filter. See “Filter Structure Diagrams” on page 2-464 for illustrations depicting the use of the tap sum data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form symmetric` or `Direct form antisymmetric`:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the tap sum accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the tap sum accumulator. This block requires power-of-two slope and a bias of zero.

**Multiplicand**

Choose how you specify the word length and the fraction length of the multiplicand data type of a direct form I transposed or biquadratic direct form I transposed filter. See “Filter Structure Diagrams” on page 2-464 for illustrations depicting the use of the multiplicand data type in this block.

This parameter is only visible when the selected filter structure is either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`:

- When you select `Same as output`, these characteristics match those of the output to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the multiplicand data type, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the multiplicand data type. This block requires power-of-two slope and a bias of zero.

**Coefficients**

Choose how you specify the word length and the fraction length of the filter coefficients (numerator and/or denominator). See “Filter Structure Diagrams” on page 2-464 for illustrations depicting the use of the coefficient data types in this block:

- When you select **Same word length as input**, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Specify word length**, you can enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the coefficients, in bits. If applicable, you can enter separate fraction lengths for the numerator and denominator coefficients.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the coefficients. If applicable, you can enter separate slopes for the numerator and denominator coefficients. This block requires power-of-two slope and a bias of zero.
- The filter coefficients do not obey the **Rounding mode** and the **Overflow mode** parameters; they are always saturated and rounded to Nearest.

### Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See “Filter Structure Diagrams” on page 2-464 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the product output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

### Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See “Filter Structure Diagrams” on page 2-464 and “Multiplication Data Types” for illustrations depicting the use of the accumulator data type in this block:

- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Same as product output**, these characteristics match those of the product output.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

### State

Use this parameter to specify how you would like to designate the state word and fraction lengths. See “Filter Structure Diagrams” on page 2-464 for illustrations depicting the use of the state data type in this block.

This parameter is not visible for direct form and direct form I filter structures.

- When you select **Same as input**, these characteristics match those of the input to the block.

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

### Output

Choose how you specify the output word length and fraction length:

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

### Specify Discrete-Time Filter Object

The **Main** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.

### Filter

Specify the discrete-time filter object (`dfilt`) that you would like the block to implement. You can do this in one of three ways:

- You can fully specify the `dfilt` object in the block mask, as shown in the default value.
- You can enter the variable name of a `dfilt` object that is defined in any workspace.
- You can enter a variable name for a `dfilt` object that is not yet defined.

### Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product and displays the filter response of the `dfilt` object specified in the **Filter** parameter. For more information on FVTool, see the Signal Processing Toolbox documentation.

---

**Note** If you specify a filter in the **Filter** parameter, you must click the **Apply** button to apply the filter before using the **View filter response** button.

---

The **Data Types** pane of the Digital Filter block dialog appears as follows when **Discrete-time filter object (DFILT)** is specified in the **Coefficient source** group box.

The fixed-point settings of the filter object specified on the **Main** pane are displayed on the **Data Types** pane. You cannot change these settings directly on the block mask. To change the fixed-point settings you must edit the filter object directly.

## Filter Structure Diagrams

The diagrams in the following sections show the filter structures supported by the Digital Filter block. They also show the data types used in the filter structures for fixed-point signals. You can set the coefficient, output, accumulator, product output, and state data types shown in these diagrams in the block dialog. This is discussed in “Dialog Box” on page 2-454.

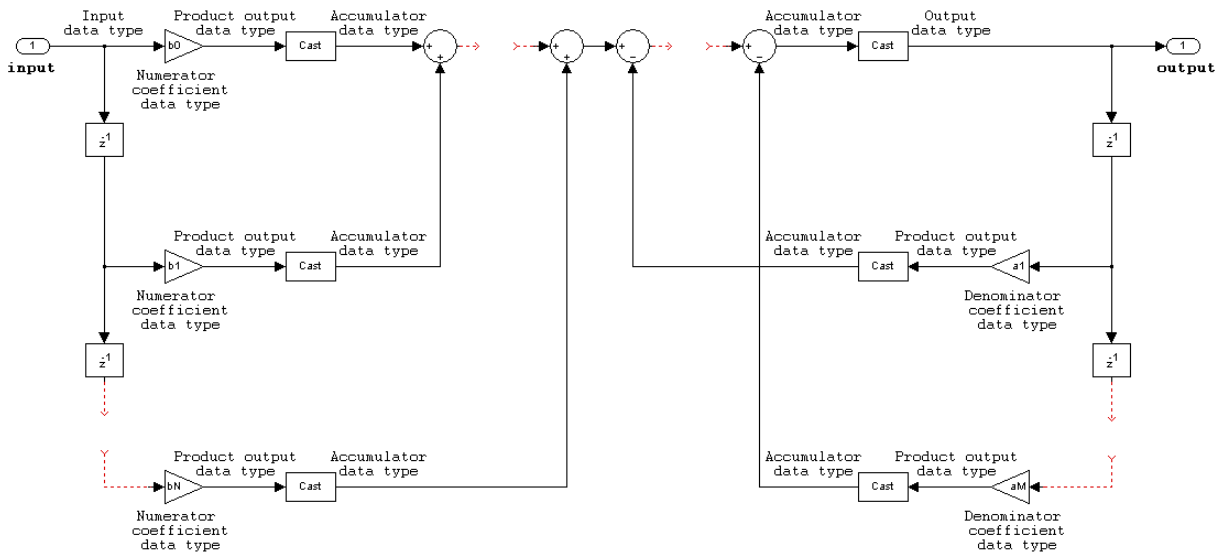

- “IIR direct form I” on page 2-465
- “IIR direct form I transposed” on page 2-466
- “IIR direct form II” on page 2-468
- “IIR direct form II transposed” on page 2-469
- “IIR biquadratic direct form I” on page 2-471
- “IIR biquadratic direct form I transposed” on page 2-472
- “IIR biquadratic direct form II” on page 2-474
- “IIR biquadratic direct form II transposed” on page 2-475
- “IIR (all poles) direct form” on page 2-477
- “IIR (all poles) direct form transposed” on page 2-479
- “IIR (all poles) direct form lattice AR” on page 2-481
- “FIR (all zeros) direct form” on page 2-482
- “FIR (all zeros) direct form symmetric” on page 2-483

- “FIR (all zeros) direct form transposed” on page 2-487
- “FIR (all zeros) lattice MA” on page 2-488

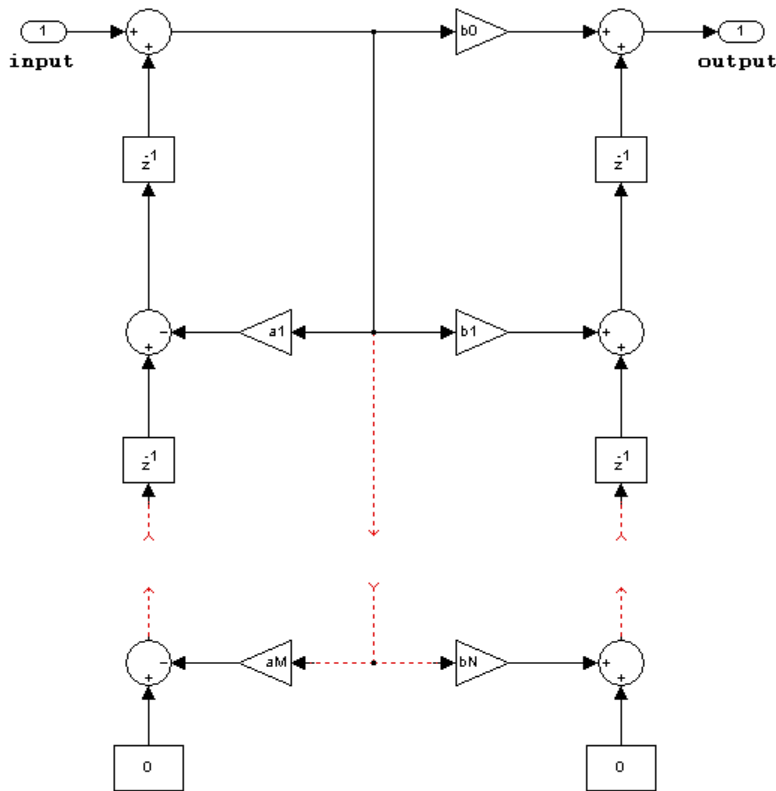

**IIR direct form I**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.
- The State data type cannot be specified on the block mask for this structure, because the input and output states have the same data types as the input and output buffers.

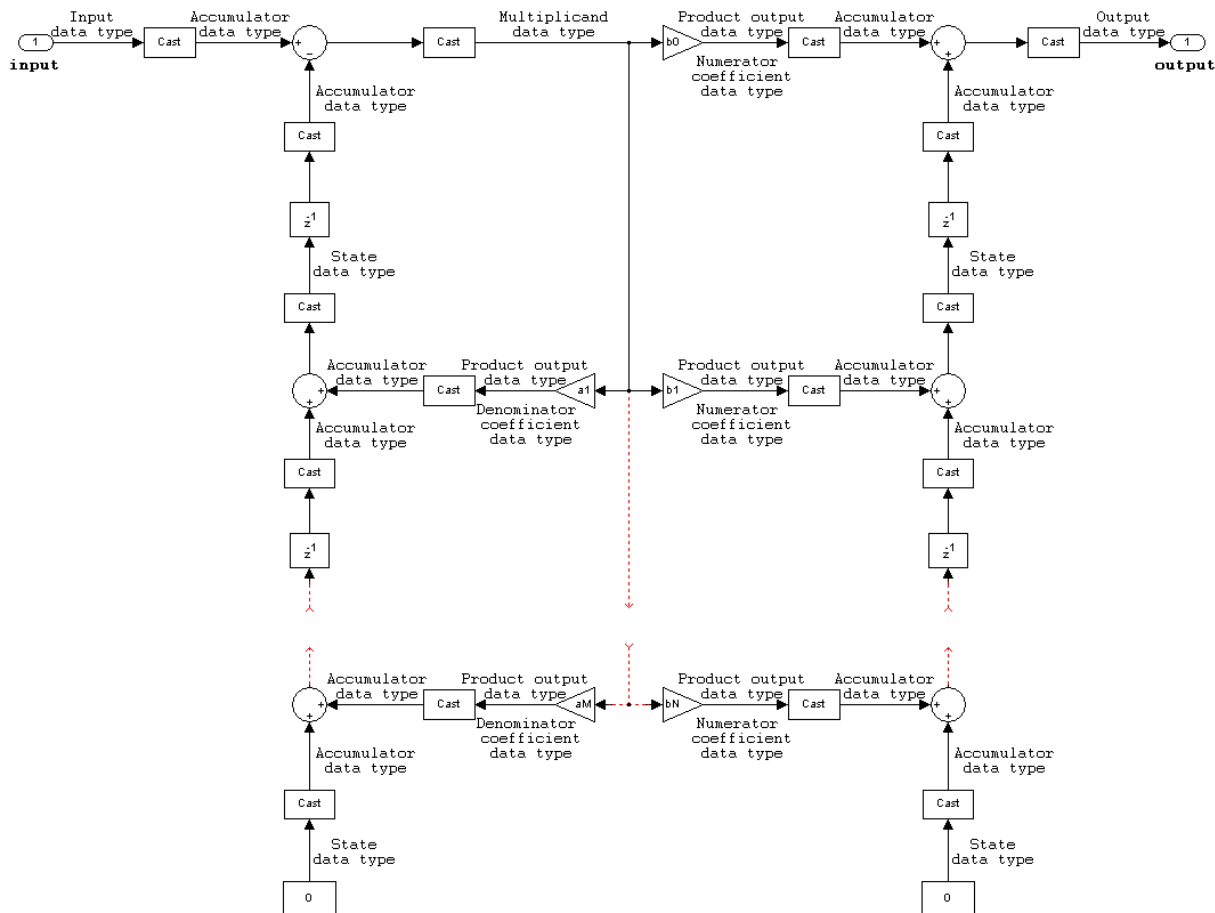

**IIR direct form I transposed**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.

- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

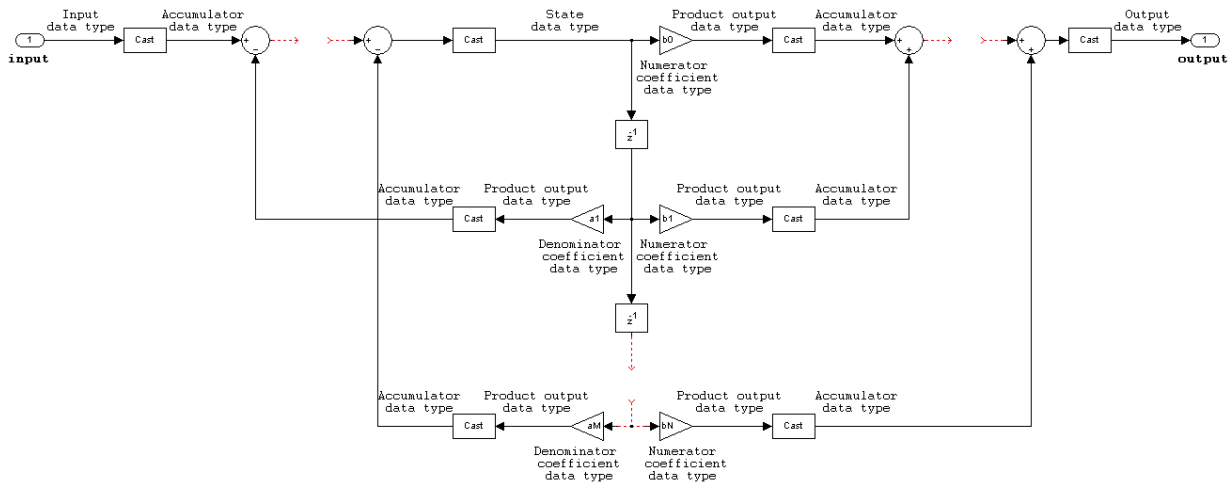

## IIR direct form II

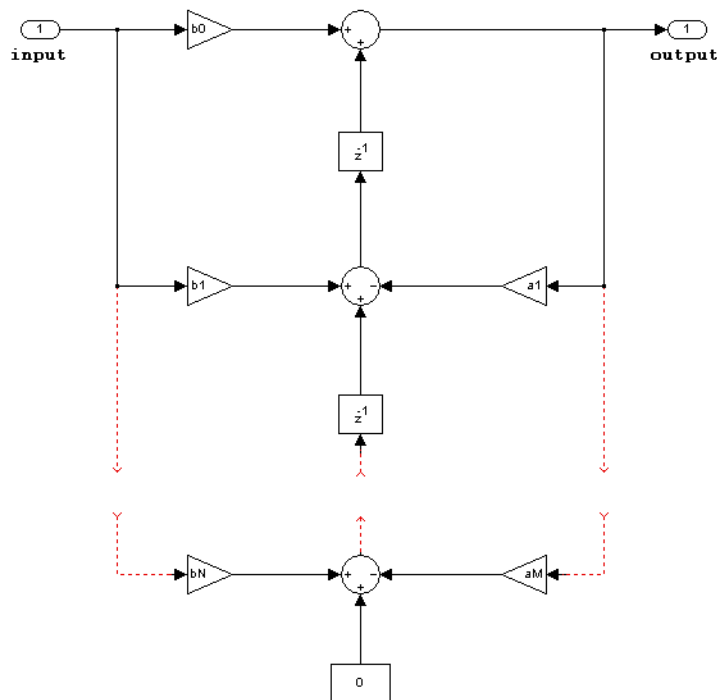

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

### IIR direct form II transposed

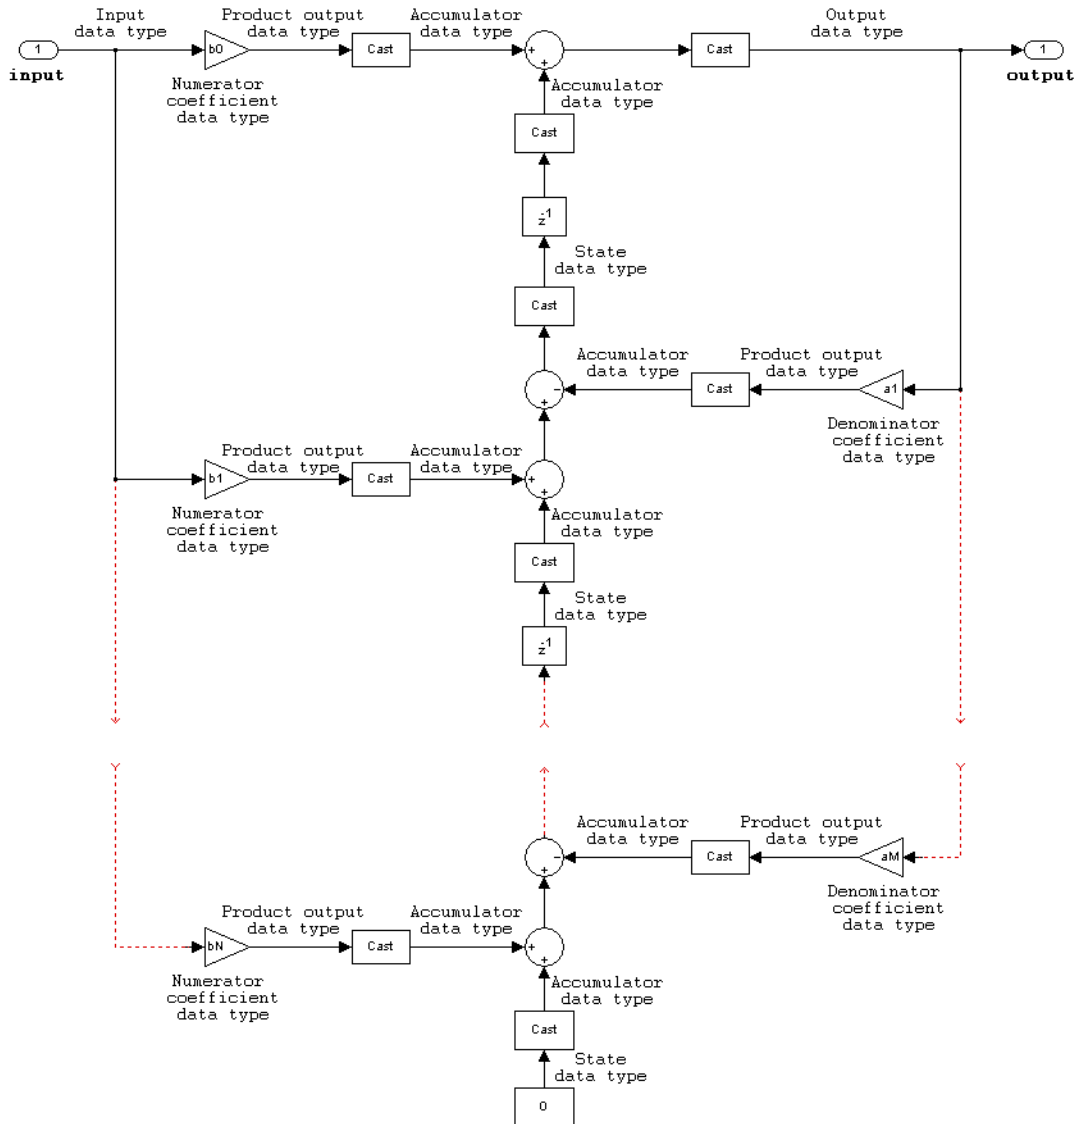

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must be the same complexity as each other.
  - When the numerator and denominator coefficients are specified via input ports and have different complexities from each other, you get an error.
  - When the numerator and denominator coefficients are specified in the dialog and have different complexities from each other, the block does not error, but instead processes the filter

as if two sets of complex coefficients are provided. The coefficient set that is real-valued is treated as if it is a complex vector with zero-valued imaginary parts.

- States are complex when either the inputs or the coefficients are complex.
- Numerator and denominator coefficients must have the same word length. They can have different fraction lengths.

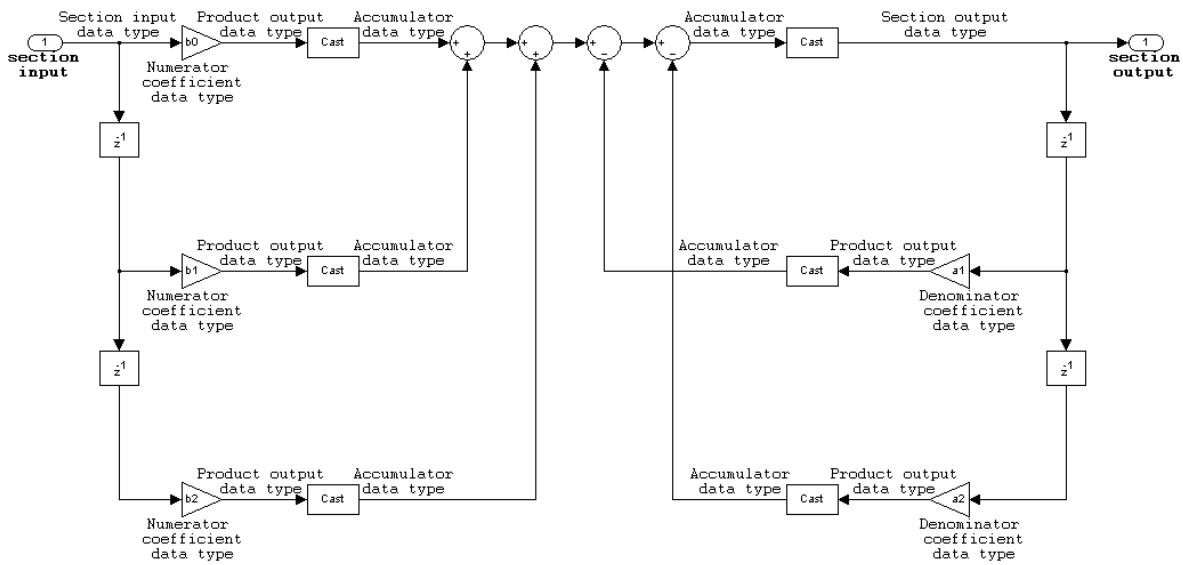

**IIR biquadratic direct form I**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a  $M$ -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the  $a_0$  element of any row is not equal to one, that row is normalized by  $a_0$  prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length  $M+1$ , where  $M$  is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and stage output data type must have the same word length but can have different fraction lengths.

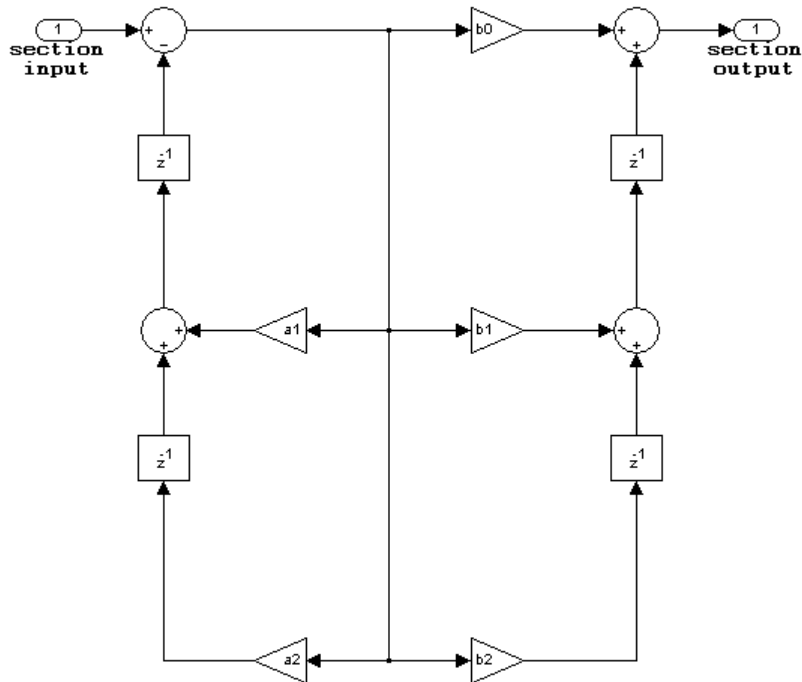

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

**IIR biquadratic direct form I transposed**

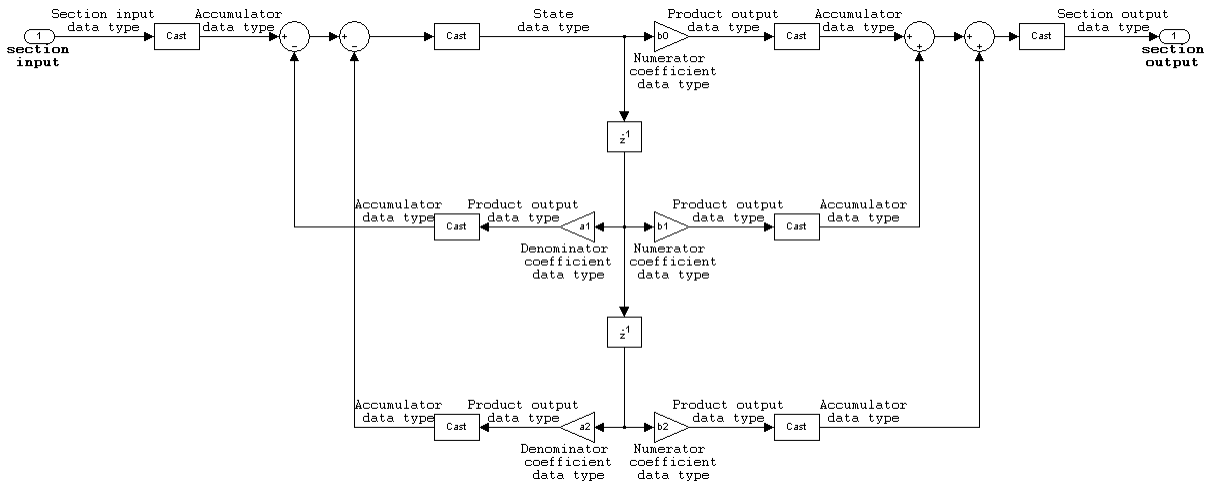

### IIR biquadratic direct form II

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a  $M$ -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the  $a_0$  element of any row is not equal to one, that row is normalized by  $a_0$  prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length  $M+1$ , where  $M$  is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

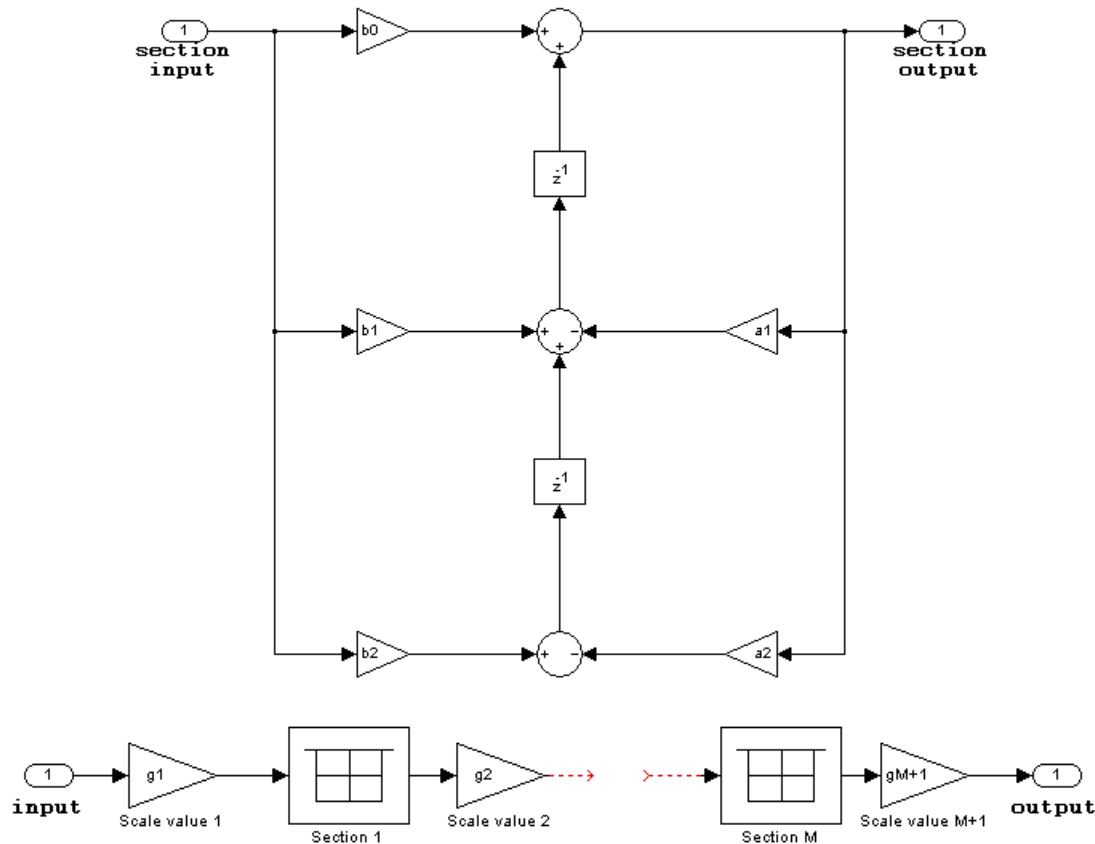

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

**IIR biquadratic direct form II transposed**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Specify the coefficients by a  $M$ -by-6 matrix in the block mask. You cannot specify coefficients by input ports for this filter structure.
- When the  $a_0$  element of any row is not equal to one, that row is normalized by  $a_0$  prior to filtering.
- States are complex when either the inputs or the coefficients are complex.
- Scale values must have the same complexity as the coefficient SOS matrix.
- The scale value parameter must be a scalar or a vector of length  $M+1$ , where  $M$  is the number of sections.
- The **Section I/O** parameter determines the data type for the section input and output data types. The section input and section output data type must have the same word length but can have different fraction lengths.

The following diagram shows the data types for one section of the filter.

The following diagram shows the data types between filter sections.

### IIR (all poles) direct form

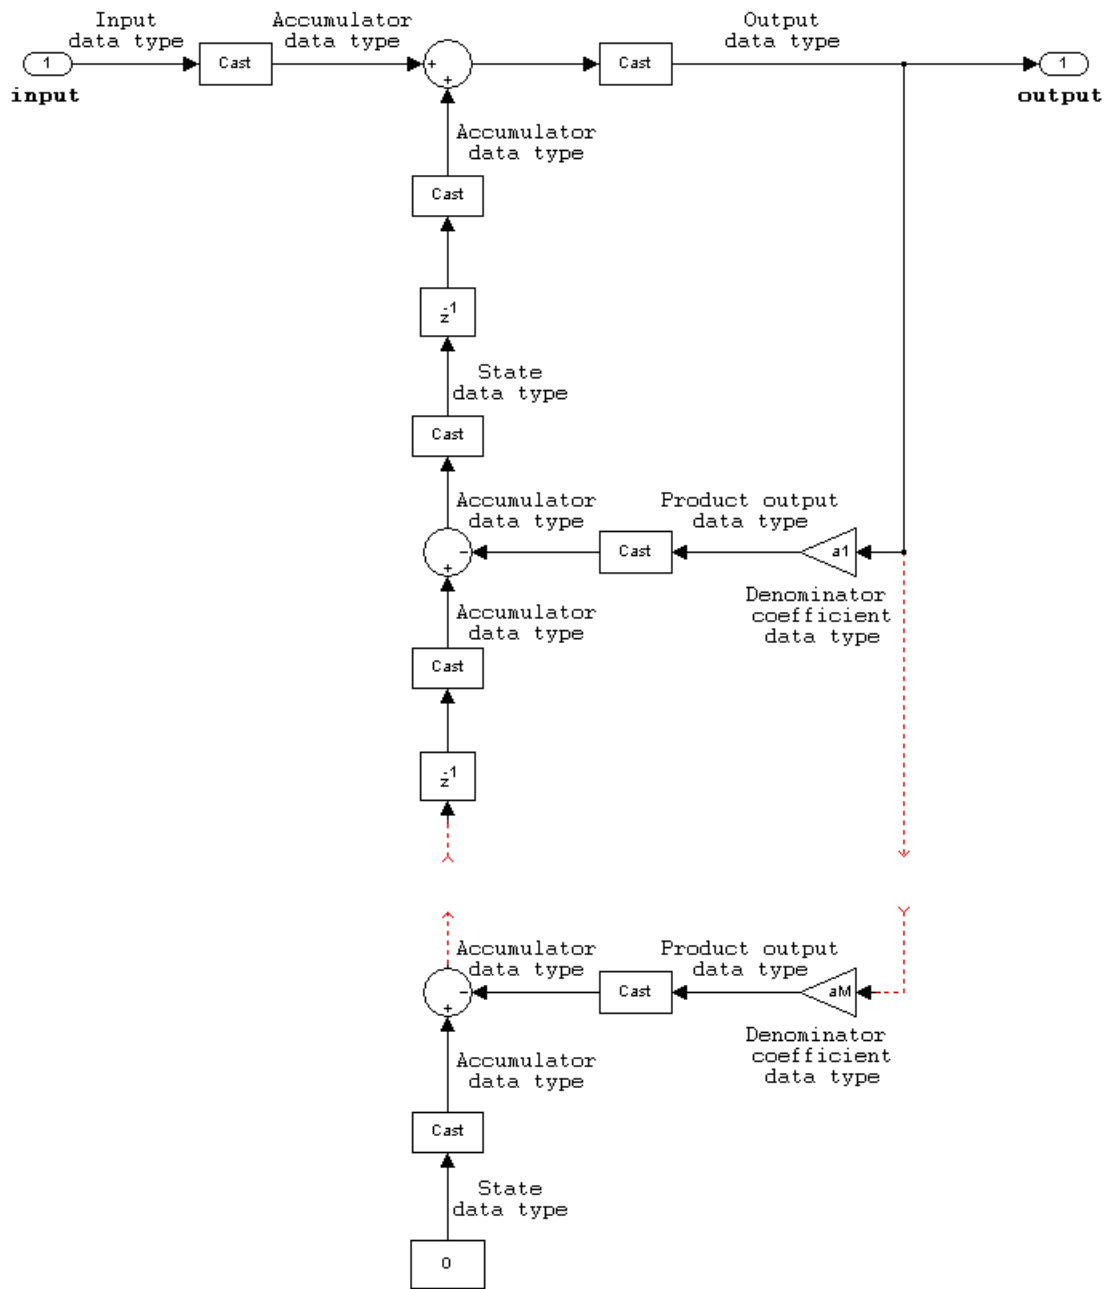

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Denominator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

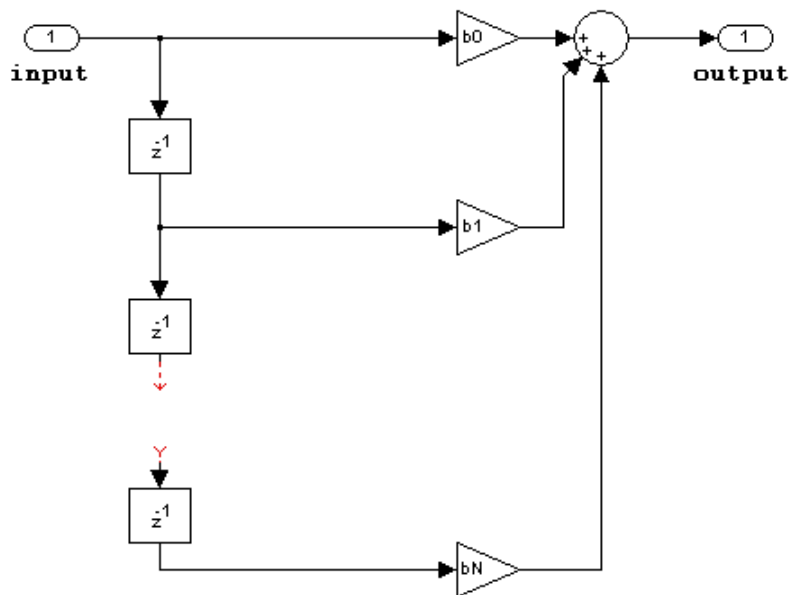

## FIR (all zeros) direct form

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.

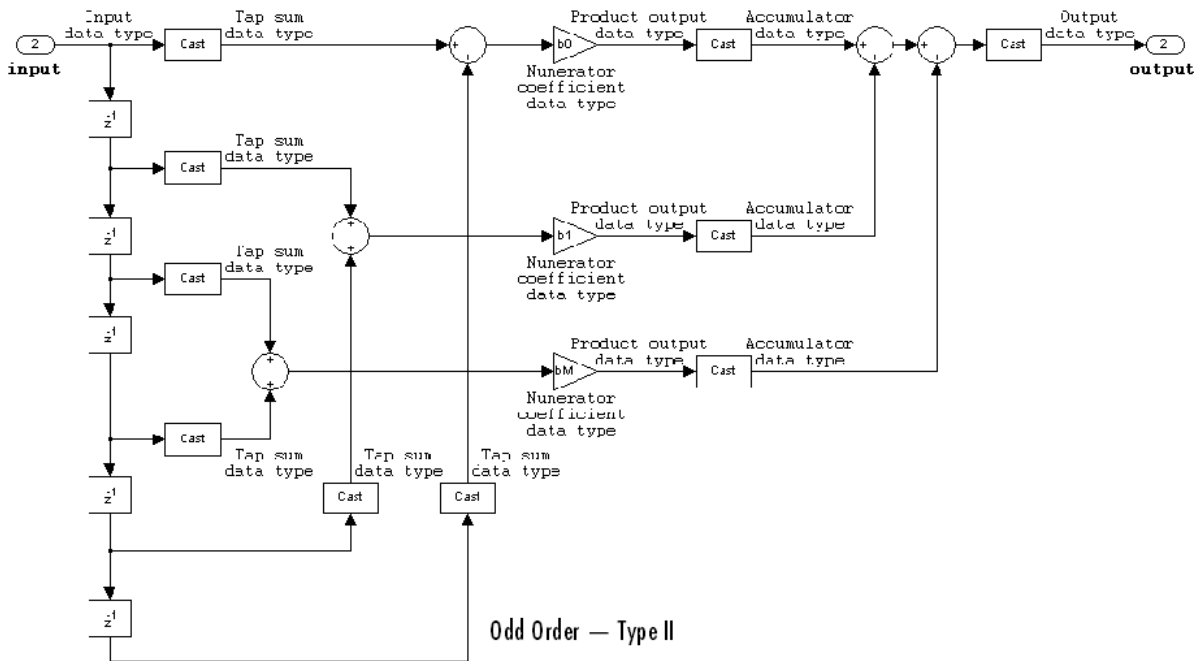

### FIR (all zeros) direct form symmetric

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are symmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

### FIR (all zeros) direct form antisymmetric

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Numerator coefficients can be real or complex.
- You cannot specify the state data type on the block mask for this structure, because the input and output states have the same data types as the input.
- It is assumed that the filter coefficients are antisymmetric. Only the first half of the coefficients are used for filtering.
- The **Tap Sum** parameter determines the data type the filter uses when it sums the inputs prior to multiplication by the coefficients.

**FIR (all zeros) direct form transposed**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs can be real or complex.
- Coefficients can be real or complex.
- States are complex when either the inputs or the coefficients are complex.

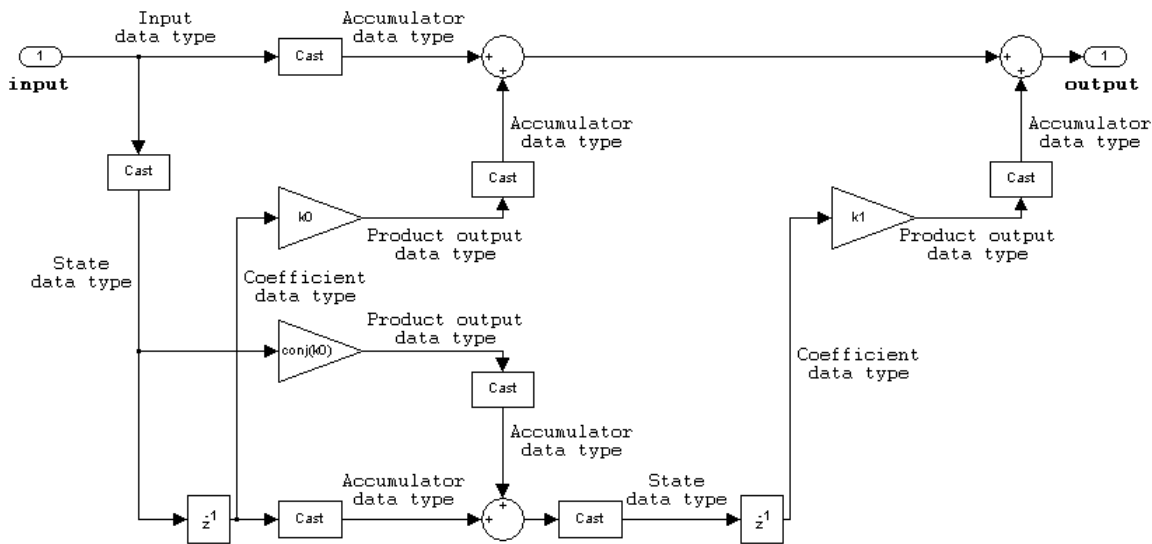

**FIR (all zeros) lattice MA**

The following constraints are applicable when processing a fixed-point signal with this filter structure:

- Inputs and coefficients can be real or complex.
- Coefficients can be real or complex.

## HDL Code Generation

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

---

**Note** Use of Digital Filter block in future releases is not recommended. Existing instances will continue to operate, but certain functionality will be disabled. See “Functionality being removed or replaced for blocks and System objects”. We strongly recommend using Discrete FIR Filter or Biquad Filter in new designs.

---

## HDL Architecture

When you specify `SerialPartition` and `ReuseAccum` for a Digital Filter block, observe the following constraints.

- If you specify **Dialog parameters** as the `Coefficient` source:
  - Set **Transfer function type** to FIR (all zeros).
  - Select **Filter structure** as one of: Direct form, Direct form symmetric, or Direct form asymmetric.

## Distributed Arithmetic Support

Distributed Arithmetic properties **DALUTPartition** and **DARadix** are supported for the default architecture, with FIR, Asymmetric FIR, and Symmetric FIR filter structures.

### AddPipelineRegisters Support

When you use **AddPipelineRegisters**, registers are placed based on the filter structure. The pipeline register placement determines the latency.

| Architecture                                   | Pipeline Register Placement  | Latency (clock cycles)   |
|--|--|--|
| FIR, Asymmetric FIR, and Symmetric FIR filters | A pipeline register is added between levels of a tree-based adder. | $\text{ceil}(\log_2(\text{FL}))$ .<br>FL is the filter length. |
| FIR Transposed                                 | A pipeline register is added after the products.                   | 1  |
| IIR SOS  | Pipeline registers are added between the filter sections.          | NS - 1.<br>NS is the number of sections.                       |

### HDL Filter Properties

|                                 |   |
|---------------------------------|---|
| <b>AddPipelineRegisters</b>     | Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).  |
| <b>CoeffMultipliers</b>         | Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set <b>CoeffMultipliers</b> to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder). |
| <b>DALUTPartition</b>           | Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set <b>DALUTPartition</b> to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).   |
| <b>MultiplierInputPipeline</b>  | Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).   |
| <b>MultiplierOutputPipeline</b> | Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).   |
| <b>ReuseAccum</b>               | Enable or disable accumulator reuse in a serial filter implementation. Set <b>ReuseAccum</b> to <code>on</code> to use a cascade-serial implementation. See also ReuseAccum (HDL Coder).  |

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).                 |

|                       |  |
|-----------------------|--|
| <b>OutputPipeline</b> | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder). |
|-----------------------|--|

### Complex Coefficients and Data Support

Except for decimator and interpolator filter structures, HDL Coder supports use of complex coefficients and complex input signals for all filter structures of the Digital Filter block.

### Restrictions

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- HDL Coder does not support the Digital Filter block **Input port(s)** option for HDL code generation.

### Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

## Digital Filter Design

Design and implement digital FIR and IIR filters

### Libraries:

DSP System Toolbox / Filtering / Filter Designs

### Description

Use this block to design, analyze, and efficiently implement floating-point filters.

The Digital Filter Design block implements a digital Finite Impulse Response (FIR) or Infinite Impulse Response (IIR) filter that you design by using the **Filter Designer** (`filterDesigner`) app. This block provides the same filter implementation as the Discrete FIR Filter or Biquad Filter blocks.

You must specify whether the block performs frame-based or sample-based processing on the input by setting the **Input processing** parameter. The block applies the specified filter to each channel of a discrete-time input signal and outputs the result. The outputs of the block numerically match the outputs of the Discrete FIR Filter or Biquad Filter block and the MATLAB `filter` function. For more information, see “Getting Started with Filter Designer”.

These blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to efficiently implement floating-point or fixed-point filters that you have already designed. These blocks provide the same exact filter implementation as the Digital Filter Design block.
- Filter Realization Wizard — Use to implement floating-point or fixed-point filters built from Sum, Gain, and Unit Delay blocks. You can either design the filter within this block, or import the coefficients of a filter that you designed elsewhere.

### Ports

#### Input

**Port\_1** — Input signal

vector | matrix

Signal to filter, specified as a vector or matrix of real values. When given matrix input, the block treats each column as an independent channel.

The sample rate,  $F_s$ , that you specify in the filter designer app must be identical to the sample rate of the input to the Digital Filter Design block. When the sampling frequencies do not match, the Digital Filter Design block returns a warning message and inherits the sample rate of the input block.

Data Types: `single` | `double`

## Output

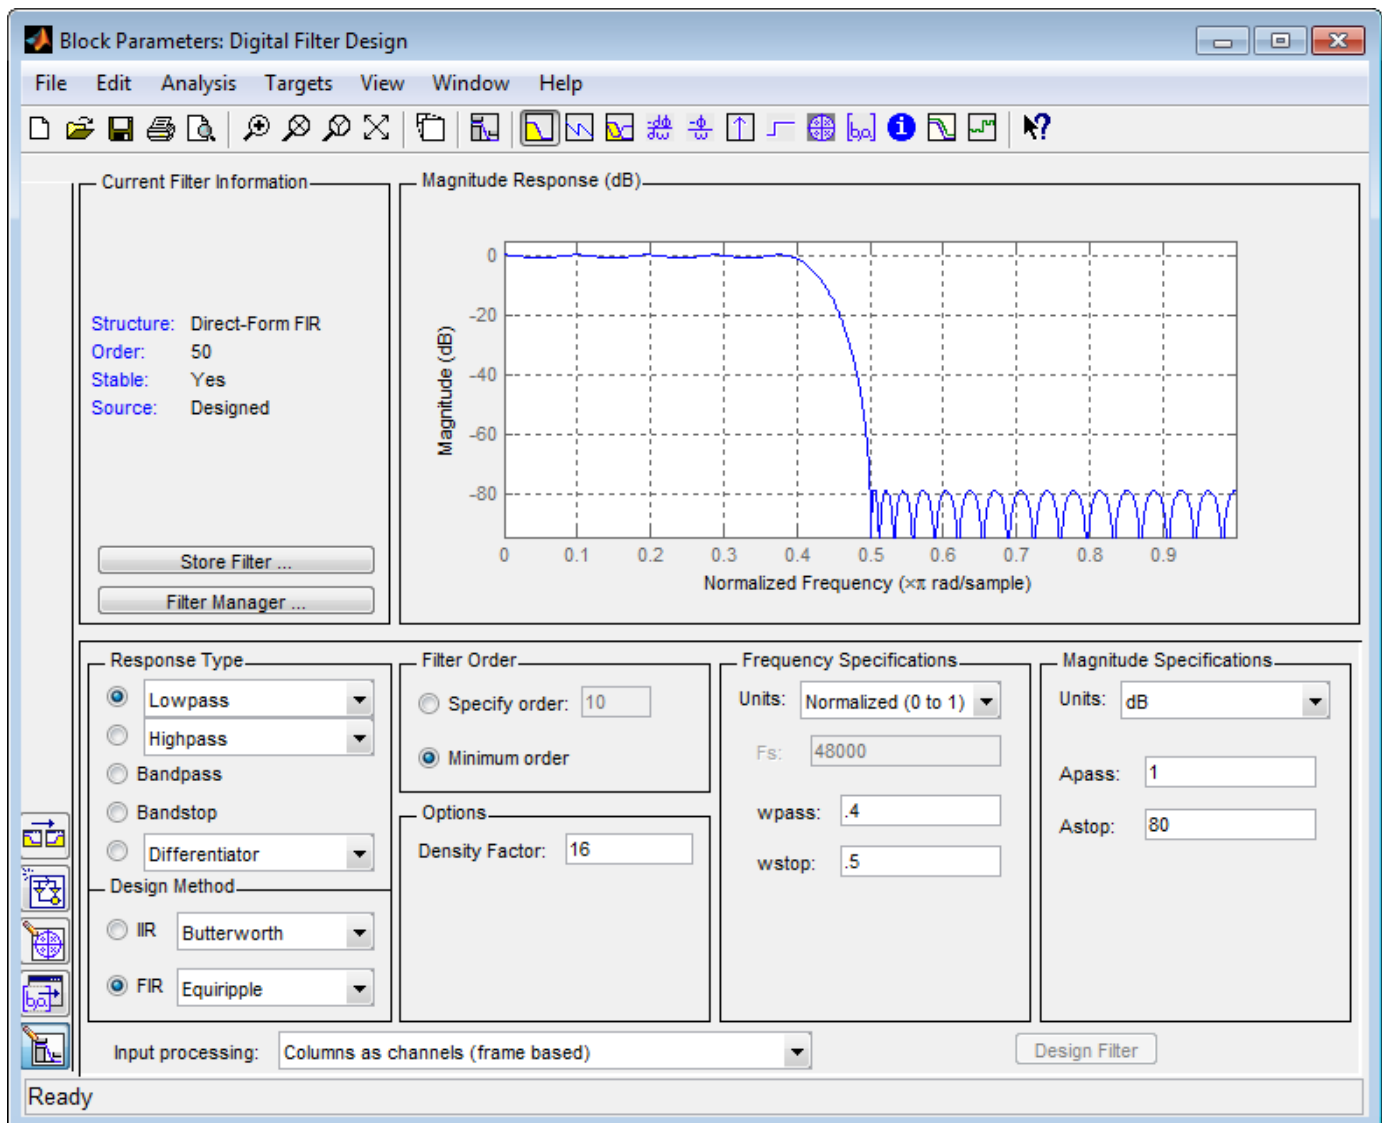

**Port 1** — Output signal  
vector | matrix

Filtered signal, returned as a vector or a matrix of real values.

Data Types: single | double

## Parameters

### Dialog Box

For more information about the parameters in this dialog box, see “Using Filter Designer”.

## Block Characteristics

|                                 |                 |

## More About

### Designing the Filter

To open filter designer, double-click the Digital Filter Design block. Use the filter designer to design or import a digital FIR or IIR filter. To learn how to design filters with this block and filter designer, see:

- “Using Digital Filter Design Block”
- **Filter Designer** app reference page. For details, see `filterDesigner`.

### Tuning the Filter During Simulation

You can tune the filter specifications in filter designer during simulations if your changes do not modify the filter length or filter order. As you apply any filter changes in filter designer, the filter is updated.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The Digital Filter Design block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Input processing** is set to `Columns as channels (frame based)`.
- **Filter Structure** (in **Import Filter from Workspace** pane) is set to `Direct-Form FIR`. You can generate SIMD code even when the filter is a `Direct-Form FIR Transposed` filter. To create a `Direct-Form FIR Transposed` filter, select **Edit > Convert Structure**, and click **Direct-Form FIR Transposed**.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

# Discrete Impulse

Generate discrete impulse

**Libraries:**  
DSP System Toolbox / Sources

## Description

The Discrete Impulse block generates an impulse (the value 1) at output sample  $D+1$ , where you specify  $D$  using the **Delay** parameter ( $D \geq 0$ ). All output samples preceding and following sample  $D+1$  are zero.

When  $D$  is a length- $N$  vector, the block generates an  $M$ -by- $N$  matrix output representing  $N$  distinct channels, where you specify frame size  $M$  using the **Samples per frame** parameter. The impulse for the  $i$ th channel appears at sample  $D(i)+1$ .

The **Sample time** parameter value,  $T_s$ , specifies the output signal sample period. The resulting frame period is  $MT_s$ .

## Ports

### Output

**Port\_1** — Discrete impulse signal  
scalar | vector | matrix

Output signal containing a discrete impulse at output sample  $D(i)+1$ , where  $D$  is a scalar or vector specified by the **Delay** parameter. For more information, see “Description” on page 2-496.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

## Parameters

### Main

**Delay (samples)** — Number of zero-valued output samples

0 (default) | scalar | vector

The number of zero-valued output samples,  $D$ , preceding the impulse, specified as a scalar or vector of integer values, greater than or equal to zero. A length- $N$  vector specifies an  $N$ -channel output.

**Sample time** — Output sample period

1 (default) | positive scalar

The sample period,  $T_s$ , of the output signal specified as a positive finite scalar. The output frame period is  $MT_s$ .

**Samples per frame** — Samples per frame

1 (default) | positive integer

The number of samples,  $M$ , in each output frame, specified as a positive integer scalar.

**Data Types****Output data type** — Output data type

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | int64 | uint64 | boolean | fixdt(1,16) | fixdt(1,16,0) | Inherit: Inherit via back propagation | <data type expression>

Specify the output data type for this block. You can select one of the following:

- A rule that inherits a data type, for example, **Inherit: Inherit via back propagation**. When you select this option, the output data type and scaling matches that of the next downstream block.
- A built-in data type, such as **double**
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For help setting data type parameters, display the **Data Type Assistant** by clicking the **Show data type assistant** button .

See “Control Data Types of Signals” (Simulink) for more information.

**Data Type Assistant****Mode** — Data type mode

Inherit (default) | Built in | Fixed point | Expression

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, **Inherit: Same as input**
- **Built in**— Lets you specify a built-in data type, for example, **double**
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Signedness** — Signedness of fixed-point data

Signed (default) | Unsigned

Specify whether the fixed-point data is signed or unsigned. Signed data can represent positive and negative values, but Unsigned data represents positive values only. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Scaling** — Method for scaling fixed-point data

Best precision (default) | Binary point

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to Fixed point

**Word length** — Bit size of the word that holds the quantized integer

16 (default) | integer from 2 to 128

Specify the bit size of the word that holds the quantized integer as a positive integer from 2 to 128. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to Fixed point

**Fraction length** — Fraction length for fixed-point data type

0 (default) | integer scalar

Specify the fraction length of the fixed-point data type as a positive or negative integer scalar.

**Dependencies**

To enable this parameter, set **Mode** to Fixed point and **Scaling** to Binary point.

**Data type override** — Data type override mode

Inherit (default) | Off

Select the data type override mode for this signal. You can select:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify.

**Dependencies**

To enable this parameter, set **Mode** to Built in or Fixed point. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Discrete Transfer Function Estimator

Compute estimate of frequency-domain transfer function of system

### Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

### Description

The Discrete Transfer Function Estimator block estimates the frequency-domain transfer function of a system using the Welch's method of averaged modified periodograms.

The block buffers the input data into overlapping segments. You can set the length of the data segment and the amount of data overlap through the parameters set in the block dialog box. The sample rate of the block is equal to  $1/T$ .  $T$  is the sample time of the inputs to the block.

The block first applies a window function to the two inputs,  $x$  and  $y$ , and then scales them by the window power. It takes the FFT of each signal, calling them  $X$  and  $Y$ . The block calculates  $P_{xx}$  which is the square magnitude of the FFT,  $X$ . The block then calculates  $P_{yx}$  which is  $X$  multiplied by the conjugate of  $Y$ . The output transfer function estimate,  $H$ , is calculated by dividing  $P_{yx}$  by  $P_{xx}$ .

### Examples

#### Estimate Frequency-Domain Transfer Function of System

This example shows how to use the Discrete Transfer Function Estimator block to estimate the frequency-domain transfer function of a system.

Open the model. The Random Source block represents the system input signal. The sample rate of the system input is 44.1 KHz. The Random Source input passes through a low-pass filter with a normalized cutoff frequency of 0.3. The filtered signal represents the system output signal. Because the Discrete Transfer Function Estimator block outputs complex values, take the magnitude of the output to see a plot of the transfer function estimate.

Run the model. The transfer function plot displays the system transfer function, a low-pass filter that matches the frequency response of the Discrete FIR Filter block.

Copyright 2018-2023 The MathWorks, Inc.

## Ports

### Input

**x** — System input signal  
vector | matrix

Specify the system input signal as a vector or a matrix.

The inputs **x** and **y** must have the same size and data type.

Data Types: double | single

**y** — System output signal  
vector | matrix

Specify the system output signal as a vector or a matrix.

The inputs  $x$  and  $y$  must have the same size and data type.

Data Types: double | single

## Output

**Output** — Transfer function estimate  
vector | matrix

Transfer function estimate, returned as a vector or a matrix. For more details on how the block computes the transfer function estimate, see “Algorithms” on page 2-505.

Data Types: double | single

## Parameters

**Window length source** — Window length source

Same as input frame length (default) | Specify on dialog

Specify the source of the window length value. You can set this parameter to:

- Same as input frame length — Window length is set to the frame size of the input.
- Specify on dialog — Window length is the value you specify in **Window length**.

**Window length** — Window length

1024 (default) | positive integer  $\geq 2$

Specify the length of the window, in samples, used to compute the spectrum estimate as a positive integer greater than or equal to 2.

### Dependencies

To enable this parameter, set **Window length source** to Specify on dialog.

**Window overlap (%)** — Percentage of overlap between windows

0 (default) | nonnegative scalar

Specify the percentage of overlap between successive data windows as a nonnegative scalar in the range [0,100).

**Averaging method** — Averaging method

Running (default) | Exponential

Specify the averaging method as Running or Exponential. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor.

**Specify forgetting factor from input port** — Specify forgetting factor from input port

off (default) | on

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

**Dependencies**

To enable this parameter, set **Averaging method** to Exponential.

**Forgetting factor** — Forgetting factor0.9 (default) | positive scalar  $\leq 1$ 

Specify the exponential weighting forgetting factor as a positive scalar  $\leq 1$ .

**Dependencies**

To enable this parameter, set **Averaging method** to Exponential and clear the **Specify forgetting factor from input port** parameter.

**Number of spectral averages** — Number of spectral averages

1 (default) | positive integer

Specify the number of spectral averages as a positive integer. The Transfer Function Estimator block computes the current estimate by averaging the last  $N$  estimates.  $N$  is the number of spectral averages.

**Dependencies**

To enable this parameter, set **Averaging method** to Running.

**FFT length source** — Source of FFT length value

Auto (default) | Property

Specify the source of the FFT length value as Auto or Property.

When the source of the FFT length is set to Auto, the block sets the FFT length to the input frame size. When the source of the FFT length is set to Property, you specify the FFT length in the **FFT length** parameter.

**FFT length** — FFT length

128 (default) | positive integer

Specify the length of the FFT that the Discrete Transfer Function Estimator block uses to compute spectral estimates as a positive integer.

**Window function** — Window function

Hann (default) | Chebyshev | Flat Top | Hamming | Kaiser | Rectangular

Specify a window function for the Discrete Transfer Function Estimator block. Possible values are:

- Hann
- Chebyshev
- Flat Top
- Hamming
- Kaiser
- Rectangular

**Sidelobe attenuation of window (dB)** — Sidelobe attenuation of window

60 (default) | positive scalar

Specify the sidelobe attenuation of the window as a positive scalar in dB.

#### Dependencies

To enable this parameter, set **Window function** to Kaiser or Chebyshev.

**Frequency range** — Frequency range of the transfer function estimate

Centered (default) | One-sided | Two-sided

Specify the frequency range of the transfer function estimate.

- **Centered** -- The block computes the centered two-sided transfer function of the real or complex input signals,  $x$  and  $y$ .
- **onesided** -- The block computes the one-sided transfer function of real input signals,  $x$  and  $y$ .
- **twosided** -- The block computes the two-sided transfer function of the real or complex input signals,  $x$  and  $y$ .

**Output magnitude squared coherence estimate** — Magnitude squared coherence estimate

off (default) | on

Select this check box to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate indicates how well two inputs correspond to each other at each frequency.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |

## Algorithms

### Welch's Method of Averaged Modified Periodograms

Give two signal inputs,  $x$  and  $y$ :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Take FFT of the signals,  $X$  and  $Y$ .
- 3 Compute the current power spectral density estimates,  $P_{xx}$ ,  $P_{yy}$ , and the current cross power spectral density estimate,  $P_{yx}$ , by taking the moving average of last  $N$  number of  $Z_1$ ,  $Z_2$ , and  $Z_3$  vectors, respectively:
  - $Z_1 = X \cdot \text{conj}(X)$
  - $Z_2 = Y \cdot \text{conj}(Y)$
  - $Z_3 = Y \cdot \text{conj}(X)$

For details on the moving average methods, see "Averaging Method" on page 4-1141.

The transfer function estimate is calculated by dividing  $P_{yx}$  by  $P_{xx}$ .

The magnitude squared coherence,  $C_{xy}$ , is defined by the following equation:

$$C_{xy} = \frac{(\text{abs}(P_{xy}) \cdot ^2)}{(P_{xx} \cdot P_{yy})}$$

## Version History

## Downsample

Resample input at lower rate by deleting samples

### Libraries:

DSP System Toolbox / Signal Operations

DSP System Toolbox HDL Support / Signal Operations

## Description

The Downsample block decreases the sampling rate of the input by deleting samples. When the block performs frame-based processing, it resamples the data in each column of the  $P_i$ -by- $Q$  input matrix independently. When the block performs sample-based processing, it treats each element of the input as a separate channel and resamples each channel of the input array across time. The resample rate is  $M$  times lower than the input sample rate, where  $M$  is the value of the downsample factor. The Downsample block resamples the input by discarding  $M-1$  consecutive samples following each sample that is output.

This block supports triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

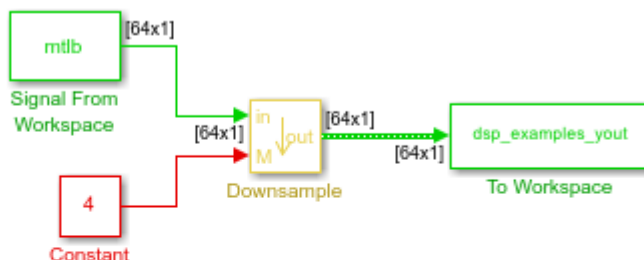

## Examples

### Downsample Signal in Single-Rate Frame-Based Processing Mode

In this example, the Downsample block decreases the sample rate by decreasing the frame size.

Open the model. The Downsample block resamples a single-channel input with a frame size of 64. In the dialog box of the Downsample block, the **Downsample factor source** parameter is set to Input port. This sets the **Input processing** and the **Rate options** parameters automatically to Columns as Channels (frame based) and Enforce single-rate processing, respectively. Specify a downsample factor of 4 from the input port.

Run the model. The block operates in the single-rate processing mode and downsamples the input by a factor of 4. The output of the block has a frame size of 64. As the block operates in the single-rate processing mode, the input and output signals of the Downsample block have the same frame rate. You can confirm this from the **Timing Legend**. To open the legend, click the **Debug** tab on the model toolstrip and click **Information Overlays > Timing Legend**.

Copyright 2008-2023 The MathWorks, Inc.

 Note: This model created workspace variables called "Fs", "mtlb", and "dsp\_examples\_yout".

### Downsample Signal In Multirate Frame-Based Processing Mode

In this example, the Downsample block decreases the sample rate by decreasing the frame rate.

Open the model. The input to the Downsample block is a single-channel signal with a frame period of one second. In the block dialog box, set the **Downsample factor, M** to 4 and **Rate options** to Allow multirate processing.

Run the model. The block operates in the multirate frame-based processing mode. With a downsample factor of 4, the output of the block has a frame period of 4 seconds. You can confirm this from the **Timing Legend**. To open the legend, click the **Debug** tab on the model toolstrip and click **Information Overlays > Timing Legend**. As the block operates in the multirate processing mode, the input and output signals of the Downsample block have the same frame size.

Copyright 2008-2023 The MathWorks, Inc.

 Note: This model creates workspace variables called "Fs", "mtlb", and "dsp\_examples\_yout".

### Downsample a Signal with One Frame Latency

Downsample a signal by a factor of 2 using the Downsample block.

## Open the System and Run the Model

Copyright 2008-2023 The MathWorks, Inc.

Note: This model creates a workspace variable called "dsp\_examples\_yout".

The Signal From Workspace block generates a two-channel signal with a frame size of 4. The timing legend shows the sample time of the signal before and after the downsampling operation. To see the legend, click the **Debug** tab > **Information Overlays** > **Timing Legend**.

Run the model. The sample time of the signal before the downsampling operation is half the sample time of the signal after the operation.

### One-Frame Latency

The **Input processing** parameter in the Downsample block is set to **Columns as channels** (frame based) and the input frame size (number of rows in the input)  $M_i$  is greater than 1. Hence, the latency of the signal is one frame. The **Initial conditions** parameter is set to  $[11 \ -11; 12 \ -12; 13 \ -13; 14 \ -14]$ . In all cases of one-frame latency, the  $M_i$  rows of the initial condition matrix appear in sequence as the first four output rows. Input sample  $D+1$  (that is, row  $D+1$  of the input matrix) appears in the output as sample  $M_i+1$ , followed by input sample  $D+1+K$ , input sample  $D+1+2K$ , and so on.

- $M_i$  - Number of input rows. In this example,  $M_i$  equals 4.
- $D$  - Sample offset parameter. In this example,  $D$  equals 1.
- $K$  - Downsample factor. In this example,  $K$  equals 2.

The Initial conditions value can be an  $M_i$ -by- $N$  matrix containing one value for each channel, or a scalar to be repeated across all elements of the  $M_i$ -by- $N$  matrix.

Here is the downsampled output signal written to the dsp\_examples\_yout variable in the base workspace.

## Ports

### Input

**in** — Data input

column vector | matrix |  $N$ -D array

Input data for which you want to decrease the sample rate, specified as a column vector or a matrix.

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the input can be an  $N$ -D array.

The block supports variable-size input signals when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, so the frame length (number of rows) and the number of channels (columns) can change during simulation. When the block accepts variable-size input signals, they can be of arbitrary frame length, that is, the input frame length does not have to be a multiple of the downsampling factor. When you specify fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-514 and “Sample-Based Processing” on page 2-517.

This port is unnamed until you set **Downsample factor source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**M** — Downsample factor

positive integer

Specify the downsample factor  $M$  as a positive integer.

### Dependency

To enable this port, set the **Downsample factor source** parameter to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### Output

**Port\_1** — Downsampled output

column vector | matrix

Downsampled output with a sampling rate that is  $1/M$  times the input sampling rate, returned as a column vector or a matrix.

When you set **Rate options** to:

- `Enforce single-rate processing` -- The block maintains the input sample rate and downsamples the signal by decreasing the output frame size by a factor of  $M$ .

The output has an upper bound size of  $\text{ceil}(P/M)$ -by- $Q$  for an input of size  $P$ -by- $Q$ .

- `Allow multirate processing` -- The block downsamples the signal such that the output sample rate is  $M$  times slower than the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-514 and “Sample-Based Processing” on page 2-517.

The output is a variable-size signal when any of these conditions are met:

- The input is a variable-size signal.
- The input is a fixed-size signal and the **Allow arbitrary frame length for fixed-size input signals** parameter is selected.
- Downsample factor is input through the port **M**

When the output is a variable-size signal, the block maintains the phase across consecutive frames of data. For more details, see “Phase Continuity” on page 2-516.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

## Parameters

**Downsample factor source** — Source of downsample factor

Dialog parameter (default) | Input port

Specify the downsample factor through one of these options:

- `Dialog parameter` -- The block enables the **Downsample factor, M** parameter in the block dialog box.
- `Input port` -- The block enables the input port **M** through which you specify the downsample factor.

**Downsample factor, M** — Downsampling factor

2 (default) | positive integer

Specify the integer factor  $M$  by which to decrease the input sample rate.

### Dependency

To enable this parameter, set **Downsample factor source** to `Dialog parameter`.

**Sample offset (0 to M–1)** — Sample offset

0 (default) | integer

The **Sample offset (0 to M–1)** parameter delays the output samples by an integer number of sample periods,  $D$ , where  $0 \leq D \leq (M-1)$ , so that you can select any of the  $M$  possible output phases. For example, when you downsample the sequence 1, 2, 3, ... by a factor of 4, you can select from four phases.

| Input Sequence | Sample Offset, $D$ | Output Sequence ( $M = 4$ )      |
|----------------|--------------------|----------------------------------|
| 1, 2, 3, ...   | 0                  | 1, 5, 9, 13, 17, 21, 25, 29, ... |

| Input Sequence | Sample Offset, $D$ | Output Sequence ( $M = 4$ )      |
|----------------|--------------------|----------------------------------|
| 1, 2, 3, ...   | 1                  | 0, 2, 6, 10, 14, 18, 22, 26, ... |
| 1, 2, 3, ...   | 2                  | 0, 3, 7, 11, 15, 19, 23, 27, ... |
| 1, 2, 3, ...   | 3                  | 0, 4, 8, 12, 16, 20, 24, 28, ... |

The initial zero in the last three output sequences in the table is a result of the **Initial conditions** parameter being set to its default value of 0. See “Latency” on page 2-517 for more information on the **Initial conditions** parameter.

When you input the downsample factor through the input port **M**, the **Sample offset (0 to M-1)** parameter is not enabled in the block dialog box. In this case, the sample offset  $D$  is automatically set to 0.

### Dependency

To enable this parameter, set **Downsample factor source** to Dialog parameter.

### Input processing — Method to process input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify the method for input processing:

- **Columns as channels (frame based)** -- When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block treats each of the  $Q$  input columns as an individual channel containing  $P_i$  sequential time samples. The block downsamples each channel independently by discarding  $M-1$  rows of the input matrix following each row that it outputs.  
  
For more information, see “What Is Frame-Based Processing?”.
- **Elements as channels (sample based)** -- When you set the **Input processing** parameter to **Elements as channels (sample based)**, the input can be a  $Q$ -D array. The Downsample block treats each element of the input as a separate channel, and resamples each channel of the input over time. The block downsamples the input array by discarding  $M-1$  samples following each sample that it passes through to the output. The input and output sizes of the Downsample block are identical.

For more information, see “What Is Sample-Based Processing?”.

### Dependency

To enable this parameter, set **Downsample factor source** to Dialog parameter.

When you set **Downsample factor source** to Input port, the **Input processing** parameter is automatically set to **Columns as channels (frame based)**.

### Rate options — Enforce single-rate or allow multirate processing

Enforce single-rate processing (default) | Allow multirate processing

Specify the method by which the block adjusts the rate at the output port to accommodate the reduced number of samples. The block performs single-rate or multirate processing depending on whether you set the **Input processing** parameter to **Elements as channels (sample based)** (sample-based processing mode) or **Columns as channels (frame based)** (frame-based processing mode).

- Elements as channels (sample based)

- Enforce single-rate processing

The block forces the output sample rate to match the input sample rate ( $T_{so} = T_{si}$ ) by repeating every  $M^{\text{th}}$  input sample  $M$  times at the output. In this mode, the block behaves like the Sample and Hold block with a repeating trigger event of period  $MT_{si}$ .

- Allow multirate processing

The sample period of the output is  $M$  times longer than the input sample period ( $T_{so} = MT_{si}$ ).

For more details, see “Sample-Based Processing” on page 2-517

- Columns as channels (frame based)

- Enforce single rate processing

The block generates the output at the slower (downsampled) rate using a proportionally smaller frame size than the input. The output has an upper bound size of  $\text{ceil}(P/M)$ , where  $P$  is the input frame length and  $M$  is the downsample factor. The input and output frame rates are equal. For more details, see “Frame-Based Processing” on page 2-514. For an example, see “Downsample Signal in Single-Rate Frame-Based Processing Mode” on page 2-506.

- Allow multirate processing

The block generates the output at the slower (downsampled) rate by using a proportionally longer frame period at the output port than at the input port. For downsampling by a factor of  $M$ , the output frame period is  $M$  times longer than the input frame period ( $T_{fo} = MT_{fi}$ ), but the input and output frame sizes are equal. For more details, see “Frame-Based Processing” on page 2-514. For an example, see “Downsample Signal In Multirate Frame-Based Processing Mode” on page 2-507.

### Dependency

To enable this parameter, set **Downsample factor source** to Dialog parameter.

When you set **Downsample factor source** to Input port, the **Rate options** parameter is automatically set to Enforce single-rate processing.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

on (default) | off

Specify whether fixed-size input signals (size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the downsampling factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable size.

When the input signal is a variable-size signal, the signal can have an arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the downsampling factor. If the input is not a

multiple of the downsampling factor, then the output is generally a variable-size signal. Therefore, to support an arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.

- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the downsampling factor.

### Dependency

To enable this parameter, set:

- **Downsample factor source** to Dialog parameter.
- **Input processing** to Columns as channels (frame based).
- **Rate options** to Enforce single-rate processing.

### Initial conditions — Initial value

0 (default) | real scalar | array

The initial block value for cases of nonzero latency. You can specify a scalar or an array of the same size as the input.

### Dependencies

This parameter does not appear when **Input processing** is set to Columns as channels (frame based) and **Rate options** is set to Enforce single-rate processing.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | Boolean   double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no  |
| <b>Multidimensional Signals</b> | no  |
| <b>Variable-Size Signals</b>    | yes   |
| <b>Zero-Crossing Detection</b>  | no  |

## More About

### Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based) and use an input signal of size  $P$ -by- $Q$ , the block treats each of the  $Q$  input columns as an individual channel containing  $P$  sequential time samples. The block downsamples each channel independently by discarding  $M-1$  rows of the input matrix following each row that it outputs.

In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block adjusts the rate at the output to accommodate the reduced number of samples.

- When you set the **Rate options** parameter to Enforce single-rate processing, the block generates the output at the slower (downsampled) rate using a proportionally smaller frame size than the input.

The output has an upper bound size of  $\text{ceil}(P/M)$ , where  $P$  is the input frame length and  $M$  is the downsample factor.

In this mode, if you input a fixed-size signal (signal dimensions do not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the downsampling factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the downsampling factor.

In this mode, if you input a variable-size signal (signal dimensions change during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame size requirements. You can input a variable-size signal of any frame size even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length   | Input Size   | Output Size                                     |
|----------------------------|-------------------------------|--|--------------|---|
| Fixed-size input signal    | Yes                           | When you select <b>Allow arbitrary frame length for fixed-size input signals</b> | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(P/M)$ -by- $Q$ |
| Variable-size input signal | Yes                           | Always   | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(P/M)$ -by- $Q$ |

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the Downsample block are of the same size, but the sample rate of the output is  $M$  times slower than that of the input. In this mode, the block treats a  $P$ -by- $Q$  matrix input as  $Q$  independent channels.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Allow multirate processing.

| Input Signal            | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size   | Output Size  |
|-------------------------|-------------------------------|--|--------------|--------------|
| Fixed-size input signal | Yes                           | Always                                   | $P$ -by- $Q$ | $P$ -by- $Q$ |

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

**Phase Continuity**

When you set the **Input processing** parameter to Columns as channels (frame based) and **Rate options** parameter to Enforce single-rate processing, under certain conditions, the Downsample block maintains the phase across consecutive frames of data.

**Phase is maintained**

| Input Conditions                         | Downsample Factor Source  | Support for Arbitrary Input Frame Length   | Output Signal        | Phase Continuity |
|--|---|--|----------------------|------------------|
| Fixed-size input signal                  | Specify in block dialog box   | When you select <b>Allow arbitrary frame length for fixed-size input signals</b> | Variable-size signal | Yes              |
| Variable-size input signal               | Specify in block dialog box   | Always   | Variable-size signal | Yes              |
| Fixed-size or variable-size input signal | Specify through input port<br>Downsample factor does not change during simulation | --   | Variable-size signal | Yes              |

Under certain conditions, the phase resets to 0 and is not maintained across consecutive frames of data.

| Input Conditions                         | Downsample Factor Source  | Support for Arbitrary Input Frame Length  | Output Signal        | Phase Continuity  |
|--|---|---|----------------------|-------------------|
| Fixed-size input signal                  | Specify in block dialog box   | When you clear <b>Allow arbitrary frame length for fixed-size input signals</b> | Fixed-size signal    | Phase is always 0 |
| Fixed-size or variable-size input signal | Specify through input port<br><br>At the event when downsample factor changes during simulation | --  | Variable-size signal | Phase resets to 0 |

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats a  $P$ -by- $Q$  matrix input as  $P*Q$  independent channels, and resamples each channel over time. The output sample period ( $T_{so}$ ) is  $M$  times longer than the input sample period ( $T_{so} = M*T_{si}$ ), and the input and output sizes are identical.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to `Elements as channels (sample based)`.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Fixed-size input signal    | Yes                           | Always                                   | $P$ -by- $Q$   | $P$ -by- $Q$   |
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

### Latency

Latency is the delay, measured in samples or frames, between the input and the output of the block.

The Downsample block has *zero-tasking latency* in the following cases:

- The downsample factor  $M$  is 1.
- The **Input processing** parameter is set to `Columns as channels (frame based)`, and the **Rate options** parameter is set to `Enforce single-rate processing`.
- The **Input processing** parameter is set to `Columns as channels (frame based)`, the **Rate options** parameter is set to `Allow multirate processing`, the **Sample offset (0 to M-1)** parameter  $D$  is set to 0, and the input frame size is equal to 1.
- The **Input processing** parameter is set to `Elements as channels (sample based)`, and the **Sample offset (0 to M-1)** parameter  $D$  is 0.

Zero-tasking latency means that the block propagates input sample  $D+1$  (received at  $t = 0$ ) as the first output sample, followed by input sample  $D+1+M$ , input sample  $D+1+2M$ , and so on. When there is zero-tasking latency, the block ignores the value of the **Initial conditions** parameter.

In all other cases, the latency is nonzero:

- When the **Input processing** parameter is set to `Elements as channels (sample based)`, the latency is one sample.
- When the **Input processing** parameter is set to `Columns as channels (frame based)` and the input frame size is greater than one, the latency is one frame.

In all cases of *one-sample latency*, the initial condition for each channel appears as the first output sample. Input sample  $D+1$  appears as the second output sample for each channel, followed by input sample  $D+1+M$ , input sample  $D+1+2M$ , and so on. The **Initial conditions** parameter can be an array of the same size as the input or a scalar to be applied to all signal channels.

In all cases of *one-frame latency*, the  $P_i$  rows of the initial condition matrix appear in sequence as the first  $P_i$  output rows. Input sample  $D+1$  (row  $D+1$  of the input matrix) appears in the output as sample  $P_i+1$ , followed by input sample  $D+1+M$ , input sample  $D+1+2M$ , and so on. The **Initial conditions** value can be an  $P_i$ -by- $Q$  matrix containing one value for each channel or a scalar to be repeated across all elements of the  $P_i$ -by- $Q$  matrix.

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Version History

Introduced before R2006a

### R2022b: Support for arbitrary input frame length and variable input frame sizes

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (signal dimensions do not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled)
- Input signal is a variable-size signal (signal dimensions change during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the downsampling factor.

For more details, see “Frame-Based Processing” on page 2-514 and “Sample-Based Processing” on page 2-517.

### **R2023a: Tune downsample factor through input port**

You can now specify the downsample factor through an input port when the Downsample block operates in the single-rate frame-based processing mode. When you specify the downsample factor through the input port, you can change the factor during simulation.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### **Best Practices**

It is good practice to follow the Downsample block with a unit delay. Doing so prevents the code generator from inserting an extra bypass register in the HDL code.

See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).

### **HDL Architecture**

This block has one default HDL architecture.

### **HDL Block Properties**

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

**Complex Data Support**

This block supports code generation for complex signals.

**Restrictions**

- **Input processing** set to Columns as channels (frame based) is not supported.
- For **Input processing** set to Elements as channels (sample based), select Allow multirate processing. With this setting, if **Sample offset** is set to 0, **Initial conditions** has no effect on generated code.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

**See Also****Blocks**

FIR Decimation | FIR Rate Conversion | Repeat | Sample and Hold | Upsample

“Convert Sample and Frame Rates in Simulink Using Rate Conversion Blocks”

“Noise Cancellation in Simulink Using Normalized LMS Adaptive Filter”

## DSP Constant (Obsolete)

Generate discrete- or continuous-time constant signal

### Library

Sources

dspobslib

### Description

---

**Note** The DSP Constant block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Constant block.

---

The DSP Constant block generates a signal whose value remains constant throughout the simulation. The **Constant value** parameter specifies the constant to output, and can be any valid MATLAB expression that evaluates to a scalar, vector, or matrix.

When **Sample mode** is set to **Continuous**, the output is a continuous-time signal. When **Sample mode** is set to **Discrete**, the **Sample time** parameter is visible, and the signal has the discrete output period specified by the **Sample time** parameter.

You can set the output signal to **Frame-based**, **Sample-based**, or **Sample-based** (interpret vectors as 1-D) with the **Output** parameter.

### Dialog Box

The **Main** pane of the DSP Constant block dialog box appears as follows.

### Constant value

Specify the constant to generate. This parameter is Tunable (Simulink); values entered here can be tuned, but their dimensions must remain fixed.

When you specify any data type information in this field, it is overridden by the value of the **Output data type** parameter in the **Data Types** pane, unless you select **Inherit** from 'Constant value'.

### Sample mode

Specify the sample mode of the output, **Discrete** for a discrete-time signal or **Continuous** for a continuous-time signal.

### Output

Specify whether the output is **Sample-based** (interpret vectors as 1-D), **Sample-based**, or **Frame-based**. When you select **Sample-based** and the output is a vector, its dimension is constrained to match the **Constant value** dimension (row or column). When you select **Sample-based** (interpret vectors as 1-D), however, the output has no specified dimensionality.

### Sample time

Specify the discrete sample period for sample-based outputs. When you select **Frame-based** for the **Output** parameter, this parameter is named **Frame period**, and is the discrete frame period for the frame-based output. This parameter is only visible when you select **Discrete** for the **Sample mode** parameter.

The **Data Types** pane of the DSP Constant block dialog box appears as follows.

### Output data type

Specify the output data type in one of the following ways:

- Choose one of the built-in data types from the list.
- Choose **Fixed-point** to specify the output data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **User-defined** to specify the output data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose **Inherit from 'Constant value'** to set the output data type and scaling to match the values of the **Constant value** parameter in the **Main** pane.
- Choose **Inherit via back propagation** to set the output data type and scaling to match the following block.

The value of this parameter overrides any data type information specified in the **Constant value** parameter in the **Main** pane, except when you select **Inherit from 'Constant value'**.

### Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

### Word length

Specify the word length, in bits, of the fixed-point output data type. This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter.

### User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the following `fixdt` function. This parameter is only visible when you select **User-defined** for the **Output data type** parameter.

### Set fraction length in output to

Specify the scaling of the fixed-point output by either of the following two methods:

- Choose **Best precision** to have the output scaling automatically set such that the output signal has the best possible precision.

- Choose **User-defined** to specify the output scaling in the **Fraction length** parameter.

This parameter is only visible when you select **Fixed-point** for the **Output data type** parameter, or when you select **User-defined** and the specified output data type is a fixed-point data type.

### **Fraction length**

For fixed-point output data types, specify the number of fractional bits, or bits to the right of the binary point. This parameter is only visible when you select **Fixed-point** or **User-defined** for the **Output data type** parameter and **User-defined** for the **Set fraction length in output to** parameter.

## **Supported Data Types**

- Double-precision floating point
- Single-precision floating point
- Fixed point
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## DWT

Compute discrete wavelet transform (DWT) of input or decompose signals into subbands with smaller bandwidths and slower sample rates

**Libraries:**  
DSP System Toolbox / Transforms

### Description

You can configure this block to compute the Discrete Wavelet Transform (DWT) of the input signal or decompose the signal into subbands with smaller bandwidths and slower sample rates. The block uses a series of highpass and lowpass FIR filters to repeatedly divide the input frequency range, as illustrated in “Multilevel Filter Banks” (the Asymmetric one).

You can specify the filter bank highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask. If you have a Wavelet Toolbox™ license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

For the same input, the DWT configuration of this block does not produce the same results as the Wavelet Toolbox `dwt` function. Because DSP System Toolbox is designed for real-time implementation and Wavelet Toolbox is designed for analysis, the products handle boundary conditions and filter states differently. To make the output of the `dwt` function match the DWT output of this block, complete the following steps:

- 1 Set the boundary condition of the `dwt` function to zero-padding. To do so, type `dwtmode('zpd')` at the MATLAB command line.
- 2 To match the latency of the block (implemented using FIR filters), add zeros to the input of the `dwt` function. The number of zeros you add must be equal to the half-length of the filter.

---

**Note** The DWT block is same as the Dyadic Analysis Filter Bank block with different default settings. For more information on block ports and parameters, see the Dyadic Analysis Filter Bank block reference page.

---

### Block Characteristics

# Dyadic Analysis Filter Bank

Decompose signals into subbands with smaller bandwidths and slower sample rates or compute discrete wavelet transform (DWT)

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

You can configure this block to decompose a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The block uses a series of highpass and lowpass FIR filters to repeatedly divide the input frequency range, as illustrated in “Multilevel Filter Banks” (the Asymmetric one).

You can specify the filter bank highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block mask. If you have a Wavelet Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

For the same input, the DWT configuration of this block does not produce the same results as the Wavelet Toolbox `dwt` function. Because DSP System Toolbox is designed for real-time implementation and Wavelet Toolbox is designed for analysis, the products handle boundary conditions and filter states differently. To make the output of the `dwt` function match the DWT output of this block, complete the following steps:

- 1 Set the boundary condition of the `dwt` function to zero-padding. To do so, type `dwtmode('zpd')` at the MATLAB command line.
- 2 To match the latency of the block (implemented using FIR filters), add zeros to the input of the `dwt` function. The number of zeros you add must be equal to the half-length of the filter.

The Dyadic Analysis Filter Bank block is same as the DWT block, but with different default settings.

## Ports

### Input

**Input 1** — Data input  
column vector | matrix

Specify the data input as a column vector or a matrix.

The block always interprets the input signal as frames and operates along the columns. It treats each column of the input as an independent channel, and the number of rows of each channel must be a multiple of  $2^n$ , where  $n$  is the number of filter bank levels that you specify in the **Number of levels** parameter. For example, a frame size of 16 is appropriate for a three-level tree (16 is a multiple of  $2^3$ ).

For more information on why the input data must meet these requirements, see the figure in “Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank” on page 2-529.

The block decomposes the input signal into either  $n + 1$  or  $2^n$  subbands. To decompose signals with a frame size that is not a multiple of  $2^n$ , use the Two-Channel Analysis Subband Filter block. You can connect multiple copies of the Two-Channel Analysis Subband Filter block to create a multilevel dyadic analysis filter bank.

Data Types: `single` | `double`

## Output

**Output 1** — Dyadic subband decomposition output  
column vector | matrix

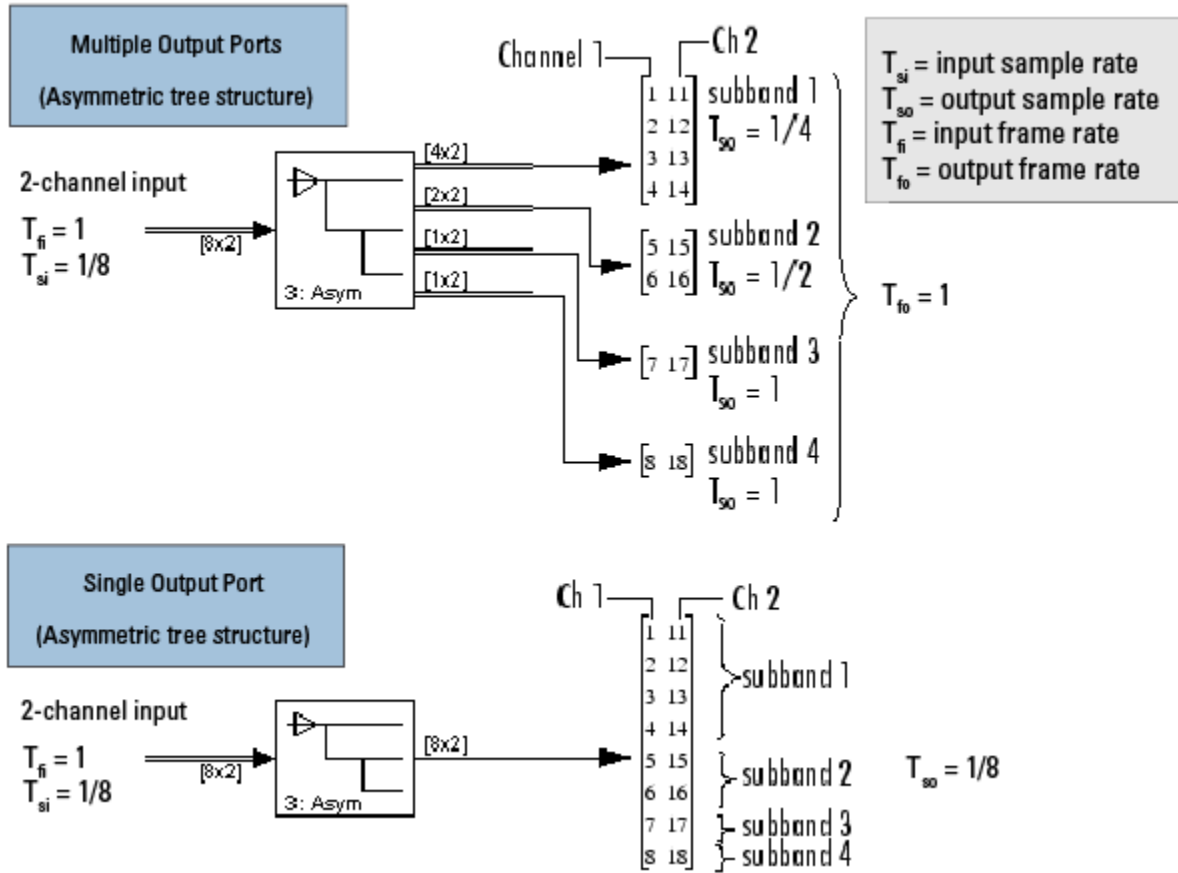

The block outputs the dyadic subband decomposition output as a column vector or a matrix. The decomposition output contains elements with the highest-frequency subband first followed by subbands in decreasing frequency.

The output characteristics vary depending on the block parameter settings, as summarized in the following list and figure:

- **Number of levels** parameter set to  $n$
- **Tree structure** parameter setting:
  - **Asymmetric** — Block produces  $n+1$  output subbands
  - **Symmetric** — Block produces  $2^n$  output subbands
- **Output** parameter setting can be **Multiple ports** or **Single port**. When you set the **Output** parameter to **Single port**, the block outputs one vector or matrix of concatenated subbands. The following figure illustrates the difference between the two settings for a 3-level asymmetric dyadic analysis filter bank. For an explanation of the illustrated output characteristics, see the table Output Characteristics for an n-Level Dyadic Analysis Filter Bank.

For more information about the filter bank levels and structures, see “Dyadic Analysis Filter Banks”.

**Outputs of a 3-Level Asymmetric Dyadic Analysis Filter Bank**

The following table summarizes the different output characteristics of the block when you set it to output from single or multiple ports.

## Output Characteristics for an n-Level Dyadic Analysis Filter Bank

|                                       | Single Output Port   | Multiple Output Ports   |
|---------------------------------------|--|---|
| <b>Output Description</b>             | Block concatenates all the subbands into one vector or matrix, and outputs the concatenated subbands from a single output port. Each output column contains subbands of the corresponding input channel. | Block outputs each subband from a separate output port. The topmost port outputs the subband with the highest frequencies. Each output column contains a subband for the corresponding input channel.   |
| <b>Output Frame Rate</b>              | <i>Not applicable</i>  | Same as input frame rate (However, the output frame sizes can vary, so the output sample rates can vary.)   |
| <b>Output Dimensions (Frame Size)</b> | Same number of rows and columns as the input.  | <p>The output has the same number of columns as the input. The number of output rows is the output frame size. For an input with frame size <math>M_i</math> output <math>y_k</math> has frame size <math>M_{o,k}</math>:</p> <ul style="list-style-type: none"> <li>• <b>Symmetric</b> — All outputs have the frame size <math>M_i / 2^n</math>.</li> <li>• <b>Asymmetric</b> — The frame size of each output (except the last) is half that of the output from the previous level. The outputs from the last two output ports have the same frame size since they originate from the same level in the filter bank.</li> </ul> $M_{o,k} = \begin{cases} M_i/2^k & (1 \leq k \leq n) \\ M_i/2^n & (k = n + 1) \end{cases}$ |
| <b>Output Sample Rate</b>             | Same as input sample rate.   | <p>Though the outputs have the same frame rate as the input, they have different frame sizes than the input. Thus, the output sample rates <math>F_{so,k}</math> are different from the input sample rate <math>F_{si}</math>:</p> <ul style="list-style-type: none"> <li>• <b>Symmetric</b> — All outputs have the sample rate <math>F_{si} / 2^n</math>.</li> <li>• <b>Asymmetric</b> —</li> </ul> $F_{so,k} = \begin{cases} F_{si}/2^k & (1 \leq k \leq n) \\ F_{si}/2^n & (k = n + 1) \end{cases}$  |

Data Types: single | double

## Parameters

The parameters displayed in the block dialog box vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

**Filter** — Type of filter used in subband decomposition

User-defined (default) | Haar | Daubechies | Symlets | Coiflets | Biorthogonal | Reverse Biorthogonal | Discrete Meyer

Specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of these options:

- **User defined** — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops.
- **Wavelet** such as **Biorthogonal** or **Daubechies** — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox `wfilters` function. Depending on the wavelet, the block enable either the **Wavelet order** or the **Filter order [synthesis / analysis]** parameter. The **Filter order [synthesis / analysis]** parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages. You must have a Wavelet Toolbox license to use wavelets.

See this table for a list of the supported wavelets.

### Specifying Filters with the Filter Parameter and Related Parameters

| Filter                      | Sample Setting for Related Filter Specification Parameters  | Corresponding Wavelet Function Syntax |
|-----------------------------|---|---------------------------------------|
| <b>User-defined</b>         | Filters based on Daubechies wavelets with wavelet order 3: <ul style="list-style-type: none"> <li>• <b>Lowpass FIR filter coefficients</b> =<br/>[0.0352 -0.0854 -0.1350 0.4599<br/>0.8069 0.3327]</li> <li>• <b>Highpass FIR filter coefficients</b> =<br/>[-0.3327 0.8069 -0.4599<br/>-0.1350 0.0854 0.0352]</li> </ul> | None                                  |
| <b>Haar</b>                 | None  | <code>wfilters('haar')</code>         |
| <b>Daubechies</b>           | <b>Wavelet order</b> = 4  | <code>wfilters('db4')</code>          |
| <b>Symlets</b>              | <b>Wavelet order</b> = 3  | <code>wfilters('sym3')</code>         |
| <b>Coiflets</b>             | <b>Wavelet order</b> = 1  | <code>wfilters('coif1')</code>        |
| <b>Biorthogonal</b>         | <b>Filter order [synthesis / analysis]</b> =<br>[3/1]   | <code>wfilters('bior3.1')</code>      |
| <b>Reverse Biorthogonal</b> | <b>Filter order [synthesis / analysis]</b> =<br>[3/1]   | <code>wfilters('rbio3.1')</code>      |
| <b>Discrete Meyer</b>       | None  | <code>wfilters('dmey')</code>         |

**Filter order [synthesis / analysis]** — Analysis and synthesis filter orders for biorthogonal filters

[1 / 1] (default) | [1 / 3] | [1 / 5] | [2 / 2] | [2 / 4] | [2 / 6] | [2 / 8] | [3 / 1] |  
[3 / 3] | [3 / 5] | [3 / 7] | [3 / 9] | [4 / 4] | [5 / 5] | [6 / 8]

Set the order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to `Biorthogonal` and set the **Filter order [synthesis / analysis]** parameter to `[2 / 6]`, the block calls the `wfilters` function with input argument `'bior2.6'`.

#### Dependencies

To enable this parameter, set the **Filter** parameter to `Biorthogonal` or `Reverse Biorthogonal`.

**Wavelet order** — Order for orthogonal wavelets

2 (default) | positive integer

Set the order of the wavelet selected in the **Filter** parameter.

#### Dependencies

To enable this parameter, set the **Filter** parameter to `Daubechies`, `Symlets`, or `Coiflets`.

**Lowpass FIR filter coefficients** — Lowpass FIR filter coefficients

`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` (default) | row vector

Specifies coefficients used by all the lowpass filters in the filter bank using a vector of filter coefficients (descending powers of  $z$ ). The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order 3.

#### Dependencies

To enable this parameter, set the **Filter** parameter to `User-defined`.

**Highpass FIR filter coefficients** — Highpass FIR filter coefficients

`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specifies coefficients used by all the highpass filters in the filter bank using a vector of filter coefficients (descending powers of  $z$ ). This parameter is enabled when you set **Filter** to `User defined`. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a Daubechies wavelet with wavelet order 3.

#### Dependencies

To enable this parameter, set the **Filter** parameter to `User-defined`.

**Number of levels** — Number of filter bank levels used in analysis (decomposition)

2 (default) | integer greater than or equal to 1

Select the number of filter bank levels. An  $n$ -level asymmetric structure has  $n+1$  outputs, and an  $n$ -level symmetric structure has  $2^n$  outputs, as shown in “Multilevel Filter Banks”. The block icon changes depending on the value of this parameter.

**Tree structure** — Structure of filter bank

Asymmetric (default) | Symmetric

Select the structure of the filter bank: *Asymmetric*, or *Symmetric*. See “Multilevel Filter Banks” for more information.

The default setting of this parameter is *Asymmetric* for the Dyadic Analysis Filter Bank block, and *Symmetric* for the DWT block.

**Output** — Single port or multiple ports

Multiple ports (default) | Single port

Set to *Multiple ports* to output each output subband on a separate port. The topmost port outputs the subband with the highest frequency band. Set to *Single port* to concatenate the subbands into one vector or matrix and output the concatenated subbands on a single port. For more information, see the Output on page 2-0 port description.

The default setting of this parameter is *Multiple ports* for the Dyadic Analysis Filter Bank block and *Single port* for the DWT block.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## More About

### Wavelets

The primary application for dyadic analysis filter banks and dyadic synthesis filter banks is coding for data compression using wavelets.

At the transmitting end, the output of the dyadic analysis filter bank is fed to a lossy compression scheme, which typically assigns the number of bits for each filter bank output in proportion to the relative energy in that frequency band. This represents the more powerful signal components by a greater number of bits than the less powerful signal components.

At the receiving end, the transmission is decoded and fed to a dyadic synthesis filter bank to reconstruct the original signal. The filter coefficients of the complementary analysis and synthesis stages are designed to cancel aliasing introduced by the filtering and resampling.

See “Calculate Channel Latencies Required for Wavelet Reconstruction” for an example using the Dyadic Analysis and Dyadic Synthesis Filter Bank blocks.

Reconstruct signals from subbands with smaller bandwidths and slower sample rates or compute inverse discrete wavelet transform (IDWT)

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

You can configure this block to compute the inverse discrete wavelet transform (IDWT) or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. When the block computes the inverse discrete wavelet transform (IDWT) of the input, the output has the same dimensions as the input. Each column of the output is the IDWT of the corresponding input column. When reconstructing a signal, the block uses a series of highpass and lowpass FIR filters to reconstruct the signal from the input subbands, as illustrated in “Multilevel Filter Banks” (the Asymmetric one). The reconstructed signal has a wider bandwidth and faster sample rate than the input subbands.

You can specify the filter bank highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block dialog box. If you have a Wavelet Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

---

**Note** To use a dyadic synthesis filter bank to perfectly reconstruct the output of a dyadic analysis filter bank, the number of levels and tree structures of both filter banks must be the same. In addition, the filters in the synthesis filter bank must be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. For an example that shows perfect reconstruction, see “Wavelet Reconstruction and Noise Reduction”.

---

This block automatically computes wavelet-based perfect reconstruction filters when the wavelet selection in the **Filter** parameter of this block is the same as the **Filter** parameter setting of the corresponding Dyadic Analysis Filter Bank block. The use of wavelets requires a Wavelet Toolbox license. To learn how to design your own perfect reconstruction filters, see “References” on page 2-542.

---

## Ports

### Input

**Input 1** — Data input  
column vector | matrix

Specify the data input as a column vector or a matrix.

The input characteristics vary depending on the block parameter settings as summarized here:

- **Number of levels** parameter set to  $n$
- **Tree structure** parameter setting:
  - **Asymmetric** — Block accepts  $n+1$  input subbands
  - **Symmetric** — Block accepts  $2^n$  input subbands
  - **Input** parameter setting can be **Multiple ports** or **Single port**.

The inputs to this block are usually the outputs of a Dyadic Analysis Filter Bank block. Since the Dyadic Analysis Filter Bank block can output from either a single port or multiple ports, the Dyadic Synthesis Filter Bank block accepts inputs to either a single port or to multiple ports.

When you set the **Input** parameter to **Multiple ports**, you must provide each subband to the block through a different input port as a vector or matrix. You should input the highest frequency band through the topmost port. When you set the **Input** parameter to **Single port**, the block input must be a vector or matrix of concatenated subbands.

---

**Note** Any output of a Dyadic Analysis Filter Bank block whose parameter settings match the corresponding settings of this block is a valid input to this block. For example, the setting of the Dyadic Analysis Filter Bank block parameter **Output** must be the same as the **Input** parameter (**Single port** or **Multiple ports**) in this block.

---

#### **Valid Inputs for Input Set to Single Port**

- Input must be a vector or matrix of concatenated subbands.
- Each input column contains the subbands for an independent signal.
- Upper input rows contain the high-frequency subbands, and the lower rows contain the low-frequency subbands.

#### **Valid Inputs for Input Set to Multiple Ports**

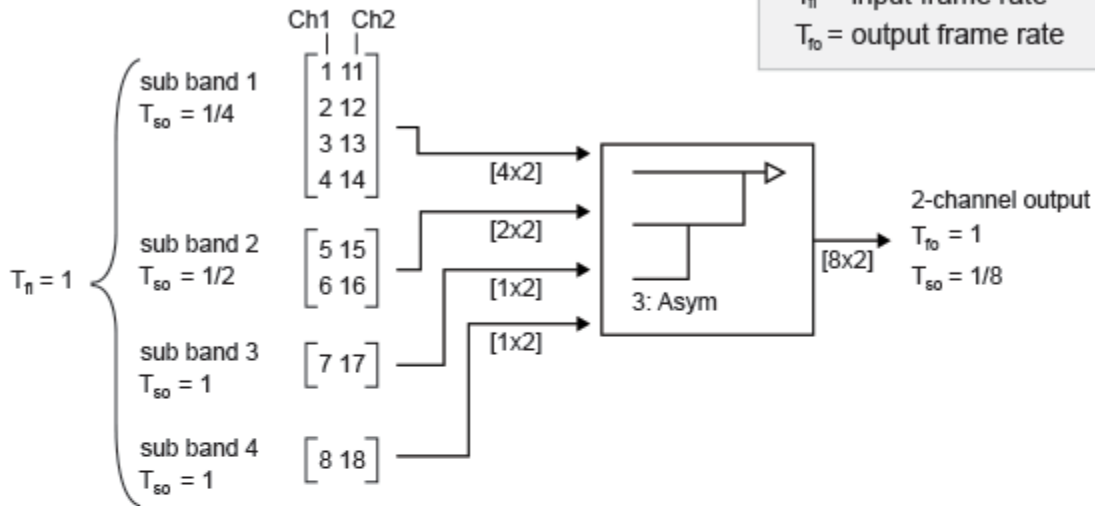

- Each subband must be provided as a vector or a matrix to separate block input ports.
- The columns of each input contains a subband for an independent signal.
- The input to the topmost input port is the subband containing the highest frequencies, and the input to the bottommost port is the subband containing the lowest frequencies.

This figure illustrates the difference between the two settings for a 3-level asymmetric dyadic synthesis filter bank.

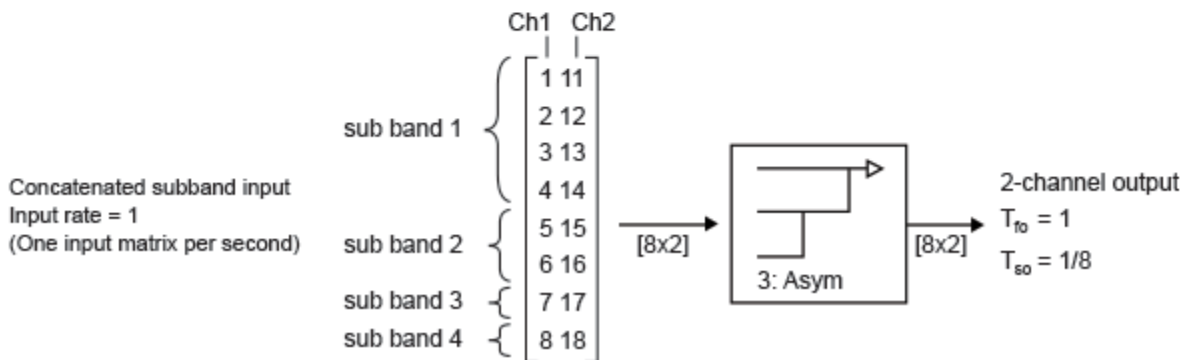

**Multiple Input Ports**  
(Asymmetric tree structure)

$T_{si}$  = input sample rate  
 $T_{so}$  = output sample rate  
 $T_{fi}$  = input frame rate  
 $T_{fo}$  = output frame rate

**Single Input Ports**  
(Asymmetric tree structure)

**Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank**

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

**Note** This block always performs frame-based processing, and its inputs must be of certain sizes. To use input subbands that do not fit the criteria of this block, use the Two-Channel Synthesis Subband Filter block. You can connect multiple copies of the Two-Channel Synthesis Subband Filter block to create a multilevel dyadic synthesis filter bank.

Data Types: single | double

## Output

### Output 1 — Reconstructed signal

column vector | matrix

The block outputs the reconstructed signal as a column vector or a matrix.

This table summarizes the output characteristics for both types of inputs. For an illustration of why the output characteristics exist, see the figure “Valid Inputs to a 3-Level Asymmetric Dyadic Synthesis Filter Bank” on page 2-537.

|                                | Input = Multiple ports   | Input = Single port<br>(Concatenated Subband Inputs)                  |
|--------------------------------|--|---|
| <b>Output Frame Rate</b>       | Same as the input frame rate.  | Same as the input rate (the rate of the concatenated subband inputs). |
| <b>Output Frame Dimensions</b> | <ul style="list-style-type: none"> <li>The output has the same number of columns as the inputs.</li> <li>The number of output rows depends on the tree structure of the filter bank:               <ul style="list-style-type: none"> <li><b>Asymmetric</b> — The number of output rows is twice the number of rows in the input to the topmost input port.</li> <li><b>Symmetric</b> — The number of output rows is the product of the number of input ports and the number of rows in an input to any input port.</li> </ul> </li> </ul> | The output has the same number of rows and columns as the input.      |

For general information about the filter banks, see “Dyadic Synthesis Filter Banks”.

Data Types: single | double

## Parameters

The parameters displayed in the block dialog box vary depending on the setting of the **Filter** parameter. Only some of the parameters described below are visible in the dialog box at any one time.

**Note** To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, all the parameters in this block must be the same as the corresponding parameters in the Dyadic Analysis Filter Bank block (except the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients**. See the descriptions of these parameters).

**Filter** — Type of filter used in filter bank

User-defined (default) | Haar | Daubechies | Symlets | Coiflets | Biorthogonal | Reverse Biorthogonal | Discrete Meyer

To determine the highpass and lowpass FIR filters in the filter bank:

- Select **User defined** to explicitly specify the filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.
- Select a wavelet such as **Biorthogonal** or **Daubechies** to specify a wavelet-based filter. The block uses the Wavelet Toolbox `wfilters` function to construct the filters. Extra parameters such as **Wavelet order** or **Filter order [synthesis / analysis]** become enabled. For a list of the supported wavelets, see the table *Specifying Filters with the Filter Parameter and Related Parameters*.

You must specify the highpass and lowpass filters in the filter bank by setting the **Filter** parameter to one of the following options:

- **User defined** — Allows you to explicitly specify the filters with two vectors of filter coefficients in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters. The block uses the same lowpass and highpass filters throughout the filter bank. The two filters should be halfband filters, where each filter passes the frequency band that the other filter stops. To use this block to perfectly reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, the filters in this block *must* be designed to perfectly reconstruct the outputs of the analysis filter bank. To learn how to design your own perfect reconstruction filters, see “References” on page 2-542.
- **Wavelet** such as **Biorthogonal** or **Daubechies** — The block uses the specified wavelet to construct the lowpass and highpass filters using the Wavelet Toolbox function `wfilters`. Depending on the wavelet, the block might enable either the **Wavelet order** or **Filter order [synthesis / analysis]** parameter. (The latter parameter allows you to specify different wavelet orders for the analysis and synthesis filter stages.) To use this block to reconstruct a signal decomposed by a Dyadic Analysis Filter Bank block, you must set both blocks to use the same wavelets with the same order. You must have a Wavelet Toolbox license to use wavelets.

### Specifying Filters with the Filter Parameter and Related Parameters

| Filter                      | Sample Setting for Related Filter Specification Parameters  | Corresponding Wavelet Function Syntax |
|-----------------------------|---|---------------------------------------|
| <b>User-defined</b>         | Filters based on Daubechies wavelets with wavelet order 3: <ul style="list-style-type: none"> <li>• <b>Lowpass FIR filter coefficients</b> =<br/>[0.0352 -0.0854 -0.1350 0.4599<br/>0.8069 0.3327]</li> <li>• <b>Highpass FIR filter coefficients</b> =<br/>[-0.3327 0.8069 -0.4599<br/>-0.1350 0.0854 0.0352]</li> </ul> | None                                  |
| <b>Haar</b>                 | None  | <code>wfilters('haar')</code>         |
| <b>Daubechies</b>           | <b>Wavelet order</b> = 4  | <code>wfilters('db4')</code>          |
| <b>Symlets</b>              | <b>Wavelet order</b> = 3  | <code>wfilters('sym3')</code>         |
| <b>Coiflets</b>             | <b>Wavelet order</b> = 1  | <code>wfilters('coif1')</code>        |
| <b>Biorthogonal</b>         | <b>Filter order [synthesis / analysis]</b> =<br>[3/1]   | <code>wfilters('bior3.1')</code>      |
| <b>Reverse Biorthogonal</b> | <b>Filter order [synthesis / analysis]</b> =<br>[3/1]   | <code>wfilters('rbio3.1')</code>      |
| <b>Discrete Meyer</b>       | None  | <code>wfilters('dmey')</code>         |

**Filter order [synthesis / analysis]** — Wavelet order for synthesis filter stage

[1 / 1] (default) | [1 / 3] | [1 / 5] | [2 / 2] | [2 / 4] | [2 / 6] | [2 / 8] | [3 / 1] | [3 / 3] | [3 / 5] | [3 / 7] | [3 / 9] | [4 / 4] | [5 / 5] | [6 / 8]

The order of the wavelet for the synthesis and analysis filter stages. For example, when you set the **Filter** parameter to **Biorthogonal** and set the **Filter order [synthesis / analysis]** parameter to [2 / 6], the block calls the `wfilters` function with input argument 'bior2.6'.

**Dependencies**

To enable this parameter, set the **Filter** parameter to **Biorthogonal** or **Reverse Biorthogonal**.

**Wavelet order** — Wavelet order

2 (default) | positive integer

Set the order of the wavelet selected in the **Filter** parameter.

**Dependencies**

To enable this parameter, set the **Filter** parameter to **Daubechies**, **Symlets**, or **Coiflets**.

**Lowpass FIR filter coefficients** — Lowpass FIR filter coefficients

[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352] (default)

Specifies coefficients used by all the lowpass filters in the filter bank using a vector of filter coefficients (descending powers of  $z$ ). This parameter is enabled when you set **Filter** to **User defined**. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block must be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order 3).

**Dependencies**

To enable this parameter, set the **Filter** parameter to **User-defined**.

**Highpass FIR filter coefficients** — Highpass FIR filter coefficients

[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327] (default)

Specifies coefficients used by all the highpass filters in the filter bank using a vector of filter coefficients (descending powers of  $z$ ). This parameter is enabled when you set **Filter** to **User defined**. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To perfectly reconstruct a signal decomposed by the Dyadic Analysis Filter Bank, the filters in this block must be designed to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is not perfect. The default values of this parameter specify a perfect reconstruction filter for the default settings of the Dyadic Analysis Filter Bank (based on a Daubechies wavelet with wavelet order 3).

**Dependencies**

To enable this parameter, set the **Filter** parameter to **User-defined**.

**Number of levels** — Number of filter bank levels

2 (default) | positive integer

Select the number of filter bank levels. An  $n$ -level asymmetric structure has  $n+1$  inputs, and an  $n$ -level symmetric structure has  $2^n$  inputs, as shown in “Multilevel Filter Banks”.

**Tree structure** — Structure of filter bank

Asymmetric (default) | Symmetric

Select the structure of the filter bank: `Asymmetric`, or `Symmetric`. See “Multilevel Filter Banks” for more details on these structures.

The default setting of this parameter is `Asymmetric` for the Dyadic Synthesis Filter Bank block, and `Symmetric` for the IDWT block.

**Input** — Input

Multiple ports (default) | Single port

Set to `Multiple ports` to accept each input subband at a separate port. The topmost port accepts the subband with the highest frequency band. Set to `Single port` to accept one vector or matrix of concatenated subbands at a single port. For more information, see `Input` on page 2-0 port description.

The default setting of this parameter is `Multiple ports` for the Dyadic Synthesis Filter Bank block, and `Single port` for the IDWT block.

When you set the **Input** parameter to `Multiple ports`, you must provide each subband to the block through a different input port as a vector or a matrix. You should input the highest frequency band through the topmost port. When you set the **Input** parameter to `Single port`, the block input must be a vector or matrix of concatenated subbands.

**Block Characteristics**

# Edge Detector

Detect transition from zero to nonzero value

## Libraries:

DSP System Toolbox / Signal Management / Switches and Counters

## Description

The Edge Detector block generates an impulse (the value 1) in a given output channel when the corresponding channel of the input transitions from zero to a nonzero value. When the input does not transition from zero to a nonzero value, the block generates a zero in the corresponding output channel.

This block supports only discrete-time fixed-step signals. Continuous signals are not supported.

The output has the same dimension and sample rate as the input. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block counts an edge that is split across two consecutive frames in the frame that contains the nonzero value. For example, if there is a zero at the bottom of the first frame and a nonzero value at the top of the second frame, the block counts the edge in the second frame.

## Examples

### Detect Edges in Signal

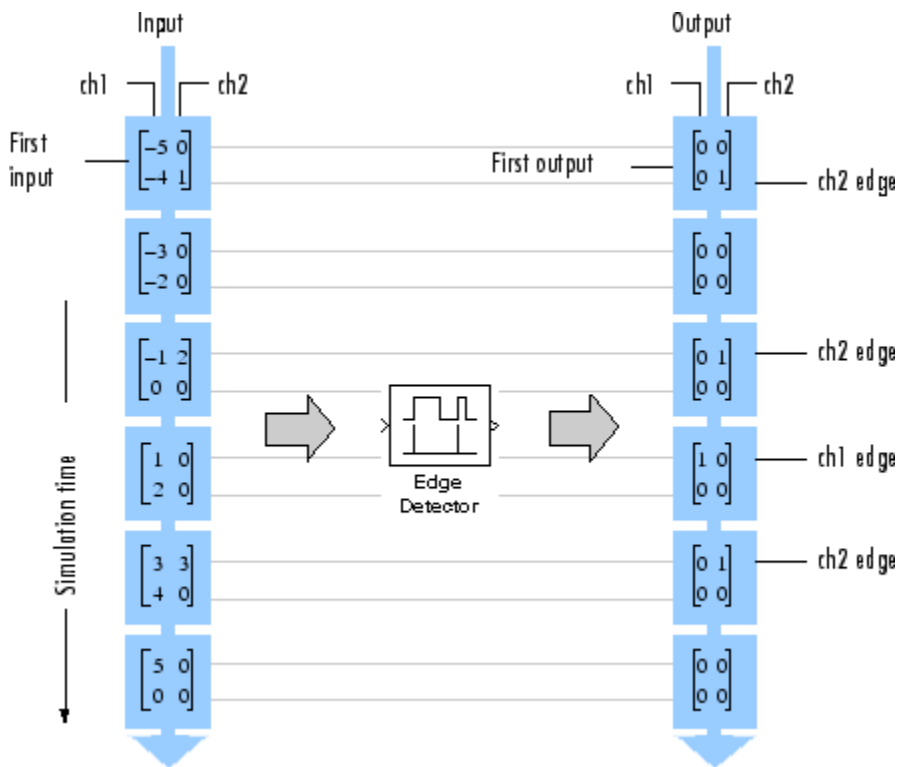

Detect edges in a signal using the Edge Detector block.

In the `ex_edgedetector_ref` model, the **Input processing** parameter of the Edge Detector block is set to `Columns as channels (frame based)`. Thus, the block interprets the 3-by-2 input as a multichannel signal with a frame size of 3. The Matrix Concatenate block concatenates the two input channels of the original signal with the two output channels of the Edge Detector block to create the four-channel workspace variable `sp_examples_yout`.

Copyright 2008-2010 The MathWorks, Inc.

As shown in the following figure, the block finds edges at sample 7 in channel 1, and at samples 2, 5, and 9 in channel 2.

Closing the model clears the "sp\_examples\_yout" variable from your workspace.

## Ports

### Input

**Input** — Input signal  
vector | matrix

Specify the input signal as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

### Output

**Output** — Output of edge detector  
vector | matrix

The block returns the output of the edge detector as a vector or a matrix.

The block might output Boolean values depending on the input data type, and whether Boolean support is enabled or disabled.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

## Parameters

### Input processing — Input processing

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of the following options:

- Columns as channels (frame based) (default) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

Counter | Event-Count Comparator

## Event-Count Comparator

Detect threshold crossing of accumulated nonzero inputs

## Library

Signal Management / Switches and Counters

dspswit3

## Description

The Event-Count Comparator block records the number of nonzero inputs to the Data port during the period that the block is enabled by a high signal (the value 1) at the Int port. Both inputs must be scalars.

When the number of accumulated nonzero inputs first equals the **Event threshold** setting, the block waits one additional sample interval, and then sets the output high (1). The block holds the output high until recording is restarted by a low-to-high (0-to-1) transition at the Int port.

The Event-Count Comparator block accepts real and complex floating-point and fixed-point inputs. However, because the block has discrete state, it does not support constant or continuous sample times. Therefore, at least one input or output port of the Event-Count Comparator block must be connected to a block whose **Sample time** parameter is discrete. The Event-Count Comparator block inherits this non-infinite discrete sample time.

## Parameters

### Event threshold

Specify the value against which to compare the number of nonzero inputs. Tunable (Simulink).

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers
- Enumerated

## Extract Triangular Matrix

Extract lower or upper triangle from input matrices

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

## Description

The Extract Triangular Matrix block creates a triangular matrix output from the upper or lower triangular elements of an  $M$ -by- $N$  input matrix. The block treats length- $M$  unoriented vector inputs as an  $M$ -by-1 matrix.

The **Extract** parameter selects between the two components of the input:

- **Upper** — Copies the elements on and above the main diagonal of the input matrix to an output matrix of the same size. The first *row* of the output matrix is therefore identical to the first *row* of the input matrix. The elements below the main diagonal of the output matrix are zero.
- **Lower** — Copies the elements on and below the main diagonal of the input matrix to an output matrix of the same size. The first *column* of the output matrix is therefore identical to the first *column* of the input matrix. The elements above the main diagonal of the output matrix are zero.

## Parameters

### Extract

The component of the matrix to copy to the output: upper triangle or lower triangle.

### Simulate using

**Code generation** (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

**Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Supported Data Types

# Farrow Rate Converter

Polynomial sample-rate converter with arbitrary conversion factor

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Farrow Rate Converter block converts the sample rate of an input signal using polynomial-fit sample-rate conversion. Polynomial-based filters are efficient at implementing fractional sample rate conversion. Farrow structures are implementations of polynomial-based filters. This block uses a Farrow structure to implement arbitrary rate-change factors efficiently. The rate-change factors can be irrational.

## Ports

### Input

**Port\_1** — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix signal.

The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single-channel signal.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

To determine the decimation factor, click the **View Info** button in the block dialog.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

### Output

**Port\_1** — Rate converted signal

scalar | vector | matrix

The Farrow Rate Converter block outputs a signal that has the same data type and complexity as the input signal.

The output signal dimensions depend on the input signal dimensions, the overall interpolation and decimation factors of the Farrow Rate Converter block, and whether you select the **Allow arbitrary**

**frame length for fixed-size input signals** parameter. You can determine the overall interpolation factor  $L$  and the decimator factor  $M$  by clicking the **View Info** button in the block dialog box.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

### Fixed-Size Input Signal

| Input Signal  | Output Signal Dimensions   |
|---|--|
| $P$ -by-1 column vector, where $P$ is a multiple of the decimation factor $M$     | $(LP/M)$ -by-1, where $L$ is the interpolation factor  |
| $P$ -by-1 column vector, where $P$ is not a multiple of the decimation factor $M$ | $\text{ceil}(LP/M)$ -by-1 when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.    |
| $P$ -by- $Q$ matrix, where $P$ is a multiple of the decimation factor $M$         | $(LP/M)$ -by- $Q$  |
| $P$ -by- $Q$ matrix, where $P$ is not a multiple of the decimation factor $M$     | $\text{ceil}(LP/M)$ -by- $Q$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

This table gives more details on the dimensions of the output signal when you input a variable-size input signal. When you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

### Variable-Size Input Signal

| Input Signal | Output Signal Dimensions     |
|--------------|------------------------------|
| $P$ -by- $Q$ | $\text{ceil}(LP/M)$ -by- $Q$ |

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

## Parameters

### Main Tab

**Sample rate of input signal (Hz)** — Sample rate of input signal in Hz

48e3 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

**Sample rate of output signal (Hz)** — Sample rate of output signal in Hz

96e3 (default) | positive scalar in Hz

Specify the sample rate of the output signal as a positive scalar in Hz. The output sample rate must be higher or lower than the input sample rate.

**Tolerance for output sample rate** — Maximum tolerance for output sample rate

0 (default) | positive scalar

Specify the maximum tolerance for the output sample rate as a positive scalar in the range [00.5].

The actual output sample rate varies but is within the specified range. For example, if you set the **Tolerance for output sample rate** to 0.01, then the actual output sample rate is in the range given by sample rate of output signal  $\pm 1\%$ . This flexibility allows for a simpler filter design.

**Filter Specification method** — Method for specifying filter coefficients

Polynomial order (default) | Coefficients

Specify the method the block uses to determine the polynomial interpolator coefficients as one of the following:

- **Polynomial order** — Specify the order of the Lagrange interpolation filter polynomial through the **Polynomial order** parameter.
- **Coefficients** — Specify the polynomial coefficients directly through the **Coefficients** parameter.

**Coefficients** — Filter polynomial coefficients

[-1 1; 1 0] (default) | real-valued square matrix

Specify the filter polynomial coefficients as a real-valued square matrix.

#### Dependencies

To enable this parameter, set **Filter specification method** to **Coefficients**.

**Polynomial order** — Order of Lagrange-interpolation-filter polynomial

3 (default) | positive integer less than or equal to 4

Specify the order of the Lagrange-interpolation-filter polynomial as 1, 2, 3, or 4.

#### Dependencies

To enable this parameter, set **Filter specification method** to **Polynomial order**.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

on (default) | off

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation

factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

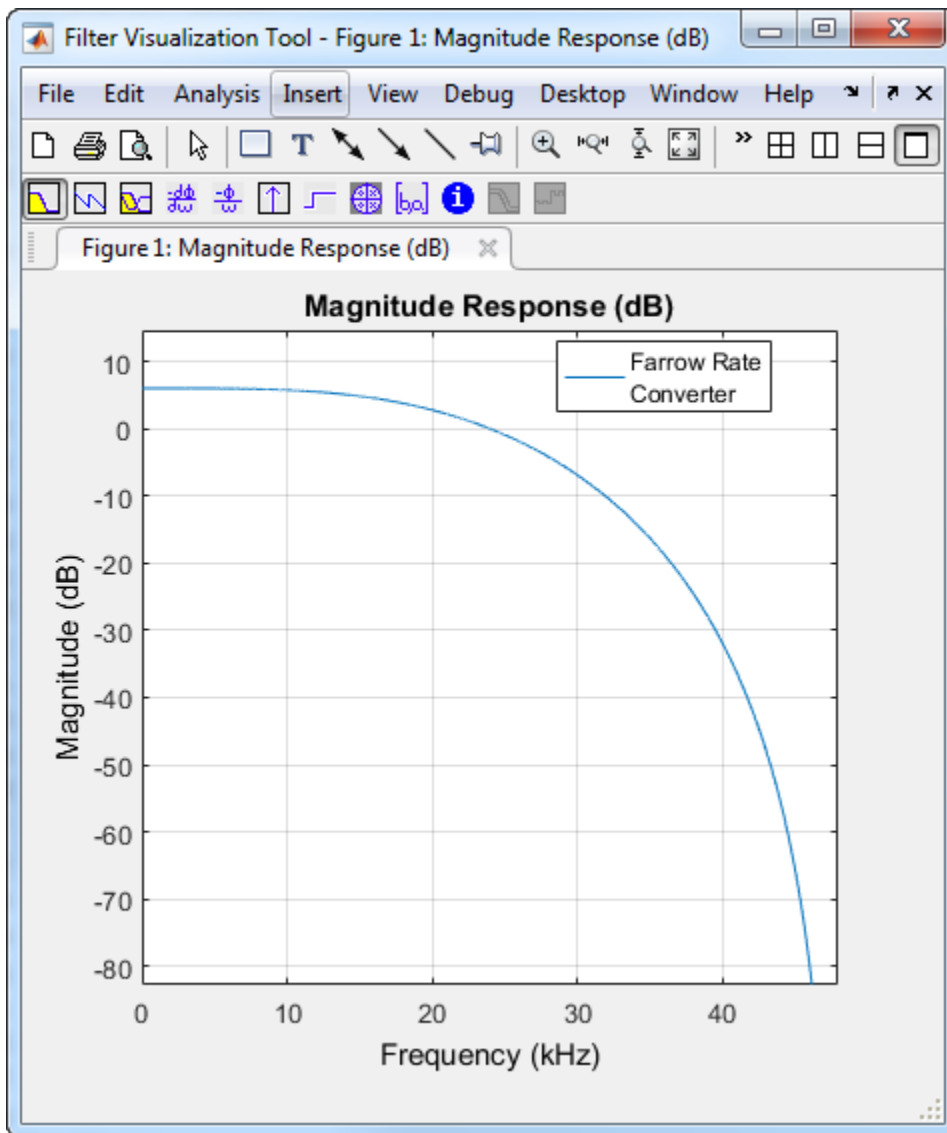

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

**View Filter Response** — View filter response  
button

Opens the FVTool and displays the magnitude/phase response of the Farrow Rate Converter. The response is based on the block parameters. FVTool updates when you change the parameters.

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

**View Info** — View info  
button

Click this button for the block to display the following information about the Farrow filter system:

- Filter Structure
- Interpolation Factor
- Decimation Factor
- Filter Length
- Stable
- Linear Phase

This button brings the functionality of the `info` method into the Simulink environment.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

### Data Types Tab

**Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

**Coefficients** — Data type of filter coefficients

`fixdt(1,16)` (default) | `fixdt(1,16,0)`

Specify the data type of the filter coefficients as a signed fixed-point object. The default `fixdt(1,16)` corresponds to a signed fixed-point type object with 16-bit coefficients. For maximum precision, the block determines the fraction length based on the coefficient values.

**Fractional Delay** — Data type of fractional delay

`fixdt(0,8)` (default) | `fixdt(0,16)`

Specify the data type of the fractional delay as an unsigned fixed-point object. The default `fixdt(0,8)` corresponds to an unsigned fixed-point data type object with 8-bit word length. For maximum precision, the block computes the fractional length based on the fractional delay values.

**Multiplicand** — Data type of multiplicand

`fixdt(1,16,13)` (default) | `fixdt(1,16,0)`

Specify the multiplicand data type as a signed fixed-point object. The default `fixdt(1,16,13)` corresponds to a signed fixed-point multiplicand data type with 16-bit word length and 13-bit fraction length.

**Output** — Data type of output

Inherit: Same word length as input (default) | Inherit: Same as accumulator |  
`fixdt(1,16)` | `fixdt(1,16,0)`

Specify the word length and fraction length of the output data type as one of the following:

- `Inherit: Same word length as input` (default) — Output word length and fraction lengths are the same as the input.
- `Inherit: Same as accumulator` — Output word length and fraction lengths are the same as the accumulator.
- `fixdt(1,16)` — Signed fixed-point data type with 16-bit word length. For maximum precision, the block computes the fraction length based on the input range and preserves the dynamic range of the input.
- `fixdt(1,16,0)` — Signed fixed-point data type with 16-bit word length and zero fraction length.

**Output Minimum** — Minimum value that the block can output

`[]` (default) | scalar

Specify the minimum value that the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value that the block can output

[] (default) | scalar

Specify the maximum value that the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|

| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner’s rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The algorithm computes interpolated values at the desired locations by varying only the fractional delay  $\mu$ . This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using  $M + 1$  FIR filters, where  $M$  is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay,  $\mu$ .
- The output is the sum of the multiplication results.

## Version History

Introduced in R2015b

### R2022b: Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

### Extended Capabilities

#### C/C++ Code Generation

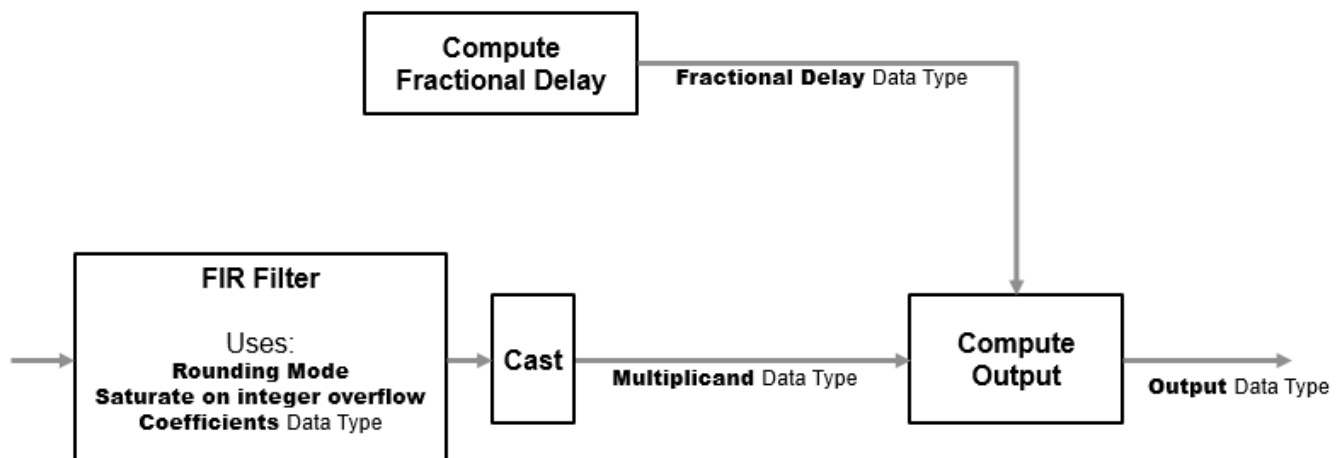

Generate C and C++ code using Simulink® Coder™.

#### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The diagram shows the data types that the Farrow Rate Converter block uses for fixed-point signals and floating-point signals. You can specify these data types using the parameters on the **Data Types** tab. If the input is floating point, all data types in the filter are the same as the input data type, single or double.

If the input is fixed point, the FIR filter defines internal data types using the **Rounding mode**, **Saturate on integer overflow**, and **Coefficients** parameters. The accumulators and products within the FIR filter use full-precision data types. The block casts the output of the FIR filter to the **Multiplicand** data type.

## Description

The Fast Block LMS Filter block implements an adaptive least mean-square (LMS) filter, where the adaptation of the filter weights occurs once for every block of data samples. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The block calculates the filter weights using the Block LMS Filter equations. For more information, see Block LMS Filter. The Fast Block LMS Filter block implements the convolution operation involved in the calculations of the filtered output,  $y$ , and the weight update function in the frequency domain using the FFT algorithm used in the Overlap-Save FFT Filter block. See Overlap-Save FFT Filter (Obsolete) for more information.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Block size** parameter determines how many samples of the input signal are acquired before the filter weights are updated. The input frame length must be a multiple of the **Block size** parameter.

The **Step-size ( $\mu$ )** parameter corresponds to  $\mu$  in the equations. You can either specify a step-size using the input port, Step-size, or enter a value in the Block Parameters: Block LMS Filter dialog box.

Use the **Leakage factor (0 to 1)** parameter to specify the leakage factor,  $0 < 1 - \mu\alpha \leq 1$ , in the leaky LMS algorithm shown below.

$$\mathbf{w}(k) = (1 - \mu\alpha)\mathbf{w}(k - 1) - f(\mathbf{u}(n), e(n), \mu)$$

Enter the initial filter weights,  $\mathbf{w}(0)$ , as a vector or a scalar in the **Initial value of filter weights** text box. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select **None** to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Reset input is a **Rising edge** or **Falling edge** (as described above)
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

## Parameters

### Filter length

Enter the length of the FIR filter weights vector. The sum of the **Block size** and the **Filter length** must be a power of 2.

### Block size

Enter the number of samples to acquire before the filter weights are updated. The number of rows in the input must be an integer multiple of the **Block size**. The sum of the **Block size** and the **Filter length** must be a power of 2.

### Specify step-size via

Select Dialog to enter a value for mu, or select Input port to specify mu using the Step-size input port.

### Step-size (mu)

Enter the step-size. Tunable (Simulink).

### Leakage factor (0 to 1)

Enter the leakage factor,  $0 < 1 - \mu\alpha \leq 1$ . Tunable (Simulink).

### Initial value of filter weights

Specify the initial values of the FIR filter weights.

### Adapt port

Select this check box to enable the Adapt input port.

### Reset input

Select this check box to enable the Reset input port.

### Output filter weights

Select this check box to export the filter weights from the Wts port.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcopy or memset function (string.h) under certain conditions.

# FFT

Fast Fourier transform (FFT) of input

**Libraries:**  
DSP System Toolbox / Transforms

## Description

The FFT block computes the fast Fourier transform (FFT) across the first dimension of an  $N$ -D input array,  $u$ . The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. To allow the block to choose the implementation, you can select **Auto**. For more information about the FFT implementations, see “Algorithms” on page 2-571.

For user-specified FFT lengths not equal to  $P$ , zero padding or truncating, or modulo-length data wrapping occurs before the FFT operation. For an FFT with  $P \leq M$ :

```
y = fft(u,M) % P ≤ M
```

Wrapping:

```
y(:,L) = fft(datawrap(u(:,L),M)) % P > M; L = 1, ..., N
```

Truncating:

```
y(:,L) = fft(u,M) % P > M; L = 1, ..., N
```

---

**Tip** When the input length,  $P$ , is greater than the FFT length,  $M$ , you may see magnitude increases in your FFT output. These magnitude increases occur because the FFT block uses modulo- $M$  data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample,  $P$ , to the FFT length,  $M$ . To do so, place a Pad block before the FFT block in your model.

---

## Ports

### Input

**Port\_1** — Input signal  
vector | matrix |  $N$ -D array

Input signal for computing the FFT. The block computes the FFT along the first dimension of the  $N$ -D input signal.

For more information on how the block computes the FFT, see “Description” on page 2-565 and “Algorithms” on page 2-571.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Output

### Port 1 — FFT of input

vector | matrix |  $N$ -D array

The FFT, computed across the first dimension of an  $N$ -D input array. When the output of the block has an integer or fixed-point data type, it is always signed.

The  $k$ th entry of the  $L$ th output channel,  $y(k,L)$ , equals the  $k$ th point of the  $M$ -point discrete Fourier transform (DFT) of the  $L$ th input channel:

$$y(k, L) = \sum_{p=1}^P u(p, L) e^{-j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

For more information on how the block computes the FFT, see “Description” on page 2-565 and “Algorithms” on page 2-571.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

### Main

#### FFT implementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Set this parameter to FFTW to support an arbitrary length input signal. The block restricts generated code with FFTW implementation to host computers capable of running MATLAB.

Set this parameter to Radix-2 for bit-reversed processing, fixed or floating-point data, or portable C-code generation using the Simulink Coder. The dimension  $M$  of the  $M$ -by- $N$  input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation. For more information about the algorithms used by the Radix-2 mode, see “Radix-2 Implementation” on page 2-571.

Set this parameter to Auto to let the block choose the FFT implementation. For floating-point inputs with non-power-of-two transform lengths, the FFTW algorithm is automatically chosen. Otherwise a Radix-2 algorithm is automatically chosen. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

#### Output in bit-reversed order — Output in bit-reversed order

off (default) | on

Designate the order of the output channel elements relative to the ordering of the input elements. When you select this check box, the output channel elements appear in bit-reversed order relative to the input ordering. If you clear this check box, the output channel elements appear in linear order relative to the input ordering.

---

**Note** The FFT block calculates its output in bit-reversed order. Linearly ordering the FFT block output requires an extra bit-reversal operation. In many situations, you can increase the speed of the FFT block by selecting the **Output in bit-reversed order** check box.

---

For more information ordering of the output, see “Linear and Bit-Reversed Output Order”.

#### Dependencies

To enable this parameter, set **FFT implementation** to Auto or Radix-2.

#### Divide output by FFT length — Divide output by FFT length

off (default) | on

When you select this parameter, the block divides the output of the FFT by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

#### Inherit FFT length from input dimensions — Inherit FFT length from input dimensions

on (default) | off

Select to inherit the FFT length from the input dimensions. When you select this check box, the input length must be a power of two.

#### Dependencies

When you do not select this check box, the **FFT length** parameter becomes available to specify the length.

#### FFT length — FFT length

64 (default) | integer

Specify FFT length as an integer greater than or equal to two.

When you set the **FFT implementation** parameter to Radix-2, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

#### Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

#### Wrap input data when FFT length is shorter than input length — Wrap or truncate input

on (default) | off

Choose to wrap or truncate the input, depending on the FFT length. If you select this parameter, modulo-length data wrapping occurs before the FFT operation when the FFT length is shorter than the input length. If you clear this check box, truncation of the input data to the FFT length occurs before the FFT operation.

#### Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

#### Data Types

#### Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

#### Limitations

The sine table values do not obey this parameter; instead, they always round to **Nearest**.

The **Rounding mode** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

#### Saturate on integer overflow — Saturate on integer overflow

`off (default) | on`

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see **overflow mode for fixed-point operations**.

#### Limitations

The **Saturate on integer overflow** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

#### Sine table — Data type of sine table values

`Inherit: Same word length as input (default) | fixdt(1,16)`

Choose how to specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Sine table** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

#### Limitations

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to **Nearest**.

#### Product output — Product output data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-573 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

### Accumulator — Accumulator data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-573 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

### Output — Output data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-573 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

- When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
- When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(FFTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) for more information.

**Output Minimum** — Minimum value block should output  
[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Output Maximum** — Maximum value block should output  
[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | yes                                     |
| <b>Variable-Size Signals</b>    | yes <sup>a</sup>                        |
| <b>Zero-Crossing Detection</b>  | no                                      |

<sup>a</sup> Variable-size signals are only supported when the Inherit FFT length from input dimensions checkbox is selected.

## Algorithms

### FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation can only run on computers capable of running MATLAB. The input data type must be floating-point.

### Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension  $M$  of the  $M$ -by- $N$  input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

### Radix-2 Algorithms for Real and Complex Signals

| Complexity of Input | Output Ordering | Algorithms Used for FFT Computation   |
|---------------------|-----------------|---|
| Complex             | Linear          | Bit-reversed operation and radix-2 DIT  |
| Complex             | Bit-reversed    | Radix-2 DIF   |
| Real                | Linear          | Bit-reversed operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms |
| Real                | Bit-reversed    | Radix-2 DIF in conjunction with the half-length and double-signal algorithms                            |

The efficiency of the FFT algorithm can be enhanced for real input signals by forming complex-valued sequences from the real-valued sequences prior to the computation of the DFT. When there are  $2N+1$  real input channels, the FFT block forms these complex-valued sequences by applying the double-signal algorithm to the first  $2N$  input channels, and the half-length algorithm to the last odd-numbered channel.

For real input signals with fixed-point data types, different numerical results might appear in the output of the last odd-numbered channel, even when all input channels are identical. This numerical difference results from differences in the double-signal algorithm and the half-length algorithm.

You can eliminate this numerical difference in two ways:

- Using full precision arithmetic for fixed-point input signals
- Changing the input data type to floating point

For more information on the double-signal algorithm, see [2], “Efficient Computation of the DFT of Two Real Sequences” on page 475. For more information on the half-length algorithm, see [2], “Efficient Computation of the DFT of a 2N-Point Real Sequence” on page 476.

### Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block’s Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

where  $K$  is the greater value of either  $M$  or  $N$  and  $k = 0, \dots, K - 1$ . The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

| Number of Table Entries for N-Point FFT |        |
|---|--------|
| floating-point                          | $3N/4$ |
| fixed-point                             | $N$    |

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB:
  - **FFT implementation** is set to FFTW.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

Use the packNGo function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used in the FFT block for fixed-point signals. You can set the **Sine table**, **Accumulator**, **Product output**, and **Output** data types displayed in the diagrams in the FFT dialog box as discussed in “Parameters” on page 2-566.

Inputs to the FFT block are first cast to the output data type and stored in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time FFT and after each butterfly stage in a decimation-in-frequency FFT.

**Decimation-in-time IFFT**

**Decimation-in-frequency IFFT**

**Butterfly stage data types**

**Twiddle multiplication data types**

The output of the multiplier appears in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

---

**Note** When the block input is fixed point, all internal data types are signed fixed point.

# Filter Realization Wizard

Construct filter realizations using digital filter blocks or Sum, Gain, and Delay blocks

## Library

Filtering / Filter Designs

dspfdesign

## Description

---

**Note** Use this block to implement fixed-point or floating-point digital filters using Sum, Gain, and Delay blocks or digital filter blocks from the DSP System Toolbox library. You can either design a filter by using the block parameters, or import the coefficients of a filter you have designed elsewhere.

The following blocks also implement digital filters, but serve slightly different purposes:

- Discrete FIR Filter and Biquad Filter— Use to implement floating-point or fixed-point filters that you have already designed
- Digital Filter Design — Use to design, analyze, and then implement floating-point filters.

---

The Filter Realization Wizard is a tool for automatically implementing a digital filter. You must specify a filter, its structure, and the data types for the inputs, outputs, and computations. The filter can support double-precision, single-precision, or fixed-point data types.

The Filter Realization Wizard can implement a digital filter in one of two ways. It can use digital filter blocks from the DSP System Toolbox library, or it can create a subsystem block that implements the specified filter using Sum, Gain, and Delay blocks. If the Filter Realization Wizard creates a block, double-click the block to open the dialog box. If it creates a subsystem, double-click the subsystem block to see the filter implementation as shown in the figure below.

For more information about filter implementation, see “Specify the Filter Implementation” on page 2-577.

The parameters of the Filter Realization Wizard are a part of a larger app, the Filter Designer (`filterDesigner`). You can use filter designer to design and analyze your filter, and then use the Filter Realization Wizard parameters to implement the filter in your models.

### Specify the Filter and Data Types

To specify a purely double-precision filter, you can either design a filter using the **Design Filter** panel, or import a filter using the **Import Filter** panel. In the **Import Filter** panel, you can specify the coefficients directly or specify the workspace variables which store the coefficients.

You can also specify a fixed-point filter or a single-precision filter by using the **Set Quantization Parameters** panel.

---

**Note** *Running* a model containing implementations of fixed-point filters requires the Fixed-Point Designer product, but you can still edit models containing such filter implementations without it. See the Fixed-Point Designer documentation for more information.

---

See the following topics to learn how to use the panels to specify your filter:

- For more information on the **Design Filter** panel, see `filterDesigner`.
- For more information on the **Import Filter** panel, see “Importing a Filter Design”.
- For more information on the **Set Quantization Parameters** panel, see “Access the Quantization Features of Filter Designer”.

To open a panel, click the appropriate button in the lower-left corner of filter designer.

### Supported Filter Structures

The Filter Realization Wizard supports the following structures:

- Direct form I

- Direct form I, second-order sections
- Direct form I transposed
- Direct form I transposed, second-order sections
- Direct form II
- Direct form II, second-order sections
- Direct form II transposed
- Direct form II transposed, second-order sections
- Direct form FIR
- Direct form FIR transposed
- Direct form symmetric FIR
- Direct form antisymmetric FIR
- Lattice all-pass
- Lattice AR
- Lattice ARMA
- Lattice MA for maximum phase
- Lattice MA for minimum phase
- Cascade
- Parallel

### Specify the Filter Implementation

You can determine how the Filter Realization Wizard models the specified filter. In the **Realize Model** panel, select the **Build model using basic elements** check box. When you select this check box and click on the **Realize Model** button, the Filter Realization Wizard creates a subsystem block that implements your filter using Sum, Gain, and Delay blocks. When you clear this check box, the Filter Realization Wizard uses a digital filter block to implement your filter. The **Build model using basic elements** check box is available only when your filter can be implemented using a digital filter block available in the DSP System Toolbox library.

The Filter Realization Wizard can generate a subsystem that represents either a double-precision or fixed-point filter. You must install the Fixed-Point Designer product to simulate a fixed-point filter. You can still edit the blocks used to implement the filter without installing the Fixed-Point Designer product.

Double-precision filter implemented with Sum, Gain, and Delay blocks

Fixed-point filter implemented with Sum, Gain, Delay, and Conversion blocks

## Implementations of Double-Precision and Fixed-Point Filters

### Command Line Alternative to Realize Model Button

You can enter `realizemdl(sysobj)` in the MATLAB command prompt to generate an architectural model of the filter System object, `sysobj`, in a Simulink subsystem block using individual sum, gain, and delay blocks, according to user-defined specifications. For more information, see `realizemdl`.

## Parameters

---

**Note** The following parameters for the Filter Realization Wizard are in the **Realize Model** pane of the filter designer app. To open different panels of filter designer, click the different buttons at the lower-left corner. For more information about relevant panels, see “Specify the Filter and Data Types” on page 2-576.

---

### Block Name

Enter the name of the new filter block.

### Destination

Specify where the new filter block should be created. This can be in a new model or in the current (most recently selected) model.

### User Defined

Specify the name of the target subsystem in which the Filter Realization Wizard should create the new filter block.

**Overwrite generated block “Filter” block**

When selected, the block overwrites any filter block in the current model with the name specified in the **Block Name** parameter. This parameter is enabled when the **Destination** parameter is set to Current.

**Build model using basic elements**

Select this check box to implement your filter using Sum, Gain, and Delay blocks. Clear this check box to implement your filter using digital filter blocks from the DSP System Toolbox library. This parameter is available only when your filter can be modeled using an available digital filter block.

**Optimize for zero gains**

Select this check box to remove zero-gain paths from the filter structure. For an example, see “Optimize the Filter Structure”.

**Optimize for unity gains**

Select this check box to substitute gains equal to 1 with a wire (short circuit). For an example, see “Optimize the Filter Structure”.

**Optimize for negative gains**

Select this check box to substitute gains equal to -1 with a wire (short circuit), and change the corresponding sums to subtractions. For an example, see “Optimize the Filter Structure”.

**Optimize delay chains**

Select this check box to substitute any delay chains made up of  $n$  unit delays with a single delay by  $n$ . For an example, see “Optimize the Filter Structure”.

**Optimize for unity scale values**

Select this check box to remove all scale value multiplications by 1 from the filter structure.

**Input processing**

Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

For more information about sample- and frame-based processing, see “Sample- and Frame-Based Concepts”.

**Rate options**

For multirate filters, specify how the block should process the input. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples.

**Realize Model**

Click to create a filter block according to the settings you’ve specified. When the **Build model using basic elements** check box is selected, the filter is implemented as a subsystem block consisting of Sum, Gain, and Delay blocks. To see the filter implementation, double-click the subsystem block in your model.

---

**Note** For more information about relevant parameters in other panels of filter designer, see “Specify the Filter and Data Types” on page 2-576.

---

## Supported Data Types

- Double-precision floating point
- Single-precision floating point — Supported only when you install Fixed-Point Designer.
- Fixed point (signed and unsigned) — Supported only when you install Fixed-Point Designer and Fixed-Point Designer.

# Filter Visualizer

Display magnitude and phase response of time-varying digital filters

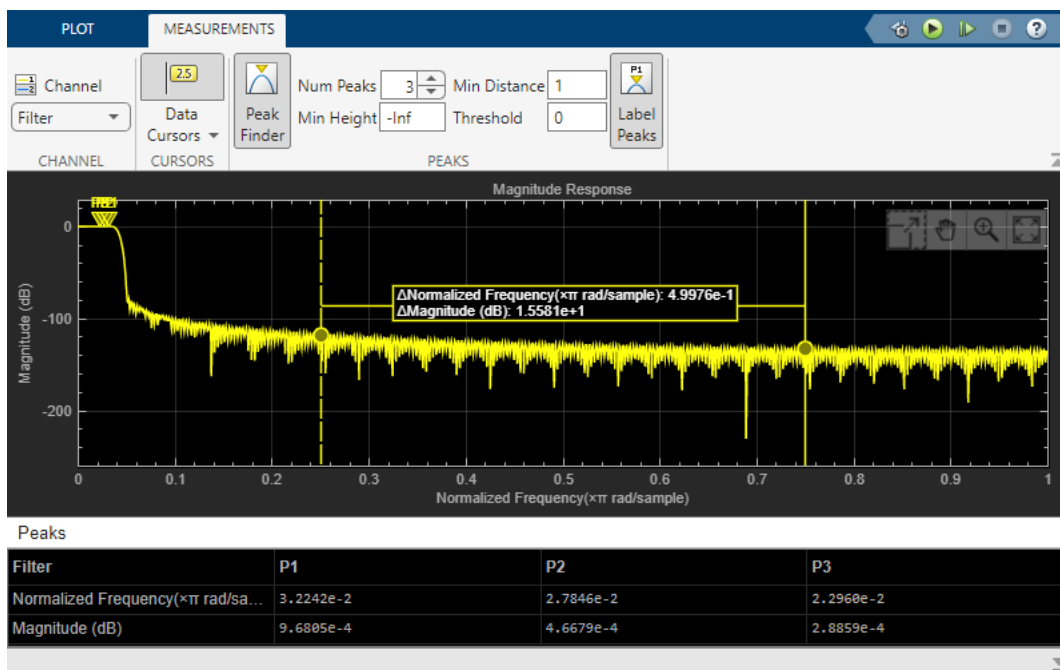

**Libraries:**  
DSP System Toolbox / Sinks

## Description

The Filter Visualizer block displays the magnitude response and phase response of time-varying digital filters or time-varying filter coefficients. You can visualize the frequency response of up to 20 filters at a time using this visualizer.

You can use the visualizer to configure the plot settings, find the peak values, enable cursor measurements, and even copy the scope display to the clipboard. For more information, see “Configure Filter Visualizer”. To access the filter visualizer programmatically, use the `dsp.DynamicFilterVisualizer` object.

## Examples

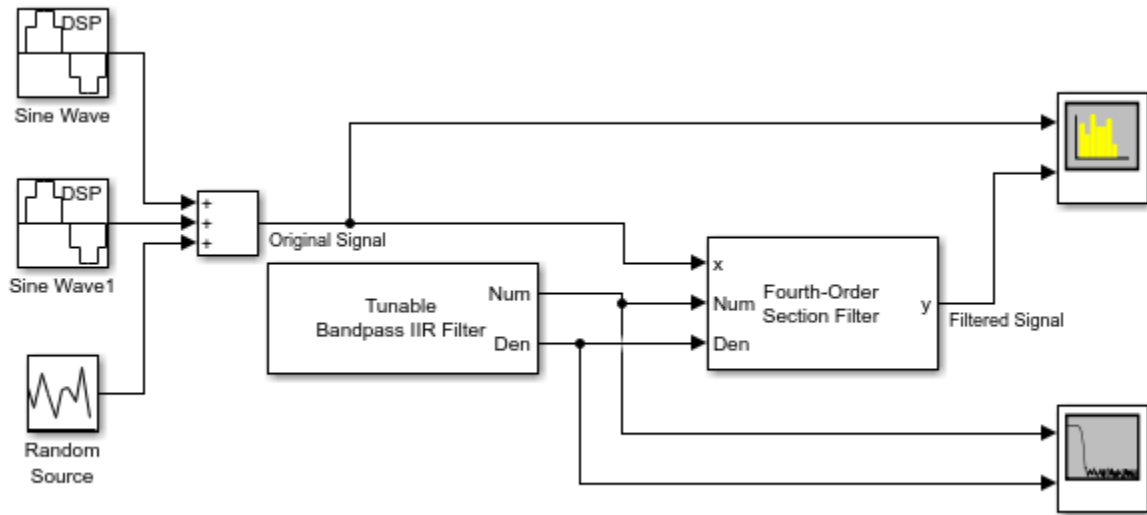

### Filter Noisy Signal Using Fourth-Order Section (FOS) Filter in Simulink

Filter a noisy sinusoidal signal using the Fourth-Order Section Filter block. The numerator and denominator coefficients of the fourth-order section filter are obtained using the Tunable Bandpass IIR Filter block. You can tune the frequency specifications of this filter during simulation.

### Open and Run the Model

The input signal is a sum of two sine waves with the frequencies of 100 Hz and 350 Hz. The sample rate is 1000 Hz and the number of samples in each frame is 1024. Add zero-mean white Gaussian noise with a variance of  $1e-4$  to the sum of the sine waves.

The Tunable Bandpass IIR Filter block designs a sixth order bandpass IIR filter with the first and second 3-dB cutoff frequencies at  $0.25 \pi$  rad/sample and  $0.75 \pi$  rad/sample, respectively. Visualize the frequency response of the filter using Filter Visualizer.

Copyright 2021-2023 The MathWorks, Inc.

Filter the noisy sinusoidal signal using the Fourth-Order Section Filter block. Visualize the original sinusoidal signal and the filtered signal using the Spectrum Analyzer.

### Tuning Frequency Specification of FOS Filter

During simulation, you can tune the frequency specifications of the FOS filter by tuning the frequency parameters in the Tunable Bandpass IIR Filter block. The filter response updates accordingly.

Change the first 3-dB cutoff frequency to  $0.65 \pi$  rad/sample in the Tunable Bandpass IIR Filter block. The first tone of the sinusoidal signal is attenuated as it no longer falls in the passband frequency of the filter.

## Ports

### Input

**Num** — Numerator coefficients

column vector | row vector |  $L$ -by-3 matrix |  $L$ -by-5 matrix

Specify the numerator coefficients of the filter as a row vector, column vector,  $L$ -by-3 matrix corresponding to a cascade of second-order sections, or an  $L$ -by-5 matrix corresponding to a cascade of fourth-order sections, where  $L$  is the number of filter sections.

If you set **Num Filters** to a value greater than 1, then the block displays a **Num** port for each filter.

When you set **Filter Type** to FIR, inputs on all **Num** ports must be column or row vectors.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

**Den** — Denominator coefficients

column vector | row vector |  $L$ -by-3 matrix |  $L$ -by-5 matrix

Specify the denominator coefficients of the filter as a row vector, column vector,  $L$ -by-3 matrix corresponding to a cascade of second-order sections, or an  $L$ -by-5 matrix corresponding to a cascade of fourth-order sections, where  $L$  is the number of filter sections.

If you set **Num Filters** to a value greater than 1, then the block displays a **Den** port for each filter.

### Dependency

To enable this port, set **Filter Type** to IIR.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

## Parameters

### Plot Tab

#### Configuration

**Num Filters** — Number of filters to display  
1 (default) | positive integer in the range [1 20]

Specify the number of filters to display as a positive integer in the range [1 20]. The value of this parameter determines the number of input ports on the block.

#### Programmatic Use

**Block Parameter:** NumFilters  
**Type:** character vector or string scalar  
**Values:** scalar in the range [1 20]

**Filter Type** — Type of filter response  
FIR (default) | IIR

Specify the filter response type as one of these options:

- FIR -- The block displays one input port per filter. You input the numerator coefficients of the filter(s) through the port(s).
- IIR -- The block displays two input ports per filter. You input the numerator and the denominator coefficients of the filter(s) through the ports.

#### Programmatic Use

**Block Parameter:** FilterType  
**Type:** character vector or string scalar  
**Values:** 'FIR', 'IIR'

**Legend** — Display signal legend  
off (default) | on

Select this option to display the legend on the plot. The legend contains the filter names in the format `Filter:Number`. If you are visualizing only one filter, the legend displays `Filter`. If you are visualizing the magnitude and phase responses of multiple filters, the visualizer displays a separate legend for each response in the format `mag(Filter:Number)` and `phase(Filter:Number)`, respectively. If you are visualizing the responses of only one filter, the legend displays `mag(Filter)` and `phase(Filter)`.

You can control which filters are visible in the scope using the legend. Click a filter name in the legend to hide the frequency response of that filter in the scope. To display the filter response, click the filter name again. To display only one filter response, right-click the name of that filter, which hides all other filter responses. To show all filter responses, press **Esc**. This setting is equivalent to

changing the **Visible** parameter in the **Plot** tab > **Settings** (  ) > **Color and Styling**.

**Tunable:** Yes

**Programmatic Use****Block Parameter:** ShowLegend**Type:**boolean**Magnitude and Phase** — Plot magnitude and phase response of filter  
button

Click the button to plot the magnitude and phase response of the filter on two separate axes. Click the button again to plot only the magnitude response.

**Tunable:** Yes**Programmatic Use****Block Parameter:** PlotAsMagnitudePhase**Type:**boolean**Configuration > Filter Visualizer Settings ( )****FFT Length** — FFT length

2048 (default) | positive integer

Specify the FFT length that the filter visualizer uses to compute the spectral estimates as a positive integer.

**Tunable:** Yes**Programmatic Use****Block Parameter:** FFTLength**Type:** character vector or string scalar**Values:** scalar**Normalized Frequency** — Display the frequency response in normalized units

on (default) | off

Select this parameter to display the frequency response of the filter in normalized frequency units.

When you select this parameter, the frequency range is [0,1] and the frequency axis (x-axis) units switch to Normalized Frequency ( $\times\pi$  rad/sample).

When you clear this parameter, the frequency range is [0  $F_s/2$ ] and the frequency axis (x-axis) units are in Hz.

**Tunable:** Yes**Programmatic Use****Block Parameter:** NormalizedFrequency**Type:**boolean**Sample Rate (Hz)** — Sample rate in Hz

44100 (default) | positive scalar

Enter the sample rate as a positive scalar in Hz.

**Tunable:** Yes

**Dependencies**

To enable this parameter, clear the **Normalized Frequency** parameter.

**Programmatic Use**

**Block Parameter:** SampleRate

**Type:** character vector or string scalar

**Values:** scalar

**Range** — Frequency range

[0, 1] (default) | two-element numeric vector

Specify the frequency range as a two-element numeric vector that is monotonically increasing and of the form [*fmin*, *fmax*].

When you select the **Normalized Frequency** parameter, *fmax* is in normalized frequency units and must be a positive scalar that is less than or equal to 1. When you clear the **Normalized Frequency** parameter, *fmax* is in Hz and must be less than or equal to  $F_s/2$ , where  $F_s$  is the value you specify in the **Sample Rate (Hz)** parameter.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** FrequencyRange

**Type:** character vector or string

**Value:** two-element numeric vector

**Display Unit** — Magnitude units

Magnitude (dB) (default) | Magnitude | Magnitude squared

Specify the magnitude units in the display as one of these:

- Magnitude
- Magnitude (dB)
- Magnitude squared

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** MagnitudeDisplay

**Type:** character vector or string scalar

**Values:** 'Magnitude (dB)', 'Magnitude', 'Magnitude squared'

**Plot Type** — Type of plot

Line (default) | Stairs | Stem

Specify the type of plot to use in the filter visualizer window as one of these:

- **Line** -- The filter visualizer connects each point on the magnitude and phase response plot with a line.
- **Stairs** -- The filter visualizer displays the filter response (magnitude, phase, or both) as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each

horizontal line represents the filter response over a frequency value and is connected to two vertical lines. Each vertical line represents a change in values occurring at a frequency.

- **Stem** -- The filter visualizer displays the frequency response as circles with vertical lines extending down to the x-axis at each of the frequency values.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** PlotType

**Type:** character vector or string scalar

**Values:** 'Stem', 'Line', 'Stairs'

**Font Size** — Font size of labels

Small (default) | Medium | Large | Extra Large

Specify the font size of all labels in the display as Small, Medium, Large, and Extra Large.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** -

**Type:** character vector or string scalar

**Title** — Display title

character vector | string

Specify the display title as a character vector or a string.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** Title

**Type:** character vector or string

**X-Scale** — Scale of frequency axis

Linear (default) | Log

Specify the scale of the frequency axis as 'Linear' or 'Log'.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** XScale

**Type:** character vector or string

**Values:** 'Linear', 'Log'

**Y-Limits** — y-axis limits

[-25 25] | [ymin ymax]

Specify the y-axis limits of the magnitude display in the Filter Visualizer as a two-element numeric vector of the form [ymin ymax]. The units of the y-axis limits depend on the **Display Unit** parameter.

**Tunable:** Yes

**Programmatic Use****Block Parameter:** YLimits**Type:** character vector or string**Value:** two-element numeric vector**Show Grid** — Show internal grid lines

on (default) | off

Select this check box to show the grid in the Filter Visualizer display.

**Tunable:** Yes**Programmatic Use****Block Parameter:** ShowGrid**Type:** logical**Preserve colors for copy to clipboard** — Preserve colors in clipboard copy

off (default) | on

When you select this parameter, the Filter Visualizer preserves the colors in the display that you copy to the clipboard using the **Copy Display** and the **Print** options in the **Share** section on the **Plot** tab.

**Tunable:** Yes**Background** — Window background

black (default) | color picker

Specify the color that you want to apply to the background of the scope figure.

**Tunable:** Yes**Axes** — Axes background color

black (default) | color picker

Specify the color that you want to apply to the background of the axes.

**Tunable:** Yes**Labels** — Color of labels

gray (default) | color picker

Specify the color of the labels, grid, and the channel names in the legend.

**Tunable:** Yes**Line** — Filter for line property settings

filter names

Select the filter for which you want to modify the visibility, line color, style, width, and marker properties.

**Tunable:** Yes**Visible** — Filter visibility

on (default) | off

Specify whether the selected filter is visible. If you clear this check box, the frequency response line disappears in the display.

You can control this parameter directly from the legend. Click a filter name in the legend to hide the frequency response of the filter in the scope. To show the filter response, click the filter name again. To show only one filter response, right-click the filter name, which hides all other filter responses. To show all filter responses, press **Esc**.

**Tunable:** Yes

#### **Programmatic Use**

**Block Parameter:** Visible

**Type:** logical

**Style** — Line style

- (default) | : | -. | -- | None

Specify the line style for the selected filter response.

**Tunable:** Yes

**Width** — Line width

1.5 (default) | 0.5 | 1 | 2 | ...

Specify the line width for the selected filter response.

**Tunable:** Yes

**Marker** — Data point markers

None (default) | + | x | ...

Specify markers for the selected filter response to show at its data points. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the drop-down list.

**Tunable:** Yes

**Color** — Line color

yellow (default) | color picker

Specify the line color for the selected filter response.

**Tunable:** Yes

#### **Share**

**Copy Display** — Send display to clipboard

button

Click this button to copy the scope display to the clipboard. You can preserve the color of the display by selecting the **Preserve colors for copy to clipboard** parameter.

**Print** — Print display

button

Click this button to save the scope display as an image or a PDF or to print the display.

## Measurements Tab

### Channel

**Channel** — Filter for which to obtain measurements

`Filter (default) | filter name`

Choose the filter response for which you need to obtain measurements. The filter names are in the format `Filter:Number`. If you are visualizing only one filter, the legend displays `Filter`. If you are visualizing the magnitude and phase responses of multiple filters, the visualizer displays a separate name for each response in the format `mag(Filter:Number)` and `phase(Filter:Number)`, respectively. If you are visualizing the responses of only one filter, the legend becomes `mag(Filter)` and `phase(Filter)`.

**Tunable:** Yes

### Dependency

To enable this parameter, pass some data through the scope.

### Cursors

**Data Cursors** — Enable cursor measurements

`button`

Click the **Data Cursors** button to enable data cursor measurements. Each cursor tracks a vertical line along the frequency response. The scope displays the difference between frequency( $x$ ) values and frequency response ( $y$ ) values of the filter at the two cursors in the box between the cursors.

**Tunable:** Yes

**Snap to data** — Snap cursors to data

`off (default) | on`

Select this parameter to position the cursors on the signal data points.

**Tunable:** Yes

**Lock cursor spacing** — Lock cursor spacing

`off (default) | on`

Select this parameter to lock the frequency difference between the two cursors.

**Tunable:** Yes

### Peaks

**Peak Finder** — Enable peak finder measurements

`button`

Select **Peak Finder** to enable peak finder measurements. An arrow appears on the plot at each maxima and a Peaks panel appears at the bottom of the scope window.

**Tunable:** Yes

**Num Peaks** — Maximum number of peaks to show

`3 (default) | positive integer less than 100`

Specify the maximum number of peaks to show as a positive integer less than 100.

**Tunable:** Yes

**Min Height** — Level above which scope detects peaks

-Inf (default) | real scalar value

Specify the level above which the scope detects peaks as a real scalar.

**Tunable:** Yes

**Min Distance** — Minimum number of samples between adjacent peaks

1 (default) | positive integer

Specify the minimum number of samples between adjacent peaks as a positive integer.

**Tunable:** Yes

**Threshold** — Minimum difference in height of peak and its neighboring samples

0 (default) | nonnegative scalar

Specify the minimum difference in the height of the peak and its neighboring samples as a nonnegative scalar.

**Tunable:** Yes

**Label Peaks** — Label peaks

button

Select **Label Peaks** to label the peaks. The scope displays the labels (**P1**, **P2**, ...) above the arrows in the plot.

**Tunable:** Yes

### Property Inspector Only

**Filter Names** — Input filter names

[] (default) | character vector | string | array of strings or character vectors.

Input filter names, specified as a character vector, string, or array of either. The names appear in the legend, **Filter Visualizer Settings**, and **Measurements** panels. If you do not specify filter names, the block displays the filter names as Filter: 1, Filter: 2, etc.

### Dependency

To see filter names, select **Legend** in the **Plot** tab.

### Programmatic Use

**Block Parameter:** FilterNames

**Type:** cell array of character vectors or string array

**Maximize Axes** — Maximize size of plots

Auto (default) | Off | On

- Auto — If you do not specify **Title** and y-label, maximize all plots by default.

- On — Maximize all plots and hide **Title** and y-label.
- Off — Do not maximize plots.

Point anywhere in the Filter Visualizer to see the maximize axes button .

**Tunable:** Yes

#### Programmatic Use

**Block Parameter:** MaximizeAxes

**Type:** character vector or string scalar

**Axes Scaling** — Y-axis scaling mode

Auto (default) | Manual | Updates | OnceAtStop

- Auto — The filter visualizer scales the axes as needed to fit the data, both during and after simulation.
- Manual — The filter visualizer does not scale the axes automatically.
- Updates — The filter visualizer scales the axes limits once after completing the number of visual updates specified in the **Number of Updates** text box (100 by default). Scaling occurs only once during each run.
- OnceAtStop — The filter visualizer scales the axes when the simulation stops.

**Tunable:** Yes

#### Programmatic Use

**Block Parameter:** AxesScaling

**Type:** character vector or string scalar

**Number of Updates** — Number of updates before scaling

100 (default) | integer

Set this property to delay auto scaling the y-axis.

**Tunable:** Yes

#### Dependency

To enable this property, set **Axes Scaling** to Updates.

#### Programmatic Use

**Block Parameter:** AxesScalingNumUpdates

**Type:** character vector or string scalar

**Values:** scalar

## Block Characteristics

|                           |  |

| <b>Multidimensional Signals</b> | no |
| <b>Variable-Size Signals</b>    | no |
| <b>Zero-Crossing Detection</b>  | no |

## More About

### Cursor Measurements

Measure signal values using vertical waveform cursors that track along the signal.

When you click the **Data Cursors** button in the **Measurements** tab of the Filter Visualizer, the display shows vertical cursors on the filter response curve that you choose in the **Channel** section. Each cursor tracks a vertical line along the curve. The scope displays the difference between  $x$ - and  $y$ -values of the curve at the two cursors in the box between the cursors.

To enable cursor measurements, you must select the **Data Cursors** button in the **Measurements** tab. The cursors appear only when the Filter Visualizer has at least one frequency response in its display.

You can use the mouse to move the vertical cursors to the left or to the right.

On the **Measurements** tab, click the **Data Cursors** drop-down list and you can select:

- **Snap to Data** — To position the cursors on frequency response data points.
- **Lock Cursor Spacing** — To lock the frequency difference between the two cursors.

For modifying the cursor measurements programmatically, see the `dsp.DynamicFilterVisualizer` object. For more information on cursor measurements, see the `CursorMeasurementsConfiguration` object.

### Peak Finder Measurements

Compute and display peak values on the scope display.

When you click on the **Peak Finder** button in the **Measurements** tab of the Filter Visualizer, an arrow appears on the plot at each maxima and a **Peaks** panel appears at the bottom of the scope window. The Filter Visualizer computes peaks from the portion of the filter response that is currently on display in the scope, and the **Peaks** panel shows the peak values and the frequencies at which these peaks occur.

The **Peaks** section in the **Measurements** tab allows you to specify the number of peaks you want the scope to display, the minimum height above which you want the scope to detect peaks, the minimum distance between peaks, and label the peaks.

The Filter Visualizer algorithm defines a peak as a local maximum with lower values present on either side of the peak. It does not consider end points as peaks. For more information on the algorithm, see the `findpeaks` function.

For modifying the peak finder measurements programmatically, use the `dsp.DynamicFilterVisualizer` object. For more information on peak finder measurements, see

the `PeakFinderConfiguration` object. For more information on these settings in the UI, see “Peaks” on page 2-0 .

# FIR Decimation

Perform polyphase FIR decimation

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters  
 DSP System Toolbox HDL Support / Filtering

## Description

The FIR Decimation block performs an efficient polyphase decimation using an integer downsampling factor  $M$  along the first dimension.

Conceptually, the FIR decimator (as shown in the schematic) consists of an anti-aliasing FIR filter followed by a downsampler. To design an FIR anti-aliasing filter, use the `designMultirateFIR` function.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The downsampler that follows downsamples each channel of filtered data by taking every  $M$ -th sample and discarding the  $M - 1$  samples that follow.  $M$  is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is  $1/M$  times the original sample rate.

Note that the actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-609.

Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-612.

## Ports

### Input

**In** — Data input  
 vector | matrix

Specify the data input as a vector or a matrix of size  $P$ -by- $Q$ . The columns in the input signal represent  $Q$  independent channels.

The block supports variable-size input signals (frame length changes during simulation) when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`. When the block accepts variable-size input signals, they can be of arbitrary frame length, that is, the input frame length does not have to be a multiple of the decimation factor. When you specify fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-607 and “Sample-Based Processing” on page 2-608.

This port is unnamed until you set **Coefficient source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

**Num** — Numerator coefficients  
vector

Specify the numerator coefficients of the FIR filter as a vector.

The transfer function  $H(z)$  of the FIR filter is given by:

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than  $1/M$ , where  $M$  is the decimation factor. To design such a filter, use the `designMultirateFIR` function.

Coefficient values obtained through **Num** are tunable, that is, they can change during simulation, while their properties must remain constant.

The data type of the **Num** input must match the data type of the **In** input.

### Dependencies

The **Num** input port appears when you set **Coefficient source** as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

### Output

**Out** — Decimator output  
vector | matrix

Output of the FIR Decimator block, returned as a vector or a matrix.

When you set **Rate options** to:

- `Enforce single-rate processing` -- The block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of  $M$ .

The output has an upper bound size of  $\text{ceil}(P/M)$ -by- $Q$  for an input of size  $P$ -by- $Q$ .

- `Allow multirate processing` -- The block decimates the signal such that the output sample rate is  $M$  times slower than the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-607 and “Sample-Based Processing” on page 2-608.

This port is unnamed until you set **Coefficient source** to **Input port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

## Parameters

### Coefficient source

**Coefficient source** — FIR filter coefficient source

**Auto** (default) | **Dialog parameters** | **Input port** | **Filter object**

Specify the FIR filter coefficient source as one of the following:

- **Dialog parameters** -- Specify the filter coefficients through the **FIR filter coefficients** parameter in the block dialog box.
- **Input port** -- Specify the filter coefficients through the **Num** input port.
- **Filter object** -- Specify the filter using a `dsp.FIRDecimator` System object.
- **Auto** -- When you select **Auto**, the block designs an FIR decimator using the decimation factor that you specify in **Decimation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [2].

### Main Tab

**FIR filter coefficients** — Lowpass FIR filter coefficients

`designMultirateFIR(1,2)` (default) | `vector`

Specify the lowpass FIR filter coefficients, in descending powers of  $z$ , as a vector. By default, `designMultirateFIR(1,2)` computes the filter coefficients.

The transfer function  $H(z)$  of the FIR filter is given by:

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than  $1/M$ , where  $M$  is the decimation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

### Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Decimation factor** — Decimation factor  
2 (default) | positive scalar

Specify the integer factor  $M$ . The block decreases the sample rate of the input sequence by this factor.

**Dependencies**

This parameter appears only when you set the **Coefficient source** to **Dialog parameters, Input port**, or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Filter structure** — FIR filter structure  
`Direct form` (default) | `Direct form transposed`

Specify the FIR filter structure as either `Direct form` or `Direct form transposed`.

**Dependencies**

This parameter appears only when you set the **Coefficient source** to **Dialog parameters, Input port**, or **Auto**.

**Filter object** — Filter object  
`dsp.FIRDecimator`

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a `dsp.FIRDecimator` System object.

You can define the System object directly in the block dialog box. Alternatively, you can define the object in a MATLAB workspace variable and specify the variable in the block dialog box.

For information on creating System objects, see “Define Basic System Objects”.

**Dependencies**

This parameter appears only when you set the **Coefficient source** to **Filter object**.

**Input processing** — Method to process input signals  
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

**Rate options** — Method by which block decimates input  
`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method by which the block should decimate the input. You can select one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of  $M$ . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.

When you set the **Rate options** parameter to `Enforce single-rate processing`, you can use the FIR Decimation block inside triggered subsystems.

- **Allow multirate processing** — When you select this option, the block decimates the signal such that the output sample rate is  $M$  times slower than the input sample rate.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

### Dependency

To enable this parameter, set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`.

**Output buffer initial conditions** — Initial conditions

0 (default) | scalar | matrix

When you set the FIR Decimation block to the frame-based processing mode, the block can exhibit one-frame latency. In the case of one-frame latency, this parameter specifies the output of the block until the first filtered input sample is available. Specify this parameter as a scalar value to be applied to all signal channels, or as a matrix containing one value for each channel.

Cases of one-frame latency can occur when the input frame size is greater than one, and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

- **Input processing** set to `Columns as channels (frame based)`

- **Rate options** set to Allow multirate processing

For more information on latency in the FIR Decimation block, see “Latency” on page 2-608.

#### Dependencies

This parameter appears only when you configure the block to perform multirate processing by setting **Rate options** to Allow multirate processing.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**View Filter Response** — View filter response  
button

Click on this button to open the Filter Visualization Tool (fvtool) and display the filter response of the filter defined in the block dialog box.

#### Data Types Tab

**Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor. The filter coefficients do not obey this parameter and always round to Nearest.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in the full-precision mode.

---

**Saturate on integer overflow** — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

---

**Coefficients Data Type** — Coefficients data type

Inherit: Same word length as input (default) | `fixdt(1,16)` | `fixdt(1,16,0)`

Specify the coefficients data type. See “Fixed Point” on page 2-615 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block.

You can set this parameter to one of the following:

- Inherit: Same word length as input
- `fixdt(1,16,0)` or `fixdt(1,16)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Dependencies**

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Filter` object, or `Auto`.

When **Coefficient source** is set to `Filter` object, **Coefficients** parameter is automatically set to `Same word length as input`.

**Coefficients Minimum** — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Dependencies**

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

**Coefficients Maximum** — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Dependencies**

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

**Product output Data Type** — Product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | `fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-615 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block.

You can set this parameter to one of the following:

- Inherit: Inherit via internal rule

For more information on this rule, see “Inherit via Internal Rule”.

- Inherit: Same as input
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Product output** parameter is automatically set to `Full` precision.

### Accumulator Data Type — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-615 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to one of the following:

- Inherit: `Inherit via internal rule`.

For more information on this rule, see “Inherit via Internal Rule”.

- Inherit: `Same as input`
- Inherit: `Same as product output`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Accumulator** parameter is automatically set to `Full` precision.

### Output Data Type — Output data type

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-615 for illustrations depicting the use of the output data type in this block.

You can set it to one of the following:

- Inherit: `Same as accumulator`

- Inherit: Same as input
- Inherit: Same as product output
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Output** parameter is automatically set to `Same as accumulator`.

**Output Minimum** — Minimum value of block output

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

**Output Maximum** — Maximum value of block output

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into  $M$  different subfilters, where  $M$  is the downsampling or decimation factor. For more details on the polyphase implementation, see “Algorithms” on page 2-609.

Let  $h(n)$  denote the FIR filter impulse response of length  $N+1$  and  $x(n)$  the input signal. Decimating the filter output by a factor of  $M$  is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting  $M = 2$ , the input values  $x(0), x(2), x(4), \dots$  are combined only with the filter coefficients  $h(0), h(2), h(4), \dots$ , and the input values  $x(1), x(3), x(5), \dots$  are combined only with the filter coefficients  $h(1), h(3), h(5), \dots$ . By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of  $M$ , there are  $M$  phases and therefore  $M$  subfilters.

## Frame-Based Processing

When you set the **Input processing** parameter to **Columns as channels (frame based)**, the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input.

- When you set the **Rate options** parameter to **Enforce single-rate processing**, the input and output of the block have the same sample rate. To decimate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame length of the output has an upper bound size of  $\text{ceil}(P/M)$ , where  $P$  is the input frame length and  $M$  is the decimation factor specified in the **Decimation factor** parameter.

In this mode, if you input a fixed-size signal (frame length does not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the decimation factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

In this mode, if you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to **Columns as channels (frame based)** and **Rate options** to **Enforce single-rate processing**.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length   | Input Size   | Output Size                                     |
|----------------------------|-------------------------------|--|--------------|---|
| Fixed-size input signal    | Yes                           | When you select <b>Allow arbitrary frame length for fixed-size input signals</b> | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(P/M)$ -by- $Q$ |
| Variable-size input signal | Yes                           | Always   | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(P/M)$ -by- $Q$ |

For an example that shows single-rate FIR decimation, see “FIR Decimation Using Single-Rate Processing”.

- When you set the **Rate options** parameter to **Allow multirate processing**, the input and output of the FIR Decimation block are of the same size, but the sample rate of the output is  $M$  times slower than that of the input. In this mode, the block treats a  $P$ -by- $Q$  matrix input as  $Q$  independent channels. The block decimates each column of the input over time by keeping the frame size constant, and making the output frame period ( $T_{fo}$ )  $M$  times longer than the input frame period ( $T_{fo} = M \cdot T_{fi}$ ).

In this mode, the block accepts only fixed-size signals and these signals can have arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Allow multirate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Fixed-size input signal    | Yes                           | Always                                   | $P$ -by- $Q$   | $P$ -by- $Q$   |
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

See “FIR Decimation Using Multirate Frame-Based Processing” for an example that uses the FIR Decimation block in this mode.

### Sample-Based Processing

When you set the **Input processing** parameter to Elements as channels (sample based), the block treats a  $P$ -by- $Q$  matrix input as  $P*Q$  independent channels, and decimates each channel over time. The output sample period ( $T_{so}$ ) is  $M$  times longer than the input sample period ( $T_{so} = M*T_{si}$ ), and the input and output sizes are identical.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Elements as channels (sample based). **Rate options** is automatically set to Allow multirate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Fixed-size input signal    | Yes                           | Always                                   | $P$ -by- $Q$   | $P$ -by- $Q$   |
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

### Latency

When you use the FIR Decimation block in the sample-based processing mode, the block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first filtered input sample (received at time  $t = 0$ ) as the first output sample. That first output sample is then followed by filtered input samples  $M+1$ ,  $2M+1$ , and so on.

When you use the FIR Decimation block in the frame-based processing mode with a frame size greater than one, the block may exhibit *one-frame latency*. Cases of one-frame latency can occur when the input frame size is greater than one and you set the **Input processing** and **Rate options** parameters of the FIR Decimation block as follows:

- **Input processing** = Columns as channels (frame based)
- **Rate options** = Allow multirate processing

In cases of one-frame latency, you can define the value of the first  $P$  output rows by setting the **Output buffer initial conditions** parameter. The default value of the **Output buffer initial conditions** parameter is  $\emptyset$ . However, you can enter a matrix containing one value for each channel of the input, or a scalar value to be applied to all channels. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample  $P+1$ . That sample is then followed by filtered input samples  $M+1$ ,  $2M+1$ , and so on.

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see Polyphase Subfilters on page 2-606.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\ & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)}) \end{aligned}$$

$M$  is the number of polyphase components, and its value equals the decimation factor that you specify.

You can write this equation as:

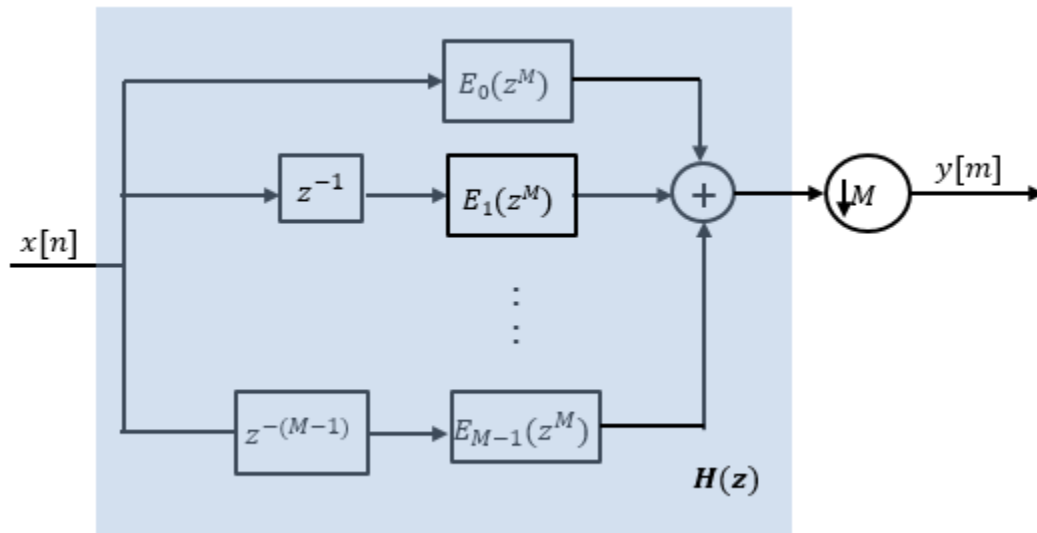

$$H(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M)$ ,  $E_1(z^M)$ , ...,  $E_{M-1}(z^M)$  are the polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

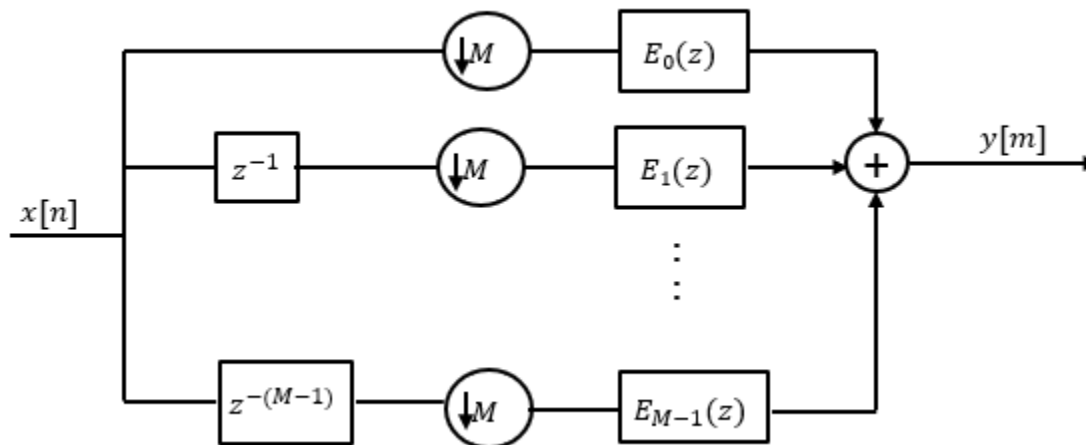

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches  $M-1$ ,  $M-2$ , and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch comes to the branch 0, the decimator outputs  $y[m]$ . The decimator effectively outputs one sample for every  $M$  samples it receives. Hence the sample rate at the output of the FIR decimation filter is  $f_s/M$ .

## Version History

Introduced before R2006a

### R2022b: Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, the block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

For more details, see “Frame-Based Processing” on page 2-607 and “Sample-Based Processing” on page 2-608.

### R2023a: Generate SIMD code for FIR Decimation block on all Intel platforms

In R2023a, if you have Embedded Coder, you can generate SIMD code for the FIR Decimation block on all Intel platforms by using the model configuration parameter **Leverage target hardware instruction set extensions**. Previously, you had to use a code replacement library to generate SIMD code. For more details, see “Code Generation” on page 2-612.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

If you have an Embedded Coder® license, you can generate SIMD code for the FIR Decimation block.

### Generate SIMD code using Intel AVX2 technology

The FIR Decimation block supports SIMD code generation using Intel AVX2 technology through a code replacement library under these conditions:

- **Filter structure** is set to `Direct` form.
- **Input processing** is set to `Columns as channels (frame based)`.
- **Rate options** is set to `Enforce single-rate processing`.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

For more information, see “SIMD Code Generation”.

### Generate SIMD code on all Intel® platforms

You can generate SIMD code for the FIR Decimation block on all Intel platforms by using the model configuration parameter **Leverage target hardware instruction set extensions**. Previously, you had to use a code replacement library to generate SIMD code.

You can generate SIMD code using the **Leverage target hardware instruction set extensions** parameter under these conditions:

- You set **Filter structure** to `Direct` form for the FIR Decimation block
- You set **Input processing** to `Columns as channels (frame based)`
- Input signal is real-valued with real filter coefficients
- Data type of the input signal is `single` or `double`

In addition, configure your model appropriately. In the **Modeling** tab of the Simulink model window, click **Model Settings** and configure these parameters under **Code Generation**.

- In the **Optimization** pane:
  - Provide a specific instruction set in the **Leverage target hardware instruction set extensions** parameter.

- Select the **Optimize reductions** parameter.
- Under **Optimization levels**, set **Level** to Maximum and **Priority** to Maximize execution speed.
- In the **Interface** pane, under **Software environment**, clear **non-finite numbers**.

For computationally intensive operations on supported blocks, SIMD intrinsics can significantly improve the performance of the generated code on Intel platforms. For more details, see “Optimize Code for Reduction Operations by Using SIMD” (Simulink Coder).

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For a FIR decimation filter with hardware-friendly control signals and simulation of HDL latency in Simulink, or for complex data with complex coefficients, use the FIR Decimator block instead of this block.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters**, **Filter object**, or **Auto**. Programmable coefficients are not supported.

### Frame-Based Input Support

HDL Coder supports the use of vector inputs to FIR Decimation blocks, where each element of the vector represents a sample in time. You can use an input vector of up to 512 samples. The frame-based implementation supports fixed-point input and output data types, and uses full-precision internal data types. The output is a column vector of reduced size, corresponding to your decimation factor. You can use real input signals with real coefficients, complex input signals with real coefficients, or real input signals with complex coefficients.

- 1 Connect a column vector signal to the FIR Decimation block input port.
- 2 Specify **Input processing** as Columns as channels (frame based).
- 3 Set **Rate options** to Enforce single-rate processing.
- 4 Right-click the block and open **HDL Code > HDL Block Properties**. Set the **Architecture** to Frame Based. The block implements a parallel HDL architecture. See “Frame-Based Architecture” (HDL Coder).

### Block Optimizations

To reduce area or increase speed, the FIR Decimator block supports block-level optimizations.

Right-click on the block or the subsystem to open the corresponding **HDL Properties** dialog box and set optimization properties.

|                        |   |
|------------------------|---|
| Serial Architectures   | <p>To use block-level optimizations to reduce hardware resources, set <b>Architecture</b> to Fully Serial or Partly Serial. See “HDL Filter Architectures” (HDL Coder).</p> <p>When you specify <b>SerialPartition</b> for a FIR Decimator block, set <b>Filter structure</b> to Direct form. The Direct form transposed structure is not supported with serial architectures. Accumulator reuse is not supported for FIR Decimation filters.</p>   |
| Distributed Arithmetic | <p>To minimize multipliers by replacing them with LUTs and shift registers, use a distributed arithmetic (DA) filter implementation. See “Distributed Arithmetic for HDL Filters” (HDL Coder).</p> <p>When you select the Distributed Arithmetic (DA) architecture and use the <b>DALUTPartition</b> and <b>DARadix</b> distributed arithmetic properties, set <b>Filter structure</b> to Direct form. The Direct form transposed structure is not supported with distributed arithmetic.</p> |
| Pipelining             | <p>To improve clock speed, use <b>AddPipelineRegisters</b> to use a pipelined adder tree rather than the default linear adder. This option is supported for Direct form architecture. You can also specify the number of pipeline stages before and after the multipliers. See “HDL Filter Architectures” (HDL Coder).</p>  |

#### HDL Filter Properties

|                                 |   |
|---------------------------------|---|
| <b>AddPipelineRegisters</b>     | Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder).  |
| <b>CoeffMultipliers</b>         | Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set <b>CoeffMultipliers</b> to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also CoeffMultipliers (HDL Coder). |
| <b>DALUTPartition</b>           | Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set <b>DALUTPartition</b> to a scalar value equal to the filter length to generate DA code without LUT partitions. See also DALUTPartition (HDL Coder).   |
| <b>DARadix</b>                  | Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 ( $2^3$ ) generates a DA implementation that computes three sums at a time. The default value is $2^1$ , which generates a fully serial DA implementation. See also DARadix (HDL Coder).   |
| <b>MultiplierInputPipeline</b>  | Specify the number of pipeline stages to add at filter multiplier inputs. See also MultiplierInputPipeline (HDL Coder).   |
| <b>MultiplierOutputPipeline</b> | Specify the number of pipeline stages to add at filter multiplier outputs. See also MultiplierOutputPipeline (HDL Coder).   |
| <b>SerialPartition</b>          | Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also SerialPartition (HDL Coder).  |

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

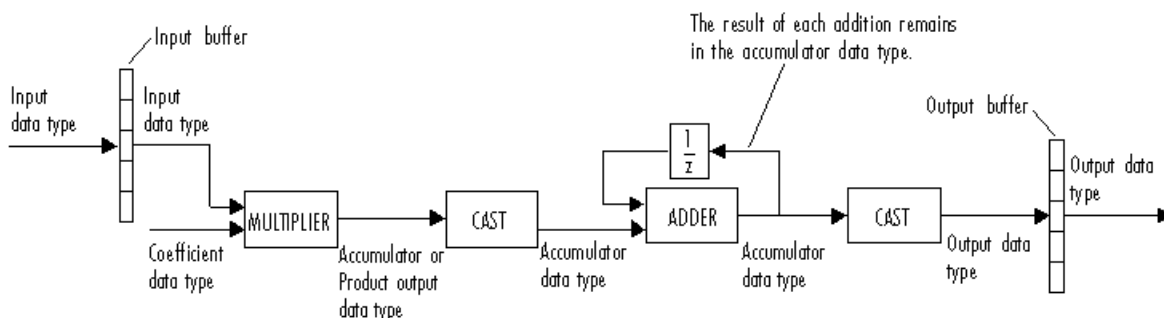

### Restrictions

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- When you select **Dialog parameters**, the following fixed-point options are not supported for HDL code generation:
  - Slope and Bias scaling
- **CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.
- Programmable coefficients are not supported.
- Frame-based input filters are not supported for:
  - Resettable and enabled subsystems
  - Complex input signals with complex coefficients. You can use either complex input signals and real coefficients, or complex coefficients and real input signals.
  - Sharing and streaming optimizations

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the FIR Decimation block for fixed-point signals.

This diagram shows that data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types”.

---

**Note** When the block input is fixed point, all internal data types are signed fixed-point values.

# FIR Interpolation

Perform polyphase FIR interpolation

**Libraries:**

DSP System Toolbox / Filtering / Multirate Filters  
 DSP System Toolbox HDL Support / Filtering

## Description

The FIR Interpolation block performs an efficient polyphase interpolation using an integer upsampling factor  $L$  along the first dimension.

Conceptually, the FIR interpolator (as shown in the schematic) consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. To design an FIR anti-imaging filter, use the `designMultirateFIR` function. The upsampler upsamples each channel of the input to a higher rate by inserting  $L-1$  zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is  $L$  times the original sample rate.

However, the actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-626.

You can use the FIR Interpolation block inside triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Under specific conditions, this block also supports SIMD code generation. For more details, see “Code Generation” on page 2-629.

## Ports

### Input

**In** — Data input  
 vector | matrix

Specify the data input as a vector or a matrix.

When you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

This port is unnamed until you set **Coefficient source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

**Num** — Numerator coefficients  
vector

Specify the numerator coefficients of the FIR filter as a vector.

The transfer function  $H(z)$  of the FIR filter is given by:

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the interpolation factor. To design such a filter, use the `designMultirateFIR` function.

Coefficient values are tunable. That is, their values can change during simulation while their properties such as size, data type, and complexity cannot change.

The data type of the **Num** input must match the data type of the **In** input.

### Dependencies

The **Num** input port appears when you set **Coefficient source** as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

### Output

**Out** — Interpolator output  
vector | matrix

Output of the FIR Interpolator block, returned as a vector or a matrix.

When **Rate options** is set to:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of  $L$ .
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is  $L$  times faster than the input sample rate.

When the input is a variable-size signal, the output is also a variable-size signal.

This port is unnamed until you set **Coefficient source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

## Parameters

### Coefficient source

**Coefficient source** — FIR filter coefficient source

**Auto** (default) | **Dialog parameters** | **Input port** | **Filter object**

Specify the FIR filter coefficient source as one of the following:

- **Dialog parameters** -- Specify the filter coefficients through the **FIR filter coefficients** parameter in the block dialog box.
- **Input port** -- Specify the filter coefficients through the **Num** input port.
- **Filter object** -- Specify the filter using a `dsp.FIRInterpolator` System object.
- **Auto** -- When you select **Auto**, the block designs an FIR interpolator using the interpolation factor you specify in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [2].

### Main Tab

**FIR filter coefficients** — Lowpass FIR filter coefficients

`designMultirateFIR(3,1)` (default) | vector

Specify the numerator coefficients of the FIR filter transfer function  $H(z)$ .

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the interpolation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

### Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Interpolation factor** — Interpolation factor

3 (default) | positive scalar

Specify the integer factor  $L$ . The block increases the sample rate of the input sequence by this factor.

### Dependencies

This parameter appears only when you set the **Coefficient source** to **Dialog parameters**, **Input port**, or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Filter object** — Filter object  
`dsp.FIRInterpolator`

Specify the name of the multirate filter object that you want the block to implement. You must specify the filter as a `dsp.FIRInterpolator` System object.

You can define the System object directly in the block dialog box. Alternatively, you can define the object in a MATLAB workspace variable and specify the variable in the block dialog box.

For information on creating System objects, see “Define Basic System Objects”.

### Dependencies

This parameter appears only when you set the **Coefficient source** to **Filter object**.

**Input processing** — Method to process input signals  
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

**Rate options** — Method by which block interpolates input  
`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method by which the block should interpolate the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate, and interpolates the signal by increasing the output frame size by a factor of  $L$ . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block interpolates the signal such that the output sample rate is  $L$  times faster than the input sample rate.

**Output buffer initial conditions** — Initial conditions  
`0` (default) | `scalar` | `matrix`

When you set the **Rate options** parameter to `Allow multirate processing` and run your models in Simulink `MultiTasking` mode, the block exhibits latency. The amount of latency for multirate, multitasking operation depends on how you set the **Input processing** parameter.

| Input processing                    | Latency                               |
|-------------------------------------|---------------------------------------|
| Elements as channels (sample based) | $L$ samples                           |
| Columns as channels (frame based)   | $L$ frames ( $K_i$ samples per frame) |

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition that the block applies to all channels. The block divides the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

Output buffer initial conditions are stored in the output data type and scaling.

See “Latency” on page 2-626 for more information about latency in the FIR Interpolation block.

### Dependencies

This parameter appears only when you configure the block to perform multirate processing by setting **Rate options** to Allow multirate processing.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**View Filter Response** — View filter response  
button

Click on this button to open the Filter Visualization Tool (fvtool) and display the filter response of the filter defined in the block dialog box.

### Data Types Tab

**Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The default is Floor. The filter coefficients do not obey this parameter and always round to Nearest.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in the full-precision mode.

---

**Saturate on integer overflow** — Saturate on integer overflow  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit`: `Inherit via internal rule`.
- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.

With these data type settings, the block operates in the full-precision mode.

---

### **Coefficients Data Type** — Coefficients data type

`Inherit`: Same word length as input (default) | `fixdt(1,16)` | `fixdt(1,16,0)`

Specify the coefficients data type. See “Fixed Point” on page 2-632 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block.

You can set this parameter to one of the following:

- `Inherit`: Same word length as input
- `fixdt(1,16,0)` or `fixdt(1,16)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### **Dependencies**

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Filter` object, or `Auto`.

When **Coefficient source** is set to `Filter` object, **Coefficients** parameter is automatically set to `Same word length as input`.

### **Coefficients Minimum** — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

### **Dependencies**

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

### **Coefficients Maximum** — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

### Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters or `Auto`.

#### **Product output Data Type** — Product output data type

Inherit: `Inherit via internal rule (default)` | `Inherit: Same as input` | `fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-632 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block.

You can set this parameter to one of the following:

- `Inherit: Inherit via internal rule`  
For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Product output** parameter is automatically set to `Full` precision.

#### **Accumulator Data Type** — Accumulator data type

Inherit: `Inherit via internal rule (default)` | `Inherit: Same as input` | `Inherit: Same as product output` | `fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-632 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to one of the following:

- `Inherit: Inherit via internal rule`.  
For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input`
- `Inherit: Same as product output`
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Accumulator** parameter is automatically set to `Full` precision.

### Output Data Type — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | `fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-632 for illustrations depicting the use of the output data type in this block.

You can set it to one of the following:

- Inherit: Same as accumulator
- Inherit: Same as input
- Inherit: Same as product output
- `fixdt(1,16,0)` -- Specify a data type object.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Dependencies

When **Coefficient source** is set to `Filter` object, **Output** parameter is automatically set to `Same as accumulator`.

### Output Minimum — Minimum value of block output

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Dependencies

This parameter appears only when you set **Coefficient source** to `Dialog` parameters, `Input port`, or `Auto`.

### Output Maximum — Maximum value of block output

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

## Dependencies

This parameter appears only when you set **Coefficient source** to Dialog parameters, Input port, or Auto.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based), the block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To interpolate the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame size of the output ( $K_o$ ) is  $L$  times larger than that of the input ( $K_o = K_i * L$ ).

For an example of single-rate FIR Interpolation, see “FIR Interpolation Using Single-Rate Processing”.

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the FIR Interpolation block are the same size. However, the sample rate of the output is  $L$  times faster than that of the input. In this mode, the block treats a  $K_i$ -by- $N$  matrix input as  $N$  independent channels. The block interpolates each column of the input over time by keeping the frame size constant ( $K_i = K_o$ ), while making the output frame period ( $T_{fo}$ )  $L$  times shorter than the input frame period ( $T_{fo} = T_{fi}/L$ ).

See “FIR Interpolation Using Multirate Frame-Based Processing” for an example that uses the FIR Interpolation block in this mode.

## Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats a  $P$ -by- $Q$  matrix input as  $P*Q$  independent channels, and interpolates each channel over time. The output sample period ( $T_{so}$ ) is  $L$  times shorter than the input sample period ( $T_{so} = T_{si}/L$ ), while the input and output sizes remain identical.

## Latency

When you run your models in the Simulink `SingleTasking` mode or set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the FIR Interpolation block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first filtered input sample (received at time  $t=0$ ) as the first output sample. That first output sample is then followed by  $L-1$  interpolated values, the second filtered input sample, and so on.

The only time the FIR Interpolation block exhibits latency is when you set the **Rate options** parameter set to `Allow multirate processing` and run your models in the Simulink `MultiTasking` mode. The amount of latency for a multirate, multitasking operation depends on how you set the **Input processing** parameter.

| Input processing                    | Latency                               |
|-------------------------------------|---------------------------------------|
| Elements as channels (sample based) | $L$ samples                           |
| Columns as channels (frame based)   | $L$ frames ( $K_i$ samples per frame) |

When the block exhibits latency, the default initial condition is zero. Alternatively, you can use the **Output buffer initial conditions** parameter to specify a matrix of initial conditions containing one value for each channel or a scalar initial condition that the block applies to all channels. The block scales the **Output buffer initial conditions** by the **Interpolation factor** and outputs the scaled initial conditions until the first filtered input sample becomes available.

When the block is in the sample-based processing mode, the block outputs the scaled initial conditions at the start of each channel, followed immediately by the first filtered input sample, then  $L-1$  interpolated values, and so on.

When the block is in the frame-based processing mode and using the default initial condition of zero, the first  $K_i*L$  output rows contain zeros, where  $K_i$  is the input frame size. The first filtered input sample (first filtered row of the input matrix) appears in the output as sample  $K_i*L+1$ . That value is then followed by  $L-1$  interpolated values, the second filtered input sample, and so on.

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Algorithms

The FIR interpolation filter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = (b_0 + b_L z^{-L} + b_{2L} z^{-2L} + \dots + b_{N-L+1} z^{-(N-L+1)}) + z^{-1}(b_1 + b_{L+1} z^{-L} + b_{2L+1} z^{-2L} + \dots + b_{N-L+2} z^{-(N-L+1)}) + \dots + z^{-(L-1)}(b_{L-1} + b_{2L-1} z^{-L} + b_{3L-1} z^{-2L} + \dots + b_N z^{-(N-L+1)})$$

$L$  is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

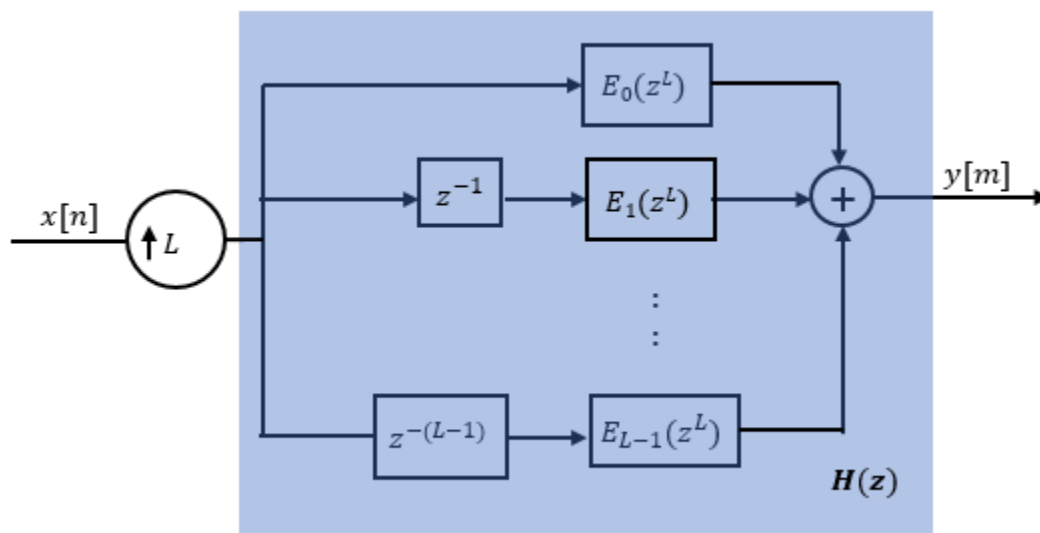

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$  are polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter  $H(z)$ .

**Conceptual Operation of FIR Interpolator**

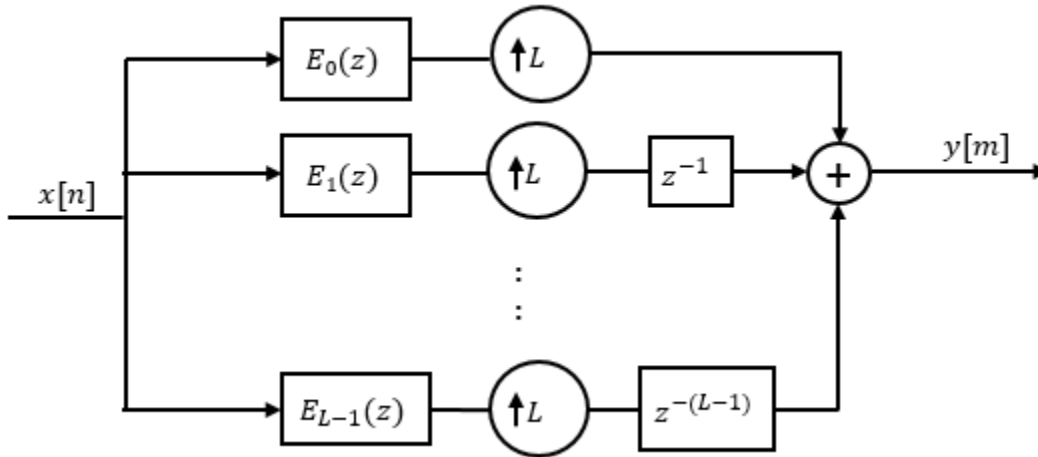

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving one sample from each branch. The interpolator effectively outputs  $L$  samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is  $Lfs$ .

## Version History

Introduced before R2006a

**R2023a: Generate SIMD code for FIR Interpolation block on all Intel platforms**

In R2023a, if you have Embedded Coder license, you can generate SIMD code for the FIR Interpolation block on all Intel platforms by using the model configuration parameter **Leverage target hardware instruction set extensions**. Previously, you had to use a code replacement library to generate SIMD code. For more details, see “Code Generation” on page 2-629.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

If you have an Embedded Coder license, you can generate SIMD code for the FIR Interpolation block.

### Generate SIMD code using Intel AVX2 technology

The FIR Interpolation block supports SIMD code generation using Intel AVX2 technology through a code replacement library under these conditions:

- **Input processing** is set to `Columns as channels (frame based)`.
- **Rate options** is set to `Enforce single-rate processing`.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

For more information, see “SIMD Code Generation”.

### Generate SIMD code on all Intel platforms

You can generate SIMD code for the FIR Interpolation block on all Intel platforms by using the model configuration parameter **Leverage target hardware instruction set extensions**. Previously, you had to use a code replacement library to generate SIMD code.

You can generate SIMD code using the **Leverage target hardware instruction set extensions** parameter under these conditions:

- You set **Input processing** to `Columns as channels (frame based)`
- Input signal is real-valued with real filter coefficients
- Data type of the input signal is `single` or `double`

In addition, configure your model appropriately. In the **Modeling** tab of the Simulink model window, click **Model Settings** and configure these parameters under **Code Generation**.

- In the **Optimization** pane:
  - Provide a specific instruction set in the **Leverage target hardware instruction set extensions** parameter.
  - Select the **Optimize reductions** parameter.
  - Under **Optimization levels**, set **Level** to Maximum and **Priority** to Maximize execution speed.
- In the **Interface** pane, under **Software environment**, clear **non-finite numbers**.

For computationally intensive operations on supported blocks, SIMD intrinsics can significantly improve the performance of the generated code on Intel platforms. For more details, see “Optimize Code for Reduction Operations by Using SIMD” (Simulink Coder).

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For an HDL-optimized filter architecture with hardware-friendly control signals, use the FIR Interpolator block. The DSP HDL Toolbox block simulates the latency of the HDL algorithm in Simulink.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Coder supports **Coefficient source** options **Dialog parameters**, **Filter object**, or **Auto**.

### Block Optimizations

To reduce area or increase speed, the FIR Decimator block supports block-level optimizations.

Right-click on the block or the subsystem to open the corresponding **HDL Properties** dialog box and set optimization properties.

|------------------------|--|
| Serial Architectures   | When you select Fully Serial architecture, the SerialPartition property is set on the FIR Interpolation Block.   |
| Distributed Arithmetic | Distributed Arithmetic properties <b>DALUTPartition</b> and <b>DARadix</b> are supported for the Distributed Arithmetic (DA) architecture with a default FIR filter structure. structures.   |
| Pipelining             | When you use <b>AddPipelineRegisters</b> , registers are placed based on the filter structure. The pipeline register placement determines the latency.<br><br>A pipeline register is added between levels of a tree-based adder, for a latency of $\text{ceil}(\log_2(PL)) - 1$ , where PL is polyphase filter length. |

### HDL Filter Properties

|                             |  |
|-----------------------------|--|
| <b>AddPipelineRegisters</b> | Insert a pipeline register between stages of computation in a filter. See also AddPipelineRegisters (HDL Coder). |
|-----------------------------|--|

|                                 |  |
|---------------------------------|--|
| <b>CoeffMultipliers</b>         | Specify the use of canonical signed digit (CSD) optimization to decrease filter area by replacing coefficient multipliers with shift-and-add logic. When you choose a fully parallel filter implementation, you can set <b>CoeffMultipliers</b> to <code>csd</code> or <code>factored-csd</code> . The default is <code>multipliers</code> , which retains multipliers in the HDL. See also <code>CoeffMultipliers</code> (HDL Coder). |
| <b>DALUTPartition</b>           | Specify distributed arithmetic partial-product LUT partitions as a vector of the sizes of each partition. The sum of all vector elements must be equal to the filter length. The maximum size for a partition is 12 taps. Set <b>DALUTPartition</b> to a scalar value equal to the filter length to generate DA code without LUT partitions. See also <code>DALUTPartition</code> (HDL Coder).   |
| <b>DARadix</b>                  | Specify how many distributed arithmetic bit sums are computed in parallel. A DA radix of 8 ( $2^3$ ) generates a DA implementation that computes three sums at a time. The default value is $2^1$ , which generates a fully serial DA implementation. See also <code>DARadix</code> (HDL Coder).   |
| <b>MultiplierInputPipeline</b>  | Specify the number of pipeline stages to add at filter multiplier inputs. See also <code>MultiplierInputPipeline</code> (HDL Coder).   |
| <b>MultiplierOutputPipeline</b> | Specify the number of pipeline stages to add at filter multiplier outputs. See also <code>MultiplierOutputPipeline</code> (HDL Coder).   |
| <b>SerialPartition</b>          | Specify partitions for partly serial or cascade-serial filter implementations as a vector of the lengths of each partition. For a fully serial implementation, set this parameter to the length of the filter. See also <code>SerialPartition</code> (HDL Coder).  |

#### HDL Block Properties

|                                  |   |
|----------------------------------|---|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ <code>ConstrainedOutputPipeline</code> ” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “ <code>InputPipeline</code> ” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “ <code>OutputPipeline</code> ” (HDL Coder).               |

#### Restrictions

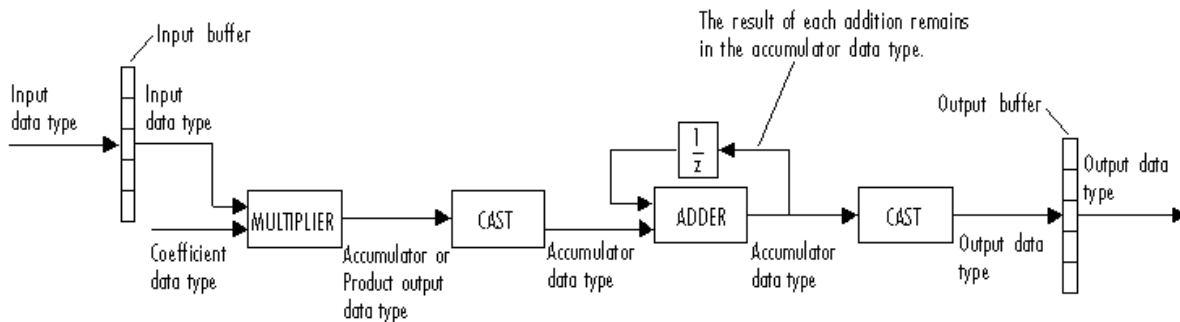

- You must set **Initial conditions** to zero. HDL code generation is not supported for nonzero initial states.
- Vector and frame inputs are not supported for HDL code generation.
- When you select **Dialog parameters**, the following fixed-point options are not supported for HDL code generation:
  - **Coefficients:** Slope and Bias scaling

- **CoeffMultipliers** options are supported only when using a fully parallel architecture. When you select a serial architecture, **CoeffMultipliers** is hidden from the HDL Block Properties dialog box.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the FIR Interpolation block for fixed-point signals.

This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed by this block, see “Multiplication Data Types”.

---

**Note** When the block input is fixed point, all internal data types are signed fixed point.

# FIR Halfband Decimator

Decimate signal using polyphase FIR halfband filter

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The FIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of 2. The block uses an FIR equiripple design or a Kaiser window design to construct the halfband filters. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. You can use the block to implement the analysis portion of a two-band filter bank to separate a signal into lowpass and highpass subbands. For more information, see “Algorithms” on page 2-639.

The block supports fixed-point operations and ARM® Cortex® code generation. For more information on ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

## Ports

### Input

**Input** — Input signal  
column vector | matrix

Specify the input signal as a column vector or a matrix of size  $P$ -by- $Q$ . If the input signal is a matrix, the block treats each column of the matrix as an independent channel. The number of rows in the input signal must be a multiple of 2.

This block supports variable-size input signals.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

### Output

**LP** — Lowpass subband of decimator output  
column vector | matrix

Lowpass subband of the decimator output, returned as a column vector or a matrix of size  $P/2$ -by- $Q$ . As the filter is a halfband filter, the downsampling factor is always 2.

When the output is fixed-point, it is signed only.

This port is unnamed until you select the **Output highpass subband** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

**HP** — Highpass subband of decimator output  
column vector | matrix

Highpass subband of the decimator output, returned as a column vector or a matrix of size  $P/2$ -by- $Q$ . As the filter is a halfband filter, the downsampling factor is always 2.

When the output is fixed-point, it is signed only.

#### Dependency

To enable this port, select the **Output highpass subband** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | fixed point

## Parameters

### Main Tab

**Filter specification** — Filter design parameters

Transition width and stopband attenuation (default) | Filter order and transition width | Filter order and stopband attenuation | Coefficients

Select the parameters that the block uses to design the FIR halfband filter.

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum-order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients — Specify the filter coefficients directly through the **Numerator** parameter.

**Filter order** — Filter order

52 (default) | even positive integer

Specify the filter order as an even positive integer.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Filter order and stopband attenuation.

**Transition width (Hz)** — Transition width

4.1e3 (default) | positive real scalar

Specify the transition width as a real positive scalar in Hz. The transition width must be less than  $1/2$  the sample rate of the input signal.

**Dependencies**

To enable this parameter, set **Filter specification** to Filter order and transition width or Transition width and stopband attenuation.

**Stopband attenuation (dB)** — Stopband attenuation

80 (default) | positive real scalar

Specify the stopband attenuation as a real positive scalar in dB.

**Dependencies**

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation or Transition width and stopband attenuation.

**Numerator** — FIR halfband filter coefficients

`firhalfband('minorder',0.407,1e-4)` (default) | row vector

Specify the FIR halfband filter coefficients directly as a row vector. The coefficients must comply with the FIR halfband impulse response format. If  $(\text{length}(\text{Numerator}) - 1)/2$  is even, where  $(\text{length}(\text{Numerator}) - 1)$  is the filter order, every other coefficient starting with the first coefficient must be 0 except the center coefficient which must be 0.5. If  $(\text{length}(\text{Numerator}) - 1)/2$  is odd, the sequence of alternating zeros with 0.5 at the center starts at the second coefficient.

**Dependencies**

To enable this parameter, set **Filter specification** to Coefficients.

**Design method** — Filter design method

Auto (default) | Equiripple | Kaiser

Specify the filter design method as one of the following:

- **Auto** -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the **Design method** parameter to **Auto**, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the block used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the block chooses in the **Auto** mode is not suitable for your application, manually specify the **Design method** as **Equiripple** or **Kaiser**.

- **Equiripple** -- The algorithm uses the equiripple method.
- **Kaiser** -- The algorithm uses the Kaiser window method.

**Dependencies**

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation, Filter order and transition width, or Transition width and stopband attenuation.

**Output highpass subband** — Output highpass subband

off (default) | on

When you select this check box, the block acts as an analysis filter bank and analyzes the input signal into highpass and lowpass subbands. When you clear this check box, the block acts as an FIR halfband decimator.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

44100 (default) | positive real scalar

Specify the sample rate of the input signal as a positive scalar in Hz.

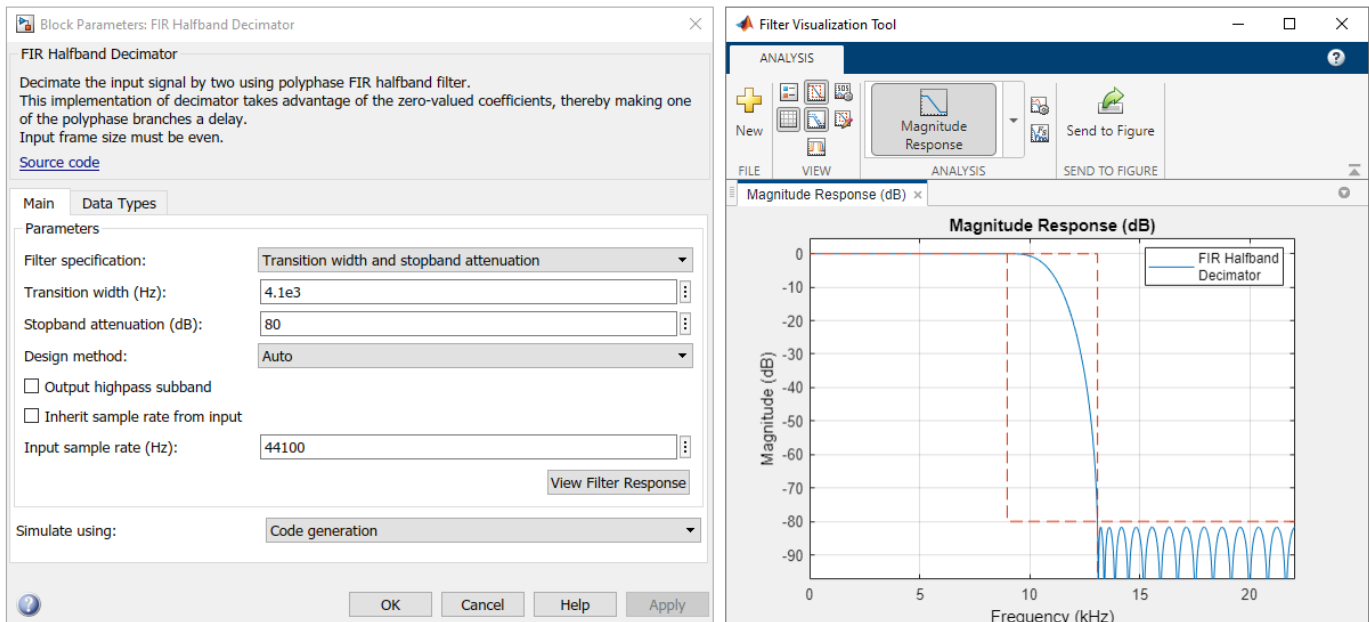

**Dependencies**

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response

button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of the FIR Halfband Decimator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Data Types Tab

**Rounding mode** — Rounding mode for output fixed-point operations

Floor (default) | Ceiling | Nearest | Round | Simplest | Zero

Select the rounding mode for output fixed-point operations. The default is Floor.

**Coefficients** — Word and fraction lengths of coefficients

fixdt(1,16) (default) | fixdt(1,16,0)

Specify the fixed-point data type of the coefficients as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16 with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object. For example, `numericType(fixdt([ ],18,15))`. Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the coefficients data type.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Halfband Filters

An ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

An ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of an ideal lowpass filter possesses some important properties that are required in a realizable approximation. The impulse response of an ideal lowpass halfband filter is:

- Equal to 0 for all even-indexed samples.
- Equal to 1/2 at  $n=0$  as shown by L'Hôpital's rule on the continuous-valued equivalent of the discrete-time impulse response

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The impulse response of an ideal highpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$

The FIR halfband decimator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the  $\ell^\infty$  norm of the error (minimax). See “Algorithms” on page 2-639 for more information.

### Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of  $\alpha$  dB, use this  $\beta$ .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order  $n$  is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where  $\Delta\omega$  is the transition width.

## Algorithms

### Filter Design Method

The FIR halfband decimator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method that optimally meets the specified filter constraints.

### Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband

Filters” on page 2-638. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

### Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 2-638, then it applies a Kaiser window defined in “Kaiser Window” on page 2-639. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

### Polyphase Implementation with Halfband Filters

The FIR halfband decimator uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response  $h(n)$  into two polyphase components results in an even polyphase component with  $z$ -transform of

$$H_0(z) = \sum_n h(2n)z^{-n},$$

and an odd polyphase component with  $z$ -transform of

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The  $z$ -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

You can represent filtering the input signal and then downsampling it by 2 using this figure.

Using the multirate noble identity for downsampling, you can move the downsampling operation before the filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to  $z^0$ . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately  $z^{-N/4}$  where  $N$  is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, the algorithm replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters.

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80,DesignMethod="Auto");
halfOrderOdd = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80,DesignMethod="Auto");
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, the FIR halfband decimator:

- Decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

## Version History

# FIR Halfband Interpolator

Interpolate signal using polyphase FIR half band filter

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The FIR Halfband Interpolator block performs interpolation of the input signal by a factor of two. The block uses an FIR equiripple design or a Kaiser window design to construct the halfband filters. The block uses an efficient polyphase implementation to filter the input. The implementation takes advantage of the zero-valued coefficients of the FIR halfband filter, making one of the polyphase branches a delay. For more information, see “Algorithms” on page 2-650. You can also use this block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

The input signal can be a real- or complex-valued column vector or a matrix. If the input signal is a matrix, the block treats each column of the matrix as an independent channel. The block supports fixed-point operations and ARM Cortex code generation. For more information on ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The block also supports SIMD code generation. For details, see “Code Generation” on page 2-654.

## Ports

### Input

#### LP — Data input

column vector | matrix

Specify the data input as a vector or a matrix. If the input signal is a matrix, the block treats each column of the matrix as an independent channel.

When you select the **Input highpass subband** parameter, this block acts as a halfband synthesis filter bank. The input at this port is then the lowpass subband output of a halfband analysis filter bank.

This port is unnamed until you select the **Input highpass subband** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

#### HP — Second input to the synthesis filter bank

column vector | matrix

Specify the second input to the synthesis filter bank as a column vector or a matrix. This signal is the highpass subband output of a halfband analysis filter bank. If the input signal is a matrix, the block treats each column of the matrix as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

### Dependency

To enable this port, select the **Input highpass subband** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

### Output

**Output** — Output of FIR halfband interpolator  
column vector | matrix

Output of the FIR halfband interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fixed point`

## Parameters

### Main Tab

**Filter specification** — Filter design parameters

Transition width and stopband attenuation (default) | Filter order and transition width | Filter order and stopband attenuation | Coefficients

Select the parameters that the block uses to design the FIR halfband filter.

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients — Specify the filter coefficients directly through the **Numerator** parameter.

**Transition width (Hz)** — Transition width in Hz

4.1e3 | positive real scalar

Specify the transition width as a real positive scalar in Hz. The transition width must be less than 1/2 the sample rate of the input signal.

### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Transition width and stopband attenuation.

**Filter order** — Filter order

52 | even positive integer

Specify the filter order as an even positive integer.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Filter order and stopband attenuation.

#### Stopband attenuation (dB) — Stopband attenuation

80 (default) | positive real scalar

Specify the stopband attenuation as a real positive scalar in dB.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation or Transition width and stopband attenuation.

#### Numerator — FIR halfband filter coefficients

`2*firhalfband("minorder",0.407,1e-4)` (default) | row vector

Specify the FIR halfband filter coefficients directly as a row vector. The coefficients must comply with the FIR halfband impulse response format. If  $(\text{length}(\text{Numerator}) - 1)/2$  is even, where  $(\text{length}(\text{Numerator}) - 1)$  is the filter order, every other coefficient starting with the first coefficient must be 0 except the center coefficient which must be 1.0. If  $(\text{length}(\text{Numerator}) - 1)/2$  is odd, the sequence of alternating zeros with 1.0 at the center starts at the second coefficient.

#### Dependencies

To enable this parameter, set **Filter specification** to Coefficients.

#### Design method — Filter design method

Auto (default) | Equiripple | Kaiser

Specify the filter design method as one of the following:

- **Auto** -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the **Design method** parameter to **Auto**, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the block used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the block chooses in the **Auto** mode is not suitable for your application, manually specify the **Design method** as **Equiripple** or **Kaiser**.

- **Equiripple** -- The algorithm uses the equiripple method.
- **Kaiser** -- The algorithm uses the Kaiser window method.

**Dependencies**

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation, Filter order and transition width, or Transition width and stopband attenuation.

**Input highpass subband** — Input highpass subband

off (default) | on

When you select this check box, the block acts as a synthesis filter bank. The block accepts two inputs to synthesize: lowpass and highpass subbands. When you clear this check box, the block acts as an IIR half band interpolator and accepts a single vector or matrix as input. By default, this check box is cleared.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input Sample Rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

44100 (default) | positive real scalar

Specify the sample rate of the input signal as a scalar in Hz.

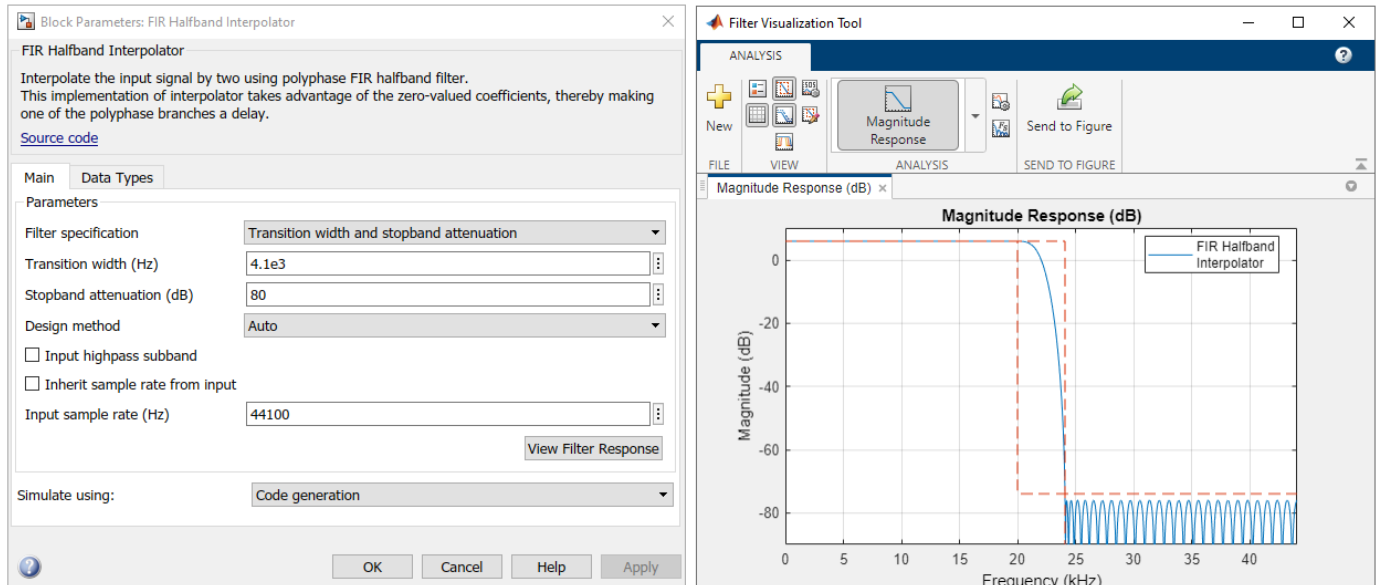

**Dependencies**

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response

button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of the FIR Halfband Interpolator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

### Data Types Tab

**Rounding mode** — Rounding mode for output fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method for the output fixed-point operations. The rounding methods are Ceiling, Convergent, Floor, Nearest, Round, Simplest, and Zero. The default is Floor.

**Coefficients** — Word and fraction lengths of coefficients

fixdt(1,16) (default) | fixdt(1,16,0)

Specify the fixed-point data type of the coefficients as one of the following:

- `fixdt(1,16)` (default) — Signed fixed-point data type of word length 16 with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length, 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the coefficients data type by using an expression that evaluates to a data type object. For example, `numericType(fixdt([ ],18,15))`. Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the coefficients data type.

## Block Characteristics

|                                 |                               |
|---------------------------------|-------------------------------|
| <b>Data Types</b>               | double   fixed point   single |
| <b>Direct Feedthrough</b>       | no                            |
| <b>Multidimensional Signals</b> | no                            |
| <b>Variable-Size Signals</b>    | yes                           |
| <b>Zero-Crossing Detection</b>  | no                            |

## More About

### Halfband Filters

An ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

An ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of an ideal lowpass filter possesses some important properties that are required in a realizable approximation. The impulse response of an ideal lowpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$  as shown by L'Hôpital's rule on the continuous-valued equivalent of the discrete-time impulse response

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The impulse response of an ideal highpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$

The FIR halfband interpolator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the  $\ell^\infty$  norm of the error (minimax). See “Algorithms” on page 2-650 for more information.

### Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of  $\alpha$  dB, use this  $\beta$ .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order  $n$  is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where  $\Delta\omega$  is the transition width.

## Algorithms

### Filter Design Method

The FIR halfband interpolator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to **Auto**. In this mode, the algorithm automatically chooses a design method that optimally meets the specified filter constraints.

### Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband

Filters” on page 2-649. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

### Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 2-649, then it applies a Kaiser window defined in “Kaiser Window” on page 2-650. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

The coefficients of the designed halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

### Polyphase Implementation with Halfband Filters

The FIR halfband interpolator uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response  $h(n)$  into two polyphase components results in an even polyphase component with  $z$ -transform of

$$H_0(z) = \sum_n h(2n)z^{-n},$$

and an odd polyphase component with  $z$ -transform of

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The  $z$ -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

You can represent the upsampling by 2 and then filtering the signal using this figure.

Using the multirate noble identity for upsampling, you can move the upsampling operation after the filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to  $z^0$ . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately  $z^{-N/4}$ , where  $N$  is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, the algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters.

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80);
halfOrderOdd = dsp.FIRHalfbandInterpolator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, the FIR halfband interpolator:

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

## Version History

Introduced in R2015b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The FIR Halfband Interpolator block supports SIMD code generation using Intel AVX2 technology when the data type of the input signal is `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

# FIR Rate Conversion

Perform polyphase FIR sample rate conversion

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

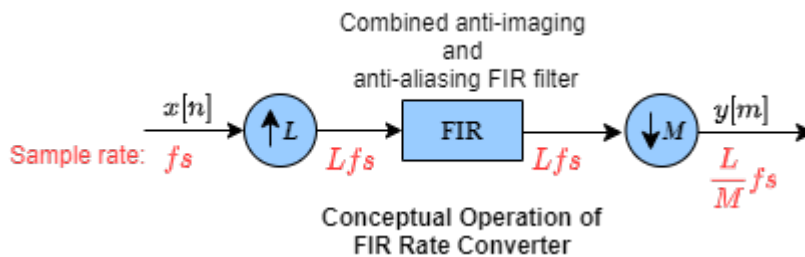

## Description

The FIR Rate Conversion block performs an efficient polyphase sample rate conversion using a rational factor  $L/M$  along the first dimension. The block treats each column of the input as a separate channel and resamples the data in each channel independently over time.

Conceptually, the rate converter combines an FIR interpolator followed by an FIR decimator. The following schematic contains an upsampler, a combined anti-imaging and anti-aliasing FIR filter, and a downsampler. To design an FIR filter which acts as a combined anti-imaging and anti-aliasing FIR filter, use the `designMultirateFIR` function.

The rate converter does the following:

- 1 Upsamples the input to a higher rate by inserting  $L-1$  zeros between input samples.
- 2 Passes the upsampled data through an FIR filter.
- 3 Downsamples the filtered data to a lower rate by discarding  $M-1$  consecutive samples following each sample that the block retains.

Note that the actual block algorithm implements a polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-667.

## Ports

### Input

**Port\_1(In1)** — Input signal  
vector | matrix

Specify the input signal as a vector or a matrix of size  $P$ -by- $Q$ . The input columns represent the  $Q$  independent channels.

The block supports variable-size input signals (frame length changes during simulation) when you set **Rate options** to `Enforce single-rate processing`. When the block accepts variable-size input

signals, they can be of arbitrary frame length, that is, the input frame length does not have to be a multiple of the decimation factor. For fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-666.

When the block input is fixed point, all internal data types are signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Output

**Port\_1(Out1)** — Rate converted signal  
vector | matrix

Rate converted signal, returned as a vector or a matrix.

When you set the **Rate options** parameter to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and resamples the signal by changing the output frame size by a factor of  $L/M$ .

The output has an upper bound size of  $\text{ceil}(LP/M)$ -by- $Q$  for an input of size  $P$ -by- $Q$ .

- **Allow multirate processing** -- The block decimates the signal such that the output signal sample rate is  $L/M$  times the input sample rate.

The output frame size is the same as the input frame size,  $F_o = (L/M) \times F_i$

All blocks connected to the output operate at  $F_o$ , and all blocks connected to the input operate at  $F_i$ .

For more details, see “Frame-Based Processing” on page 2-666.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Parameters

**Coefficient source** — Mode of operation  
`Auto` (default) | `Dialog parameters` | `Filter object`

The FIR Rate Conversion block can operate in three different modes. Select the mode in the **Coefficient source** group box.

- **Dialog parameters** — Enter information about the filter, such as FIR filter coefficients in the block dialog box.
- **Filter object** — Specify the filter using a `dsp.FIRRateConverter` System object.
- **Auto** (default) — The block determines the filter coefficients.

The settings in the FIR Rate Conversion block dialog box change based on the mode selected.

### Main Tab

**Interpolation factor** — Interpolation factor  
3 (default) | positive integer

Specify the interpolation factor,  $L$ , as a positive integer. The block upsamples the signal by this value before filtering it.

#### Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**FIR filter coefficients** — FIR filter coefficients  
`designMultirateFIR(3,2)` (default) | `vector`

Specify the FIR filter coefficients in descending powers of  $z$ . By default, the block uses the `designMultirateFIR(3,2)` function to compute the filter coefficients.

#### Dependencies

To enable this parameter, set **Coefficient source** to **Dialog parameters**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Decimation factor** — Decimation factor  
 2 (default) | `positive integer`

Specify the decimation factor,  $M$ , as a positive integer. The block downsamples the signal by this value after filtering it.

#### Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Rate options** — Enforce single-rate or allow multirate processing  
`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify whether to enforce single-rate processing or allow multirate processing.

- **Enforce single-rate processing** -- The output frame size  $P_o$  is  $L/M$  times the input frame size  $P_i$ , where  $L$  is the interpolation factor and  $M$  is the decimation factor.

$$P_o = (L/M) \times P_i$$

The output signal rate in Simulink equals the input signal rate.

$$F_o = F_i$$

- **Allow multirate processing** -- The output frame size equals the input frame size.

$$P_o = P_i$$

The output signal rate in Simulink is  $L/M$  times the input signal rate.

$$F_o = (L/M) \times F_i$$

All blocks connected to the output operate at  $F_o$ , and all blocks connected to the input operate at  $F_i$ .

### Filter object — Filter object

FRC (default) | `dsp.FIRRateConverter` System object

Specify the multirate filter object that you want the block to implement. The specified filter object must be a `dsp.FIRRateConverter` System object.

You can define the System object in the block mask or in a MATLAB workspace variable.

For information on creating System objects, see “Define Basic System Objects”.

### Dependencies

This parameter appears when **Coefficient source** is set to **Filter object**.

### Allow arbitrary frame length for fixed-size input signals — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

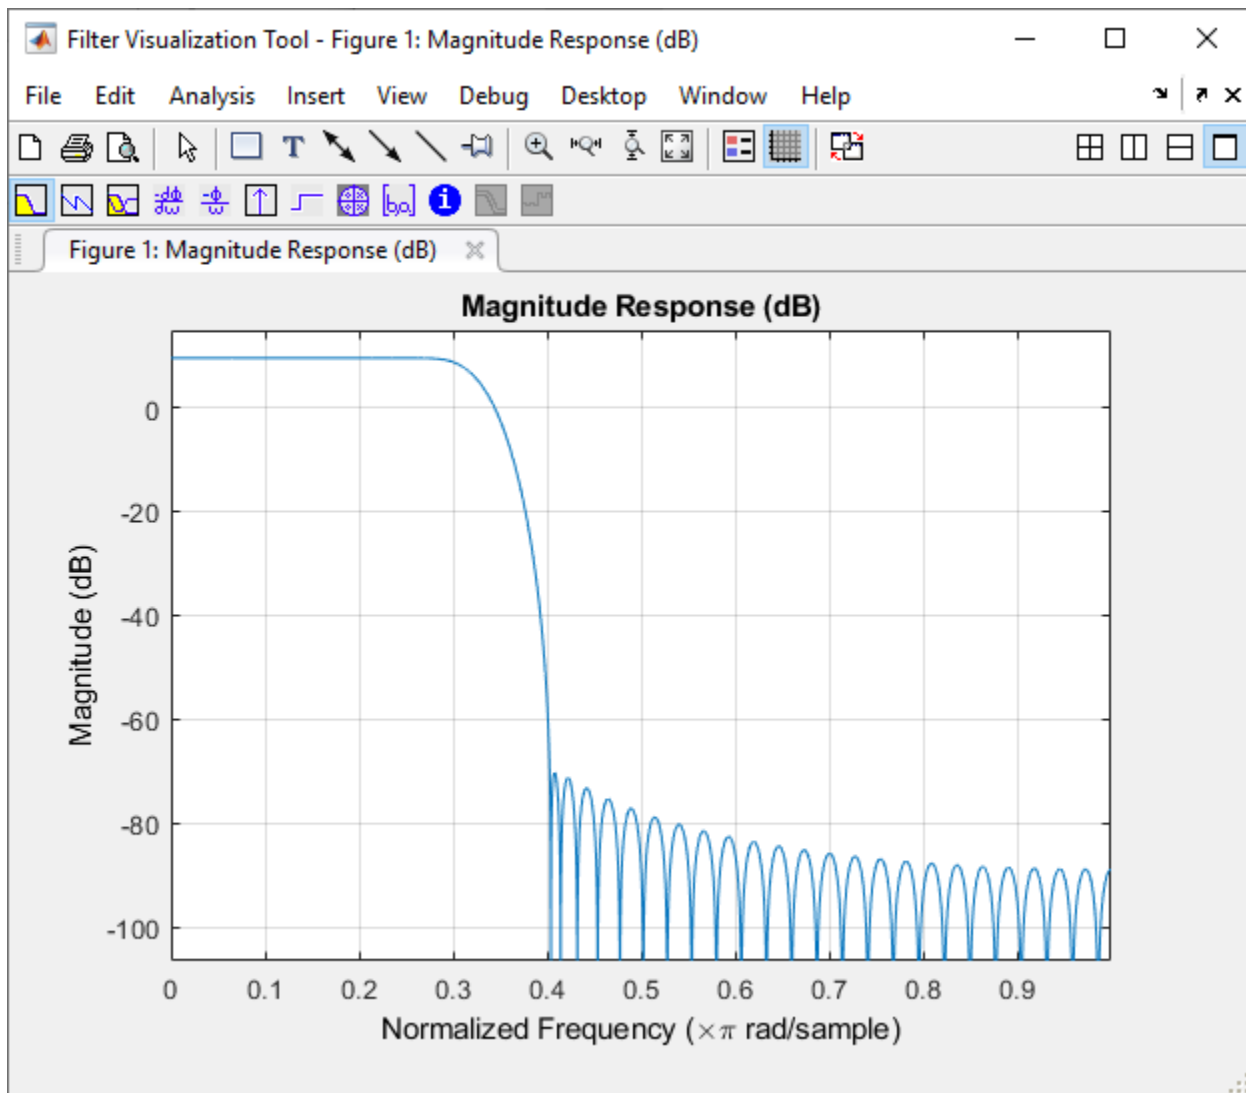

### Dependency

To enable this parameter, set **Rate options** to `Enforce single-rate processing`.

### View Filter Response — Visualize filter response

button

Select this parameter to open the Filter Visualization Tool, `fvtool`, and display the magnitude response of the FIR filter. The response is based on the parameters selected in the block dialog box. Changes made to these parameters update `fvtool`.

To update the magnitude response while `fvtool` is running, modify the block parameters and click **Apply**.

To view the magnitude response and phase response simultaneously, click the **Magnitude and Phase responses** button on the toolbar.

### Data Types Tab

When **Coefficient source** is set to **Filter object**, the fixed-point settings of the filter object specified on the **Main tab** are displayed on the **Data Types tab**. You cannot change these settings directly on the block dialog box. To change the fixed-point settings, you must edit the filter object.

For more information on System objects, see the “What Are System Objects?”.

When **Coefficient source** is set to **Auto**, the block chooses the filter coefficients automatically. For more information on the filter design algorithm that the block uses, see “Specify FIR Filter Coefficients” on page 2-665.

### Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

The filter coefficients do not obey this parameter and always round to Nearest.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.
- **Output** data type is Inherit: Same as accumulator.

With these data-type settings, the block operates in a full-precision mode.

---

#### Dependencies

To enable this parameter, set **Coefficient source** to either **Dialog parameters** or **Auto**.

**Saturate on integer overflow** — Overflow handling method  
off (default) | on

Select this parameter to saturate the result of the fixed-point operation. Clear this parameter to wrap the result of the fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data-type settings, the block operates in a full-precision mode.

---

#### Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

**Coefficients** — Coefficients data type  
Inherit: Same word length as input (default) | fixdt(1,16) | fixdt(1,16,0)

**Coefficients** specifies the data type of the filter coefficients.

- **Inherit: Same word length as input** -- The block inherits the word length of the coefficients from the fixed-point input. The fraction length is determined based on the coefficient values in order to obtain the best possible precision.
- **fixdt(1,16)** -- The coefficients data type is a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits.
- **fixdt(1,16,0)** -- The coefficients data type is a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Coefficients** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the filter coefficients data type, see “Fixed Point” on page 2-670.

### Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

**Coefficients Minimum** — Minimum value of filter coefficients

[ ] (default) | scalar

Specify the minimum value of the filter coefficients. Simulink uses this minimum value to perform automatic scaling of fixed-point data types.

**Coefficients Maximum** — Maximum value of filter coefficients

[ ] (default) | scalar

Specify the maximum value of the filter coefficients. Simulink uses this maximum value to perform automatic scaling of fixed-point data types.

**Product output** — Product output data type

Inherit: *Inherit via internal rule* (default) | Inherit: Same as input |  
fixdt(1,16,0)

**Product output** specifies the data type of the output of a product operation in the FIR Rate Conversion block.

- **Inherit: Inherit via internal rule** — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the product output data type, see “Fixed Point” on page 2-670.

### Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

#### Accumulator — Accumulator data type

Inherit: `Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixdt(1,16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the FIR Rate Conversion block. For illustrations on how this block uses the accumulator data type, see “Fixed Point” on page 2-670.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

#### Output — Output data type

Inherit: `Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | fixdt(1,16,0)`

**Output** specifies the data type of the output of the FIR Rate Conversion block.

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the output data type to be the same as the product output data type.
- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For a diagrammatic representation of how this block uses the output data type, see “Fixed Point” on page 2-670.

### Dependencies

This parameter is editable only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

**Output Minimum** — Minimum value the block can output

[ ] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value block can output

[ ] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. For more information, see “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block dialog box.

### Dependencies

This parameter appears only when **Coefficient source** is set to either **Dialog parameters** or **Auto**.

## More About

### Specify FIR Filter Coefficients

When you select the **Dialog parameters** option, you use the **FIR filter coefficients** parameter to specify the numerator coefficients of the FIR filter transfer function  $H(z)$ .

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

The coefficient vector you specify must have a length greater than the interpolation factor ( $N + 1 > L$ ). The FIR filter must be a lowpass filter with a normalized cutoff frequency no greater than  $\min(1/L, 1/M)$ . The block internally initializes all filter states to zero.

When you select the **Auto** mode, the block designs an FIR multirate filter with the decimation factor specified in **Decimation factor** and interpolation factor specified in **Interpolation factor**. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block. For more information on the filter design algorithm, see Orfanidis [1].

### Specify Resampling Rate

This section applies only to the single-rate processing mode when the **Rate options** parameter is set to **Enforce single-rate processing**.

You specify the resampling rate of the FIR Rate Conversion block using the **Decimation factor** and **Interpolation factor** parameters. For a  $P_i$ -by- $Q$  matrix input, the **Decimation factor**  $M$  and the **Interpolation factor**  $L$  must satisfy these requirements:

- $M$  and  $L$  must be relatively prime integers. That is, the ratio  $M/L$  cannot be reduced to a ratio of smaller integers.
- $\frac{M}{L} = \frac{P_i}{P_o}$ , where  $P_i$  and  $P_o$  are the integer frame sizes of the input and output, respectively.

You can satisfy the second requirement by setting the **Decimation factor**,  $M$ , to equal the input frame size  $P_i$ . When you do so, the output frame size  $P_o$  equals the **Interpolation factor**  $L$ .

By changing the frame size in this way, the block is able to hold the frame period constant ( $T_{\hat{f}} = T_{f_0}$ ) and achieve the desired conversion of the sample period, such that

$$T_{so} = \frac{M}{L} \times T_{si}$$

where  $T_{so}$  is the output sample period.

This figure shows how the FIR Rate Conversion block converts a 4-by-1 input with a sample period of  $3/4$  to a 3-by-1 output with a sample period of 1. The frame period ( $T_f$ ) of 3 remains constant.

### Frame-Based Processing

The FIR Rate Conversion block resamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block resamples the input.

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. To resample the output while maintaining the input sample rate, the block resamples the data in each column of the input such that the frame length of the output has an upper bound size of  $\text{ceil}(LP/M)$ , where  $L$  is the interpolation factor specified in the **Interpolation factor** parameter,  $P$  is the input frame length, and  $M$  is the decimation factor specified in the **Decimation factor** parameter.

In this mode, if you input a fixed-size signal (frame length does not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be a multiple of the decimation factor. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

In this mode, if you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Rate options** to Enforce single-rate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length   | Input Size   | Output Size                                      |
|----------------------------|-------------------------------|--|--------------|--|
| Fixed-size input signal    | Yes                           | When you select <b>Allow arbitrary frame length for fixed-size input signals</b> | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(LP/M)$ -by- $Q$ |
| Variable-size input signal | Yes                           | Always   | $P$ -by- $Q$ | Upper bound size of $\text{ceil}(LP/M)$ -by- $Q$ |

- When you set the **Rate options** parameter to Allow multirate processing, the input and output of the FIR Rate Conversion block are of the same size, but the sample rate of the output is  $L/M$  times that of the input. In this mode, the block treats a  $P$ -by- $Q$  matrix input as  $Q$  independent channels. The block decimates each column of the input over time by keeping the frame size constant, and making the output frame period ( $T_{fo}$ )  $M/L$  times the input frame period ( $T_{fo} = (M/L)*T_{fi}$ ).

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Rate options** to Allow multirate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Fixed-size input signal    | Yes                           | Always                                   | $P$ -by- $Q$   | $P$ -by- $Q$   |
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

## Algorithms

The FIR rate converter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter: This FIR filter is a combined anti-imaging and anti-aliasing filter.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H(z) = & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\
 & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\
 & \vdots \\
 & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_{N-L}z^{-(N-L+1)})
 \end{aligned}$$

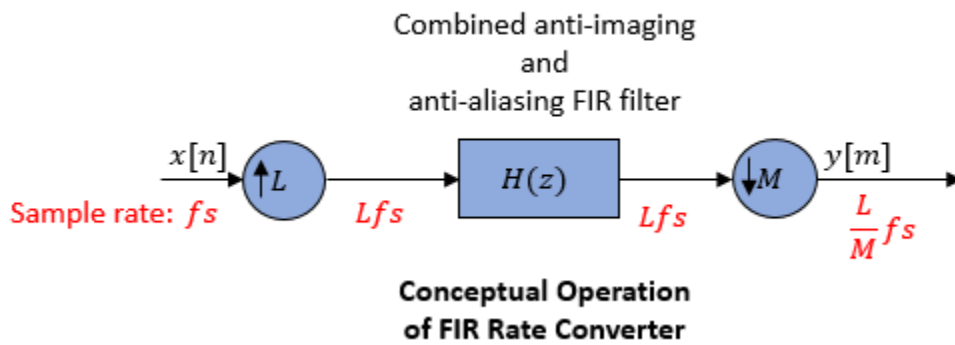

$L$  is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

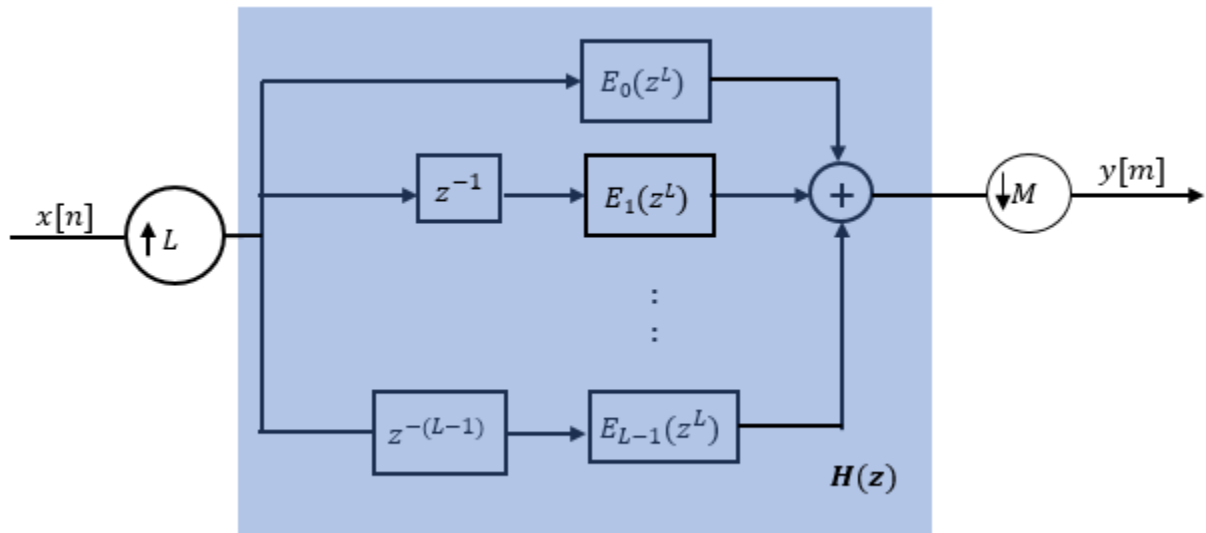

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$  are polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR rate converter contains an upsampler, followed by a combined anti-imaging, anti-aliasing FIR filter  $H(z)$ , which is followed by a downsampler.

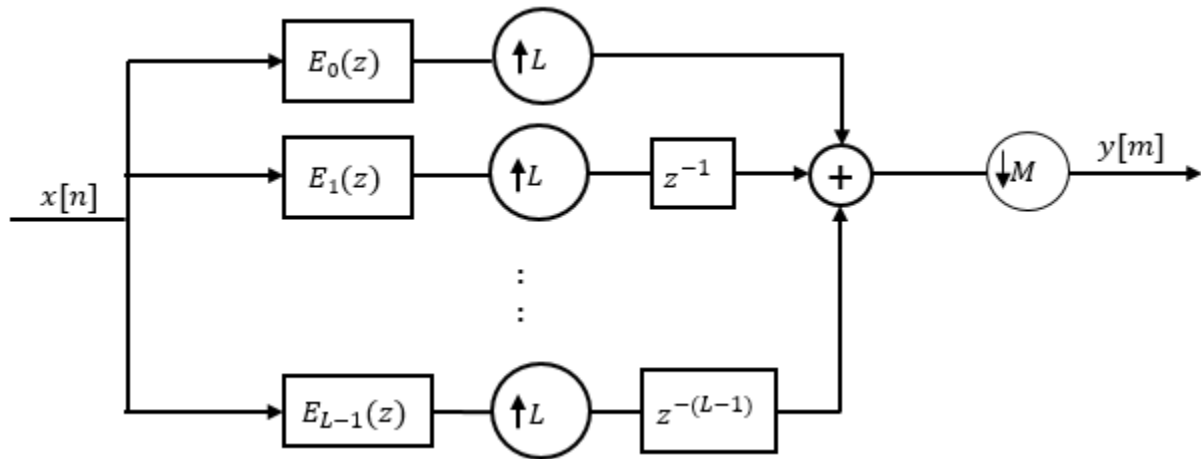

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for interpolation.

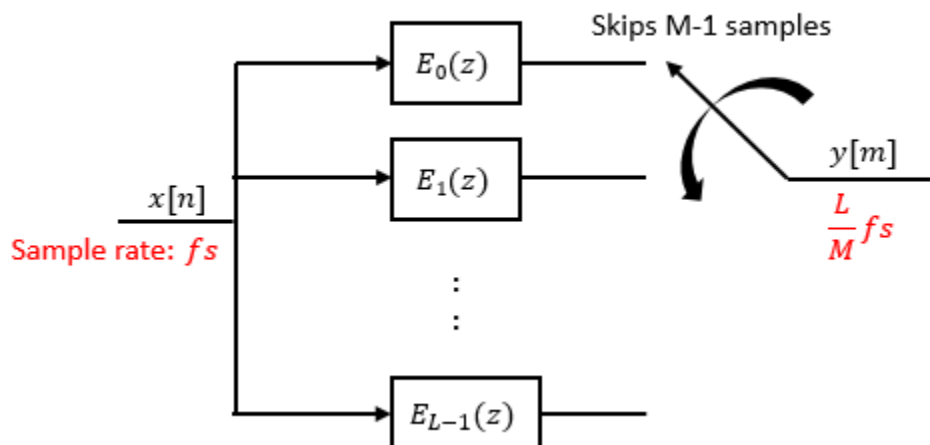

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and the adder with a commutator switch. To account for the downsampler that follows, the switch moves in steps of size  $M$ . The switch receives the first sample from branch 0 and moves in the counter clockwise direction, each time skipping  $M-1$  branches.

As an example, consider a rate converter with  $L$  set to 5 and  $M$  set to 3. The polyphase components are  $E_0(z)$ ,  $E_1(z)$ ,  $E_2(z)$ ,  $E_3(z)$ , and  $E_4(z)$ . The switch starts on the first branch 0, skips branches 1 and 2, receives the next sample from branch 3, then skips branches 4 and 0, receives the next sample from branch 2, and so on. The sequence of branches from which the switch receives the data sample is [0, 3, 1, 4, 2, 0, 3, 1, ...].

The rate converter implements the  $L/M$  conversion by first applying the interpolation factor  $L$  to the incoming data, and using the commutator switch at the end to receive only 1 in  $M$  samples, effectively accounting for the downsampling factor  $M$ . Hence, the sample rate at the output of the FIR rate converter is  $Lfs/M$ .

## Version History

Introduced before R2006a

### R2022b: Support for arbitrary input frame length

Starting in R2022b, this block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and the block allows for multirate processing
- Input signal is a fixed-size signal, the block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter
- Input signal is a variable-size signal (frame length changes during simulation)

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the decimation factor.

For more details, see “Frame-Based Processing” on page 2-666.

## Extended Capabilities

### C/C++ Code Generation

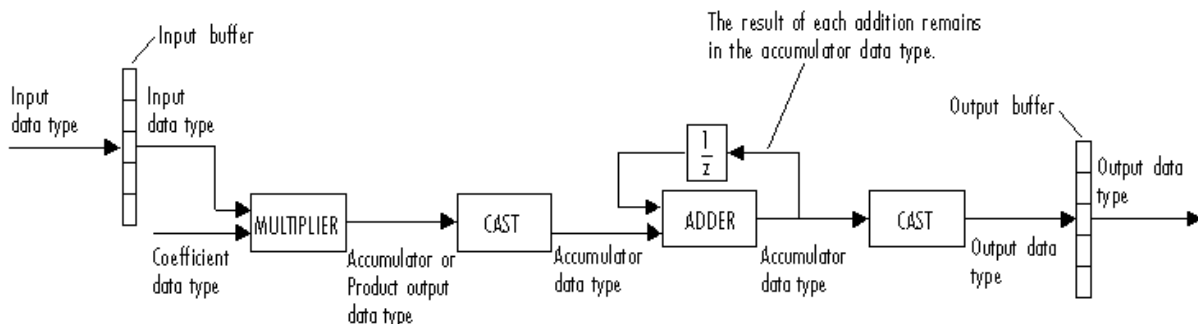

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This diagram shows the data types used within the FIR Rate Conversion block for fixed-point signals.

You can set the coefficient, product output, accumulator, and output data types in the block dialog box. The diagram shows that input data is stored in the input buffer in the same data type and scaling as the input. Filtered data resides in the output buffer in the output data type and scaling that you set in the block dialog. The block stores any initial conditions in the output buffer using the output data type and scaling that you set in the block dialog box.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on how the complex multiplication is performed in the block, see “Multiplication Data Types”.

---

**Note** When the block input is fixed point, all internal data types are signed fixed point.

# Flip

Flip input vertically or horizontally

**Libraries:**

DSP System Toolbox / Signal Management / Indexing

## Description

The Flip block vertically or horizontally reverses the  $M$ -by- $N$  input matrix,  $u$ . The block determines the dimension to flip along using the **Flip along** parameter.

This block supports Simulink virtual buses.

## Ports

### Input

**Input** — Input signal  
matrix

Input signal, specified as a matrix of size  $M$ -by- $N$ .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

### Output

**Output** — Flipped output  
matrix

Flipped output, returned as a matrix of size  $M$ -by- $N$ . The output always has the same dimensionality as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

## Parameters

**Flip along** — Specify dimension to flip along

Columns (default) | Rows

Specify the dimension along which to flip the input as **Columns** or **Rows**. When you set this parameter to **Columns**, the block flips the input vertically. When you set this parameter to **Rows**, the block flips the input horizontally.

When you set this parameter to **Columns**, the block flips the input *vertically* so the first row of the input becomes the last row of the output.

`y = flipud(u)` % Equivalent MATLAB code

When flipping the input vertically, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

When you set this parameter to **Rows**, the block flips the input *horizontally* so the first column of the input becomes the last column of the output.

```
y = fliplr(u) % Equivalent MATLAB code
```

When flipping the input horizontally, the block treats length- $N$  unoriented vector inputs as 1-by- $N$  row vectors.

## Forward Substitution

Solve  $LX = B$  for  $X$  when  $L$  is lower triangular matrix

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

### Description

The Forward Substitution block solves the linear system  $LX = B$  by simple forward substitution of variables, where:

- $L$  is the lower triangular  $M$ -by- $M$  matrix input to the **L** port.
- $B$  is the  $M$ -by- $N$  matrix input to the **B** port.
- $X$  is the  $M$ -by- $N$  output matrix and is the solution of the system of equations.

The block does not check the rank of the inputs. The block only uses the elements in the *lower triangle* of input  $L$  and ignores the upper elements. When you select **Input L is unit-lower triangular**, the block assumes the elements on the diagonal of  $L$  are 1s. This is useful when matrix  $L$  is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the  $D$  matrix.

### Ports

#### Input

**L** — Input lower triangular matrix  
 $M$ -by- $M$  matrix

Specify the input lower triangular  $M$ -by- $M$  matrix  $L$  through this port. Inputs  $L$  and  $B$  must have the same number of rows.

When the input  $L$  is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

**B** —  $B$  matrix  
 $M$ -by- $N$  matrix |  $M$ -by-1 vector

Specify the  $B$  matrix in the  $LX = B$  equation as an  $M$ -by- $N$  matrix or a  $M$ -by-1 vector.

When you specify an  $M$ -by-1 vector, the block treats the length- $M$  vector input at port **B** as an  $M$ -by-1 matrix. Inputs  $L$  and  $B$  must have the same number of rows.

When the input  $B$  is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Output

**X** — Solution of system of equations

*M*-by-*N* matrix | *M*-by-1 matrix

The block returns the output as an *M*-by-*N* matrix or an *M*-by-1 matrix. The size of *X* matrix is same as the size of the *B* matrix.

When the inputs are fixed-point, the output matrix *X* is signed only fixed-point.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

### Main Tab

**Input L is unit-lower triangular** — Diagonal elements of input matrix have a value of 1

off (default) | on

Select this check box only when all elements on the diagonal of *L* have a value of 1. When you do so, the block optimizes its behavior by skipping an unnecessary division operation.

Do not select this check box if any elements on the diagonal of *L* do not have a value of 1. When you clear the **Input L is unit-lower triangular** check box, the block always performs the division operation.

**Diagonal of complex input L is real** — Diagonal elements of complex input are real

off (default) | on

Select to optimize simulation speed when the diagonal elements of complex input *L* are real.

---

**Note** When *L* is a complex fixed-point signal, you must select either **Input L is unit-lower triangular** or **Diagonal of complex input L is real**. In these cases, the block ignores any imaginary part of the diagonal of *L*.

---

### Dependencies

This parameter is visible only when **Input L is unit-upper triangular** is not selected.

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### **Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

### **Product output** — Product output data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as first input` | `fixdt(1,16,0)`

**Product output** specifies the data type of the output of a product operation in the Backward Substitution block. For more information on the product output data type, see “Fixed Point” on page 2-678 and “Multiplication Data Types”.

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as first input` — The block specifies the product output data type to be the same as the first input data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

### **Accumulator** — Accumulator data type

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as product output` | Inherit: `Same as first input` | `fixdt(1,16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Backward Substitution block. For illustrations on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-678 section.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as first input** — The block specifies the accumulator data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output** — Output data type

**Inherit: Same as first input** (default) | **fixdt(1,16,0)**

**Output** specifies the data type of the output of the Backward Substitution block. For more information on the output data type, see the “Fixed Point” on page 2-678 section.

- **Inherit: Same as first input** — The block specifies the output data type to be the same as the first input data type.
- **fixdt(1,16,0)** — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output Minimum** — Minimum value the block can output

**[]** (default) | **scalar**

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Output Maximum** — Maximum value block can output

**[]** (default) | **scalar**

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

**off** (default) | **on**

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |

# Fourth-Order Section Filter

Implement cascade of fourth-order section filters

## Libraries:

DSP System Toolbox / Filtering / Filter Implementations

## Description

The Fourth-Order Section Filter block implements a cascade of fourth-order section filters in Simulink. You can specify the numerator and denominator coefficients of the filter in the block parameters dialog box or through input ports.

## Ports

### Input

**x** — Input signal  
vector | matrix

Input signal, specified as a vector or a matrix. The input can be a variable size signal. That is, the frame size of the signal can change during simulation but the number of channels cannot.

This port is unnamed until you set the **Coefficient source** parameter to Input ports.

Data Types: single | double

**Num** — Numerator coefficients  
 $P$ -by-5 matrix

Specify the numerator coefficients of the fourth-order section filter as a  $P$ -by-5 matrix, where  $P$  is the number of filter sections. For more details on this input port, see **Numerator coefficients of filter**.

While the simulation is running, you can change the number of sections (rows) in the numerator coefficients. You can also change the coefficient values.

### Dependencies

This port appears only when you set the **Coefficient source** parameter to Input ports.

Data Types: single | double

**Den** — Denominator coefficients  
 $P$ -by-5 matrix |  $P$ -by-4 matrix

Specify the denominator coefficients of the fourth-order section filter as a  $P$ -by-5 matrix or a  $P$ -by-4 matrix, where  $P$  is the number of filter sections. For more details on this input port, see **Denominator coefficients of filter**.

While the simulation is running, you can change the number of sections (rows) in the denominator coefficients. You can also change the coefficient values.

### Dependencies

This port appears only when you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

### Output

**y** — Filtered output  
vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input. The output signal is complex if either the input signal, numerator coefficients, or the denominator coefficients are complex.

This port is unnamed until you set the **Coefficient source** parameter to `Input ports`.

Data Types: `single` | `double`

### Parameters

**Coefficient source** — Filter coefficient source

Dialog parameters (default) | `Input ports` | `Filter object`

Specify the filter coefficient source as one of the following:

- `Dialog parameters` -- Specify the filter coefficients through the **Numerator coefficients of filter** and the **Denominator coefficients of filter** parameters in the block dialog box.
- `Input ports` -- Specify the filter coefficients through the **Num** and **Den** input ports.
- `Filter object` -- Specify the filter coefficients using a `dsp.FourthOrderSectionFilter` object.

To view the filter response, set this parameter to `Dialog parameters` or `Filter object`, and then click the **View Filter Response** button.

**Numerator coefficients of filter** — Numerator coefficients

[0.07795634 0 -0.15591268 0 0.07795634; 0.06188520 0 -0.12377039 0 0.06188520]  
(default) |  $P$ -by-5 matrix

Specify the numerator coefficients **b** of the fourth-order section filter as a  $P$ -by-5 matrix, where  $P$  is the number of filter sections.

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & b_{31} & b_{41} \\ b_{02} & b_{12} & b_{22} & b_{32} & b_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & b_{3P} & b_{4P} \end{bmatrix}$$

In the transfer function form, the fourth-order section filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **a** -- Denominator coefficients matrix. For more details on how to specify this matrix, see **Denominator coefficients of filter**.
- *k* -- Row index.

You cannot change the size of this parameter during simulation, but you can change its value.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Coefficient source** to Dialog parameters.

Data Types: single | double

**Denominator coefficients of filter** — Denominator coefficients

[1 0 1.32091343 0 0.63273879; 1 0 1.04859957 0 0.29614035] (default) | *P*-by-5 matrix | *P*-by-4 matrix

Specify the denominator coefficients **a** of the fourth-order section filter as a *P*-by-5 matrix or a *P*-by-4 matrix, where *P* is the number of filter sections.

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & a_{31} & a_{41} \\ a_{02} & a_{12} & a_{22} & a_{32} & a_{42} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & a_{3P} & a_{4P} \end{bmatrix}$$

The block algorithm assumes that the value of the leading coefficients is always 1. If the denominator is of size *P*-by-4, the block algorithm places 1s in the first column to make the denominator size *P*-by-5. If the denominator is of size *P*-by-5 and the elements in the first column do not equal 1, the algorithm ignores the values in the first column and appends them with 1s.

In the transfer function form, the fourth-order section filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + b_{3k}z^{-3} + b_{4k}z^{-4}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + a_{3k}z^{-3} + a_{4k}z^{-4}}$$

where,

- **b** -- Numerator coefficients matrix. For more details on how to specify this matrix, see **Numerator coefficients of filter**.
- *k* -- Row index.

You cannot change the size of this parameter during simulation, but you can change its value.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Coefficient source** to Dialog parameters.

Data Types: single | double

**Filter** — Filter object`dsp.FourthOrderSectionFilter` object

Specify the filter coefficients using a `dsp.FourthOrderSectionFilter` object. You can enter this object directly in the **Filter** parameter. Alternatively, you can create this object in the MATLAB workspace or model workspace and specify the filter variable in the **Filter** parameter. When you specify the filter as a variable and you simulate the model, you cannot change the complexity, data type, and size of the filter coefficients in the workspace between simulations.

**Dependencies**

To enable this parameter, set **Coefficient source** to `Filter` object.

**View Filter Response** — Visualize frequency response`gui` button

Click this button to open the Dynamic Filter Visualizer window and display the magnitude and phase response of the fourth-order section filter. The response is based on the coefficients that you specify in the block dialog box. If you set **Coefficient source** to `Input ports` and click **Apply**, you cannot view the magnitude response using this button. To view the response in the visualizer, you must specify the filter coefficients directly in the block dialog box or through the `dsp.FourthOrderSectionFilter` object.

To update the filter response while the visualizer is running, modify the coefficients in the block dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Filter Visualizer”.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Block Characteristics

| <b>Zero-Crossing Detection</b>  | no                        |

## Version History

Introduced in R2022a

### R2022b: Enhancements to Fourth-Order Section Filter block

Starting in R2022b, when you pass numerator and denominator coefficients through the input ports of the Fourth-Order Section Filter block, you can change the number of sections (rows) in the filter coefficients while the simulation is running.

You can also specify the coefficients in the block dialog box using a `dsp.FourthOrderSectionFilter` object. Set **Coefficient source** to `Filter` object and specify a `dsp.FourthOrderSectionFilter` object directly in the **Filter** parameter. Alternatively, you can create this object in the MATLAB workspace or model workspace and specify the filter variable in the **Filter** parameter.

## Extended Capabilities

Biquad Filter

## Frame Conversion

(Removed) Specify sampling mode of output signal

---

**Note** The Frame Conversion block has been removed.

---

### Library

Signal Management / Signal Attributes

dspsigattribs

### Description

The Frame Conversion block passes the input through to the output and sets the output sampling mode to the value of the **Sampling mode of output signal** parameter, which can be either **Frame-based** or **Sample-based**. The output sampling mode can also be inherited from the signal at the Ref (reference) input port, which you make visible by selecting the **Inherit output sampling mode from <Ref> input port** check box.

The Frame Conversion block does not make any changes to the input signal other than the sampling mode. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length- $M$  1-D vector and the block is in **Frame-based** mode, the output is a frame-based  $M$ -by-1 matrix — that is, a single channel.

### Parameters

#### Inherit output sampling mode from <Ref> input port

Select to enable the Ref port from which the block inherits the output sampling mode.

#### Sampling mode of output signal

Specify the sampling mode of the output signal, **Frame-based** or **Sample-based**.

### Supported Data Types

| Port | Supported Data Types   |
|------|--|

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

**HDL Architecture**

This block has one default HDL architecture.

**HDL Block Properties**

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).               |

**Complex Data Support**

This block supports code generation for complex signals.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

## Frame Status Conversion (Obsolete)

Specify frame status of output as sample based or frame based

### Library

dspobslib

### Description

---

**Note** The Frame Status Conversion block has been removed.

---

The Frame Status Conversion block passes the input through to the output, and sets the output frame status to the **Output signal** parameter, which can be either **Frame-based** or **Sample-based**. The output frame status can also be inherited from the signal at the **Ref** (reference) input port, which is made visible by selecting the **Inherit output frame status from Ref input port** check box.

When the **Output signal** parameter setting or the inherited signal's frame status differs from the input frame status, the block changes the input frame status accordingly, but does not otherwise alter the signal. In particular, the block does not rebuffer or resize 2-D inputs. Because 1-D vectors cannot be frame based, when the input is a length- $M$  1-D vector, and the **Output signal** parameter is set to **Frame-based**, the output is a frame-based  $M$ -by-1 matrix (that is, a single channel).

When the **Output signal** parameter or the inherited signal's frame status matches the input frame status, the block passes the input through to the output unaltered.

### Parameters

#### Inherit output frame status from Ref input port

When selected, enables the **Ref** input port from which the block inherits the output frame status.

#### Output signal

The output frame status, **Frame-based** or **Sample-based**.

## Supported Data Types

# From Audio Device

Read audio data from computer's audio device

## Compatibility

---

**Note** The From Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Reader block from Audio Toolbox instead.

---

## Library

Sources

dspsrcs4

## Description

The From Audio Device block reads audio data from an audio device in real time. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device from which to acquire audio. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update this list.

Use the **Number of channels** parameter to specify the number of audio channels in the signal. For example:

- Enter 2 if the audio source is two channels (stereo).
- Enter 1 if the audio source is single channel (mono).
- Enter 6 if you are working with a 5.1 speaker system.

The block's output is an  $M$ -by- $N$  matrix, where  $M$  is the number of consecutive samples and  $N$  is the number of audio channels.

Use the **Sample rate (Hz)** parameter to specify the number of samples per second in the signal. If the audio data is processed in uncompressed pulse code modulation (PCM) format, it should typically be sampled at one of the standard audio device rates: 8000, 11025, 22050, 44100, or 48000 Hz.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** parameter to specify the data type of the audio data that the device is placing in the buffer. You can choose:

- 8-bit integer
- 16-bit integer
- 24-bit integer
- 32-bit float
- Determine from output data type

If you choose **Determine from output data type**, the following table summarizes the block's behavior.

| Output Data Type   | Device Data Type      |
|--|-----------------------|
| Double-precision floating point or single-precision floating point | 32-bit floating point |
| 32-bit integer   | 24-bit integer        |
| 16-bit integer   | 16-bit integer        |
| 8-bit integer  | 8-bit integer         |

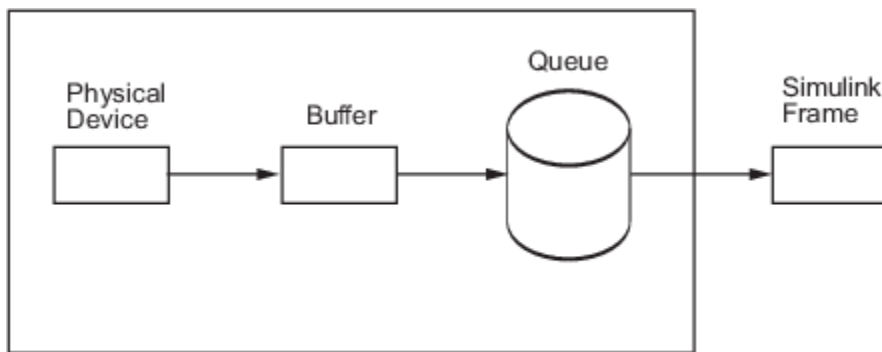

If you choose **Determine from output data type** and the device does not support a data type, the block uses the next lowest precision data type supported by the device.

Use the **Frame size (samples)** parameter to specify the number of samples in the block's output. Use the **Output data type** parameter to specify the data type of audio data output by the block.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

### Buffering

The From Audio Device block buffers the data from the audio device using the process illustrated by the following figure.

From Audio Device Block

- 1 At the start of the simulation, the audio device begins writing the input data to a buffer. This data has the data type specified by the **Device data type** parameter.
- 2 When the buffer is full, the From Audio Device block writes the contents of the buffer to the queue. Specify the size of this queue using the **Queue duration (seconds)** parameter.

- 3 As the audio device appends audio data to the bottom of the queue, the From Audio Device block pulls data from the top of the queue to fill the Simulink frame. This data has the data type specified by the **Output data type** parameter.

Select the **Automatically determine buffer size** check box to allow the block to calculate a conservative buffer size using the following equation:

$$size = 2^{\lceil \log_2 \frac{sr}{10} \rceil}$$

In this equation, *size* is the buffer size, and *sr* is the sample rate. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the buffer size in samples.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially empty, fills up. If the queue is full, the block drops the incoming data from the audio device. You can monitor dropped samples using the optional **Overrun** output port. When the simulation throughput rate is higher than the hardware throughput rate, the From Audio Device block waits for new samples to become available.

### Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. You can specify channel mapping as a vector of audio channel indices corresponding to each channel of data being read. The default value in the **Device Input Channels** parameter is 1:MAXINPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Input Channels** parameter in the dialog box.

Example: The selected input audio device contains 8 channels. You want to read data from only channels 2, 4, 6, and redirect the data as follows:

- Audio Device channel 2 to first data channel
- Audio Device channel 4 to second data channel
- Audio Device channel 6 to third data channel

Thus you would specify the **Device Input Channels** as [2 4 6].

### Troubleshooting

#### Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue fills up and the block begins to lose audio data. Select the **Output number of samples by which the queue was overrun** check box to add an output port indicating when the queue was full. Here are several ways to deal with this situation:

- *Increase the queue duration.*

The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data demand can lag behind the hardware's data supply.

- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the queue. If the buffer is too big, Simulink must wait for the device to fill the buffer before it moves the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes and convert sample-based signals to frame-based signals throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

### Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

| Platform | Command   |
|----------|---|
| Mac      | <pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh)  export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre> |
| Linux    | <pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh)  export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>   |
| Windows  | <pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>  |

### Audio Hardware API

In order to communicate with the audio hardware on a given computer, the To Audio Device and From Audio Device blocks use the open-source PortAudio library. The PortAudio library supports a range of APIs designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows®: DirectSound, WDM—KS, ASIO™
- Linux®: OSS, ALSA

- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp', 'portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp', 'portaudioHostApi', N)
```

where  $N$  is a scalar. Choose  $N$  based on the API choice above.

## Parameters

### Device

Specify the device from which to acquire audio data.

### Use default mapping between Device Input Channels and Data

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

### Number of channels

Specify the number of audio channels. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is enabled.

### Device Input Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

### Sample rate (Hz)

Specify the number of samples per second in the signal.

### Device data type

Specify the data type used by the device to acquire audio data.

### Automatically determine buffer size

Select this check box to enable the block to use a conservative buffer size.

### Buffer size (samples)

Specify the size of the buffer that the block uses to communicate with the audio device. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

**Queue duration (seconds)**

Specify the size of the queue in seconds.

**Output number of samples by which the queue was overrun**

Select this check box to output the number of samples lost to queue overrun since the last transfer of a frame from the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-695.

**Frame size (samples)**

Specify the number of samples in the block's output signal.

**Output data type**

Select the data type of the block's output.

**Supported Data Types**

| Port    | Supported Data Types  |
|---------|---|
| Output  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• 32-bit signed integers</li> <li>• 16-bit signed integers</li> <li>• 8-bit unsigned integers</li> </ul> |
| Overrun | 32-bit unsigned integer   |

# Frequency-Domain Adaptive Filter

Compute output, error, and coefficients using frequency domain FIR adaptive filter

## Libraries:

DSP System Toolbox / Filtering / Adaptive Filters

## Description

The Frequency-Domain Adaptive Filter block implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The **Filter length** and the **Block length** parameters specify the filter length and the block length values the algorithm uses. When you select the **Output filter FFT coefficients** check box, the block outputs the discrete Fourier transform of the current filter coefficients. The block offers the constrained and unconstrained versions of the algorithm with partitioned and nonpartitioned modes. For details, see “Algorithms” on page 2-705.

## Ports

### Input

**Input** — Data input  
column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The data input and the desired signal input must have the same size and data type. The length of the input vector must be divisible by the **Block length** parameter value.

The data input can be a variable-size signal as long as the frame length is a multiple of the **Block length**. You can change the number of elements in the column vector during the model simulation.

Data Types: `single` | `double`

**Desired** — Desired signal  
column vector

The frequency-domain adaptive filter adapts its filter weights to minimize the error, **Error**, and converge the input signal to match the desired signal as closely as possible.

The data input and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the **Block length** parameter value.

The desired signal can be a variable-size signal as long as the frame length is a multiple of the **Block length**. You can change the number of elements in the column vector during the model simulation.

Data Types: `single` | `double`

**Mu** — Step size input

real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is 1, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

**Dependencies**

This port appears when you select the **Specify step size from port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`**Leak** — Leakage factor input

real scalar in the range (0,1]

Leakage factor used in leaky adaptive filter, specified as a real scalar in the range (0,1]. When the value is less than 1, the block implements a leaky adaptive algorithm. When the value is 1, the block provides no leakage in the adapting method.

**Dependencies**

This port appears when you select the **Specify leakage factor from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`**Avrg** — Averaging factor input

real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed fast Fourier transform (FFT) input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

**Dependencies**

This port appears when you select the **Specify averaging factor from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`**Offset** — Offset for normalization terms

nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. Use this value to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

**Dependencies**

This port appears when you select the **Specify offset from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`**Adapt** — Enable filter coefficient updates

nonnegative real scalar

If you input a nonzero scalar value through this port, the block continuously updates its filter coefficients. If you input a zero through this port, the filter coefficients do not update, and their values remain at the current value.

**Dependencies**

This port appears when you select the **Enable adapt port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Reset** — Enable filter states reset

nonnegative real scalar

If you input a nonzero scalar value through this port, the block resets all internal states. If you input a zero through this port, the internal states are not reset.

**Dependencies**

This port appears when you select the **Enable reset port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Output****Output** — Filtered output

column vector

Filtered output, returned as a column vector. The block adapts its filter weights to converge the input signal to match the desired signal as closely as possible. The filter outputs the converged signal.

Data Types: `single` | `double`

**Error** — Difference between output and desired signal

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The block adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how **Error** is computed, see “References” on page 2-707.

Data Types: `single` | `double`

Complex Number Support: Yes

**FFTCoeffs** — Current FFT coefficients of filter

row vector

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For **Constrained FDAF** and **Unconstrained FDAF** algorithms, the length of this vector is equal to the sum of the **Filter length** value and the **Block length** value. This port initially outputs the FFT values of the **Initial time-domain coefficients** parameter. During the model simulation, this port outputs the FFT values of the current filter coefficients.

**Dependencies**

This port appears when you select the **Output filter FFT coefficients** check box.

Data Types: `single` | `double`

Complex Number Support: Yes

## Parameters

**Method** — Method to calculate filter coefficients

Constrained FDAF (default) | Partitioned constrained FDAF | Unconstrained FDAF | Partitioned unconstrained FDAF

Method used to calculate the filter coefficients, specified as::

- **Constrained FDAF** -- Imposes a gradient constraint on the filter tap weights.
- **Partitioned constrained FDAF** -- Partitions the impulse response of the filter to reduce latency.
- **Unconstrained FDAF** -- No gradient constraint is imposed on the filter tap weights.
- **Partitioned unconstrained FDAF** -- Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 2-705.

**Filter length** — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

**Block length** — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficients update, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this parameter. For details on how this data is processed by the filter, see “Algorithms” on page 2-705. The length of the input vector must be divisible by the **Block length** parameter value. The default value of the **Block length** parameter is set to the value of the **Filter length** parameter.

**Specify step size from port** — Flag to specify step size

off (default) | on

When you select this check box, the adaptation step size is input through the **Mu** port. When you clear this check box, the step size is specified on the block dialog through the **Step size** parameter.

**Step size** — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Setting the **Step size** parameter to 1 provides the fastest convergence during adaptation.

**Tunable:** Yes

### Dependencies

This parameter appears when you clear the **Specify step size from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Specify leakage factor from port** — Flag to specify leakage factor

off (default) | on

When you select this check box, the leakage factor is input through the **Leak** port. When you clear this check box, the leakage factor is specified on the block dialog through the **Leakage factor** parameter.

**LeakageFactor** — Adaptation leakage factor

1 (default) | real scalar in the range (0,1]

Leakage factor used in leaky adaptive filter, specified as a real scalar in the range (0,1]. When the value is less than 1, the block implements a leaky adaptive algorithm. When the value is 1, the block provides no leakage in the adapting method.

**Tunable:** Yes**Dependencies**

This parameter appears when you clear the **Specify leakage factor from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Specify averaging factor from port** — Flag to specify averaging factor

off (default) | on

When you select this check box, the averaging factor for signal power is input through the **Avrg** port. When you clear this check box, the averaging factor is specified on the block dialog through the **Averaging factor** parameter.

**Averaging factor** — Averaging factor for signal power

0.9 (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

**Tunable:** Yes**Dependencies**

This parameter appears when you clear the **Specify averaging factor from port** check box.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Specify offset from port** — Flag to specify offset

off (default) | on

When you select this check box, the offset for the normalization terms in the coefficient updates is input through the **Offset** port. When you clear this check box, the offset is specified on the block dialog through the **Offset** parameter.

**Offset** — Offset for normalization terms

0 (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. Use this value to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

**Tunable:** Yes

**Dependencies**

This parameter appears when you clear the **Specify offset from port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Initial FFT input signal power** — Initial FFT input signal power

1 (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar value.

If you change this value during the simulation, the change takes effect only after a reset event occurs.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Initial time-domain coefficients** — Initial time-domain coefficients of filter

0 (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the value you specify in the **Filter length** parameter. The adaptive filter block uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value during the simulation, the change takes effect only after a reset event occurs.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Enable adapt port** — Flag to enable coefficient update

off (default) | on

When you select this check box, the **Adapt** input port is enabled. If you input a nonzero scalar value through this port, the block continuously updates its filter coefficients. If you input a zero through this port, the filter coefficients do not update and their values remain at the current value.

**Enable reset port** — Flag to reset internal states

off (default) | on

When you select this check box, the **Reset** input port is enabled. If you input a nonzero scalar value through this port, the block resets all internal states. If you input a zero through this port, the internal states are not reset.

**Output filter FFT coefficients** — Flag to output the DFT of the filter coefficients  
off (default) | on

When you select this check box, the **FFTCoeffs** output port is enabled. Through this port, the block outputs the discrete Fourier transform of the current filter coefficients.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

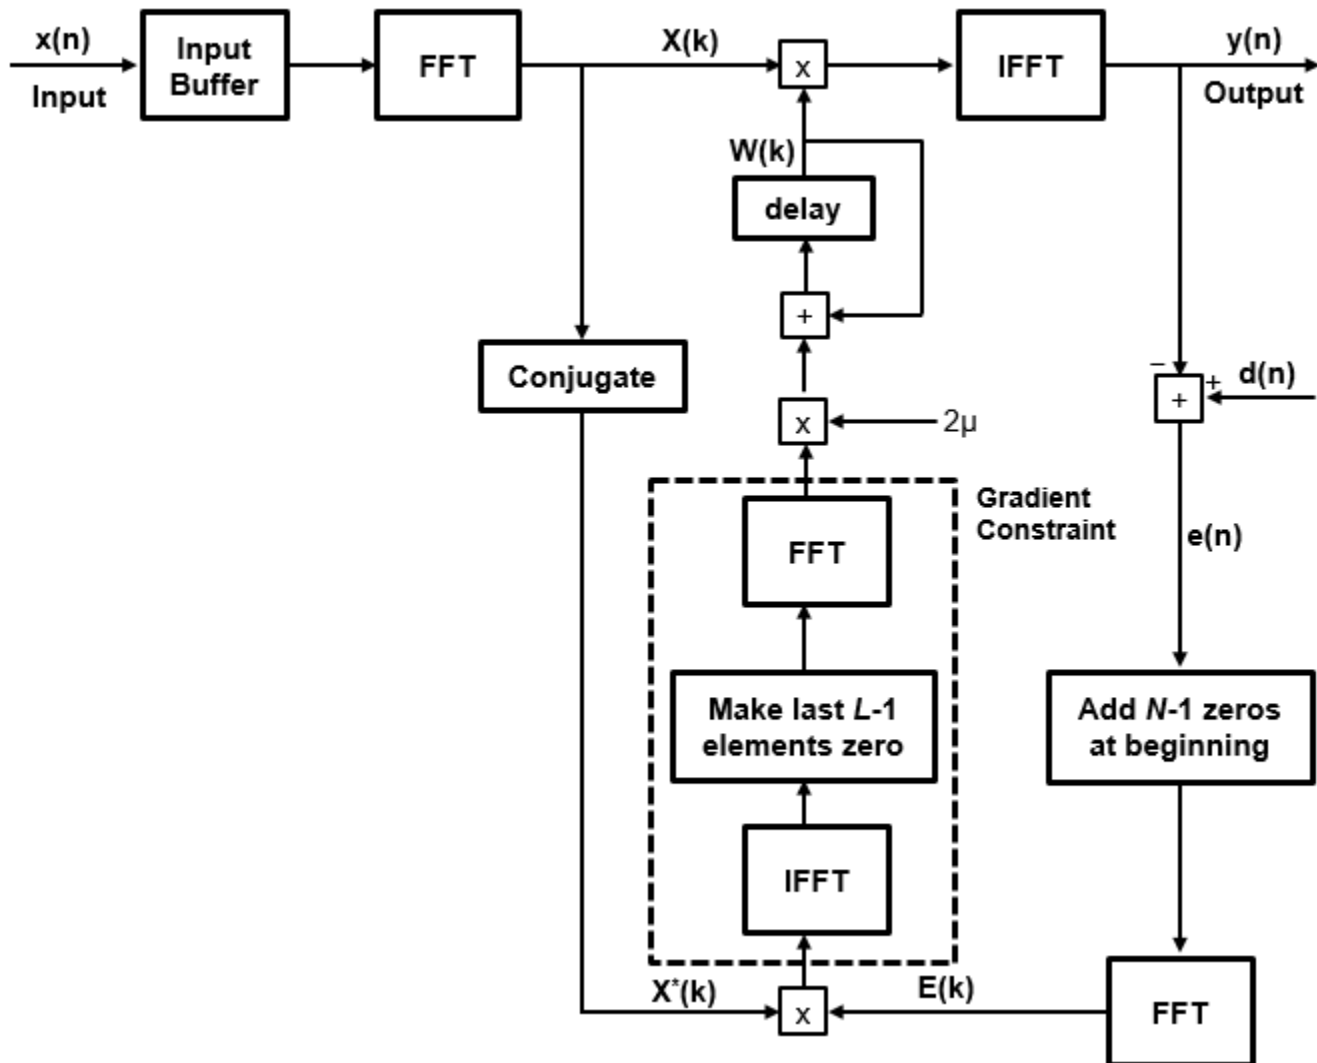

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the "Algorithms" on page 4-611 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

### Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.

where:

- $N$  -- Filter length
- $L$  -- Block length
- $\mu$  -- Step size parameter
- $x(n)$  -- Input signal
- $X(k)$  -- Transformed input signal in the frequency domain
- $d(n)$  -- Desired signal
- $e(n)$  -- Error between the desired signal and the filter output
- $E(k)$  -- Transformed error signal in the frequency domain
- $W(k)$  -- Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

## Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

## Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

# Frequency-Domain FIR Filter

Filter input signal in the frequency domain

## Libraries:

DSP System Toolbox / Filtering / Filter Implementations

## Description

The Frequency-Domain FIR Filter block implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering becomes more efficient than time-domain filtering as the impulse response grows longer. You can specify the filter coefficients directly in the frequency domain by setting **Numerator domain** to Frequency.

This block uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the Frequency-Domain FIR Filter block partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, select the **Partition numerator to reduce latency** check box. For more details on these two methods and on reducing latency through impulse response partitioning, see “Algorithms” on page 2-715.

## Ports

### Input

**x** — Data Input  
vector | matrix

Data input, specified as a vector or matrix. This block supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

**NUM** — Time domain FIR filter coefficients  
row vector

Time domain FIR filter coefficients, specified as a row vector.

### Dependencies

This port appears when you set **Numerator domain** to Time and select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**NUMFFT** — Frequency domain FIR filter coefficients  
row vector

Frequency domain FIR filter coefficients, specified as a row vector or a matrix. When you clear the **Partition numerator to reduce latency** parameter, the coefficients input through this port must be a row vector. The FFT length is equal to the length of the vector input. When you select the **Partition numerator to reduce latency** parameter, **Frequency response** must be a  $2P$ -by- $N$  matrix, where  $P$  is the partition size, and  $N$  is the number of partitions.

### Dependencies

This port appears when you set **Numerator domain** to Frequency and select the **Specify frequency response from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### Output Arguments

**y** — Filtered output  
vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

This port is unnamed until you select the **Output filter latency** parameter and click **Apply**.

Data Types: `single` | `double`

**latency** — Filter latency  
positive integer

Filter latency, returned as a scalar. This latency is inherent to overlap-add and overlap-save methods and does not include the group delay of the filter. This port appears only when you select the **Output filter latency** check box.

This port is unnamed until you select the **Output filter latency** check box and click **Apply**.

Data Types: `uint32`

## Parameters

**Frequency-domain filter method** — Filtering method in frequency domain  
`Overlap-save (default)` | `Overlap-add`

Filtering method in the frequency domain, specified as either `Overlap-save` or `Overlap-add`. For more details on these two methods, see “Algorithms” on page 2-715

**Numerator domain** — Numerator domain  
`Time (default)` | `Frequency`

Domain of the filter coefficients, specified as one of the following:

- Time -- Specify the time-domain filter coefficients in the **Filter coefficients** parameter or through the **NUM** input port.
- Frequency -- Specify the filter's frequency response in the **Frequency response** parameter or through the **NUMFFT** input port.

**Specify coefficients from input port** — Flag to specify lowpass filter coefficients  
off (default) | on

When you select this check box, the FIR filter coefficients are input through the port, **NUM**. When you clear this check box, the coefficients are specified on the block dialog through the **Filter coefficients** parameter.

To view the filter response, clear this check box, specify the coefficients on the block dialog, and click on the **View Filter Response** button.

#### Dependencies

To enable this parameter, set **Numerator domain** to Time.

**Filter coefficients** — filter coefficients  
fir1(100,0.3) (default) | row vector

FIR filter coefficients, specified as a row vector.

#### Dependencies

To enable this parameter, set **Numerator domain** to Time and clear the **Specify coefficients from input port** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64  
Complex Number Support: Yes

**Specify frequency response from input port** — Flag to specify frequency-domain filter coefficients  
off (default) | on

When you select this check box, the FIR filter coefficients in the frequency domain are input through the port, **NUMFFT**. When you clear this check box, the coefficients are specified on the block dialog through the **Frequency response** parameter.

To view the filter response, clear this check box, specify the frequency response on the block dialog, and click on the **View Filter Response** button.

#### Dependencies

To enable this parameter, set **Numerator domain** to Frequency.

**Frequency response** — Filter coefficients  
fft(fir1(100,0.3),202) (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When you clear the **Partition numerator to reduce latency** parameter, **Frequency response** must be a row vector. The FFT length is equal to the length of the **Frequency response** vector. When you select the **Partition**

**numerator to reduce latency** parameter, **Frequency response** must be a  $2P$ -by- $N$  matrix, where  $P$  is the partition size, and  $N$  is the number of partitions.

### Dependencies

To enable this parameter, set **Numerator domain** to Frequency and clear the **Specify frequency response from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`  
Complex Number Support: Yes

**Partition numerator to reduce latency** — Flag to partition the numerator to reduce latency  
off (default) | on

Flag to partition the numerator to reduce latency, specified as one of the following:

- off -- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is FFT length -  $NumLen + 1$ .  $NumLen$  is the length of the numerator vector you specify in the **Filter coefficients** parameter.
- on -- In this mode, the block partitions the numerator into segments of length specified by the **Numerator partition length** parameter. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

**Numerator partition length** — Partition length of numerator  
32 (default) | positive integer

Partition length of the numerator, specified as a positive integer less than or equal to the length of the numerator.

### Dependencies

This parameter applies only when you set **Numerator domain** to Time and select the **Partition numerator to reduce latency** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Time-domain numerator length** — Time-domain numerator length  
101 (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

### Dependencies

This parameter applies only when you set **Numerator domain** to Frequency and clear the **Partition numerator to reduce latency** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Inherit FFT length from numerator length** — Flag to inherit FFT length from the numerator length  
on (default) | off

When you select this check box, the FFT length equals twice the numerator length. When you clear this check box, you specify the FFT length through the **FFT length** parameter.

#### Dependencies

This parameter applies only when you set **Numerator domain** to Time and clear the **Partition numerator to reduce latency** parameter.

**FFT length** — FFT length  
1024 (default) | positive integer

The FFT length you specify must be greater than or equal to the length of the numerator vector you specify in the **Filter coefficients** parameter.

#### Dependencies

This parameter applies when you set **Numerator domain** to Time, clear the **Partition numerator to reduce latency** and the **Inherit FFT length from numerator length** parameters.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Filter is real** — Flag to specify if filter is real  
true (default) | false

Flag to specify if the filter is real, specified as true or false.

#### Dependencies

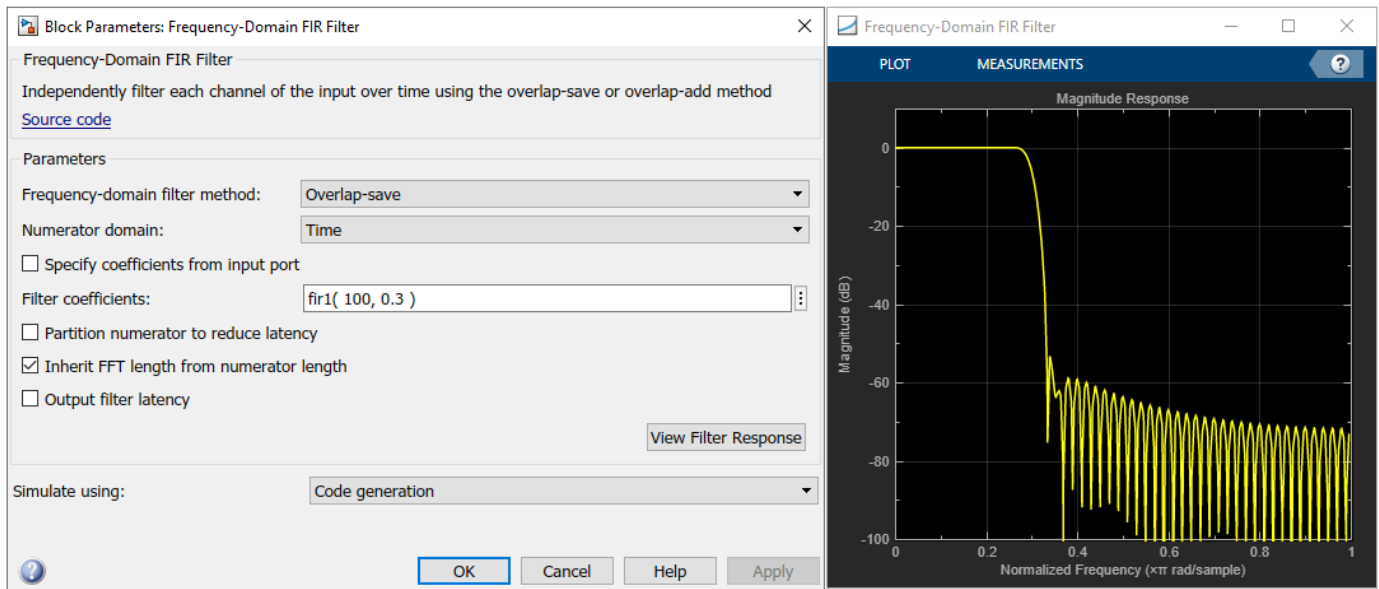

This parameter applies when **Numerator domain** to Frequency.

**Output filter latency** — Flag to output filter latency  
'off' (default) | 'on'

When you select this check box and click **Apply**, the block outputs the filter latency through the **latency** port.

**View Filter Response** — Visualize frequency response  
button

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the frequency domain FIR filter. The response is based on the parameters you select in the block dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Filter Visualizer”.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

### Overlap-Save

The overlap-save method is implemented using the following approach:

The input stream is partitioned into overlapping blocks of size  $FFTLen$ , with an overlap factor of  $NumLen - 1$  samples.  $FFTLen$  is the FFT length and  $NumLen$  is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$  FFT of the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last  $FFTLen - NumLen + 1$  samples are saved. The remaining samples are dropped.

The latency of overlap-save is  $FFTLen - NumLen + 1$ . The first  $FFTLen - NumLen + 1$  samples are equal to zero. The filtered value of the first input sample appears as the  $FFTLen - NumLen + 2$  output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than  $NumLen$ .

## Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length  $FFLen - NumLen + 1$ , with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first  $NumLen + 1$  samples are modified by adding the values of the last  $NumLen + 1$  samples from the previous computed IFFT.

The latency of overlap-add is  $FFLen - NumLen + 1$ . The first  $FFLen - NumLen + 1$  samples are equal to zero. The filtered value of the first input sample appears as the  $FFLen - NumLen + 2$  output sample.

## Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

## Description

The From Multimedia File block reads audio samples, video frames, or both from a multimedia file and generates a signal with one of the following data types and amplitude ranges.

| Output Data Type | Output Amplitude Range                            |
|------------------|---|
| double           | $\pm 1$   |
| single           | $\pm 1$   |
| int16            | $-32768$ to $32767$ ( $-2^{15}$ to $2^{15} - 1$ ) |
| uint8            | 0 to 255  |

The block imports data from the file into a Simulink model.

---

**Note** This block supports code generation for a host computer that has file I/O available. You cannot use this block with Simulink Desktop Real-Time software because that product does not support file I/O. The generated code for this block relies on prebuilt library files. For more details, see “Code Generation” on page 2-727.

---

## Limitations

To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

## Ports

The output ports of the From Multimedia File block change according to the content of the multimedia file. If the file contains only video frames, the **Image** port, intensity **I** port, **R,G,B** ports, or **Y,Cb,Cr** ports appear based on the settings on the block dialog box. If the file contains only audio samples, the **Audio** port appears on the block. If the file contains both audio and video, you can select the data to emit. This section describes these ports in more detail.

### Output

**Image** — Color image or video frame  
array

Color image or video frame, returned as an  $M$ -by- $N$ -by- $P$  array.  $M$  and  $N$  are the number of rows and columns in each image.  $P$  is the number of color channels in each image.

**Dependencies**

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `RGB` and **Image signal** parameter to `One multidimensional signal`.
- This port is named as **Simulink Image** if the **Output color format** parameter is set to `RGB` and the **Image signal** parameter is set to `Simulink image signal`.

Data Types: `single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Simulink.ImageType`

**I** — Grayscale image or video frame  
matrix

Grayscale image or video frame, returned as an  $M$ -by- $N$  matrix.  $M$  and  $N$  are the number of rows and columns in the grayscale image.

**Dependencies**

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `Intensity`.

Data Types: `single | double | int8 | int16 | int32 | uint8 | uint16 | uint32`

**R** — Red color component of image or video frame  
matrix

Red color component of the image or video frame, returned as an  $M$ -by- $N$  matrix.  $M$  and  $N$  are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

**Dependencies**

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `RGB` and **Image signal** parameter to `Separate color signals`.

Data Types: `single | double | int8 | int16 | int32 | uint8 | uint16 | uint32`

**G** — Green color component of image or video frame  
matrix

Green color component of the image or video frame, returned as an  $M$ -by- $N$  matrix.  $M$  and  $N$  are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

#### Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **RGB** and **Image signal** parameter to **Separate color signals**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**B** — Blue color component of image or video frame  
matrix

Blue color component of the image or video frame, returned as an  $M$ -by- $N$  matrix.  $M$  and  $N$  are the number of rows and columns in the image.

Outputs from the **R**, **G**, or **B** ports must have the same dimensions.

#### Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **RGB** and **Image signal** parameter to **Separate color signals**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Y** — Luma component of image or video frame  
matrix

Luma component of the image or video frame, returned as an  $M$ -by- $N$  matrix.  $M$  and  $N$  are the number of rows and columns in the image.

#### Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to **Video only** or **Video and audio**.
- Set the **Output color format** parameter to **YCbCr 4:2:2**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Cb** — Blue-difference chrominance component of image or video frame  
matrix

Blue-difference chrominance component of the image or video frame, returned as an  $M$ -by- $N/2$  matrix.  $M$  and  $N$  are the number of rows and columns in the input image.

#### Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single | double | int8 | int16 | int32 | uint8 | uint16 | uint32`

**Cr** — Red-difference chrominance component of image or video frame matrix

Red-difference chrominance component of the image or video frame, returned as an  $M$ -by- $N/2$  matrix.  $M$  and  $N$  are the number of rows and columns in each input image.

#### Dependencies

To enable this port:

- Set the **File name** parameter to the name of a multimedia file that contains video or image data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `YCbCr 4:2:2`.

Data Types: `single | double | int8 | int16 | int32 | uint8 | uint16 | uint32`

**Audio** — Audio signal vector | matrix

Audio signal, returned as an  $M$ -element vector or an  $M$ -by- $N$  matrix.  $M$  is the number of samples in each channel and  $N$  is the number of channels.

#### Dependencies

To enable this port, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

Data Types: `single | double | int16 | uint8`

**EOF** — End-of-file indicator scalar

End-of-file indicator, returned as a logical scalar for each video frame or audio sample. The end-of-file indicator is 1 when the block outputs the final video frame or audio sample from the file, and is 0 otherwise.

#### Dependencies

To enable this port, select the **Output end-of-file indicator** parameter.

Data Types: `Boolean`

## Parameters

### Main Tab

**File name** — Name of multimedia file

speech\_dft.mp3 (default) | character vector

Specify the name of the multimedia file for the block to read. The block determines the type of file (audio and video, audio only, or video only) and provides the associated parameters.

If the location of the file does not appear on the MATLAB path, use the **Browse** button to specify the full path. If the location of the file appears on the MATLAB path, enter only the file name.

On Windows platforms, this parameter supports URLs that point to MMS (Microsoft Media Server) streams.

**Inherit sample time from file** — Inherit sample time from file

on (default) | off

Specify whether the block inherits the sample time from the multimedia file or uses a specified sample time. When you select this parameter, the block inherits the sample time from the input multimedia file. When you clear this parameter, the block uses the sample time that you specify in the **Desired sample time** parameter.

---

**Tip** Select this parameter when you do not know the intended sample rate of the multimedia file.

---

**Desired sample time** — Block sample time

1/30 (default) | real positive scalar

Specify the block sample time.

### Dependencies

To enable this parameter, clear the **Inherit sample time from file** parameter.

**Number of times to play file** — Number of times to play multimedia file

inf (default) | positive integer

Specify the number of times to play the input multimedia file. The default value of `inf` specifies that the block repeats playing the multimedia file until the simulation stop time.

**Read range** — Range of audio samples

[1 Inf] (default) | two-element vector

Specify the sample range from which to read as a two-element row vector in the form of `[StartSample EndSample]`, where *StartSample* is the sample at which file reading starts, and *EndSample* is the sample at which file reading stops.

**Dependencies**

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

**Output end-of-file indicator** — End-of-file indicator

`off (default) | on`

Use this parameter to determine whether the output is the last video frame or audio sample in the multimedia file. When you select this parameter, a Boolean output port labeled **EOF** appears on the block. The output from the **EOF** port defaults to 1 when the last video frame or audio sample is output from the block. Otherwise, the output from the **EOF** port defaults to 0.

**Multimedia outputs** — Type of media

`Audio only (default) | Video and audio | Video only`

Specify the type of media to read from a file containing both video and audio data.

**Dependencies**

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains both audio and video data.

**Samples per audio channel** — Samples per audio channel

`1024 (default) | positive integer`

Specify number of samples per audio channel. This parameter becomes available for files containing audio.

**Dependencies**

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only`.

**Output color format** — Color format of video

`RGB (default) | Intensity | YCbCr 4:2:2`

Specify the output color format of the input video data. The block supports the RGB, Intensity, and YCbCr 4:2:2 color formats.

If you select RGB, use the **Image signal** parameter to specify how to output a color signal.

**Dependencies**

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

**Image signal** — Output port configuration for RGB video

One multidimensional signal (default) | Separate color signals | Simulink image signal

Specify how the block outputs an RGB color video. If you select:

- **One multidimensional signal** -- The block outputs an  $M$ -by- $N$ -by- $P$  color video signal through the **Image** port, where  $P$  is the number of color planes.
- **Separate color signals** -- The block outputs the video data using three separate color channels, divided across the **R**, **G**, and **B** ports. Each port outputs one  $M$ -by- $N$  plane of an RGB video stream.
- **Simulink image signal** -- The block outputs a video in `Simulink.ImageType` datatype.

### Dependencies

To enable this parameter:

- Set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.
- Set the **Output color format** parameter to `RGB`.

### Data Types Tab

**Audio output data type** — Audio output data type

double (default) | single | int16 | uint8

Specify the data type for the audio samples output at the **Audio** port.

### Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains audio data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Audio only` or `Video and audio`.

**Video output data type** — Video output data type

single (default) | double | int8 | uint8 | int16 | uint16 | int32 | uint32 | Inherit from file

Specify the data type of the video frames output at the **R**, **G**, **B**, or **Image** ports..

### Dependencies

To enable this parameter, set the **File name** parameter to the name of a multimedia file that contains video data. If the specified file contains both audio and video data, set the **Multimedia outputs** parameter to `Video only` or `Video and audio`.

## Block Characteristics

|                           |  |
|---------------------------|--|
| <b>Data Types</b>         | double   integer <sup>a</sup>   single |
| <b>Direct Feedthrough</b> | no                                     |

|                                 |    |
|---------------------------------|----|
| <b>Multidimensional Signals</b> | no |
| <b>Variable-Size Signals</b>    | no |
| <b>Zero-Crossing Detection</b>  | no |

a Supports 16- and 32-bit signed and 8-bit unsigned integers.

## More About

### Supported Platforms and File Types

The supported file formats available to you depends on the codecs installed on your system.

#### Windows Platforms Supported File Formats

With the necessary Windows DirectShow codecs installed on your system, the From Multimedia File Block supports many video and audio file formats. This block performs best on platforms with Version 9.0 or later of DirectX® software.

The following table lists the most common file formats.

| <b>Multimedia Types</b> | <b>File Name Extensions</b>   |
|-------------------------|---|
| Image files             | .jpg, .bmp, .png  |
| Video files             | .qt, .mov, .avi, .asf, .asx, .wmv, .mpg, .mpeg, .mp2, .mp4, .m4v                      |
| Audio files             | .wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .au, .snd, .mp4, .m4a, .flac, .ogg, .opus |

The default for image files is .png, for video files is .avi, and for audio files is .mp3.

Windows 7 and later versions of Windows ship with a limited set of 64-bit video and audio codecs. If the From Multimedia File block cannot work on a compressed multimedia file, save the multimedia file to a file format supported by the block.

If you use Windows, use Windows Media® Player Version 11 or later with this block for best results.

#### Non- Windows Platform Supported File Formats

The following table lists the most common file formats.

| <b>Multimedia Types</b> | <b>File Name Extensions</b>   |
|-------------------------|---|
| Video files             | .avi, .mj2, .mov, .mp4, .m4v  |
| Audio files             | .avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .au, .opus, .snd |

The default for video files is .avi and for audio files is .mp3.

### Sample Rates

The sample rate that the block uses depends on the audio and video sample rate. While the From Multimedia File block operates at a single rate in Simulink, the underlying audio and video streams can produce different rates. In some cases, when the block outputs both audio and video, it makes a small adjustment to the video rate.

### Sample Time Calculations Used for Video and Audio Files

$$\text{Sample time} = \frac{\text{ceil}(\text{AudioSampleRate}/\text{FPS})}{\text{AudioSampleRate}}.$$

When the audio sample time  $\frac{\text{AudioSampleRate}}{\text{FPS}}$  is noninteger, the equation cannot reduce to  $\frac{1}{\text{FPS}}$ .

In this case, to prevent synchronization problems, the block drops the corresponding video frame when the audio stream leads the video stream by more than  $\frac{1}{\text{FPS}}$ .

In summary, the block outputs one video frame at each Simulink time step. To calculate the number of audio samples to output at each time step, the block divides the audio sample rate by the video frame rate (fps). If the audio sample rate does not divide evenly by the number of video frames per second, the block rounds the number of audio samples up to the nearest whole number. If necessary, the block periodically drops a video frame to maintain synchronization for large files.

### Running Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

| Platform | Command   |
|----------|---|
| Mac      | <pre>setenv DYLD_LIBRARY_PATH "\$ {DYLD_LIBRARY_PATH}:\$MATLABROOT/bin/ maci64" (csh/tcsh)  export DYLD_LIBRARY_PATH= \$DYLD_LIBRARY_PATH:\$MATLABROOT/bin/ maci64 (Bash)</pre> <p>For more information, see Append library path to "DYLD_LIBRARY_PATH" in MAC.</p> |
| Linux    | <pre>setenv LD_LIBRARY_PATH \$ {LD_LIBRARY_PATH}:\$MATLABROOT/bin/ glnxa64 (csh/tcsh)  export LD_LIBRARY_PATH= \$LD_LIBRARY_PATH:\$MATLABROOT/bin/ glnxa64 (Bash)</pre>   |
| Windows  | <pre>set PATH=%PATH%;%MATLABROOT%\bin\win64</pre>   |

## Version History

Introduced before R2006a

### R2022b: Support for OPUS audio file format

The From Multimedia File block supports audio files in the OPUS file format (.opus).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

## From Wave Device (Obsolete)

Read audio data from standard audio device in real-time (32-bit Windows operating systems only)

### Library

dspwin32

### Description

---

**Note** The From Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Audio Device block.

---

The From Wave Device block reads audio data from a standard Windows audio device in real-time. It is compatible with most popular Windows hardware, including Sound Blaster cards. (Models that contain both this block and the To Wave Device block require a *duplex-capable* sound card.)

The **Use default audio device** parameter allows the block to detect and use the system's default audio hardware. This option should be selected on systems that have a single sound device installed, or when the default sound device on a multiple-device system is the desired source. In cases when the default sound device is not the desired input source, clear **Use default audio device**, and select the desired device in the **Audio device menu** parameter.

When the audio source contains two channels (stereo), the **Stereo** check box should be selected. When the audio source contains a single channel (mono), the **Stereo** check box should be cleared. For stereo input, the block's output is an  $M$ -by-2 matrix containing one frame ( $M$  consecutive samples) of audio data from each of the two channels. For mono input, the block's output is an  $M$ -by-1 matrix containing one frame ( $M$  consecutive samples) of audio data from the mono input. The frame size,  $M$ , is specified by the **Samples per frame** parameter. For  $M=1$ , the output is sample based; otherwise, the output is frame based.

The audio data is processed in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. You can select one of these rates from the **Sample rate** parameter. To specify a different rate, select the **User-defined** option and enter a value in the **User-defined sample rate** parameter.

The **Sample Width (bits)** parameter specifies the number of bits used to represent the signal samples read by the audio device. The following settings are available:

- 8 — allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — allocates 24 bits to each sample, allowing a resolution of 16777216 levels (only for use with 24-bit audio devices)

Higher sample width settings require more memory but yield better fidelity. The output from the block is independent of the **Sample width (bits)** setting. The output data type is determined by the **Data type** parameter setting.

## Buffering

Since the audio device accepts real-time audio input, Simulink software must read a continuous stream of data from the device throughout the simulation. Delays in reading data from the audio hardware can result in hardware errors or distortion of the signal. This means that the From Wave Device block must read data from the audio hardware as quickly as the hardware itself acquires the signal. However, the block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running from within Simulink rather than as generated code. (Simulink operations are generally slower than comparable hardware operations, and execution speed routinely varies during the simulation as the host operating system services other processes.) The block must therefore rely on a buffering strategy to ensure that signal data can be read on schedule without losing samples.

At the start of the simulation, the audio device begins writing the input data to a (hardware) buffer with a capacity of  $T_b$  seconds. The From Wave Device block immediately begins pulling the earliest samples off the buffer (first in, first out) and collecting them in length- $M$  frames for output. As the audio device continues to append inputs to the bottom of the buffer, the From Wave Device block continues to pull inputs off the top of the buffer at the best possible rate.

The following figure shows an audio signal being acquired and output with a frame size of 8 samples. The buffer of the sound board is approaching its five-frame capacity at the instant shown, which means that the hardware is adding samples to the buffer more rapidly than the block is pulling them off. (If the signal sample rate was 8 kHz, this small buffer could hold approximately 0.005 second of data.)

When the simulation throughput rate is higher than the hardware throughput rate, the buffer remains empty throughout the simulation. If necessary, the From Wave Device block simply waits for new samples to become available on the buffer (the block does not interpolate between samples). More typically, the simulation throughput rate is lower than the hardware throughput rate, and the buffer tends to fill over the duration of the simulation.

## Troubleshooting

When the buffer size is too small in relation to the simulation throughput rate, the buffer might fill before the entire length of signal is processed. This usually results in a device error or undesired device output. When this problem occurs, you can choose to either increase the buffer size or the simulation throughput rate:

- *Increase the buffer size*

The **Queue duration** parameter specifies the duration of signal,  $T_b$  (in real-time seconds), that can be buffered in hardware during the simulation. Equivalently, this is the maximum length of time that the block's data acquisition can lag the hardware's data acquisition. The number of frames buffered is approximately

$$\frac{T_b F_s}{M}$$

where  $F_s$  is the sample rate of the signal and  $M$  is the number of samples per frame. The required buffer size for a given signal depends on the signal length, the frame size, and the speed of the simulation. Note that increasing the buffer size might increase model latency.

- *Increase the simulation throughput rate*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes (and convert sample-based signals to frame-based signals) throughout the model to reduce the amount of block-to-block communication overhead. This can drastically increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder. Native code runs much faster than Simulink, and should provide rates adequate for real-time audio processing.

More general ways to improve throughput rates include simplifying the model, and running the simulation on a faster PC processor. See “Delay and Latency” and “Optimize Performance” (Simulink) for other ideas on improving simulation performance.

## Parameters

### Sample rate (Hz)

The sample rate of the audio data to be acquired. Select one of the standard Windows rates or the User-defined option.

### User-defined sample rate (Hz)

The (nonstandard) sample rate of the audio data to be acquired.

### Sample width (bits)

The number of bits used to represent each signal sample.

### Stereo

Specifies stereo (two-channel) inputs when selected, mono (one-channel) inputs when cleared. Stereo output is  $M$ -by-2; mono output is  $M$ -by-1.

### Samples per frame

The number of audio samples in each successive output frame,  $M$ . When the value of this parameter is 1, the block outputs a sample-based signal.

### Queue duration (seconds)

The length of signal (in seconds) to buffer to the hardware at the start of the simulation.

**Use default audio device**

Reads audio input from the system's default audio device when selected. Clear to enable the **Audio device ID** parameter and select a device.

**Audio device**

The name of the audio device from which to read the audio output (lists the names of the installed audio device drivers). Select **Use default audio device** when the system has only a single audio card installed.

**Data type**

The data type of the output: double-precision, single-precision, signed 16-bit integer, or unsigned 8-bit integer.

**Supported Data Types**

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

## From Wave File (Obsolete)

Read audio data from Microsoft Wave (.wav) file

## Library

dspwin32

## Description

**Note** The From Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the From Multimedia File block.

The From Wave File block streams audio data from a Microsoft® Wave (.wav) file and generates a signal with one of the data types and amplitude ranges in the following table.

**Note** AVI files are the only supported file type for non-Windows platforms.

| Output Data Type | Output Amplitude Range                        |
|------------------|---|
| double           | $\pm 1$                                       |
| single           | $\pm 1$                                       |
| int16            | -32768 to 32767 ( $-2^{15}$ to $2^{15} - 1$ ) |
| uint8            | 0 to 255                                      |

The audio data must be in uncompressed pulse code modulation (PCM) format.

```
y = wavread('filename') % Equivalent MATLAB code
```

The block supports 8-, 16-, 24-, and 32-bit Microsoft Wave (.wav) files.

The **File name** parameter can specify an absolute or relative path to the file. When the file is on the MATLAB path or in the current folder (the folder returned by typing `pwd` at the MATLAB command line), you need only specify the file name. You do not need to specify the .wav extension.

**Note** The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

For an audio file containing  $C$  channels, the block's output is an  $M$ -by- $C$  matrix containing one frame ( $M$  consecutive samples) of audio data from each channel. The frame size,  $M$ , is specified by the

**Samples per output frame** parameter. For  $M=1$ , the output is sample based; otherwise, the output is frame based.

The output frame period,  $T_{fo}$ , is

$$T_{fo} = \frac{M}{F_s}$$

where  $F_s$  is the data sample rate in Hz.

To reduce the required number of file accesses, the block acquires  $L$  consecutive samples from the file during each access, where  $L$  is specified by the **Minimum number of samples for each read from file** parameter ( $L \geq M$ ). For  $L < M$ , the block instead acquires  $M$  consecutive samples during each access. Larger values of  $L$  result in fewer file accesses, which reduces run-time overhead.

Use the **Data type** parameter to specify the data type of the block's output. Your choices are `double`, `single`, `uint8`, or `int16`.

Select the **Loop** check box if you want to play the file more than once. Then, enter the number of times to play the file. The number you enter must be a positive integer or `inf`.

Use the **Number of times to play file** parameter to enter the number of times to play the file. The number you enter must be a positive integer or `inf`, to play the file until you stop the simulation.

The **Samples restart** parameter determines whether the samples from the audio file repeat immediately or repeat at the beginning of the next frame output from the output port. When you select `immediately after last sample`, the samples repeat immediately. When you select `at beginning of next frame`, the frame containing the last sample value from the audio file is zero padded until the frame is filled. The block then places the first sample of the audio file in the first position of the next output frame.

Use the **Output start-of-file indicator** parameter to determine when the first audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled SOF appears on the block. The output from the SOF port is 1 when the first audio sample in the file is output from the block. Otherwise, the output from the SOF port is 0.

Use the **Output end-of-file indicator** parameter to determine when the last audio sample in the file is output from the block. When you select this check box, a Boolean output port labeled EOF appears on the block. The output from the EOF port is 1 when the last audio sample in the file is output from the block. Otherwise, the output from the EOF port is 0.

The block icon shows the name, sample rate (in Hz), number of channels (1 or 2), and sample width (in bits) of the data in the specified audio file. All sample rates are supported; the sample width must be either 8, 16, 24, or 32 bits.

## Parameters

### File name

Enter the path and name of the file to read. Paths can be relative or absolute.

---

**Note** The From Wave File block does not support .wav file names that contain a + character. To read .wav files that have a + character in the file name, use the From Multimedia File block.

---

**Samples per output frame**

Enter the number of samples in each output frame,  $M$ . When the value of this parameter is 1, the block outputs a sample-based signal.

**Minimum number of samples for each read from file**

Enter the number of consecutive samples to acquire from the file with each file access,  $L$ .

**Data type**

Select the output data type: double, single, uint8, or int16. The data type setting determines the output's amplitude range.

**Loop**

Select this check box if you want to play the file more than once.

**Number of times to play file**

Enter the number of times you want to play the file.

**Samples restart**

Select immediately after last sample to repeat the audio file immediately. Select at beginning of next frame to place the first sample of the audio file in the first position of the next output frame.

**Output start-of-file indicator**

Use this check box to determine whether the output contains the first audio sample in the file.

**Output end-of-file indicator**

Use this check box to determine whether the output contains the last audio sample in the file.

**Supported Data Types**

- Double-precision floating point
- Single-precision floating point
- 16-bit signed integer
- 8-bit unsigned integer

## G711 Codec

Quantize narrowband speech input signals

## Library

Quantizers

dspquant2

## Description

The G711 Codec block is a logarithmic scalar quantizer designed for narrowband speech. Narrowband speech is defined as a voice signal with an analog bandwidth of 4 kHz and a Nyquist sampling frequency of 8 kHz. The block quantizes a narrowband speech input signal so that it can be transmitted using only 8-bits. The G711 Codec block has three modes of operation: encoding, decoding, and conversion. You can choose the block's mode of operation by setting the **Mode** parameter.

If, for the **Mode** parameter, you choose **Encode PCM to A-law**, the block assumes that the linear PCM input signal has a dynamic range of 13 bits. Because the block always operates in saturation mode, it assigns any input value above  $2^{12} - 1$  to  $2^{12} - 1$  and any input value below  $-2^{12}$  to  $-2^{12}$ . The block implements an A-law quantizer on the input signal and outputs A-law index values. When you choose **Encode PCM to mu-law**, the block assumes that the linear PCM input signal has a dynamic range of 14 bits. Because the block always operates in saturation mode, it assigns any input value above  $2^{13} - 1$  to  $2^{13} - 1$  and any input value below  $-2^{13}$  to  $-2^{13}$ . The block implements a mu-law quantizer on the input signal and outputs mu-law index values.

If, for the **Mode** parameter, you choose **Decode A-law to PCM**, the block decodes the input A-law index values into quantized output values using an A-law lookup table. When you choose **Decode mu-law to PCM**, the block decodes the input mu-law index values into quantized output values using a mu-law lookup table.

If, for the **Mode** parameter, you choose **Convert A-law to mu-law**, the block converts the input A-law index values to mu-law index values. When you choose **Convert mu-law to A-law**, the block converts the input mu-law index values to A-law index values.

---

**Note** Set the **Mode** parameter to **Convert A-law to mu-law** or **Convert mu-law to A-law** only when the input to the block is A-law or mu-law index values.

---

If, for the **Mode** parameter, you choose **Encode PCM to A-law** or **Encode PCM to mu-law**, the **Overflow diagnostic** parameter appears on the block parameters dialog box. Use this parameter to determine the behavior of the block when overflow occurs. The following options are available:

- **Ignore** — Proceed with the computation and do not issue a warning message.
- **Warning** — Display a warning message in the MATLAB Command Window, and continue the simulation.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** Like all diagnostic parameters on the Configuration Parameters dialog box, **Overflow diagnostic** parameter is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

---

## Parameters

### Mode

- When you choose **Encode PCM to A-law**, the block implements an A-law encoder.
- When you choose **Encode PCM to mu-law**, the block implements a mu-law encoder.
- When you choose **Decode A-law to PCM**, the block decodes the input index values into quantized output values using an A-law lookup table.
- When you choose **Decode mu-law to PCM**, the block decodes the input index values into quantized output values using a mu-law lookup table.
- When you choose **Convert A-law to mu-law**, the block converts the input A-law index values to mu-law index values.
- When you choose **Convert mu-law to A-law**, the block converts the input mu-law index values to A-law index values.

### Overflow diagnostic

Use this parameter to determine the behavior of the block when overflow occurs.

- Select **Ignore** to proceed with the computation without a warning message.
- Select **Warning** to display a warning message in the MATLAB Command Window and continue the simulation.
- Select **Error** to display an error dialog box and terminate the simulation.

This parameter is only visible if, for the **Mode** parameter, you select **Encode PCM to A-law** or **Encode PCM to mu-law**.

## Halfband Filter (Obsolete)

(Removed) Design halfband filter

## Compatibility

---

**Note** The Halfband Filter block has been removed from the DSP System Toolbox block library. Existing instances of the Halfband Filter block will continue to operate. To model FIR halfband decimators and interpolators, use the FIR Halfband Decimator and FIR Halfband Interpolator blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to FIR, and **FilterType** is set to Decimator and Interpolator. To model IIR halfband decimators and interpolators, use the IIR Halfband Decimator and IIR Halfband Interpolator blocks. These blocks replace the functionality of the Halfband Filter block, when **Impulse response** is set to IIR, and **FilterType** is set to Decimator and Interpolator.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “Halfband Filter Design — Main Pane” on page 5-616 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter type and order.

#### Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select either Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

#### Response type

Specify the filter response as Lowpass (the default) or Highpass.

#### Filter type

Select Single-rate, Decimator, or Interpolator. By default, the block specifies a single-rate filter.

#### Order

Enter the filter order. This option is enabled only when the **Filter order mode** is set to Specify.

### Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

**Frequency constraints**

When **Order mode** is **Specify**, set this parameter to **Unconstrained** or **Transition width**.

**Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

**Input Fs**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Transition width**

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

**Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands.

**Magnitude constraints**

Specify **Unconstrained** (the default), or select **Stopband attenuation** to constrain the response in the stopband explicitly.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).

**Astop**

When **Magnitude units** is **Stopband attenuation**, enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are **equiripple**, and **Kaiser window**. For IIR halfband filters, the available design options are **Butterworth**, **elliptic**, and **IIR quasi-linear phase**.

**Design Options**

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

**Minimum phase**

Select the check box to specify a minimum-phase design.

**Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

**Stopband Decay**

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. The block applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

**Filter Implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

**Use basic elements to enable filter customization**

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

**Optimize for unit-scale values**

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The **Inherited** (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

### Supported Data Types

| Port   | Supported Data Types   |

# Hampel Filter

Filter outliers using Hampel identifier

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

The Hampel Filter block detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics, which is robust against outliers. For each sample of the input signal, the block computes the median of a window composed of the current sample and  $\frac{Len - 1}{2}$  adjacent samples on each side of the current sample.

$Len$  is the window length you specify through the **Window length** parameter. The block also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 2-748.

## Ports

### Input

**x** — Data input  
vector | matrix

The block accepts multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$ , and  $n \geq 1$ .  $m$  is the number of samples in each frame (channel), and  $n$  is the number of channels. The block also accepts variable-size inputs. That is, you can change the size of each input channel during simulation. However, the number of channels cannot change.

This port is unnamed until you select the **Specify threshold from input port** parameter.

Data Types: single | double

**T** — Threshold  
real scalar greater than or equal to 0

Threshold for outlier detection, specified as a real scalar greater than or equal to 0. For information on how this parameter is used to detect the outlier, see “Algorithms” on page 2-748.

### Dependencies

This port appears when you select the **Specify threshold from input port** parameter.

Data Types: single | double

## Output

**y** — Filtered output  
vector | matrix

The size and data type of this output matches the size and data type of the input.

This port is unnamed until you select the **Output outlier status** check box.

Data Types: single | double

**outlier** — Output the outlier status  
vector | matrix

A value of 1 in this output indicates that the corresponding element in the input is an outlier. This output has the same size as the input.

## Dependencies

To enable this port, select the **Output outlier status** check box.

Data Types: Boolean

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Window length** — Length of sliding window  
11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the block computes the median and median absolute deviation of the data in the window.

**Specify threshold from input port** — Flag to specify threshold  
off (default) | on

When you select this check box, the threshold is input through the **T** port. When you clear this check box, the threshold is specified on the block dialog through the **Threshold for outlier detection (standard deviations)** parameter.

**Threshold for outlier detection (standard deviations)** — Threshold  
3 (default) | real scalar greater than or equal to 0

Threshold for outlier detection, specified as a real scalar greater than or equal to 0. For information on how this parameter is used to detect the outlier, see “Algorithms” on page 2-748.

**Tunable:** Yes

## Dependencies

This parameter appears when you clear the **Specify threshold from input port** check box.

**Output outlier status** — Flag to output the outlier status  
off (default) | on

Select this parameter to output a matrix of **boolean** values that has the same size as the input. Each element in this matrix indicates whether the corresponding element in the input is an outlier. A value of 1 indicates an outlier.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution**: Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation**: Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## More About

### Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence  $x_1, x_2, x_3, \dots, x_n$  and a sliding window of length  $k$ , define point-to-point median and standard-deviation estimates using:

- Local median —  $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation —  $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$ , where  $\kappa = \frac{1}{\sqrt{2} \text{erfc}^{-1}(1/2)} \approx 1.4826$

The quantity  $\sigma_i / \kappa$  is known as the median absolute deviation (MAD).

If a sample  $x_i$  is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold  $n_\sigma$ , then the Hampel identifier declares  $x_i$  an outlier and replaces it with  $m_i$ . If  $n_\sigma$  is 0, then the Hampel filter behaves as a regular median filter.

## Algorithms

For a given sample of data,  $x_s$ , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median,  $m_i$ , and standard deviation,  $\sigma_i$ , over the current window of data.
- Compares the current sample with  $n_\sigma \times \sigma_i$ , where  $n_\sigma$  is the threshold value. If  $|x_s - m_i| > n_\sigma \times \sigma_i$ , the filter identifies the current sample,  $x_s$ , as an outlier and replaces it with the median value,  $m_i$ .

Consider a frame of data that is passed into the Hampel filter.

|   |   |   |   |    |   |    |   |   |
|---|---|---|---|----|---|----|---|---|
| 1 | 2 | 4 | 9 | 23 | 8 | 12 | 4 | 2 |
|---|---|---|---|----|---|----|---|---|

In this example, the Hampel filter slides a window of length 5 ( $Len$ ) over the data. The filter has a threshold value of 2 ( $n_\sigma$ ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with  $Len - 1$  zeros. To compute the first sample of the output, the window centers on the  $\left[\frac{Len - 1}{2} + 1\right]^{\text{th}}$  sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample:  $x_s = 0$ .
- Window of data:  $win = [0 \ 0 \ 0 \ 0 \ 1]$ .
- Local median:  $m_i = \text{median}([0 \ 0 \ 0 \ 0 \ 1]) = 0$ .
- Median absolute deviation:  $mad_i = \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$ . For this window of data,  $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$ .

- Standard deviation:  $\sigma_i = \kappa \times mad_i = 0$ , where  $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$ .
- The current sample,  $x_s = 0$ , does not obey the relation for outlier detection.  
 $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

Therefore, the Hampel filter outputs the current input sample,  $x_s = 0$ .

Repeat this procedure for every succeeding sample until the algorithm centers the window on the  $\left[End - \frac{Len - 1}{2}\right]^{\text{th}}$  sample, marked as End. Because the window centered on the last  $\frac{Len - 1}{2}$  samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

# Highpass Filter

Design FIR or IIR highpass filter

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

The Highpass Filter block independently filters each channel of the input signal over time using the given design specifications. You can control whether the block implements an IIR or FIR highpass filter using the **Filter type** parameter. You can specify the passband and stopband edge frequencies in Hz or in normalized frequency units.

This block supports ARM Cortex code generation. Under certain conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-755.

## Ports

### Input

**Port\_1** — Input signal to filter  
column vector | matrix

Input signal, specified as a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length.

Data Types: `single` | `double` | `fixed point`

### Output

**Port\_1** — Filtered signal  
vector | matrix

Filtered signal, returned as a vector or matrix. The output has the same size and complexity characteristics as the input. If the output has a fixed-point data type, it is always signed.

Data Types: `single` | `double` | `fixed point`

## Parameters

### Main

**Filter type** — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR highpass filter or an IIR highpass filter.

**Design minimum order filter** — Design filter with minimum order

on (default) | off

When you select this check box, the block designs a filter with minimum order. When you clear this check box, you can specify the **Filter order** as a positive integer.

**Filter order** — Order of highpass filter

50 (default) | positive integer

Specify the order of the highpass filter as a positive integer.

#### **Dependencies**

To enable this parameter, clear the **Design minimum order filter** check box.

**Stopband edge frequency (Hz)** — Stopband edge frequency

8e3 (default) | real positive scalar

Specify the stopband edge frequency of the highpass filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the stopband edge frequency is in Hz and must be less than the passband edge frequency.
- **Use normalized frequency (0 to 1)** -- The value of the stopband edge frequency is in normalized frequency units. The value must be a positive scalar less than the passband edge frequency.

#### **Dependencies**

To enable this parameter, select the **Design minimum order filter** check box.

**Passband edge frequency (Hz)** — Passband edge frequency

12e3 (default) | real positive scalar

Specify the passband edge frequency of the highpass filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the passband edge frequency is in Hz and must be less than half the value of the input sample rate.
- **Use normalized frequency (0 to 1)** -- The value of the passband edge frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Minimum stopband attenuation (dB)** — Minimum stopband attenuation

80 (default) | real positive scalar

Specify the minimum attenuation in the stopband as a real positive scalar in dB.

**Maximum passband ripple (dB)** — Maximum passband ripple

0.1 (default) | real positive scalar

Specify the maximum ripple of the filter response in the passband as a real positive scalar in dB.

**Sample rate mode** — Mode to specify the input sample rate

Specify on dialog (default) | Inherit from input port | Use normalized frequency (0 to 1)

Specify the input sample rate using one of these options:

- **Specify on dialog** -- Specify the input sample rate in the block dialog box using the **Input sample rate (Hz)** parameter.
- **Inherit from input port** -- The block inherits the sample rate from the input signal.
- **Use normalized frequency (0 to 1)** -- Specify the passband edge and the stopband edge frequencies in normalized frequency units (0 to 1).

**Input sample rate (Hz)** — Input sample rate

44100 (default) | scalar

Specify the input sample rate as a scalar in Hz.

**Dependencies**

To enable this parameter, set the **Sample rate mode** parameter to **Specify on dialog**.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run:

- **Interpreted execution (default)**

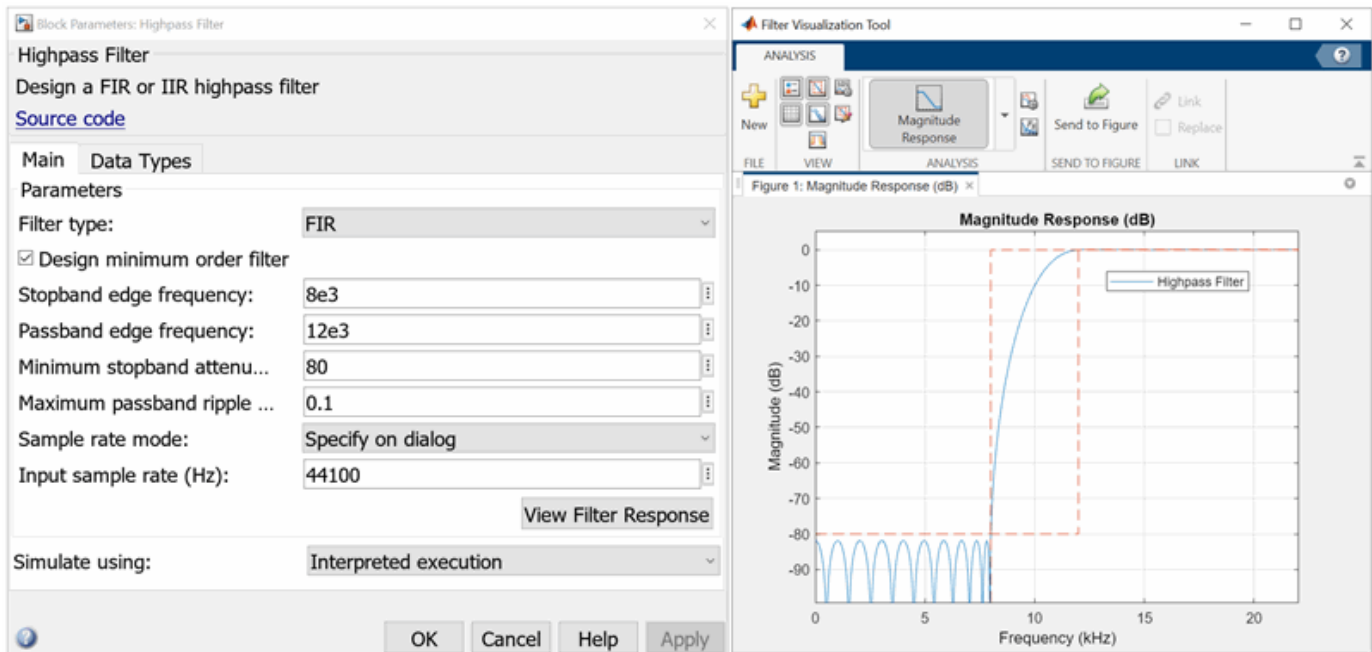

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

- **Code generation**

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.

**View Filter Response** — Open Filter Visualization Tool button

Opens the Filter Visualization Tool (`fvtool`) and displays the magnitude/phase response of the highpass filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

## Data Types

### Rounding mode — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Rounding method for the output fixed-point operations.

### Coefficients — Coefficient data type

fixdt(1,16) (default) | fixdt(1,16,0) | <data type expression>

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16,15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the data type. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

### FIR Highpass Filter

For the minimum order design, the algorithm uses generalized Remez FIR filter design algorithm. For the specified order design, the algorithm uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct` form structure.

### IIR Highpass Filter

In the IIR configuration, the algorithm uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The algorithm uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the highpass filter.

## Version History

### Introduced in R2015b

#### R2023a: Support for normalized frequencies

When you set the **Sample rate mode** parameter to `Use normalized frequency (0 to 1)`, you can specify the passband and stopband edge frequencies in normalized frequency units (0 to 1).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Highpass Filter block supports ARM Cortex code generation. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The Highpass Filter block also supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to FIR.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

# Highpass Filter (Obsolete)

Design highpass filter

## Compatibility

---

**Note** The Highpass Filter (Obsolete) block has been replaced by the Highpass Filter block. Existing instances of the Highpass Filter (Obsolete) block will continue to operate. For new models, use the Highpass Filter block.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “Highpass Filter Design — Main Pane” on page 5-619 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.

- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select **Minimum** (the default) or **Specify**. Selecting **Specify** enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to IIR, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

#### Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**.

#### Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to IIR and the **Order mode** to **Specify**.

#### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

#### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

#### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

### Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values  $F_{stop}$  and  $F_{pass}$  represents the transition region where the filter response is not constrained.

### Frequency constraints

When **Order mode** is **Specify**, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Stopband edge and passband edge** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband edge** — Define the filter by specifying the edge of the passband.
- **Stopband edge** — Define the filter by specifying the edge of the stopband.
- **Stopband edge and 3 dB point** — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the stopband.
- **3 dB point** — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- **3 dB point and passband edge** — For IIR filters, define the filter by specifying the frequency of the 3 dB point in the filter response and the edge of the passband.
- **6 dB point** — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input Fs** parameter.

### Input Fs

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Fstop

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**Fpass**

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

**F3dB**

When **Frequency constraints** is 3 dB point, Stopband edge and 3 dB point, or 3 dB point and passband edge, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**F6dB**

When **Frequency constraints** is 6 dB point, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands.

**Magnitude constraints**

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will be available for the **Magnitude constraints** parameter: Unconstrained, Passband ripple, Passband ripple and stopband attenuation or Stopband attenuation.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Astop**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Apass**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is Equi ripple.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

## Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

### Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select **passband** or **stopband** or **both** from the drop-down list.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterbuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterbuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## Filter Implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

**Use symbolic names for coefficients**

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

**Supported Data Types**

| <b>Port</b> | <b>Supported Data Types</b>   |
|-------------|---|
| Input       | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |
| Output      | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |

**Version History**

**Introduced in R2006b**

# Hilbert Filter

Design Hilbert filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-769.

## Dialog Box

See “Hilbert Filter Design — Main Pane” on page 5-623 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Filter order mode

Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Filter order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

### Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

#### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **kHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input sample rate** parameter.

#### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

#### Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

**Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is `Equiripple`.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**FIR Type**

Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select either 3 or 4 from the drop-down list.

**Filter Implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use `Direct-form FIR`, and IIR filters use `Cascade minimum-multiplier allpass`.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Version History

Introduced in R2006b

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Hilbert Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator:
  - **Interpolation Factor** cannot be equal to 1.
  - **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.
- Input port dimensions cannot be equal to [1 1].

The SIMD technology significantly improves the performance of the generated code.

# Histogram

Histogram of input or sequence of inputs

**Libraries:**

DSP System Toolbox / Statistics

## Description

The Histogram block computes the frequency distribution of the input elements along each column or along the entire input. You can specify the dimension using the **Find the histogram over** parameter. The block distributes the input elements based on their value into a number of discrete bins specified by the **Number of bins** parameter. For more details, see “Algorithms” on page 2-775.

When the input data is real, the bin boundaries are cast into the double data type. When the input data is complex, bin boundaries for double-precision inputs are cast into double, and bin boundaries for integer inputs are cast into double and squared. For an example, see “Compute the Histogram of Real and Complex Data”.

To track the frequency distribution of inputs over a period of time, select the **Running histogram** parameter.

When the input is complex, the block sorts the elements by their magnitude.

## Ports

### Input

**In** — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

This port is unnamed until you select the **Running histogram** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point | bus

**Rst** — Reset port

scalar

Specify the reset event that causes the block to reset the running histogram. The reset signal and the input data signal must have the same rate.

### Dependencies

To enable this port, select the **Running histogram** parameter, and set the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

## Output

**Port\_1** — Histogram output  
vector | matrix |  $N$ -D array

Outputs the histogram data as a vector, matrix, or array. The output primarily depends on the settings of the **Running histogram** and **Find the histogram over** parameters.

For example, consider a two-dimensional input signal of size  $M$ -by- $N$ .

When you clear the **Running histogram** parameter, the block computes the frequency distribution in each column of input or along the entire input. When you set **Find the histogram over** to:

- **Each column** — The block computes a histogram for each column of the input. The output is an  $n$ -by- $N$  matrix, where  $n$  is the **Number of bins**. The  $j$ th column of the output matrix contains the histogram for the data in the  $j$ th column of the  $M$ -by- $N$  input matrix.
- **Entire input** — The block computes a histogram for the entire input vector, matrix, or  $N$ -D array. The output is an  $n$ -by-1 vector, where  $n$  is the **Number of bins**.

When you select the **Running histogram** parameter, the block computes the frequency distribution of all inputs over a period of time. In this case, when you set **Find the histogram over** to:

- **Each column** — The block computes a running histogram for each column of the input. The output is an  $n$ -by- $N$  matrix, where  $n$  is the **Number of bins**. The  $j$ th column of the output matrix contains the running histogram for the data in the  $j$ th column of the  $M$ -by- $N$  matrix input.
- **Entire input** — The block computes the running histogram for the entire input vector, matrix, or  $N$ -D array. The output is an  $n$ -by-1 vector, where  $n$  is the **Number of bins**.

The output data type is `uint32` when the input has a data type other than `single` or `double`. The largest number that can be represented by `uint32` is  $2^{32}-1$ . If the range of any input exceeds this value, the block wraps the value back to 0.

Data Types: `single` | `double` | `uint32`

## Parameters

### Main Tab

**Lower limit of histogram** — Lower boundary of lowest-valued bin  
scalar

Specify the lower boundary of the lowest-valued bin as a real scalar. This parameter does not accept NaN or Inf. If the input has a value less than **Lower limit of histogram**, the block places this element in the lowest-valued bin.

**Upper limit of histogram** — Upper boundary of highest-valued bin  
scalar

Specify the upper boundary of the highest-valued bin as a real scalar. This parameter does not accept NaN or Inf. If the input has a value greater than **Upper limit of histogram**, the block places this element in the highest-valued bin.

**Number of bins** — Number of histogram bins  
positive integer

Specify the number of histogram bins as a positive integer.

**Find the histogram over** — Compute histogram over each column or entire input  
Each column (default) | Entire input

Specify whether the histogram is computed over each column or the entire input. The options for this parameter are affected by the setting of the **Running histogram** parameter.

When you clear the **Running histogram** parameter, and you set **Find the histogram over** parameter to:

- Each column — The block computes the histogram over each column.
- Entire input — The block outputs the histogram over the entire input.

When you select the **Running histogram** parameter, and you set **Find the histogram over** parameter to:

- Each column — The block computes the running histogram over each column.
- Entire input — The block outputs the running histogram over the entire input.

**Normalized** — Normalize output  
off (default) | on

When you select this parameter, the block output,  $y$ , is normalized. In mathematical terms,  $\text{sum}(y) = 1$ . This parameter does not apply for fixed-point input signals.

**Running histogram** — Track frequency distribution over time  
off (default) | on

When you select this parameter, the block tracks the frequency distribution of inputs over a period of time.

**Reset port** — Reset event  
Non-zero sample (default) | None | Rising edge | Falling edge | Either edge

The block resets the running histogram and empties all the bins whenever a reset event is detected at the optional **Rst** port. The reset sample time must equal the input sample time.

Use this parameter to specify the reset event:

- Non-zero sample — Triggers a reset operation at each sample time when the **Rst** input is not zero.

- None — Disables the **Rst** port.
- Rising edge — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- Falling edge — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- Either edge — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.

---

**Note** When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. When the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, select the **Running histogram** parameter.

## Data Types Tab

---

**Note** To use these parameters, the data input must be complex and fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

---

### Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

### Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

### Product output — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- `Inherit: Same as input` — The product output data type is the same as the input data type.
- `fixdt([],16,0)` — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

### Accumulator — Accumulator data type

Inherit: Same as input (default) | Inherit: Same as product output | fixdt([],16,0)

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as input` — The accumulator data type is the same as the input data type.
- `Inherit: Same as product output` — The accumulator data type is the same as the product output data type.
- `fixdt([],16,0)` — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | no                                      |

## Algorithms

### Histogram

The histogram value for a given bin represents the frequency of occurrence of the input values bracketed by that bin. **Upper limit of histogram** specifies the upper boundary of the highest-valued bin,  $B_M$ . **Lower limit of histogram** specifies the lower boundary of the lowest-valued bin,  $B_m$ . The bins have equal width, given by:

$$\Delta = \frac{B_M - B_m}{n}.$$

The bins are centered at the following locations:

$$B_m + \left(k + \frac{1}{2}\right)\Delta \quad k = 0, 1, 2, \dots, n - 1.$$

$n$  is the number of bins, specified by the **Number of bins** parameter.

Input values that fall on the border between two bins are placed into the lower-valued bin. Each bin includes its upper boundary. For example, a bin of width 4 centered on the value 5 contains the input value 7, but not 3. Input values greater than the **Upper limit of histogram** parameter are placed in the highest-valued bin. Similarly, values less than the **Lower limit of histogram** parameter are placed in the lowest-valued bin.

The block sorts the complex data into bins by magnitude. The magnitude is the sum of the squares of the real and imaginary components of the complex data.

## Version History

Introduced before R2006a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

#### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

# IDCT

Inverse discrete cosine transform (IDCT) of input

**Libraries:**

DSP System Toolbox / Transforms

## Description

The IDCT block computes the inverse discrete cosine transform (IDCT) of the input signal  $u$ . When the input is an  $M$ -by- $N$  matrix, the block computes the IDCT of each channel in the matrix.

Here is the equivalent MATLAB code.

```
y = idct(u)
```

## Ports

### Input

**Input 1** — Input signal

vector | matrix |  $N$ -D array

Specify the input signal as a vector, matrix, or an  $N$ -D array.

For all  $N$ -D input arrays, the block computes the IDCT across the first dimension. The size of the first dimension (frame size) must be a power of two. To work with other frame sizes, use the Pad block to pad or truncate the frame size to a power-of-two length.

When the input is an  $M$ -by- $N$  matrix, the block treats each input column as an independent channel containing  $M$  consecutive samples.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point | bus

### Output

**Output 1** — IDCT output

vector | matrix |  $N$ -D array

The block outputs the IDCT of the input signal as a vector, matrix, or an  $N$ -D array.

When the block outputs an  $M$ -by- $N$  matrix, the  $l^{\text{th}}$  column contains the length- $M$  IDCT of the corresponding input column.

$$y(m, l) = \sum_{k=1}^M w(k)u(k, l)\cos\frac{\pi(2m-1)(k-1)}{2M}, \quad m = 1, \dots, M$$

where

$$w(k) = \begin{cases} \frac{1}{\sqrt{M}}, & k = 1 \\ \sqrt{\frac{2}{M}}, & 2 \leq k \leq M \end{cases}$$

When the input is fixed-point (signed and unsigned), the output is signed fixed-point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point` | `bus`

## Parameters

### Main Tab

**Sine and cosine computation** — Sine and cosine computation

`Table lookup (default)` | `Trigonometric fcn`

Set the block to compute sines and cosines by either looking up sine and cosine values in a speed-optimized table (`Table lookup`), or by making sine and cosine function calls (`Trigonometric fcn`).

To compute sines and cosines, set the parameter to one of these values:

- `Table lookup` -- The block computes and stores the trigonometric values before the simulation starts, and retrieves them during the simulation. When you generate code from the block, the processor running the generated code stores the trigonometric values computed by the block in a speed-optimized table, and retrieves the values during code execution.

The block runs much more quickly, but requires extra memory for storing the precomputed trigonometric values.

- `Trigonometric fcn` -- The block computes sine and cosine values during the simulation. When you generate code from the block, the processor running the generated code computes the sine and cosine values while the code runs.

The block runs more slowly, but does not need extra data memory. For code generation, the block requires a support library to emulate the trigonometric functions, increasing the size of the generated code.

### Data Types Tab

**Rounding mode** — Rounding mode

`Floor (default)` | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. The sine table values do not obey this parameter; they always round to `Nearest`.

**Saturate on integer overflow** — Saturate on integer overflow

`off (default)` | `on`

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

---

### Sine table — Sine table

`Inherit: Same word length as input (default) | fixd(1,16)`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters. The block always saturates and rounds off the sine table values to `Nearest`.

### Product output — Product output

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixd(1,16,0)`

Specify the product output data type. See “Fixed-Point Data Types” on page 2-781 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator — Accumulator

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixd(1,16,0)`

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-781 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output — Output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input |  
fixd(1,16,0)

Specify the output data type. See “Fixed-Point Data Types” on page 2-781 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The internal rule first calculates an ideal output word length and fraction length using the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(DCTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output Minimum — Output minimum

[] (default) | scalar

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Output Maximum — Output Maximum

[] (default) | scalar

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## More About

### Fixed-Point Data Types

The following diagrams show the data types used within the IDCT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the block parameters dialog box of the IDCT block.

Inputs to the IDCT block are first cast to the output data type and stored in the output buffer. Each butterfly stage processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type.

**Butterfly Stage Data Types**

**Twiddle Multiplication Data Types**

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

**Note** When the block input is fixed point, all internal data types are signed fixed point.

## IDWT

Inverse discrete wavelet transform (IDWT) of input or reconstruct signals from subbands with smaller bandwidths and slower sample rates

**Libraries:**  
DSP System Toolbox / Transforms

### Description

You can configure this block to compute the inverse discrete wavelet transform (IDWT) or reconstruct a signal from subbands with smaller bandwidths and slower sample rates. When the block computes the inverse discrete wavelet transform (IDWT) of the input, the output has the same dimensions as the input. Each column of the output is the IDWT of the corresponding input column. When reconstructing a signal, the block uses a series of highpass and lowpass FIR filters to reconstruct the signal from the input subbands, as illustrated in “Multilevel Filter Banks” (the Asymmetric one). The reconstructed signal has a wider bandwidth and faster sample rate than the input subbands.

You can specify the filter bank highpass and lowpass filters by providing vectors of filter coefficients. You can do so directly on the block dialog box. If you have a Wavelet Toolbox license, you can specify wavelet-based filters by selecting a wavelet from the **Filter** parameter. You must set the filter bank structure to asymmetric or symmetric, and specify the number of levels in the filter bank.

---

**Note** The IDWT block is the same as the Dyadic Synthesis Filter Bank block with different default settings. For more information on block ports and parameters, see the Dyadic Synthesis Filter Bank block reference page.

---

## IFFT

Inverse fast Fourier transform (IFFT) of input

**Libraries:**  
DSP System Toolbox / Transforms

### Description

The IFFT block computes the inverse fast Fourier transform (IFFT) across the first dimension of an  $N$ -D input array. The block uses one of two possible FFT implementations. You can select an implementation based on the FFTW library or an implementation based on a collection of Radix-2 algorithms. To allow the block to choose the implementation, you can select **Auto**. For more information about the FFT implementations, see “Algorithms” on page 2-792.

When you specify an FFT length not equal to the length of the input vector (or first dimension of the input array), the block implements zero-padding, truncating, or modulo- $M$  (FFT length) data wrapping. This occurs before the IFFT operation. For an IFFT with  $P \leq M$ :

```
y = ifft(u,M) % P ≤ M
```

Wrapping:

```
y(:,L) = ifft(datawrap(u(:,L),M)) % P > M; L = 1, ..., N
```

Truncating:

```
y(:,L) = ifft(u,M) % P > M; L = 1, ..., N
```

---

**Tip** When the input length,  $P$ , is greater than the FFT length,  $M$ , you may see magnitude increases in your IFFT output. These magnitude increases occur because the IFFT block uses modulo- $M$  data wrapping to preserve all available input samples.

To avoid such magnitude increases, you can truncate the length of your input sample,  $P$ , to the FFT length,  $M$ . To do so, place a Pad block before the IFFT block in your model.

---

### Ports

#### Input

**Port\_1** — Input signal  
vector | matrix |  $N$ -D array

Input signal for computing the IFFT. The block computes the IFFT along the first dimension of the  $N$ -D input signal. The input can be floating-point or fixed-point, real, or complex, and conjugate symmetric.

For more information on how the block computes the IFFT, see “Description” on page 2-786 and “Algorithms” on page 2-792.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Output

### Port 1 — IFFT of input

`vector` | `matrix` | `N-D array`

The IFFT, computed across the first dimension of an  $N$ -D input array. For more information on how the block computes the IFFT, see “Description” on page 2-786 and “Algorithms” on page 2-792.

The  $k$ th entry of the  $L$ th output channel,  $y(k,L)$ , is equal to the  $k$ th point of the  $M$ -point inverse discrete Fourier transform (IDFT) of the  $L$ th input channel:

$$y(k, L) = \frac{1}{M} \sum_{p=1}^P u(p, L) e^{j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

The output has the same dimensions as the input. If the input signal has a floating-point data type, the data type of the output signal uses the same floating-point data type. Otherwise, the output can be any signed fixed-point data type. The block computes scaled and unscaled versions of the IFFT.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Parameters

### Main

#### FFT implementation — FFT implementation

`Auto (default)` | `Radix-2` | `FFTW`

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with `FFTW` implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or portable C-code generation using the Simulink Coder. The dimension  $M$  of the  $M$ -by- $N$  input matrix, must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the `FFTW` implementation. For more information about the algorithms used by the `Radix-2` mode, see “Radix-2 Implementation” on page 2-792.

Set this parameter to `Auto` to let the block choose the FFT implementation. For floating-point inputs with non-power-of-two transform lengths, the `FFTW` algorithm is automatically chosen. Otherwise a `Radix-2` algorithm is automatically chosen. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

#### Input is in bit-reversed order — Input is in bit-reversed order

`off (default)` | `on`

Select or clear this check box to designate the order of the input channel elements. Select this check box when the input is in bit-reversed order, and clear it when the input is in linear order. The block yields invalid outputs when you do not set this parameter correctly.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter. Also, it cannot be selected when you set the **FFT implementation** parameter to FFTW.

For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

#### Dependencies

To enable this parameter, set **FFT implementation** to Auto or Radix-2.

#### Input is conjugate symmetric — Input is conjugate symmetric

off (default) | on

Select this option when the block inputs conjugate symmetric data and you want real-valued outputs. Selecting this check box optimizes the block's computation method.

The FFT block yields conjugate symmetric output when you input real-valued data. Taking the IFFT of a conjugate symmetric input matrix produces real-valued output. Therefore, if the input to the block is both floating point and conjugate symmetric, and you select this check box, the block produces real-valued outputs.

You cannot select this check box if you have cleared the **Inherit FFT length from input dimensions** check box, and you are specifying the FFT length using the **FFT length** parameter.

If you input conjugate symmetric data to the IFFT block and do not select this check box, the IFFT block outputs a complex-valued signal with small imaginary parts. The block outputs invalid data if you select this option with non conjugate symmetric input data.

#### Divide output by FFT length — Divide output by FFT length

on (default) | off

When you select this check box, the block computes its output according to the IDFT equation, discussed in the Description on page 2-786 section.

When you clear this check box, the block computes the output using a modified version of the IDFT:  $M \cdot y(k, l)$ , which is defined by the following equation:

$$M \cdot y(k, l) = \sum_{p=1}^P u(p, l) e^{j2\pi(p-1)(k-1)/M} \quad k = 1, \dots, M$$

The modified IDFT equation does not include the multiplication factor of  $1/M$ .

#### Inherit FFT length from input dimensions — Inherit FFT length from input dimensions

on (default) | off

Select to inherit the FFT length from the input dimensions. If you do not select this parameter, the **FFT length** parameter becomes available to specify the length. You cannot clear this parameter when you select either the **Input is in bit-reversed order** or the **Input is conjugate symmetric** parameter.

#### FFT length — FFT length

64 (default) | integer

Specify FFT length as an integer greater than or equal to two.

When you set the **FFT implementation** parameter to Radix-2, or when you check the **Output in bit-reversed order** check box, this value must be a power of two.

#### Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

**Wrap input data when FFT length is shorter than input length** — Wrap or truncate the input

on (default) | off

Choose to wrap or truncate the input, depending on the FFT length. If you select this parameter, modulo-length data wrapping occurs before the FFT operation when the FFT length is shorter than the input length. If you clear this parameter, truncation of the input data to the FFT length occurs before the FFT operation.

#### Dependencies

To enable this parameter, clear the **Inherit FFT length from input dimensions** check box.

#### Data Types

**Rounding mode** — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

#### Limitations

The sine table values do not obey this parameter; instead, they always round to **Nearest**.

The **Rounding mode** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is **Inherit: Inherit via internal rule**.
- **Accumulator** data type is **Inherit: Inherit via internal rule**.

With these data type settings, the block operates in full-precision mode.

**Saturate on integer overflow** — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see **overflow mode for fixed-point operations**.

#### Limitations

The **Saturate on integer overflow** parameter has no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

#### **Sine table** — Data type of sine table values

`Inherit: Same word length as input (default) | fixdt(1,16)`

Choose how you specify the word length of the values of the sine table. The fraction length of the sine table values always equals the word length minus one. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Sine table** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

#### **Limitations**

The sine table values do not obey the **Rounding mode** and **Saturate on integer overflow** parameters; instead, they are always saturated and rounded to Nearest.

#### **Product output** — Product output data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixdt(1,16,0)`

Specify the product output data type. See “Fixed Point” on page 2-794 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

#### **Accumulator** — Accumulator data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixdt(1,16,0)`

Specify the accumulator data type. See “Fixed Point” on page 2-794 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) for more information.

### Output — Output data type

Inherit: `Inherit via internal rule (default) | Inherit: Same as input | fixdt(1,16,0)`

Specify the output data type. See “Fixed Point” on page 2-794 for illustrations depicting the use of the output data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`.

When you select `Inherit: Inherit via internal rule`, the block calculates the output word length and fraction length automatically. The equations that the block uses to calculate the ideal output word length and fraction length depend on the setting of the **Divide output by FFT length** check box.

- When you select the **Divide output by FFT length** check box, the ideal output word and fraction lengths are the same as the input word and fraction lengths.
- When you clear the **Divide output by FFT length** check box, the block computes the ideal output word and fraction lengths according to the following equations:

$$WL_{idealoutput} = WL_{input} + \text{floor}(\log_2(FFTlength - 1)) + 1$$

$$FL_{idealoutput} = FL_{input}$$

Using these ideal results, the internal rule then selects word lengths and fraction lengths that are appropriate for your hardware. For more information, see “Inherit via Internal Rule”.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) for more information.

### Output Minimum — Minimum value block should output

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Output Maximum — Maximum value block should output

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | yes                                     |
| <b>Variable-Size Signals</b>    | yes <sup>a</sup>                        |
| <b>Zero-Crossing Detection</b>  | no                                      |

<sup>a</sup> Variable-size signals are only supported when the Inherit FFT length from input dimensions checkbox is selected.

## Algorithms

### FFTW Implementation

The FFTW implementation provides an optimized FFT calculation including support for power-of-two and non-power-of-two transform lengths in both simulation and code generation. Generated code using the FFTW implementation will be restricted to MATLAB host computers. The data type must be floating-point. Refer to Simulink Coder for more details on generating code.

### Radix-2 Implementation

The Radix-2 implementation supports bit-reversed processing, fixed or floating-point data, and allows the block to provide portable C-code generation using the Simulink Coder. The dimension  $M$  of the  $M$ -by- $N$  input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible choose the FFTW implementation.

With Radix-2 selected, the block implements one or more of the following algorithms:

- Butterfly operation
- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm

### Radix-2 Algorithms for Real or Complex Input Complexity

| Parameter Settings   | Algorithms Used for IFFT Computation  |
|--|---|
| <input type="checkbox"/> Input is in bit-reversed order<br><input type="checkbox"/> Input is conjugate symmetric                       | Bit-reversal operation and radix-2 DIT  |
| <input checked="" type="checkbox"/> Input is in bit-reversed order<br><input type="checkbox"/> Input is conjugate symmetric            | Radix-2 DIT   |
| <input type="checkbox"/> Input is in bit-reversed order<br><input checked="" type="checkbox"/> Input is conjugate symmetric            | Bit-reversal operation and radix-2 DIT in conjunction with the half-length and double-signal algorithms |
| <input checked="" type="checkbox"/> Input is in bit-reversed order<br><input checked="" type="checkbox"/> Input is conjugate symmetric | Radix-2 DIT in conjunction with the half-length and double-signal algorithms                            |

### Radix-2 Optimization for the Table of Trigonometric Values

In certain situations, the block's Radix-2 algorithm computes all the possible trigonometric values of the twiddle factor

$$e^{j\frac{2\pi k}{K}}$$

where  $K$  is the greater value of either  $M$  or  $N$  and  $k = 0, \dots, K - 1$ . The block stores these values in a table and retrieves them during simulation. The number of table entries for fixed-point and floating-point is summarized in the following table:

| Number of Table Entries for N-Point FFT |        |
|---|--------|
| floating-point                          | $3N/4$ |
| fixed-point                             | $N$    |

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB:
  - **FFT implementation** is set to FFTW.
  - **Inherit FFT length from input dimensions** is cleared, and **FFT length** is set to a value that is not a power of two.

Use the packNGo function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used within the IFFT block for fixed-point signals. You can set the sine table, accumulator, product output, and output data types displayed in the diagrams in the IFFT block dialog box, as discussed in “Parameters” on page 2-787.

The IFFT block first casts input to the output data type and then stores it in the output buffer. Each butterfly stage then processes signals in the accumulator data type, with the final output of the butterfly being cast back into the output data type. The block multiplies in a twiddle factor before each butterfly stage in a decimation-in-time IFFT, and after each butterfly stage in a decimation-in-frequency IFFT.

**Decimation-in-time IFFT****Decimation-in-frequency IFFT****Butterfly stage data types****Twiddle multiplication data types**

The output of the multiplier is in the accumulator data type because both of the inputs to the multiplier are complex. For details on the complex multiplication performed, see “Multiplication Data Types”.

---

**Note** When the block input is fixed point, all internal data types are signed fixed point.

## IIR Halfband Interpolator

Interpolate signal using polyphase IIR halfband filter

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The IIR Halfband Interpolator block performs efficient polyphase interpolation of the input signal by a factor of 2. To design the halfband filter, you can use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than the quasi-linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or a wave digital form.

You can also use the block to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

## Ports

### Input

**LP** — Data input

column vector | matrix

Specify the data input as a vector or a matrix. If the input signal is a matrix, the block treats each column of the matrix as an independent channel.

When you select the **Input highpass subband** parameter, this block acts as a halfband synthesis filter bank. The input at this port is then the lowpass subband output of a halfband analysis filter bank.

This port is unnamed until you select the **Input highpass subband** parameter.

Data Types: `single` | `double`

**HP** — Second input to the synthesis filter bank

column vector | matrix

Specify the second input to the synthesis filter bank as a column vector or a matrix. This signal is the highpass subband output of a halfband analysis filter bank. If the input signal is a matrix, the block treats each column of the matrix as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

### Dependency

To enable this port, select the **Input highpass subband** parameter.

Data Types: `single` | `double`

**coeffs1** — Branch 1 allpass polynomial coefficients

*N*-by-1 vector | *N*-by-2 matrix

Specify the allpass polynomial filter coefficients of the first branch as an *N*-by-1 vector or *N*-by-2 matrix of *N* first-order or second-order allpass sections.

### Dependencies

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Make the first branch a pure delay** parameter
- Select the **Specify coefficients from input port** parameter

Data Types: `single` | `double`

**coeffs2** — Branch 2 allpass polynomial coefficients

*N*-by-1 vector | *N*-by-2 matrix

Specify the allpass polynomial filter coefficients of the second branch as an *N*-by-1 vector or *N*-by-2 matrix of *N* first-order or second-order allpass sections.

### Dependencies

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Select the **Specify coefficients from input port** parameter

Data Types: `single` | `double`

### Output

**Output** — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double`

## Parameters

**Filter specification** — Filter design parameters

Transition width and stopband attenuation (default) | Filter order and stopband attenuation | Filter order and transition width | Coefficients

Select the parameters that the block uses to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients— Specify the filter coefficients directly using the enabled parameters.

**Transition width (Hz)** — Transition width

4.1e3 (default) | positive real scalar

Specify the transition width of the IIR halfband filter as a real positive scalar in Hz. The transition width must be less than 1/2 the sample rate of the input signal.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Transition width and stopband attenuation.

**Filter order** — Order of the IIR halfband filter

9 (default) | positive integer

Specify the filter order as a positive integer. If you set **Design method** to Elliptic, then **Filter order** must be an odd integer greater than one. If you set **Design method** to Quasi-linear phase, then **Filter order** must be a multiple of four.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Filter order and stopband attenuation.

**Stopband attenuation (dB)** — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Specify the minimum attenuation needed in the stopband of the IIR halfband filter as a real positive scalar in dB.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation or Transition width and stopband attenuation.

**Design method** — Design method

Elliptic (default) | Quasi-linear phase

Specify the design method for the IIR halfband filter.

- **Elliptic** (default) — The filter has a nonlinear phase and uses few coefficients.
- **Quasi-linear phase** — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

#### Dependencies

To enable this parameter, set **Filter specification** to any option except **Coefficients**.

**Internal allpass structure** — Filter structure in coefficient mode

Minimum multiplier (default) | Wave Digital Filter

Specify the internal allpass filter implementation structure as **Minimum multiplier** or **Wave Digital Filter**. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property. The default is **Minimum multiplier**.

#### Dependencies

To enable this parameter, set **Filter specification** to **Coefficients**.

**Make the first branch a pure delay** — Make the first branch a pure delay

off (default) | on

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply.

By default, this check box is not selected.

#### Dependencies

To enable this parameter, set **Filter specification** to **Coefficients**.

**Delay length in samples for branch 1** — Length of the delay

1 (default) | finite positive scalar

Specify the length of the first branch delay as a finite positive scalar. The default is 1.

#### Dependencies

To enable this parameter, set:

- **Filter specification** to **Coefficients**
- Select the **Make the first branch a pure delay** parameter

**Specify coefficients from input port** — Specify coefficients from input port

off (default) | on

When you select this check box, you can input the branch 1 allpass polynomial coefficients and branch 2 allpass polynomial coefficients through the input ports **coeffs1** and **coeffs2**. When you clear this check box, you specify the coefficients in the block dialog box through the **Branch 1 allpass polynomial coefficients** and **Branch 2 allpass polynomial coefficients** parameters.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier

**Branch 1 allpass polynomial coefficients** — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass polynomial filter coefficients of the first branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

This parameter is tunable, that is, you can change its value during simulation.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Make the first branch a pure delay** parameter
- Clear the **Specify coefficients from input port** parameter

**Branch 2 allpass polynomial coefficients** — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass polynomial filter coefficients of the second branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

This parameter is tunable, that is, you can change its value during simulation.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Specify coefficients from input port** parameter

**Branch 1 Wave Digital coefficients** — Allpass filter coefficients of first branch in wave digital filter form

[0.1284563; 0.7906755] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass filter coefficients of the first branch in wave digital filter (WDF) form as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

The magnitude of each WDF coefficient must not be greater than 1.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Wave Digital Filter
- Clear the **Make the first branch a pure delay** parameter

**Branch 2 Wave Digital coefficients** — Allpass filter coefficients of second branch in wave digital filter form

[0.4295667] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass filter coefficients of the second branch in wave digital filter (WDF) form as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

The magnitude of each WDF coefficient must not be greater than 1.

#### Dependencies

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Wave Digital Filter

**Last section of branch 2 is first order** — Make the last section of the second branch as first order

off (default) | on

When you select this check box, the block treats the last section of the second branch as a first order section. When the coefficients of the second branch are in an  $N$ -by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When you clear this check box, the block treats the last section of the second branch as a second-order section. When the coefficients of the second branch are in an  $N$ -by-1 matrix, the block ignores this parameter.

By default, this check box is cleared.

#### Dependencies

To enable this parameter, set **Filter specification** to Coefficients.

**Input highpass subband** — Input highpass subband

off (default) | on

When you select this check box, the block acts as a synthesis filter bank. The block accepts two inputs to synthesize: lowpass and highpass subbands. When you clear this check box, the block acts as an IIR halfband interpolator and accepts a single vector or matrix as input. By default, this check box is cleared.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. The block calculates the sample rate based on the sample time of the input port. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

22050 (default) | positive real scalar

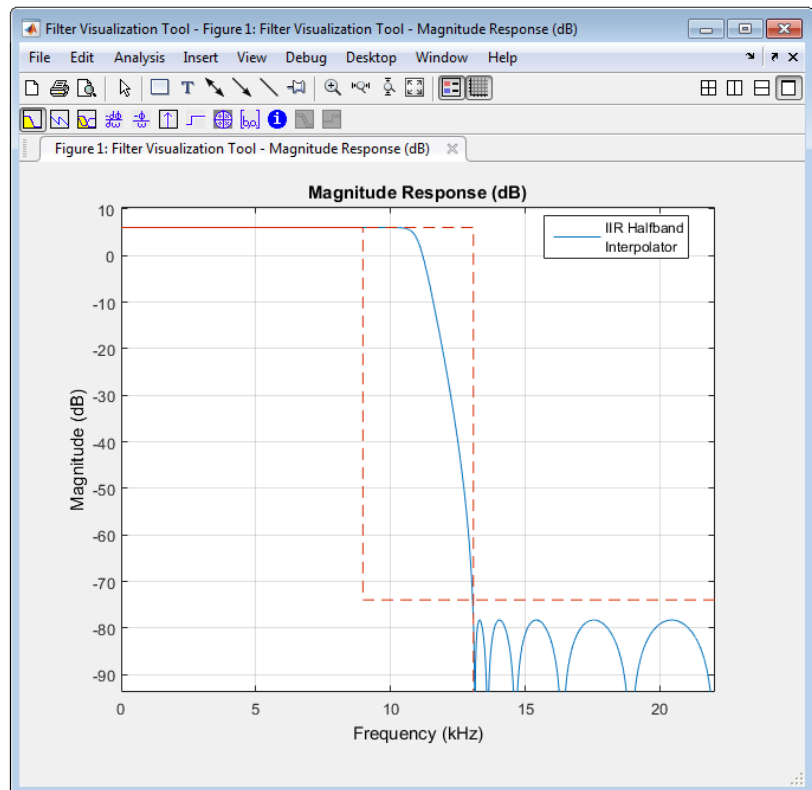

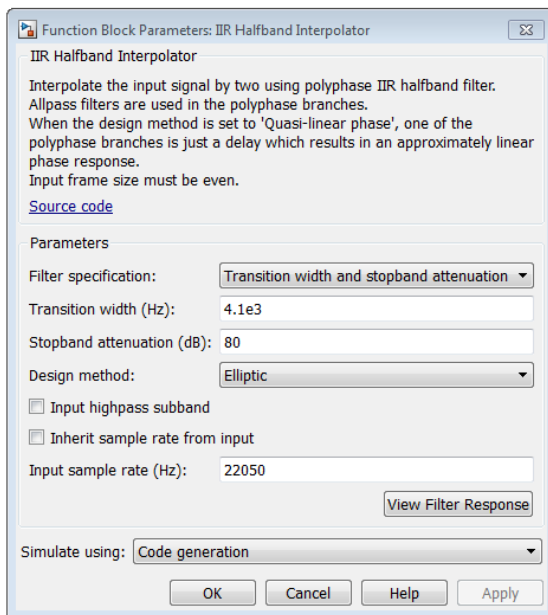

Specify the sample rate of the input signal as a scalar in Hz.

### Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of the IIR Halfband Interpolator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

### Polyphase Implementation with Halfband Filters

When you filter your signal, the IIR halfband interpolator uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at a lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

### Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

### Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where,  $k$  is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where  $N$  is the order of the IIR halfband filter.

You can represent the upsampling-by-2 operation followed by the filtering operation using this figure.

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at a lower rate.

To efficiently implement the halfband interpolator, this algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. The commutator switch operates at twice the input sample rate. This is shown in the following figure.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

### Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

You can represent the synthesis filter bank as in this diagram.

The IIR halfband interpolator implements the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, the IIR halfband interpolator:

- Filters the input before upsampling
- Acts as a synthesis filter bank
- Has a nonlinear phase response and uses few coefficients with the elliptic design method
- Has near-linear phase response at the cost of additional coefficients with the quasi-linear phase design method, where one of the branches is a pure delay

## IIR Halfband Decimator

Decimate signal using polyphase IIR halfband filter

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters

### Description

The IIR Halfband Decimator block performs polyphase decimation of the input signal by a factor of 2. To design the halfband filter, you can specify the block to use an elliptic design or a quasi-linear phase design. The block uses these design methods to compute the filter coefficients. To filter the inputs, the block uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than the quasi-linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or a wave digital form.

You can also use the block to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. For more details, see “Algorithms” on page 2-813.

### Ports

#### Input

**x** — Input signal  
column vector | matrix

Specify the input signal as a column vector or a matrix of size  $P$ -by- $Q$ . If the input signal is a matrix, the block treats each column of the matrix as an independent channel. The number of rows in the input signal must be a multiple of 2.

This block supports variable-size input signals.

This port is unnamed until you select the **Specify coefficients from input port** parameter.

Data Types: `single` | `double`

**coeffs1** — Branch 1 allpass polynomial coefficients  
 $N$ -by-1 vector |  $N$ -by-2 matrix

Specify the allpass polynomial filter coefficients of the first branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Make the first branch a pure delay** parameter
- Select the **Specify coefficients from input port** parameter

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**coeffs2** — Branch 2 allpass polynomial coefficients

$N$ -by-1 vector |  $N$ -by-2 matrix

Specify the allpass polynomial filter coefficients of the second branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Select the **Specify coefficients from input port** parameter

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Output**

**LP** — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of the decimator output, returned as a column vector or a matrix of size  $P/2$ -by- $Q$ . As the filter is a halfband filter, the downsampling factor is always 2.

This port is unnamed until you select the **Output highpass subband** parameter.

Data Types: single | double

**HP** — Highpass subband of decimator output

column vector | matrix

Highpass subband of the decimator output, returned as a column vector or a matrix of size  $P/2$ -by- $Q$ . As the filter is a halfband filter, the downsampling factor is always 2.

This port is unnamed until you select the **Output highpass subband** parameter.

Data Types: single | double

**Parameters**

**Filter specification** — Filter design parameters

Transition width and stopband attenuation (default) | Filter order and transition width | Filter order and stopband attenuation | Coefficients

Select the parameters that the block uses to design the IIR halfband filter. Because the filter design has only two degrees of freedom, you can specify only two of the three parameters:

- Transition width and stopband attenuation (default) — Design the filter using **Transition width (Hz)** and **Stopband attenuation (dB)**. This design is the minimum order design.
- Filter order and transition width — Design the filter using **Filter order** and **Transition width (Hz)**.
- Filter order and stopband attenuation — Design the filter using **Filter order** and **Stopband attenuation (dB)**.
- Coefficients— Specify the filter coefficients directly using the enabled parameters.

**Transition width (Hz)** — Transition width in Hz

4.1e3 (default) | positive real scalar

Specify the transition width of the IIR halfband filter as a real positive scalar in Hz. The transition width must be less than 1/2 the sample rate of the input signal.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Transition width and stopband attenuation.

**Filter order** — Order of the IIR halfband filter

9 (default) | positive integer

Specify the filter order as a finite positive integer. If you set **Design method** to Elliptic, then **Filter order** must be an odd integer greater than one. If you set **Design method** to Quasi-linear phase, then **Filter order** must be a multiple of four.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and transition width or Filter order and stopband attenuation.

**Stopband attenuation (dB)** — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Specify the minimum attenuation needed in the stopband of the IIR halfband filter as a real positive scalar in dB.

#### Dependencies

To enable this parameter, set **Filter specification** to Filter order and stopband attenuation or Transition width and stopband attenuation.

**Design method** — Design method

Elliptic (default) | Quasi-linear phase

Specify the design method for the IIR halfband filter.

- **Elliptic** — The filter has a nonlinear phase and uses few coefficients.
- **Quasi-linear phase** — The first branch of the polyphase filter structure is a pure delay, which results in an approximately linear phase response.

#### Dependencies

To enable this parameter, set **Filter specification** to any option except **Coefficients**.

**Internal allpass structure** — Internal allpass filter implementation structure

Minimum multiplier (default) | Wave Digital Filter

Specify the internal allpass filter implementation structure as **Minimum multiplier** or **Wave Digital Filter**. Each structure uses a different coefficients set, independently stored in the corresponding coefficients property.

#### Dependencies

To enable this parameter, set **Filter specification** to **Coefficients**.

**Make the first branch a pure delay** — Make first branch a pure delay

off (default) | on

When you select this check box, the first branch of the polyphase filter structure becomes a pure delay, and the **Branch 1 allpass polynomial coefficients** and **Branch 1 Wave Digital coefficients** parameters do not apply.

By default, this check box is not selected.

#### Dependencies

To enable this parameter, set **Filter specification** to **Coefficients**.

**Delay length in samples for branch 1** — Length of delay

1 (default) | positive scalar

Specify the length of the first branch delay as a positive scalar.

#### Dependencies

To enable this parameter, set:

- **Filter specification** to **Coefficients**
- Select the **Make the first branch a pure delay** parameter

**Specify coefficients from input port** — Specify coefficients from input port

off (default) | on

When you select this check box, you can input the branch 1 allpass polynomial coefficients and branch 2 allpass polynomial coefficients through the input ports **coeffs1** and **coeffs2**. When you clear this check box, you specify the coefficients in the block dialog box through the **Branch 1 allpass polynomial coefficients** and **Branch 2 allpass polynomial coefficients** parameters.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier

**Branch 1 allpass polynomial coefficients** — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass polynomial filter coefficients of the first branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

This parameter is tunable, that is, you can change its value during simulation.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Make the first branch a pure delay** parameter
- Clear the **Specify coefficients from input port** parameter

**Branch 2 allpass polynomial coefficients** — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass polynomial filter coefficients of the second branch as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

This parameter is tunable, that is, you can change its value during simulation.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Minimum multiplier
- Clear the **Specify coefficients from input port** parameter

**Branch 1 Wave Digital coefficients** — Allpass filter coefficients of first branch in wave digital filter form

[0.1284563; 0.7906755] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass filter coefficients of the first branch in wave digital filter (WDF) form as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

The magnitude of each WDF coefficient must not be greater than 1.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Wave Digital Filter
- Clear the **Make the first branch a pure delay** parameter

**Branch 2 Wave Digital coefficients** — Allpass filter coefficients of second branch in wave digital filter form

[0.4295667] (default) |  $N$ -by-1 |  $N$ -by-2

Specify the allpass filter coefficients of the second branch in wave digital filter form as an  $N$ -by-1 vector or  $N$ -by-2 matrix of  $N$  first-order or second-order allpass sections.

The magnitude of each WDF coefficient must not be greater than 1.

**Dependencies**

To enable this parameter, set:

- **Filter specification** to Coefficients
- **Internal allpass structure** to Wave Digital Filter

**Last section of branch 2 is first order** — Last section of branch 2 is first order

off (default) | on

When you select this check box, the block treats the last section of the second branch as a first order section. When the coefficients of the second branch are in an  $N$ -by-2 matrix, the block ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section.

When you clear this check box, the block treats the last section of the second branch as a second-order section. When the coefficients of the second branch are in an  $N$ -by-1 matrix, the block ignores this parameter.

**Dependencies**

To enable this parameter, set **Filter specification** to Coefficients.

**Output highpass subband** — Output highpass subband

off (default) | on

When you select this check box, the block acts as an analysis filter bank, producing two power-complementary outputs. When you clear this check box, the block acts as an IIR halfband decimator and accepts a single vector or matrix as input.

**Inherit sample rate from input** — Inherit sample rate from input signal

off (default) | on

When you select this check box, the block inherits its sample rate from the input signal. When you clear this check box, you specify the sample rate in **Input sample rate (Hz)**.

**Input sample rate (Hz)** — Sample rate of input signal

44100 (default) | positive real scalar

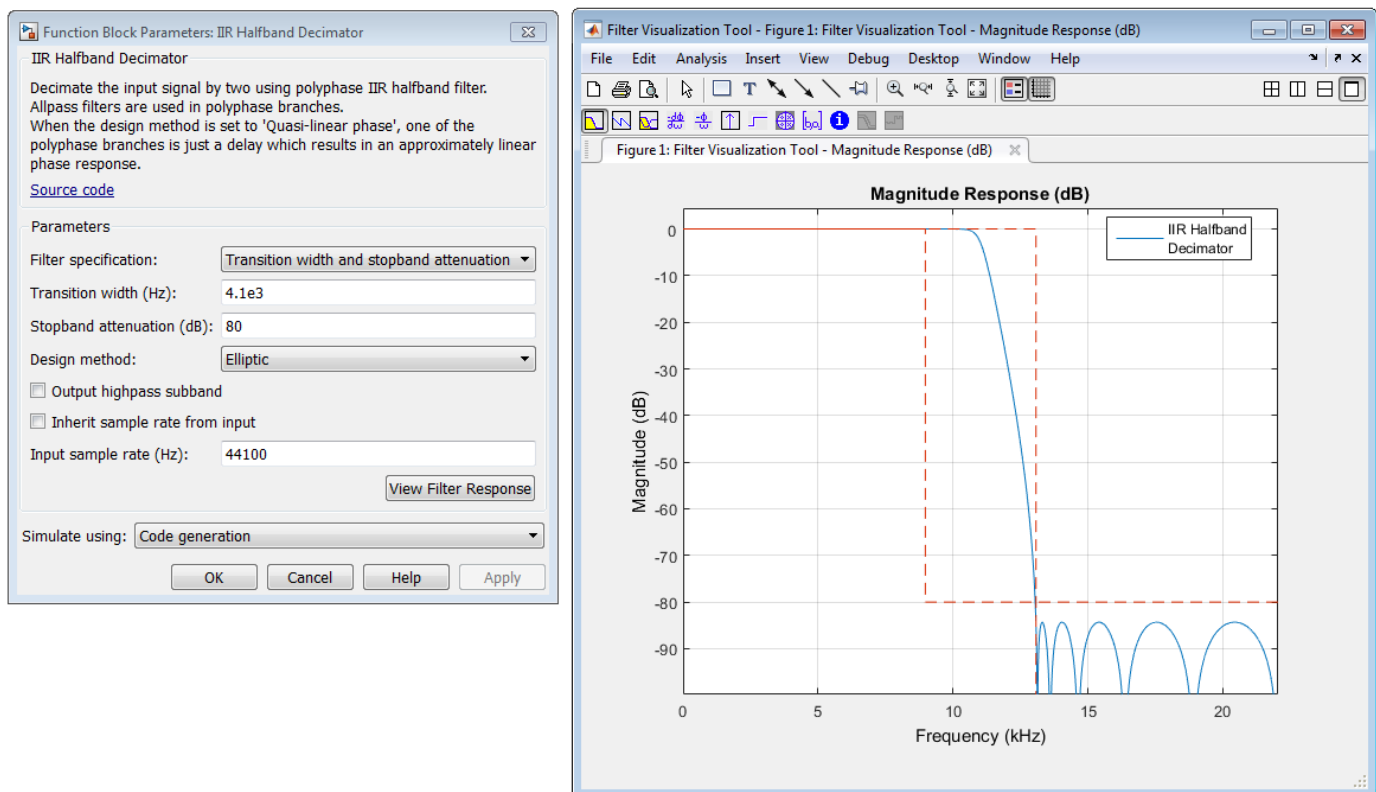

Specify the sample rate of the input signal as a scalar in Hz.

### Dependencies

To enable this parameter, clear the **Inherit sample rate from input** parameter.

**View Filter Response** — View Filter Response button

Click this button to open the Filter Visualization Tool (FVTool) and display the magnitude and phase response of the IIR Halfband Decimator. The response is based on the values you specify in the block parameters dialog box. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

### Polyphase Implementation with Halfband Filters

When you filter your signal, the IIR halfband decimator uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at a lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

### Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

### Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where  $k$  is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where  $N$  is the order of the IIR halfband filter.

You can represent filtering the input signal and then downsampling it by 2 using this figure.

Using the multirate noble identity for downsampling, you can move the downsampling operation before the filtering operation. This change enables you to filter at a lower rate.

To implement the halfband decimator efficiently, this algorithm replaces the delay block and downsampling operator with a commutator switch.

### Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

You can represent the analysis filter bank as in this diagram.

The IIR halfband decimator generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, the IIR halfband decimator:

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has a nonlinear phase response and uses few coefficients with the elliptic design method.
- Has near-linear phase response at the cost of additional coefficients with the quasi-linear phase design method, where one of the branches is a pure delay

## Inherit Complexity

Change complexity of input to match reference signal

## Library

Signal Management / Signal Attributes

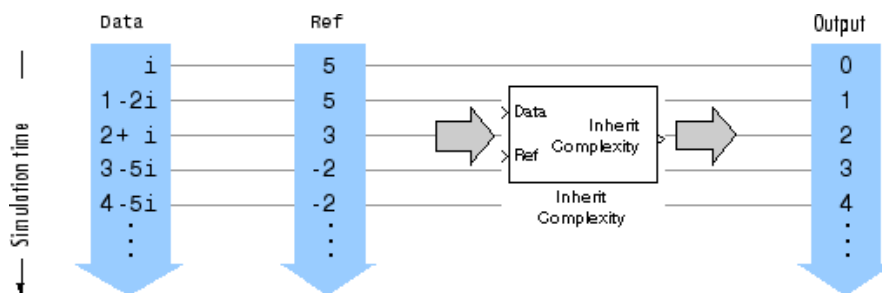

dpsigattribs

## Description

The Inherit Complexity block alters the input data at the Data port to match the complexity of the reference input at the Ref port. When the Data input is real, and the Ref input is complex, the block appends a zero-valued imaginary component,  $0i$ , to each element of the Data input.

When the Data input is complex, and the Ref input is real, the block outputs the real component of the Data input.

When both the Data input and Ref input are real, or when both the Data input and Ref input are complex, the block propagates the Data input with no change.

## Supported Data Types

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

The Inherit Complexity block supports HDL code generation for these input types:

- Input complexities, such as real or complex, at the data and reference port
- Vector, matrix, and bus inputs

### HDL Architecture

This block has one default HDL architecture.

### HDL Block Properties

| General                          |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

### Limitations

The block has these HDL code generation limitations:

- Half-precision data type is not supported.
- Non-virtual bus input is not supported.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

## Integer Delay (Obsolete)

Delay input by integer number of sample periods

### Library

dspobslib

### Description

---

**Note** The Integer Delay block will be removed from the product in a future release. We strongly recommend replacing this block with the Delay block.

---

The Integer Delay block delays a discrete-time input by the number of sample intervals specified in the **Delay** parameter. Noninteger delay values are rounded to the nearest integer, and negative delays are clipped at 0.

#### Sample-Based Operation

When the input is a sample-based  $M$ -by- $N$  matrix, the block treats each of the  $M \times N$  matrix elements as an independent channel. The **Delay** parameter,  $v$ , can be an  $M$ -by- $N$  matrix of positive integers that specifies the number of sample intervals to delay each channel of the input, or a scalar integer by which to equally delay all channels.

For example, when the input is  $M$ -by-1 and  $v$  is the matrix  $[v(1) \ v(2) \ \dots \ v(M)]'$ , the first channel is delayed by  $v(1)$  sample intervals, the second channel is delayed by  $v(2)$  sample intervals, and so on. Note that when a channel is delayed for  $\Delta$  sample-time units, the output sample at time  $t$  is the input sample at time  $t - \Delta$ . When  $t - \Delta$  is negative, then the output is the corresponding value specified by the **Initial conditions** parameter.

A 1-D vector of length  $M$  is treated as an  $M$ -by-1 matrix, and the output is 1-D.

The **Initial conditions** parameter specifies the output of the block during the initial delay in each channel. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input.

#### Fixed Initial Conditions

A fixed initial condition in sample-based mode can be specified as one of the following:

- Scalar value to be repeated at each sample time of the initial delay (for every channel). For a 2-by-2 input with the parameter settings below,

the block generates the following sequence of matrices at the start of the simulation,

$$\begin{bmatrix} -1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^1 & -1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^2 & u_{12}^1 \\ -1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^3 & u_{12}^2 \\ u_{21}^1 & -1 \end{bmatrix}, \begin{bmatrix} u_{11}^4 & u_{12}^3 \\ u_{21}^2 & u_{22}^1 \end{bmatrix}, \dots$$

where  $u_{ij}^k$  is the  $ij$ th element of the  $k$ th matrix in the input sequence.

- Array of size  $M$ -by- $N$ -by- $d$ . In this case, you can set different fixed initial conditions for each element of a sample-based input. This setting is explained further in the Array bullet in “Time-Varying Initial Conditions” on page 2-820.

Initial conditions cannot be specified by full matrices.

### Time-Varying Initial Conditions

A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector of length  $d$ , where  $d$  is the maximum value specified for any channel in the **Delay** parameter. The vector can be a  $L$ -by- $d$ , 1-by- $d$ , or 1-by-1-by- $d$ . The  $d$  elements of the vector are output in sequence, one at each sample time of the initial delay.

For a scalar input and the parameters shown below,

the block outputs the sequence -1, -1, -1, 0, 1, ... at the start of the simulation.

- Array of dimension  $M$ -by- $N$ -by- $d$ , where  $d$  is the value specified for the **Delay** parameter (the maximum value when the **Delay** is a vector) and  $M$  and  $N$  are the number of rows and columns, respectively, in the input matrix. The  $d$  pages of the array are output in sequence, one at each sample time of the initial delay. For a 2-by-3 input, and the parameters below,

the block outputs the matrix sequence

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}, \begin{bmatrix} 2 & 4 & 6 \\ 1 & 3 & 5 \end{bmatrix}, \begin{bmatrix} 3 & 6 & 9 \\ 0 & 4 & 8 \end{bmatrix}$$

at the start of the simulation. Note that setting **Initial conditions** to an array with the same matrix for each entry implements constant initial conditions; a different constant initial condition for each input matrix element (channel).

Initial conditions cannot be specified by full matrices.

### Frame-Based Operation

When the input is a frame-based  $M$ -by- $N$  matrix, the block treats each of the  $N$  columns as an independent channel, and delays each channel as specified by the **Delay** parameter.

For frame-based inputs, the **Delay** parameter can be a scalar integer by which to equally delay all channels. It can also be a 1-by- $N$  row vector, each element of which serves as the delay for the corresponding channel of the  $N$ -channel input. Likewise, it can also be an  $M$ -by-1 column vector, each element of which serves as the delay for one of the corresponding  $M$  samples for each channel. The **Delay** parameter can be an  $M$ -by- $N$  matrix of positive integers as well; in this case, each element of each channel is delayed by the corresponding element in the delay matrix. For instance, if the fifth element of the third column of the delay matrix was 3, then the fifth element of the third channel of the input matrix is always delayed by three sample-time units.

When a channel is delayed for  $\Delta$  sample-time units, the output sample at time  $t$  is the input sample at time  $t - \Delta$ . When  $t - \Delta$  is negative, then the output is the corresponding value specified in the **Initial conditions** parameter.

The **Initial conditions** parameter specifies the output during the initial delay. Both fixed and time-varying initial conditions can be specified. The initial delay for a particular channel is the time elapsed from the start of the simulation until the first input in that channel is propagated to the output.

### Fixed Initial Conditions

The settings shown below specify fixed initial conditions. The value entered in the **Initial conditions** parameter is repeated at the output for each sample time of the initial delay. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value to be repeated for all channels of the output at each sample time of the initial delay. For a general  $M$ -by- $N$  input with the parameter settings below,

The image shows a screenshot of a software interface with two input fields. The first field is labeled "Delay (samples):" and contains the number "5". The second field is labeled "Initial conditions:" and contains the number "0".

the first five samples in each of the  $N$  channels are zero. Notice that when the frame size is larger than the delay, all of these zeros are all included in the first output from the block.

- Array of size 1-by- $N$ -by- $D$ . In this case, you can also specify different fixed initial conditions for each channel. See “Time-Varying Initial Conditions” on page 2-821 for details.

Initial conditions cannot be specified by full matrices.

### Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For time-varying initial conditions, the values specified in the **Initial conditions** parameter are output in sequence during the initial delay. A time-varying initial condition in frame-based mode can be specified in the following ways:

- Vector of length  $D$ , where each of the  $N$  channels have the same initial conditions sequence specified in the vector.  $D$  is defined as follows:

- When an element of the delay entry is less than the frame size,

$$D = d + 1$$

where  $d$  is the maximum delay.

- When the all elements of the delay entry are greater than the input frame size,

$$D = d + \text{input frame size} - 1$$

Only the first  $d$  entries of the initial condition vector are used; the rest of the values are ignored, but you must include them nonetheless. For a two-channel ramp input  $[1:100; 1:100]'$  with a frame size of 4 and the parameter settings below,

the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -4 & -1 \\ -5 & -2 \\ 1 & -3 \\ 2 & -4 \end{bmatrix}, \begin{bmatrix} 3 & -5 \\ 4 & 1 \\ 5 & 2 \\ 6 & 3 \end{bmatrix}, \begin{bmatrix} 7 & 4 \\ 8 & 5 \\ 9 & 6 \\ 10 & 7 \end{bmatrix}, \dots$$

Note that since one of the delays, 2, is less than the frame size of the input, 4, the length of the **Initial conditions** vector is the sum of the maximum delay and 1 (5+1), which is 6. The first five entries of the initial conditions vector are used by the channel with the maximum delay, and the rest of the entries are ignored. Since the first channel is delayed for less than the maximum delay (2 sample time units), it only makes use of two of the initial condition entries.

- Array of size 1-by- $N$ -by- $D$ , where  $D$  is defined in “Time-Varying Initial Conditions” on page 2-821. In this case, the  $k$ th entry of each 1-by- $N$  entry in the array corresponds to an initial condition for the  $k$ th channel of the input matrix. Thus, a 1-by- $N$ -by- $D$  initial conditions input allows you to specify different initial conditions for each channel. For instance, for a two-channel ramp input  $[1:100; 1:100]'$  with a frame size of 4 and the parameter settings below,

the block outputs the following sequence of frames at the start of the simulation.

$$\begin{bmatrix} -1 & -2 \\ -3 & -4 \\ -5 & -6 \\ -7 & -8 \end{bmatrix}, \begin{bmatrix} -9 & -10 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

Note that the channels have distinct time varying initial conditions; the initial conditions for channel 1 correspond to the first entry of each length-2 row vector in the initial conditions array, and the initial conditions for channel 2 correspond to the second entry of each row vector in the

initial conditions array. Only the first five entries in the initial conditions array are used; the rest are ignored.

The 1-by- $N$ -by- $D$  array entry can also specify different fixed initial conditions for every channel; in this case, every 1-by- $N$  entry in the array would be identical, so that the initial conditions for each column are fixed over time.

Initial conditions cannot be specified by full matrices.

### Resetting the Delay

The block resets the delay whenever it detects a reset event at the optional Rst port. The reset sample time must be a positive integer multiple of the input sample time.

You specify the reset event in the **Reset port** parameter:

- None disables the Rst port.
- Rising edge — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- Falling edge — Triggers a reset operation when the Rst input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero.

---

**Note** When running simulations in the Simulink **MultiTasking** mode, sample-based reset signals have a one-sample latency, and frame-based reset signals have one frame of latency. Thus, there is a one-sample or one-frame delay between the time the block detects a reset event, and when it applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Parameters

### Delay

The number of sample periods to delay the input signal.

### Initial conditions

The value of the block's output during the initial delay.

### Reset port

Determines the reset event that causes the block to reset the delay. For more information, see “Resetting the Delay” on page 2-823.

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled by the **Reset port** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

# Interpolation

Interpolate values of real input samples

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Interpolation block interpolates discrete, real inputs by using linear or FIR interpolation. The block accepts a vector, a matrix, or an  $N$ -D array. The block outputs a scalar, a vector, a matrix, or an  $N$ -D array of the interpolated values.

You must specify the interpolation points, the times at which to interpolate values in a one-based interpolation array  $I_{pts}$ . An entry of 1 in  $I_{pts}$  refers to the first sample of the input data, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. Depending on the dimensions of the input data,  $I_{pts}$  can be a scalar, a length- $P$  row, or a column vector, a  $P$ -by- $N$  matrix, or an  $N$ -D array where  $P$  is the size of the first dimension of the  $N$ -D array. In most cases,  $P$  can be any positive integer. For more information about valid interpolation arrays, refer to the tables in “Pts” on page 2-0 and “Interpolation points” on page 2-0.

In most cases, the block applies  $I_{pts}$  across the first dimension of an  $N$ -D input array or to each input vector. You can set the block to apply the same interpolation array for all input data, static interpolation points entered on the block mask, or to use a different interpolation array for each  $N$ -D array, matrix, or vector input, time-varying interpolation points received through the Pts input port.

## Ports

### Input

**In** — Input signal

scalar | vector | matrix |  $N$ -D array

Input signal, specified as a scalar, vector, matrix, or  $N$ -D array.

This port is unnamed until **Source of interpolation points** is set to **Input port**.

Data Types: single | double

**Pts** — Interpolation points

scalar | vector | matrix |  $N$ -D array

Interpolation points, specified as a scalar, vector, matrix, or  $N$ -D array.

For more details on the block's behavior when the **Source of interpolation points** parameter is set to **Input port**, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-829.

### Dependencies

This port is unavailable until **Source of interpolation points** is set to **Input port**.

Data Types: `single` | `double`

## Output

**Out** — Output signal  
 scalar | vector | matrix | *N*-D array

Output signal, specified as a vector, matrix, or *N*-D array.

This port is unnamed until `Source of interpolation points` is set to `Input port`.

Data Types: `single` | `double`

## Parameters

**Source of interpolation points** — Interpolation point input method

`Specify via dialog` (default) | `Input port`

Choose how you want to specify the interpolation points:

- `Specify via dialog` -- The `Interpolation points` parameter becomes available. Use this option for static interpolation points.
- `Input port` -- The `Pts` port appears on the block. The block uses the input to this port as the interpolation points. Use this option for time-varying interpolation points.

For more information, see “Specifying Static Interpolation Points” on page 2-828 and “Specifying Time-Varying Interpolation Points” on page 2-828.

**Interpolation points** — Interpolation points

`[1.1 4.8 2.67 1.6 3.2]'` (default) | scalar | vector | matrix | *N*-D array

The array of points in time at which to interpolate the input signal ( $I_{pts}$ ). An entry of 1 in  $I_{pts}$  refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. See “How the Block Applies Interpolation Arrays to Inputs” on page 2-829.

**Tunable:** Yes

## Dependencies

This parameter becomes available only when the `Source of interpolation points` is set to `Specify via dialog`. For more information, see “Specifying Static Interpolation Points” on page 2-828.

**Interpolation mode** — Interpolation mode

`Linear` (default) | `FIR`

Sets the block to interpolate by either `Linear` or `FIR` interpolation. For more information, see “Linear Interpolation Mode” on page 2-831 and “FIR Interpolation Mode” on page 2-832.

**Interpolation filter half-length** — Half length of FIR interpolation filter

3 (default) | positive integer

Specify the half-length of the FIR interpolation filter ( $P$ ). To perform the interpolation in FIR mode, the block uses the nearest  $2 \times P$  low-rate samples. In most cases,  $P$  low-rate samples must appear below and above each interpolation point. If you interpolate at a low-rate sample point, the block includes that low-rate sample in the required  $2 \times P$  samples and requires only  $2 \times P - 1$  neighboring low-rate samples. If an interpolation point does not have the required number of neighboring low-rate samples, the block interpolates that point using linear interpolation.

#### Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-832.

#### Interpolation points per input sample — Interpolation points per sample

3 (default)

Number of points per input sample, upsampling factor ( $L$ ), at which the block computes a unique FIR interpolation filter. To perform the FIR interpolation, the block uses a polyphase structure that has  $L$  filter arms of length  $2 \times P$ .

For example, if  $L=4$ , the block constructs a polyphase filter with four arms. The block then interpolates at points corresponding to  $1 + i/L$ ,  $2 + i/L$ ,  $3 + i/L$ ..., where the integers 1, 2, and 3 represent the low-rate samples, and  $i=0, 1, 2, 3$ . To interpolate at a point that does not directly correspond to an arm of the polyphase filter requires an extra computation. The block first rounds that point down to the nearest value that does correspond to an arm of the polyphase filter. To interpolate at the point 2.2, the block rounds 2.2 down to 2, and computes the FIR interpolation by using the first arm of the polyphase filter structure. Similarly, to interpolate the point 2.65, the block rounds the value down to 2.5 and uses the third arm of the polyphase filter structure.

#### Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-832.

#### Normalized input bandwidth — Normalized input bandwidth

0.5 (default) | scalar in (0 1]

The bandwidth of the input divided by  $F_s/2$  (half the input sample frequency), specified as a scalar in the range (0 1].

#### Dependencies

This parameter becomes available only when the `Interpolation` mode is set to FIR. For more information, see “FIR Interpolation Mode” on page 2-832.

#### Out of range interpolation points — Error handling for out-of-range points

Clip (default) | Clip and warn | Error

Valid values in the interpolation array  $I_{pts}$  range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector  $D$ , all entries of  $I_{pts}$  must range from 1 to 5.  $I_{pts}$  cannot contain entries such as 7 or -9 because there is no 7th or -9th entry in  $D$ .

The **Out of range interpolation points** parameter sets how the block handles interpolation points that fall outside the valid range. The parameter has these settings:

- **Clip** — The block replaces any out-of-range values in  $I_{pts}$  with the closest value in the valid range (from 1 to the number of input samples), and then proceeds with computations by using the clipped version of  $I_{pts}$ .
- **Clip and warn** — In addition to **Clip**, the block issues a warning at the MATLAB command line every time clipping occurs.
- **Error** — When the block encounters an out-of-range value in  $I_{pts}$ , the simulation stops, and the block issues an error at the MATLAB command line.

As an example of clipping, suppose the block is set to clip out-of-range interpolation points and gets these input vector and interpolation points:

- $D = [11 \ 22 \ 33 \ 44]'$
- $I_{pts} = [10 \ 2.6 \ -3]'$

Because  $D$  has four samples, valid interpolation points range from 1 to 4. The block clips the interpolation point 10 to 4 and the point -3 to 1, resulting in the clipped interpolation vector  $I_{ptsClipped} = [4 \ 2.6 \ 1]'$ .

## Block Characteristics

| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## More About

### Specifying Static Interpolation Points

To supply the block with a static interpolation array, that is an interpolation array applied to every vector or  $N$ -D array of input data), perform the following steps:

- 1 Set the **Source of interpolation points** parameter to **Specify via dialog**.
- 2 Enter the interpolation array in the **Interpolation points** parameter. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-829.

### Specifying Time-Varying Interpolation Points

To supply the block with time-varying interpolation arrays, where the block uses a different interpolation array for each vector or  $N$ -D array input, perform the following steps:

- 1 Set the **Source of interpolation points** parameter to **Input port**. The **Pts** port appears on the block.

- 2 Generate a signal of interpolation arrays and supply it to the **Pts** port. The block uses the input to this port as the interpolation points. To learn about interpolation arrays, see “How the Block Applies Interpolation Arrays to Inputs” on page 2-829.

### How the Block Applies Interpolation Arrays to Inputs

The interpolation array  $I_{Pts}$  represents the points in time at which to interpolate values of the input signal. An entry of 1 in  $I_{Pts}$  refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when  $I_{Pts}$  is a vector, it can be of any length.

Valid values in the interpolation array,  $I_{Pts}$ , range from 1 to the number of samples in each channel of the input. To learn how the block handles out-of-range interpolation values, see **Out of range interpolation points**.

Depending on the dimension of the input and the dimension of  $I_{Pts}$ , the block usually applies  $I_{Pts}$  to the input in one of the following ways:

- Applies the  $I_{Pts}$  array across the first dimension of an  $N$ -D array, resulting in an  $N$ -D array output.
- Applies the vector  $I_{Pts}$  to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

These tables summarize how the block applies the interpolation array  $I_{Pts}$  to all the possible types of inputs and shows the resulting output dimensions.

The first table describes the block's behavior when the **Source of interpolation points is Specify via dialog**.

### Specify Interpolation Points Through Dialog Box

| Input Dimensions             | Valid Dimensions of Interpolation Array / $I_{Pts}$ | How Block Applies $I_{Pts}$ to Input  | Output Dimensions (Frame-Based) |
|------------------------------|---|---|---------------------------------|
| $M$ -by- $N$ -by- $K$ matrix | $P$ -by-1 column                                    | Applies $I_{Pts}$ to the first dimension of the input   | $P$ -by- $N$ -by- $K$ array     |
|                              | $P$ -by- $N$ -by- $K$ matrix                        | Applies each column of $I_{Pts}$ (each element of $I_{Pts}$ ) to the corresponding column of the input matrix | $P$ -by- $N$ -by- $K$ array     |
| $M$ -by- $N$ matrix          | 1-by- $N$ row                                       | Applies each column of $I_{Pts}$ (each element of $I_{Pts}$ ) to the corresponding column of the input matrix | 1-by- $N$ row                   |
|                              | $P$ -by-1 column                                    | Applies $I_{Pts}$ to each input column  | $P$ -by- $N$ matrix             |
|                              | $P$ -by- $N$ matrix                                 | Applies the columns of $I_{Pts}$ to the corresponding columns of the input matrix                             |                                 |

| Input Dimensions                   | Valid Dimensions of Interpolation Array / Pts | How Block Applies / Pts to Input          | Output Dimensions (Frame-Based)                                  |
|------------------------------------|---|---|--|
| $M$ -by-1 column                   | $P$ -by-1 column                              | Applies $I_{Pts}$ to the input column     | $P$ -by-1 column   |
| 1-by- $N$ row<br>(not recommended) | 1-by- $N$ row                                 | Not Applicable. Block copies input vector | 1-by- $N$ row, a copy of the input vector                        |
|                                    | $P$ -by-1 column                              |   | $P$ -by- $N$ matrix where each row is a copy of the input vector |
|                                    | $P$ -by- $N$ matrix                           |   |  |

The next table describes the block's behavior when the **Source of interpolation points** is Input port.

**Specify Interpolation Points Through Input Port**

| Input Dimensions                   | Valid Dimensions of Interpolation Array / Pts    | How Block Applies / Pts to Input  | Output Dimensions (Frame-Based)                                  |
|------------------------------------|--|---|--|
| $M$ -by- $N$ -by- $K$ matrix       | Unoriented vector or column vector of length $P$ | Applies $I_{Pts}$ to the first dimension of the input   | $P$ -by- $N$ -by- $K$ array                                      |
|                                    | $P$ -by- $N$ -by- $K$ matrix                     | Applies each column of $I_{Pts}$ (each element of $I_{Pts}$ ) to the corresponding column of the input matrix | $P$ -by- $N$ -by- $K$ array                                      |
| $M$ -by- $N$ matrix                | 1-by- $N$ row                                    | Applies each column of $I_{Pts}$ (each element of $I_{Pts}$ ) to the corresponding column of the input matrix | 1-by- $N$ row  |
|                                    | $P$ -by-1 column                                 | Applies $I_{Pts}$ to each input column  | $P$ -by- $N$ matrix  |
|                                    | $P$ -by- $N$ matrix                              | Applies the columns of $I_{Pts}$ to the corresponding columns of the input matrix                             |  |
| $M$ -by-1 column                   | $P$ -by-1 column                                 | Applies $I_{Pts}$ to the input column   | $P$ -by-1 column   |
| 1-by- $N$ row<br>(not recommended) | 1-by- $N$ row                                    | Not Applicable. Block copies input vector   | 1-by- $N$ row, a copy of the input vector                        |

|                                    | $P$ -by- $N$ matrix                              |   |  |

## Algorithms

### Linear Interpolation Mode

When Interpolation mode is set to Linear, the block interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

For instance, if the input signal  $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$ , the plot on the left shows the samples in  $D$  and the plot on the right shows the linearly interpolated values between the samples in  $D$ .

The following figure illustrates the case of a block in linear interpolation mode that is set to clip out-of-range interpolation points. The vector  $D$  supplies the input data and the vector  $I_{pts}$  supplies the interpolation points:

- $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$
- $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$

The block clips the invalid interpolation points and outputs the linearly interpolated values in a vector,  $[1 \ 1.65 \ 2.175 \ 0.25]'$ .

Interpolated Values of D at Clipped Interpolation Points

$D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$   
 $lpts = [-4 \ 2.7 \ 4.3 \ 10]'$

Valid interpolation points range from 1 to 5, so -4 is clipped to 1 and 10 is clipped to 5.

Clipped  $lpts = [1 \ 2.7 \ 4.3 \ 5]'$

Output =  $[1 \ 1.65 \ 2.175 \ 0.25]'$

### FIR Interpolation Mode

When `Interpolation` mode is set to FIR, the block interpolates data values by using an FIR interpolation filter, specified by various block parameters. For more information, see “FIR Interpolation Mode” on page 2-1529 in the Variable Fractional Delay block reference.

# Inverse Short-Time FFT

Recover time-domain signals by performing inverse short-time fast Fourier transform (FFT)

## Libraries:

DSP System Toolbox / Transforms / Matrix Operations

## Description

The Inverse Short-Time FFT block reconstructs the time-domain signal from the frequency-domain output of the Short-Time FFT block using a two-step process. First, the block implements the overlap-add algorithm.

$$x[n] = \frac{L}{W(0)} \sum_{p=-\infty}^{\infty} \left[ \frac{1}{N} \sum_{k=0}^{N-1} X[pL, k] e^{j2\pi kn/N} \right]$$

Then, the block rebuffers the signal in order to reconstruct the time-domain signal. Depending on the analysis window used by the Short-Time FFT block, the Inverse Short-Time FFT block might or might not achieve perfect reconstruction of the time-domain signal.

## Ports

### Input

**X[nL,k]** — Frequency-domain input signal  
unoriented vector | column vector | matrix

Specify the frequency-domain input signal as a vector or a matrix. The FFT length is equal to the number of rows in the input at the **x[nL,k]** port. Hence the number of input rows must be greater than or equal to the window length.

Data Types: single | double

**w[n]** — Analysis window  
vector

Specify the analysis window at the **w[n]** port.

Data Types: single | double

### Output

**x[n]** — Inverse short-time FFT output  
vector | matrix

The block outputs the inverse short-time FFT output at the port **x[n]**.

Data Types: single | double

## Parameters

**Analysis window length** — Length of analysis window

512 (default) | positive integer greater than 1

Enter the length of the analysis window as a positive integer greater than 1.

**Overlap between consecutive STFFT frames (in samples)** — Overlap length

384 (default) | nonnegative integer

Enter the number of samples of overlap for each frame of the input signal as a nonnegative integer. This value should be the same as the **Overlap between consecutive windows (in samples)** parameter in the dialog box of the Short-Time FFT block.

**Samples per output frame** — Number of samples per output frame

512 (default) | positive integer

Enter the desired frame size of the output signal as a positive integer.

**Input is conjugate symmetric** — Input to the block is conjugate symmetric

on (default) | off

Select this check box when the input to the block is both floating point and conjugate symmetric and you want real-valued outputs. If you select this check box when the input is not conjugate symmetric, the output of the block is invalid. This parameter cannot be used for fixed-point signals.

**Assert if analysis window does not support perfect signal reconstruction** — Error if analysis window does not support perfect signal reconstruction

off (default) | on

Select this check box to display an error when the analysis window used by the Short-Time FFT block does not support perfect signal reconstruction.

A time-domain signal input to the Short-time FFT block cannot be perfectly reconstructed.

To determine if the signal can be perfectly reconstructed, the Inverse Short-time FFT block uses the values you enter in the **Analysis window length** and **Reconstruction error tolerance** parameters.

**Reconstruction error tolerance** — Reconstruction error tolerance of original signal

1e-4 (default) | real scalar

Enter the amount of acceptable error in the reconstruction of the original signal as a real scalar.

### Dependency

To enable this parameter, select the **Assert if analysis window does not support perfect signal reconstruction** check box.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|

| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## Version History

Introduced before R2006a

## References

[1] Quatieri, Thomas E. *Discrete-Time Speech Signal Processing*. Englewood Cliffs, NJ: Prentice-Hall, 2001.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the input length is not a power of 2, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the input length is a power of 2, you can generate standalone C and C++ code from this block.

# Inverse Sinc Filter

Design inverse sinc filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-841.

## Dialog Box

See “Inverse Sinc Filter Design — Main Pane” on page 5-626 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

#### Order mode

Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

#### Response type

Select **Lowpass** or **Highpass** to design an inverse sinc lowpass or highpass filter.

**Filter type**

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

**Order**

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**.

**Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

**Interpolation Factor**

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

**Frequency Specifications**

The parameters in this group allow you to specify your filter response curve.

Regions between specification values such as **Passband frequency** and **Stopband frequency** represent transition regions where the filter response is not constrained.

**Frequency constraints**

When **Order mode** is **Specify**, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — For IIR filters, define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — For IIR filters, define the filter by specifying frequencies for the edges of the stopbands.
- **Cutoff (6dB) frequency** — For FIR filters, define the filter response by specifying the locations of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

**Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **kHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input sample rate** parameter.

**Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### **Stopband frequency**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### **Cutoff (6dB) frequency**

When **Frequency constraints** is Cutoff (6dB) frequency, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

## **Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands.

### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

### **Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

## **Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default FIR method is **Equiripple**.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

#### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

Specify the phase constraint of the filter as **Linear**, **Maximum**, or **Minimum**.

### Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set **Stopband shape**, **Stopband decay** specifies the amount of decay applied to the stopband. the following conditions apply to **Stopband decay** based on the value of **Stopband Shape**:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. The block applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Sinc frequency factor

A frequency dilation factor. The **Sinc frequency factor**,  $C$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$  for a highpass design.

### Sinc power

Negative power of passband magnitude response. The **Sinc power**,  $P$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$  for a highpass design.

## Filter Implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Version History

Introduced in R2006b

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Inverse Sinc Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to Single-rate, Decimator, or Interpolator.
- For **Filter type** that is set to Single-rate, **Structure** is set to Direct-form FIR or Direct-form FIR transposed.
- For **Filter type** that is set to Decimator, **Structure** is set to Direct-form FIR polyphase decimator and **Rate options** is set to Enforce single-rate processing.
- For **Filter type** that is set to Interpolator, **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

## Kalman Adaptive Filter (Obsolete)

Compute filter estimates for inputs using Kalman adaptive filter algorithm

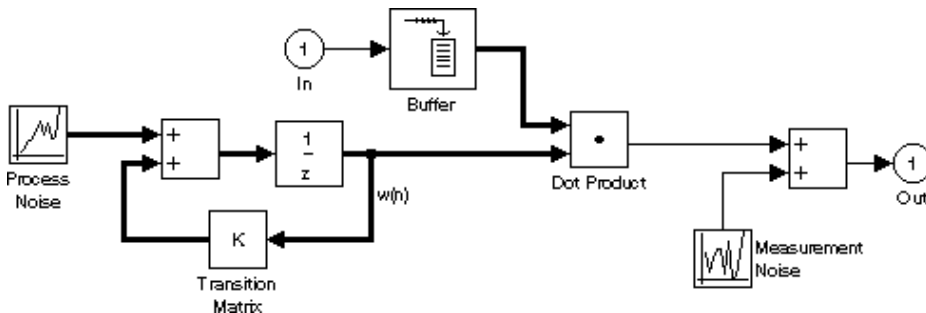

### Library

dspobslib

### Description

**Note** The Kalman Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Kalman Filter block.

The Kalman Adaptive Filter block computes the optimal linear minimum mean-square estimate (MMSE) of the FIR filter coefficients using a one-step predictor algorithm. This Kalman filter algorithm is based on the following physical realization of a dynamic system.

The Kalman filter assumes that there are no deterministic changes to the filter taps over time (that is, the transition matrix is identity), and that the only observable output from the system is the filter output with additive noise. The corresponding Kalman filter is expressed in matrix form as

$$g(n) = \frac{K(n-1)u(n)}{u^H(n)K(n-1)u(n) + Q_M}$$

$$y(n) = u^H(n)\hat{w}(n)$$

$$e(n) = d(n) - y(n)$$

$$\hat{w}(n+1) = \hat{w}(n) + e(n)g(n)$$

$$K(n) = K(n-1) - g(n)u^H(n)K(n-1) + Q_p$$

The variables are as follows

| Variable         | Description  |
|------------------|--|
| $n$              | The current algorithm iteration                      |
| $u(n)$           | The buffered input samples at step $n$               |
| $K(n)$           | The correlation matrix of the state estimation error |
| $g(n)$           | The vector of Kalman gains at step $n$               |
| $\widehat{w}(n)$ | The vector of filter-tap estimates at step $n$       |
| $y(n)$           | The filtered output at step $n$                      |
| $e(n)$           | The estimation error at step $n$                     |
| $d(n)$           | The desired response at step $n$                     |
| $Q_M$            | The correlation matrix of the measurement noise      |
| $Q_P$            | The correlation matrix of the process noise          |

The correlation matrices,  $Q_M$  and  $Q_P$ , are specified in the parameter dialog by scalar variance terms to be placed along the matrix diagonals, thus ensuring that these matrices are symmetric. The filter algorithm based on this constraint is also known as the random-walk Kalman filter.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the input covariance matrix  $K(n)$ . This decreases the total number of computations by a factor of two.

The block icon has port labels corresponding to the inputs and outputs of the Kalman algorithm. Note that inputs to the In and Err ports must be sample-based scalars with the same complexity. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

| Block Ports | Corresponding Variables   |
|-------------|---|
| In          | $u$ , the scalar input, which is internally buffered into the vector $u(n)$ |
| Out         | $y(n)$ , the filtered scalar output   |
| Err         | $e(n)$ , the scalar estimation error  |
| Taps        | $\widehat{w}(n)$ , the vector of filter-tap estimates                       |

An optional Adapt input port is added when you select the **Adapt port** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the Adapt input is nonzero. A zero-valued input to the Adapt port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero Adapt input.

The **FIR filter length** parameter specifies the length of the filter that the Kalman algorithm estimates. The **Measurement noise variance** and the **Process noise variance** parameters specify the correlation matrices of the measurement and process noise, respectively. The **Measurement noise variance** must be a scalar, while the **Process noise variance** can be a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

The **Initial value of filter taps** specifies the initial value  $\widehat{w}(0)$  as a vector, or as a scalar to be repeated for all vector elements. The **Initial error correlation matrix** specifies the initial value  $K(0)$ , and can be a diagonal matrix, a vector of values to be placed along the diagonal, or a scalar to be repeated for the diagonal elements.

## Parameters

### FIR filter length

The length of the FIR filter.

### Measurement noise variance

The value to appear along the diagonal of the measurement noise correlation matrix. Tunable (Simulink).

### Process noise variance

The value to appear along the diagonal of the process noise correlation matrix. Tunable (Simulink).

### Initial value of filter taps

The initial FIR filter coefficients.

### Initial error correlation matrix

The initial value of the error correlation matrix.

### Adapt port

Enables the Adapt port.

# Kalman Filter

Predict or estimate states of dynamic systems

## Library

Filtering/Adaptive Filters

dspadpt3

## Description

Use the Kalman Filter block to predict or estimate the state of a dynamic system from a series of incomplete and/or noisy measurements. Suppose you have a noisy linear system that is defined by the following equations:

$$\begin{aligned}x_k &= Ax_{k-1} + w_{k-1} \\z_k &= Hx_k + v_k\end{aligned}$$

This block can use the previously estimated state,  $\hat{x}_{k-1}$ , to predict the current state at time  $k$ ,  $x_k^-$ , as shown by the following equation:

$$\begin{aligned}x_k^- &= A\hat{x}_{k-1} \\P_k^- &= A\hat{P}_{k-1}A^T + Q\end{aligned}$$

The block can also use the current measurement,  $z_k$ , and the predicted state,  $x_k^-$ , to estimate the current state value at time  $k$ ,  $\hat{x}_k$ , so that it is a more accurate approximation:

$$\begin{aligned}K_k &= P_k^- H^T (HP_k^- H^T + R)^{-1} \\ \hat{x}_k &= x_k^- + K_k(z_k - Hx_k^-) \\ \hat{P}_k &= (I - K_k H)P_k^-\end{aligned}$$

The variables in the previous equations are defined in the following table.

| Variable  | Definition      | Default Value or Initial Condition |
|-----------|-----------------|------------------------------------|
| $x$       | State           | N/A                                |
| $\hat{x}$ | Estimated state | <code>zeros([6, 1])</code>         |
| $x^-$     | Predicted state | N/A                                |

| Variable  | Definition                   | Default Value or Initial Condition   |
|-----------|------------------------------|--|
| $A$       | State transition matrix      | $\begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$ |
| $w$       | Process noise                | N/A  |
| $z$       | Measurement                  | N/A  |
| $H$       | Measurement matrix           | $\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$   |
| $v$       | Measurement noise            | N/A  |
| $\hat{P}$ | Estimated error covariance   | $10 \cdot \text{eye}(6)$   |
| $P$       | Predicted error covariance   | N/A  |
| $Q$       | Process noise covariance     | $0.05 \cdot \text{eye}(6)$   |
| $K$       | Kalman gain                  | N/A  |
| $R$       | Measurement noise covariance | $\text{eye}(4)$  |
| $I$       | Identity matrix              | N/A  |

In the previous equations,  $z$  is a vector of measurement values. Most of the time, the block processes  $Z$ , an M-by-N matrix, where M is the number of measurement values and N is the number of filters.

Use the **Number of filters** parameter to specify the number of filters to use to predict or estimate the current value.

Use the **Enable filters** parameter to specify which filters are enabled or disabled at each time step. If you select **Always**, the filters are always enabled. If you choose **Specify via input port <Enable>**, the Enable port appears on the block. The input to this port must be a row vector of 1s and 0s whose length is equal to the number of filters. For example, if there are 3 filters and the input to the Enable port is [1 0 1], only the first and third filter are enabled at this time step. If you select the **Reset the estimated state and estimated error covariance when filters are disabled** check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values.

---

**Note** All filters have the same state transition matrix, measurement matrix, initial conditions, and noise covariance, but their state, measurement, enable, and MSE signals are unique. Within the state, measurement, enable, and MSE signals, each column corresponds to a filter.

---

Use the **Measurement matrix source** parameter to specify how to enter the measurement matrix values. If you select **Specify via dialog**, the **Measurement matrix** parameter appears in the dialog box. If you select **Input port <H>**, the H port appears on the block. Use this port to specify your measurement matrix.

## Parameters

### Number of filters

Specify the number of filters to use to predict or estimate the current value.

### Enable filters

Specify which filters are enabled or disabled at each time step. If you select **Always**, the filters are always enabled. If you choose **Specify via input port <Enable>**, the Enable port appears on the block.

### Reset the estimated state and estimated error covariance when filters are disabled

If you select this check box, the estimated and predicted states as well as the estimated error covariance that correspond to the disabled filters are reset to their initial values. This parameter is visible if, for the **Enable filters** parameter, you select **Specify via input port <Enable>**.

### Initial condition for estimated state

Enter the initial condition for the estimated state.

### Initial condition for estimated error covariance

Enter the initial condition for the estimated error covariance.

### State transition matrix

Enter the state transition matrix.

### Process noise covariance

Enter the process noise covariance.

### Measurement matrix source

Specify how to enter the measurement matrix values. If you select **Specify via dialog**, the **Measurement matrix** parameter appears in the dialog box. If you select **Input port <H>**, the H port appears on the block.

### Measurement matrix

Enter the measurement matrix values. This parameter is visible if you select **Specify via dialog** for the **Measurement matrix source** parameter.

### Measurement noise covariance

Enter the measurement noise covariance.

### Output estimated measurement <Z\_est>

Select this check box if you want the block to output the estimated measurement.

### Output estimated state <X\_est>

Select this check box if you want the block to output the estimated state.

### Output MSE of estimated state <MSE\_est>

Select this check box if you want the block to output the mean-squared error of the estimated state.

### Output predicted measurement <Z\_prd>

Select this check box if you want the block to output the predicted measurement.

### Output predicted state <X\_prd>

Select this check box if you want the block to output the predicted state.

**Output MSE of predicted state <MSE\_prb>**

Select this check box if you want the block to output the mean-squared error of the predicted state.

## LDL Factorization

Factor square Hermitian positive definite matrices into lower, upper, and diagonal components

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Factorizations

### Description

The LDL Factorization block uniquely factors the square Hermitian positive definite input matrix  $S$  as

$$S = LDL^*$$

where  $L$  is a lower triangular square matrix with unity diagonal elements,  $D$  is a diagonal matrix, and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ . Only the diagonal and lower triangle of the input matrix are used. Any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

### Ports

#### Input

**Port\_1** — Input signal  
matrix

Input signal, specified as a square matrix.

The algorithm requires that the input be square and Hermitian positive definite. When the input is not positive definite, the block reacts as specified by the **Non-positive definite input** parameter.

If the input is fixed point, it must be signed fixed point with a power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

#### Output

**Port\_1** — Output signal  
matrix

The output is a composite matrix with lower triangle elements  $l_{ij}$  from  $L$ , diagonal elements  $d_{ij}$  from  $D$  and upper triangle elements  $u_{ij}$  from  $L^*$ , where  $L$  is a lower triangular square matrix that has unity diagonal elements,  $D$  is a diagonal matrix, and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ .

The output format is shown below for a 5-by-5 matrix.

|          |          |          |          |          |
|----------|----------|----------|----------|----------|
| $d_{11}$ | $u_{12}$ | $u_{13}$ | $u_{14}$ | $u_{15}$ |
| $l_{21}$ | $d_{22}$ | $u_{23}$ | $u_{24}$ | $u_{25}$ |
| $l_{31}$ | $l_{32}$ | $d_{33}$ | $u_{34}$ | $u_{35}$ |
| $l_{41}$ | $l_{42}$ | $l_{43}$ | $d_{44}$ | $u_{45}$ |
| $l_{51}$ | $l_{52}$ | $l_{53}$ | $l_{54}$ | $d_{55}$ |

$$u_{ij} = l_{ji}^*$$

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

### Main Tab

**Non-positive definite input** — Non-positive definite input action

Warning (default) | Ignore | Error

Specify the action when nonpositive definite matrix inputs occur:

- Ignore — Proceed with the computation and do not issue an alert. The output is not a valid factorization. A partial factorization is present in the upper-left corner of the output.
- Warning — Display a warning message in the MATLAB Command Window and continue the simulation. The output is not a valid factorization. A partial factorization is present in the upper-left corner of the output.
- Error — Display an error dialog box and terminate the simulation.

### Data Types Tab

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

### Intermediate product — Intermediate product data type

Inherit: `Same as input (default) | fixdt(1,16,0)`

Specify the intermediate product data type. As shown in *Fixed-Point Conversion* section in “Extended Capabilities” on page 2-0, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set the data type to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Alternatively, you can set the **Intermediate product** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Product output — Product output data type

Inherit: `Inherit via internal rule (default) | Inherit: Same as input | fixdt([],16,0)`

**Product output** specifies the data type of the output of a product operation in the LDL Factorization block.

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

For more information, see “Multiplication Data Types” and *Fixed-Point Conversion* in “Extended Capabilities” on page 2-0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Accumulator — Accumulator data type

Inherit: `Inherit via internal rule (default) | Inherit: Same as input | Inherit: Same as product output | fixdt([],16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the LDL Factorization block.

- **Inherit: Inherit via internal rule** — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

#### **Output** — Output data type

`Inherit: Same as input (default) | fixdt([], 16, 0)`

**Output** specifies the data type of the output of the LDL Factorization block. For more information on the output data type, see the 'Fixed-Point Conversion' section in “Extended Capabilities” on page 2-0 .

- **Inherit: Same as input** — The block specifies the output data type to be the same as the input data type.
- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type that has a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

#### **Output Minimum** — Minimum value that block can output

`[] (default) | scalar`

Specify the minimum value that the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Output Maximum** — Maximum value that block can output

`[] (default) | scalar`

Specify the maximum value that the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

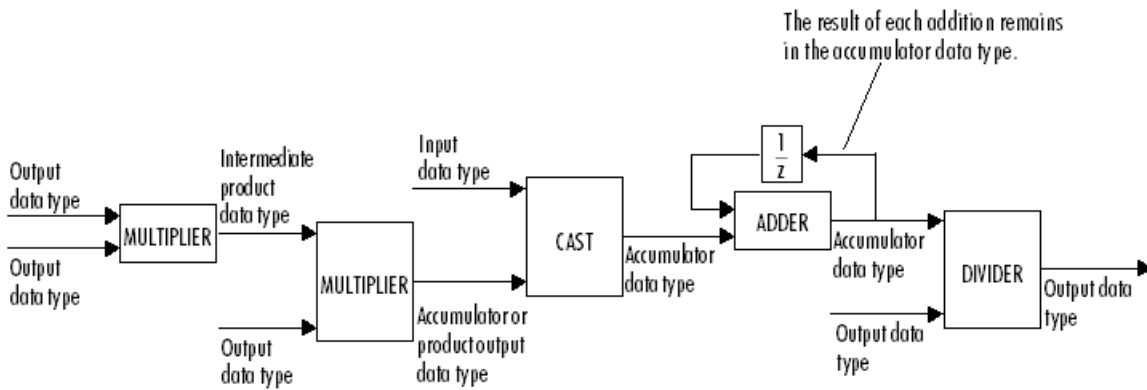

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

### Fixed-Point Data Types

This diagram shows the data types used within the LDL Factorization block for fixed-point signals.

You can set the intermediate product, product output, accumulator, and output data types in the block dialog box.

When the input is real, the output of the second multiplier is in the product output data type. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

## LDL Inverse

Compute inverse of Hermitian positive definite matrix using LDL factorization

## Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

## Description

The LDL Inverse block computes the inverse of the Hermitian positive definite input matrix  $S$  by performing an LDL factorization.

$$S^{-1} = (LDL^*)^{-1}$$

$L$  is a lower triangular square matrix with unity diagonal elements,  $D$  is a diagonal matrix, and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ . Only the diagonal and lower triangle of the input matrix are used, and any imaginary component of the diagonal entries is disregarded.

LDL factorization requires half the computation of Gaussian elimination (LU decomposition), and is always stable. It is more efficient than Cholesky factorization because it avoids computing the square roots of the diagonal elements.

The algorithm requires that the input be Hermitian positive definite. When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid inverse.
- **Warning** — Display a warning message in the MATLAB command window, and continue the simulation. The output is not a valid inverse.
- **Error** — Display an error dialog and terminate the simulation.

---

**Note** The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

---

## Parameters

### Non-positive definite input

Response to nonpositive definite matrix inputs.

## LDL Solver

Solve  $SX=B$  for  $X$  when  $S$  is square Hermitian positive definite matrix

## Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dpsolvers

## Description

The LDL Solver block solves the linear system  $SX=B$  by applying LDL factorization to the matrix at the S port, which must be square ( $M$ -by- $M$ ) and Hermitian positive definite. Only the diagonal and lower triangle of the matrix are used, and any imaginary component of the diagonal entries is disregarded. The input to the B port is the right side  $M$ -by- $N$  matrix,  $B$ . The  $M$ -by- $N$  output matrix  $X$  is the unique solution of the equations.

A length- $M$  unoriented vector input for right side  $B$  is treated as an  $M$ -by-1 matrix.

When the input is not positive definite, the block reacts with the behavior specified by the **Non-positive definite input** parameter. The following options are available:

- **Ignore** — Proceed with the computation and do not issue an alert. The output is not a valid solution.
- **Warning** — Proceed with the computation and display a warning message in the MATLAB Command Window. The output is not a valid solution.
- **Error** — Display an error dialog and terminate the simulation.

---

**Note** The **Non-positive definite input** parameter is a diagnostic parameter. Like all diagnostic parameters on the Configuration Parameters dialog, it is set to **Ignore** in the code generated for this block by Simulink Coder code generation software.

---

## Algorithm

The LDL algorithm uniquely factors the Hermitian positive definite input matrix  $S$  as

$$S = LDL^*$$

where  $L$  is a lower triangular square matrix with unity diagonal elements,  $D$  is a diagonal matrix, and  $L^*$  is the Hermitian (complex conjugate) transpose of  $L$ .

The equation

$$LDL^*X = B$$

is solved for  $X$  by the following steps:

- 1 Substitute

$$Y = DL^*X$$

- 2 Substitute

$$Z = L^*X$$

- 3 Solve one diagonal and two triangular systems.

$$LY = B$$

$$DZ = Y$$

$$L^*X = Z$$

## Parameters

### Non-positive definite input

Response to nonpositive definite matrix inputs.

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

# Least Squares Polynomial Fit

Compute polynomial coefficients that best fit input data in least-squares sense

## Library

Math Functions / Polynomial Functions

dsppolyfun

## Description

The Least Squares Polynomial Fit block computes the coefficients of the  $n$ th order polynomial that best fits the input data in the least-squares sense, where you specify  $n$  in the **Polynomial order** parameter. A distinct set of  $n+1$  coefficients is computed for each column of the  $M$ -by- $N$  input,  $u$ .

For a given input column, the block computes the set of coefficients,  $c_1, c_2, \dots, c_{n+1}$ , that minimizes the quantity

$$\sum_{i=1}^M (u_i - \hat{u}_i)^2$$

where  $u_i$  is the  $i$ th element in the input column, and

$$\hat{u}_i = f(x_i) = c_1 x_i^n + c_2 x_i^{n-1} + \dots + c_{n+1}$$

The values of the independent variable,  $x_1, x_2, \dots, x_M$ , are specified as a length- $M$  vector by the **Control points** parameter. The same  $M$  control points are used for all  $N$  polynomial fits, and can be equally or unequally spaced. The equivalent MATLAB code is shown below.

```
c = polyfit(x,u,n) % Equivalent MATLAB code
```

For convenience, the block treats length- $M$  unoriented vector input as an  $M$ -by-1 matrix.

Each column of the  $(n+1)$ -by- $N$  output matrix,  $c$ , represents a set of  $n+1$  coefficients describing the best-fit polynomial for the corresponding column of the input. The coefficients in each column are arranged in order of descending exponents,  $c_1, c_2, \dots, c_{n+1}$ .

## Parameters

### Control points

The values of the independent variable to which the data in each input column correspond. For an  $M$ -by- $N$  input, this parameter must be a length- $M$  vector. Tunable (Simulink).

### Polynomial order

The order,  $n$ , of the polynomial to be used in constructing the best fit. The number of coefficients is  $n+1$ .

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

# Levinson-Durbin

Solve linear system of equations using Levinson-Durbin recursion

## Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dsp solvers

## Description

The Levinson-Durbin block solves the  $n$ th-order system of linear equations

$$Ra = b$$

in the cases where:

- $R$  is a Hermitian, positive-definite, Toeplitz matrix.
- $b$  is identical to the first column of  $R$  shifted by one element and with the opposite sign.

$$\begin{bmatrix} r(1) & r^*(2) & \dots & r^*(n) \\ r(2) & r(1) & \dots & r^*(n-1) \\ \vdots & \vdots & \ddots & \vdots \\ r(n) & r(n-1) & \dots & r(1) \end{bmatrix} \begin{bmatrix} a(2) \\ a(3) \\ \vdots \\ a(n+1) \end{bmatrix} = \begin{bmatrix} -r(2) \\ -r(3) \\ \vdots \\ -r(n+1) \end{bmatrix}$$

The input to the block,  $r = [r(1) \ r(2) \ \dots \ r(n+1)]$ , can be a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel and solves it separately. Each channel of the input contains lags 0 through  $n$  of an autocorrelation sequence, which appear in the matrix  $R$ .

The block can output the polynomial coefficients,  $A$ , the reflection coefficients,  $K$ , and the prediction error power,  $P$ , in various combinations. The **Output(s)** parameter allows you to enable the  $A$  and  $K$  outputs by selecting one of the following settings:

- **A** — For each channel, port A outputs  $A = [1 \ a(2) \ a(3) \ \dots \ a(n+1)]$ , the solution to the Levinson-Durbin equation.  $A$  has the same dimension as the input. You can also view the elements of each output channel as the coefficients of an  $n$ th-order autoregressive (AR) process.
- **K** — For each channel, port K outputs  $K = [k(1) \ k(2) \ \dots \ k(n)]$ , which contains  $n$  reflection coefficients and has the same dimension as the input, less one element. A scalar input channel

causes an error when you select K. You can use reflection coefficients to realize a lattice representation of the AR process described later in this page.

- **A and K** — The block outputs both representations at their respective ports. A scalar input channel causes an error when you select **A and K**.

Select the **Output prediction error power (P)** check box to output the prediction error power for each channel,  $P$ . For each channel,  $P$  represents the power of the output of an FIR filter with taps  $A$  and input autocorrelation described by  $r$ , where  $A$  represents a prediction error filter and  $r$  is the input to the block. In this case,  $A$  is a whitening filter.  $P$  has one element per input channel.

When you select the **If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0** check box (default), an input channel whose  $r(1)$  element is zero generates a zero-valued output. When you clear this check box, an input with  $r(1) = 0$  generates NaNs in the output. In general, an input with  $r(1) = 0$  is invalid because it does not construct a positive-definite matrix  $R$ . Often, however, blocks receive zero-valued inputs at the start of a simulation. The check box allows you to avoid propagating NaNs during this period.

### Applications

One application of the Levinson-Durbin formulation implemented by this block is in the Yule-Walker AR problem, which concerns modeling an unknown system as an autoregressive process. You would model such a process as the output of an all-pole IIR filter with white Gaussian noise input. In the Yule-Walker problem, the use of the signal's autocorrelation sequence to obtain an optimal estimate leads to an  $Ra = b$  equation of the type shown above, which is most efficiently solved by Levinson-Durbin recursion. In this case, the input to the block represents the autocorrelation sequence, with  $r(1)$  being the zero-lag value. The output at the block's A port then contains the coefficients of the autoregressive process that optimally models the system. The coefficients are ordered in descending powers of  $z$ , and the AR process is minimum phase. The prediction error,  $G$ , defines the gain for the unknown system, where  $G = \sqrt{P}$ :

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(n+1)z^{-n}}$$

The output at the block's K port contains the corresponding reflection coefficients,  $[k(1) \ k(2) \ \dots \ k(n)]$ , for the lattice realization of this IIR filter. The Yule-Walker AR Estimator block implements this autocorrelation-based method for AR model estimation, while the Yule-Walker Method block extends the method to spectral estimation.

Another common application of the Levinson-Durbin algorithm is in linear predictive coding, which is concerned with finding the coefficients of a moving average (MA) process (or FIR filter) that predicts the next value of a signal from the current signal sample and a finite number of past samples. In this case, the input to the block represents the signal's autocorrelation sequence, with  $r(1)$  being the zero-lag value, and the output at the block's A port contains the coefficients of the predictive MA process (in descending powers of  $z$ ).

$$H(z) = A(z) = 1 + a(2)z^{-1} + \dots + a(n+1)z^{-n}$$

These coefficients solve the following optimization problem:

$$\min_{\{a_i\}} E \left[ \left| x_n - \sum_{i=1}^N a_i x_{n-i} \right|^2 \right]$$

Again, the output at the block's K port contains the corresponding reflection coefficients,  $[k(1) k(2) \dots k(n)]$ , for the lattice realization of this FIR filter. The Autocorrelation LPC block in the Linear Prediction library implements this autocorrelation-based prediction method.

**Fixed-Point Data Types**

The diagrams in this section show the data types used within the Levinson-Durbin block for fixed-point signals.

After initialization the block performs  $n$  updates. At the  $(j+1)$  update,

$$\text{value in accumulator} = r(j+1) + \sum a_j(i) \times r(j-i+1)$$

The following diagram displays the fixed-point data types used in this calculation:

The block then updates the reflection coefficients  $K$  according to

$$K_{j+1} = \text{value in accumulator} / P_j$$

The block then updates the prediction error power  $P$  according to

$$P_{j+1} = P_j - P_j \times K_{j+1} \times \text{conj}(K_{j+1})$$

The next diagram displays the fixed-point data types used in this calculation:

The polynomial coefficients  $A$  are then updated according to

$$a_{j+1}(i) = a_j(i) + K_{j+1} \times \text{conj}(a_j(j-1+i))$$

This diagram displays the fixed-point data types used in this calculation:

## Algorithm

The algorithm requires  $O(n^2)$  operations for each input channel. This implementation is therefore much more efficient for large  $n$  than standard Gaussian elimination, which requires  $O(n^3)$  operations per channel.

## Parameters

### Main Tab

### Output(s)

Specify the solution representation of  $Ra = b$  to output: model coefficients (A), reflection coefficients (K), or both (A and K). When the input is a scalar or row vector, you must set this parameter to A.

### Output prediction error power (P)

Select to output the prediction error at port P.

### If the value of lag 0 is zero, A=[1 zeros], K=[zeros], P=0

When you select this check box and the first element of the input,  $r(1)$ , is zero, the block outputs the following vectors, as appropriate:

- $A = [1 \text{ zeros}(1, n)]$
- $K = [\text{zeros}(1, n)]$
- $P = 0$

When you clear this check box, the block outputs a vector of NaNs for each channel whose  $r(1)$  element is zero.

### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

### Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-865 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-865 for illustrations depicting the use of the accumulator data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A rule that inherits a data type, for example, `Inherit: Same as product output`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Polynomial coefficients (A)

Specify the polynomial coefficients (A) data type. See “Fixed-Point Data Types” on page 2-865 for illustrations depicting the use of the A data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **A** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Reflection coefficients (K)

Specify the polynomial coefficients (A) data type. See “Fixed-Point Data Types” on page 2-865 for illustrations depicting the use of the K data type in this block. You can set it to an expression that evaluates to a valid data type, for example, `fixdt(1,16,15)`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **K** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Prediction error power (P)

Specify the prediction error power (P) data type. See “Fixed-Point Data Types” on page 2-865 for illustrations depicting the use of the P data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **P** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Minimum

Specify the minimum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

### Maximum

Specify the maximum values that the polynomial coefficients, reflection coefficients, or prediction error power should have. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink))
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

### Product Output Data Type Assistant Parameters

#### Mode

Select how you would like to specify the data type properties of the **Product output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

### **Signedness**

Specify the **Signedness** for the **Product output** data type.

### **Scaling**

Specify the **Scaling** for the **Product output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

### **Word length**

Specify the **Word length** for the **Product output** data type.

### **Fraction length**

Specify the **Fraction length** for the **Product output** data type.

### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## **Accumulator Data Type Assistant Parameters**

### **Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

**Scaling**

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Accumulator** data type.

**Fraction length**

Specify the **Fraction length** for the **Accumulator** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Polynomial Coefficients (A) Data Type****Mode**

Select how you would like to specify the data type properties of the **Polynomial coefficients (A)** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, **Inherit: Inherit via internal rule**
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, **fixdt(1,16,0)**

**Signedness**

Specify the **Signedness** for the **Polynomial coefficients (A)** data type.

**Scaling**

Specify the **Scaling** for the **Polynomial coefficients (A)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Polynomial coefficients (A)** data type.

#### **Fraction length**

Specify the **Fraction length** for the **Polynomial coefficients (A)** data type.

#### **Data type override**

Specify the data type override mode. You can select one of the following options:

- `Inherit` — Inherits the data type override setting specified for the model.
- `Off` — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to `Built in` or `Fixed Point`. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### **Reflection Coefficients (K) Data Type**

#### **Mode**

Select how you would like to specify the data type properties of the **Reflection coefficients (K)** data type. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

#### **Signedness**

Specify the **Signedness** for the **Reflection coefficients (K)** data type.

#### **Scaling**

Specify the **Scaling** for the **Reflection coefficients (K)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Reflection coefficients (K)** data type.

#### **Fraction length**

Specify the **Fraction length** for the **Reflection coefficients (K)** data type.

#### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

#### **Prediction Error Power Data Type Assistant Parameters**

##### **Mode**

Select how you would like to specify the data type properties of the **Prediction error power (P)** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

##### **Signedness**

Specify the **Signedness** for the **Prediction error power (P)** data type.

##### **Scaling**

Specify the **Scaling** for the **Prediction error power (P)** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

##### **Word length**

Specify the **Word length** for the **Prediction error power (P)** data type.

##### **Fraction length**

Specify the **Fraction length** for the **Prediction error power (P)** data type.

##### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.

- `Off` — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to `Built in` or `Fixed Point`. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## LMS Adaptive Filter (Obsolete)

Compute filter estimates for input using LMS adaptive filter algorithm

### Library

dspobslib

### Description

**Note** The LMS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the LMS Filter block.

The LMS Adaptive Filter block implements an adaptive FIR filter using the stochastic gradient algorithm known as the normalized least mean-square (LMS) algorithm.

$$y(n) = \widehat{w}^H(n-1)u(n)$$

$$e(n) = d(n) - y(n)$$

$$\widehat{w}(n) = \widehat{w}(n-1) + \frac{u(n)}{a + u^H(n)u(n)}\mu e^*(n)$$

The variables are as follows.

| Variable         | Description                                    |
|------------------|--|
| $n$              | The current algorithm iteration                |
| $u(n)$           | The buffered input samples at step $n$         |
| $\widehat{w}(n)$ | The vector of filter-tap estimates at step $n$ |
| $y(n)$           | The filtered output at step $n$                |
| $e(n)$           | The estimation error at step $n$               |
| $d(n)$           | The desired response at step $n$               |
| $\mu$            | The adaptation step size                       |

To overcome potential numerical instability in the tap-weight update, a small positive constant ( $a = 1e-10$ ) has been added in the denominator.

To turn off normalization, clear the **Use normalization** check box in the parameter dialog. The block then computes the filter-tap estimate as

$$\widehat{w}(n) = \widehat{w}(n-1) + u(n)\mu e^*(n)$$

The block icon has port labels corresponding to the inputs and outputs of the LMS algorithm. Note that inputs to the In and Err ports must be sample-based scalars. The signal at the Out port is a scalar, while the signal at the Taps port is a sample-based vector.

| Block Ports | Corresponding Variables   |
|-------------|---|
| In          | $u$ , the scalar input, which is internally buffered into the vector $u(n)$ |
| Out         | $y(n)$ , the filtered scalar output   |
| Err         | $e(n)$ , the scalar estimation error  |
| Taps        | $\hat{w}(n)$ , the vector of filter-tap estimates                           |

An optional **Adapt** input port is added when you select the **Adapt input** check box in the dialog. When this port is enabled, the block continuously adapts the filter coefficients while the **Adapt** input is nonzero. A zero-valued input to the **Adapt** port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero **Adapt** input.

The **FIR filter length** parameter specifies the length of the filter that the LMS algorithm estimates. The **Step size** parameter corresponds to  $\mu$  in the equations. Typically, for convergence in the mean square,  $\mu$  must be greater than 0 and less than 2. The **Initial value of filter taps** specifies the initial value  $\hat{w}(0)$  as a vector, or as a scalar to be repeated for all vector elements. The **Leakage factor** specifies the value of the leakage factor,  $1 - \mu\alpha$ , in the leaky LMS algorithm below. This parameter must be between 0 and 1.

$$\hat{w}(n+1) = (1 - \mu\alpha)\hat{w}(n) + \frac{u(n)}{u^H(n)u(n)}\mu e^*(n)$$

## Examples

See the `lmsadtde` demo.

## Parameters

### FIR filter length

The length of the FIR filter.

### Step-size

The step-size, usually in the range (0, 2). Tunable (Simulink).

### Initial value of filter taps

The initial FIR filter coefficients.

### Leakage factor

The leakage factor, in the range [0, 1]. Tunable (Simulink).

### Use normalization

Select this check box to compute the filter-tap estimate using the normalized equations.

### Adapt input

Enables the **Adapt** port when selected.

## LMS Filter

Compute output, error, and weights using LMS adaptive algorithm

### Libraries:

DSP System Toolbox / Filtering / Adaptive Filters  
 DSP System Toolbox HDL Support / Filtering

## Description

The LMS Filter block can implement an adaptive FIR filter by using five different algorithms. The block estimates the filter weights or coefficients needed to minimize the error,  $e(n)$ , between the output signal  $y(n)$  and the desired signal,  $d(n)$ . The output is the filtered input signal, which is the estimate of the desired signal. The Error port outputs the result of subtracting the output signal from the desired signal.

Under specific conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-886.

## Ports

### Input

**Input** — Input signal  
 scalar | vector

Connect the signal that you want to filter, specified as a scalar or column vector.

When the input is fixed-point, it must be signed.

When you set the **Algorithm** parameter to Sign-Error LMS, Sign-Data LMS, or Sign-Sign LMS, the data input through the **Input** port must be real.

Data Types: single | double | fixed point

**Desired** — Desired signal  
 vector | matrix

Connect the desired signal, specified as a vector or matrix. The desired signal must have the same data type, complexity, and dimensions as the Input signal.

When **Input** is fixed-point, the desired signal must be a signed fixed-point.

When you set the **Algorithm** parameter to Sign-Error LMS, Sign-Data LMS, or Sign-Sign LMS, the data input through the **Desired** port must be real.

Data Types: single | double | fixed point

**Step-size** — Step-size  
 scalar

Enter the step size  $\mu$ . For convergence of the normalized LMS equations,  $0 < \mu < 2$ . Input type must match the type of the Input port.

When **Input** is fixed-point, the step-size must be a signed fixed-point.

#### Dependencies

This port appears only when you set the **Specify step size** via parameter to **Input port**.

Data Types: `single` | `double` | `fixed point`

#### **Adapt** — Update filter weights

scalar | vector

When the input to this port is greater than zero, the block continuously updates the filter weights. When the input to this port is less than or equal to zero, the filter weights remain at their current values.

#### Dependencies

This port appears only when you set the **Adapt port** parameter to **on**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `Boolean`

#### **Reset** — Reset filter weights

scalar | vector

Signal to reset the value of the filter weights to their initial values, specified as a vector. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

For reset event types, see the **Reset** parameter.

#### Dependencies

This port appears only when you set the **Reset port** parameter to **Rising edge**, **Falling edge**, **Either edge**, or **Non-zero sample**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `Boolean`

#### Output

##### **Output** — Output signal

scalar | vector

Outputs the filtered input signal, which is the estimate of the desired signal. It is the same size and complexity as the input signal.

The output signal has the same data type as the desired signal.

Data Types: `single` | `double` | `fixed point`

##### **Error** — Error between Output and Desired signals

scalar | vector

Outputs the result of subtracting the output signal from the desired signal.

The error signal has the same data type as the desired signal.

Data Types: `single` | `double` | `fixed point`

**Wts** — Updated filter weights  
`scalar` | `vector`

For each iteration, the block outputs the current updated filter weights from this port.

The weights data type must match the type of the `Input` port for floating-point signals. Obeys the `Weights` parameter for fixed-point signals.

### Dependencies

This port appears only when you set the `Output filter weights` parameter to `On`.

Data Types: `single` | `double` | `fixed point`

## Parameters

### Main Tab

**Algorithm** — Select algorithm

`LMS` (default) | `Normalized LMS` | `Sign-Error LMS` | `Sign-Data LMS` | `Sign-Sign LMS`

Choose the algorithm used to calculate the filter weights.

**Filter length** — Filter length

`32` (default) | `scalar`

Enter the length of the FIR filter weights vector.

**Specify step size via** — Specify step size via

`Dialog` (default) | `Input port`

- `Dialog` -- Specify step size by using the **Step size ( $\mu$ )** parameter.
- `Input port` -- Specify step size by using the `Step-size` port.

**Step size ( $\mu$ )** — Step size

`0.1` (default) | `positive scalar`

Enter the step size  $\mu$ . For convergence of the normalized LMS equations,  $0 < \mu < 2$ .

**Tunable:** Yes

### Dependencies

This parameter appears only when you set the `Specify step size via` parameter to `Dialog`.

**Leakage factor (0 to 1)** — Leakage factor

`1.0` (default) | `scalar`

Enter the leakage factor,  $0 < 1 - \mu\alpha \leq 1$ .

**Tunable:** Yes

**Initial value of filter weights** — Initial value of filter weights

0 (default) | vector | scalar

Enter the initial filter weights  $\mathbf{w}(0)$  as a vector or a scalar. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector length is equal to the filter length and all of its values are equal to the scalar value.

**Adapt port** — Enable Adapt port

on (default) | off

Select this check box to enable the **Adapt** input port.

**Reset port** — Reset port

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

When you want to reset the value of filter weights to their initial values, use the **Reset port** parameter. The reset signal must be the same rate as the data signal input.

Select **None** to disable the **Reset** port. To enable the **Reset** port, select one of the following from the list:

- **Rising edge** — Triggers a reset operation when the **Reset** input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the **Reset** input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the **Reset** input is a **Rising edge** or **Falling edge**
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

**Output filter weights** — Output filter weights

on (default) | off

Select the **Output filter weights** parameter to export the filter weights from the **Wts** port. For each iteration, the block outputs the current updated filter weights from this port.

### Data Type Tab

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Parameters** — Parameters

Same word length as first input (default) | Specify word length | Binary point scaling

Choose how you specify the word length and the fraction length of the leakage factor and step size:

- **Same word length as first input** -- The word length of the leakage factor and step size match that of the first input to the block. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- **Specify word length** -- You can enter the word length of the leakage factor and step size, in bits. In this mode, the fraction length of the leakage factor and step size is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- **Binary point scaling** -- You can enter the word length and the fraction length of the leakage factor and step size, in bits. The leakage factor and the step size must have the same word length, but the fraction lengths can differ.

For the **Specify step size via** parameter, if you choose **Input port**, the word length of the leakage factor is the same as the word length of the step size input at the **Step-size** port. The fraction length of the leakage factor is automatically set to the best precision possible based on the word length of the leakage factor.

#### Dependencies

This parameter is visible only if you set the **Specify step size via** parameter to **Dialog**

**Weights** — Word and fraction length of filter weights

Same as first input (default) | Binary point scaling

Choose how you specify the word length and fraction length of the filter weights of the block:

- **Same as first input** -- The word length and fraction length of the filter weights match those of the first input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the filter weights, in bits.

**Product and quotient** — Word and fraction length of product and quotient

Same as first input (default) | Binary point scaling

Choose how you specify the word length and fraction length of  $\mathbf{u}'\mathbf{u}$ ,  $\mathbf{W}'\mathbf{u}$ ,  $\mu \cdot e$ ,  $Q \cdot \mathbf{u}$ , and the quotient,  $Q$ . Here,  $\mathbf{u}$  is the input vector,  $\mathbf{W}$  is the vector of filter weights,  $\mu$  is the step size,  $e$  is the error, and  $Q$  is the quotient, which is defined as  $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$

- **Same as first input** -- The word length and fraction length of these quantities match those of the first input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of these quantities, in bits. The word length of the quantities must be the same, but the fraction lengths can differ.

**Accumulator** — Word and fraction lengths of accumulators

Same as `first input` (default) | `Binary point scaling`

Use this parameter to specify how you want to designate the word and fraction lengths of the accumulators for the  $\mathbf{u}'\mathbf{u}$  and  $\mathbf{W}'\mathbf{u}$  operations.

---

**Note** Do not use this parameter to designate the word and fraction lengths of the accumulator for the  $Q \cdot \mathbf{u}$  operation. The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

---

- `Same as first input` -- These characteristics match those of the input to the block.
- `Binary point scaling` -- You can enter the word length and the fraction length of the accumulators, in bits. The word length of both the accumulators must be the same, but the fraction lengths can differ.

For illustrations depicting the use of the accumulator data type in this block, see “Fixed Point” on page 2-887 and “Multiplication Data Types”.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | <code>double</code>   <code>fixed point</code>   <code>integer</code>   <code>single</code> |
| <b>Direct Feedthrough</b>       | <code>no</code>   |
| <b>Multidimensional Signals</b> | <code>no</code>   |
| <b>Variable-Size Signals</b>    | <code>yes</code>  |
| <b>Zero-Crossing Detection</b>  | <code>no</code>   |

## More About

### LMS Filter Algorithms

When you select LMS for the `Algorithm` parameter, the block calculates the filter weights by using the least mean-square (LMS) algorithm. This algorithm is defined by these equations.

$$\begin{aligned}
 y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The various LMS adaptive filter algorithms available in this block are defined as:

- LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$$

- Normalized LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n) \mathbf{u}(n)}$$

In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant,  $\varepsilon$ , has been added in the denominator. For double-precision floating-point input,  $\varepsilon$  is the output of the `eps` function. For single-precision floating-point input,  $\varepsilon$  is the output of `eps("single")`. For fixed-point input,  $\varepsilon$  is 0.

- Sign-Error LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$$

- Sign-Data LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

- Sign-Sign LMS --

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

| Variable          | Description  |
|-------------------|--|
| $n$               | The current time index   |
| $\mathbf{u}(n)$   | The vector of buffered input samples at step $n$   |

| $\varepsilon$     | A constant that corrects any potential numerical instability that occurs during the update of weights. |

## Version History

Introduced before R2006a

## References

- [1] Hayes, M.H. *Statistical Digital Signal Processing and Modeling*. New York: John Wiley & Sons, 1996.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

The LMS Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Algorithm** is set to LMS or Normalized LMS.
- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### HDL Architecture

By default, the LMS Filter implementation uses a linear sum for the FIR section of the filter.

The LMS Filter implements a tree summation (which has a shorter critical path) under the following conditions:

- The LMS Filter is used with real data.
- The word length of the Accumulator **W'u** data type is at least `ceil(log2(filter length))` bits wider than the word length of the Product **W'u** data type.
- The Accumulator **W'u** data type has the same fraction length as the Product **W'u** data type.

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see "ConstrainedOutputPipeline" (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "InputPipeline" (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see "OutputPipeline" (HDL Coder).               |

### Complex Data Support

This block supports code generation for complex signals.

### Restrictions

- HDL Coder does not support the Normalized LMS algorithm of the LMS Filter.
- The Reset port supports only Boolean and unsigned inputs.
- The Adapt port supports only Boolean inputs.
- **Filter length** must be greater than or equal to 2.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

### Fixed-Point Data Types

The following diagrams show the data types used within the LMS Filter block for fixed-point signals. The table summarizes the definitions of variables used in the diagrams.

| Variable                            | Definition   |
|-------------------------------------|--|
| <b>u</b>                            | Input vector   |
| <b>W</b>                            | Vector of filter weights   |
| $\mu$                               | Step size  |
| $e$                                 | Error  |
| $Q$                                 | Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$                |
| Product $\mathbf{u}'\mathbf{u}$     | Product data type in Energy calculation diagram                          |
| Accumulator $\mathbf{u}'\mathbf{u}$ | Accumulator data type in Energy calculation diagram                      |
| Product $\mathbf{W}'\mathbf{u}$     | Product data type in Convolution diagram                                 |
| Accumulator $\mathbf{W}'\mathbf{u}$ | Accumulator data type in Convolution diagram                             |
| Product $\mu \cdot e$               | Product data type in Product of step size and error diagram              |
| Product $Q \cdot \mathbf{u}$        | Product and accumulator data type in Weight update diagram. <sup>1</sup> |

<sup>1</sup>The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

**Energy calculation (for normalized LMS algorithm only)**

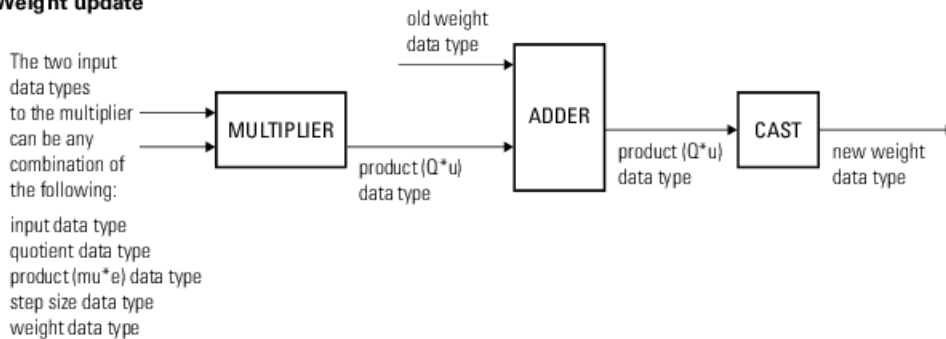

**Convolution**

**Output error signal**

**Product of step size and error (for LMS and Sign-Data LMS algorithms only)****Quotient (for normalized LMS only)****Weight update**

You can set the data type of the parameters, weights, products, quotient, and accumulators in the block mask. Fixed-point inputs, outputs, and mask parameters of this block must have these characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.
- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the  $\mathbf{u}'\mathbf{u}$ ,  $\mathbf{W}'\mathbf{u}$ ,  $\mu \cdot e$ , and  $Q \cdot \mathbf{u}$  operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the  $\mathbf{u}'\mathbf{u}$  and  $\mathbf{W}'\mathbf{u}$  operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details, see “Multiplication Data Types”.

# LMS Update

Estimate weights of LMS adaptive filter

## Libraries:

DSP System Toolbox / Filtering / Adaptive Filters

## Description

The LMS Update block estimates the weights of an LMS adaptive filter. Specify data and error as inputs and the block computes the filter weights based on the algorithm specified in the **Algorithm** parameter. For more details on the algorithms, see “Algorithms” on page 2-896.

You can configure the block to operate as a tapped-delay line FIR filter or as an adaptive linear combiner using the **Adaptive filter mode** parameter. The block can also adapt multiple filters independently when you specify the **Number of adaptive filters** parameter to a value greater than 1.

You can use this block to compute the adaptive filter weights in applications such as system identification, inverse modeling, and filtered-x LMS algorithms, which are used in acoustic noise cancellation. For more details, see “References” on page 2-897.

## Input/Output Ports

### Input

**Input** — Data input

scalar | column vector

Data input to the adaptive filter, specified as one of these:

- Scalar -- When you set the **Adaptive filter mode** parameter to Tapped delay-line FIR filter, the input to the block should be a scalar.

The block algorithm buffers the input samples to generate the vector  $\mathbf{u}(n) = [u(n), u(n-1), \dots, u(n-L+1)]$ , where  $L$  is the length of the adaptive filter and  $n$  is the time index. The block algorithm then passes the vector through the filter.

- Column vector of length  $L$  -- When you set the **Adaptive filter mode** parameter to Adaptive linear combiner, the block does not buffer the input samples, and the input to the block should be in the form of a column vector. The block multiplies the vector with the filter weights to generate the filter output. In this case, there is no relationship between the input samples.

When you set the **Number of adaptive filters** parameter to a value greater than 1, the block assumes that all filters run on the same input.

When you set the **Algorithm** parameter to Sign-Error LMS, Sign-Data LMS, or Sign-Sign LMS, the data input through the **Input** port must be real.

Data Types: `single` | `double`

**Error** — Error

scalar | column vector

Specify the error between the output signal and the desired signal as a:

- Scalar when the number of adaptive filters  $N = 1$ .
- Column vector of length  $N$  when  $N > 1$ .

When you set the **Algorithm** parameter to `Sign–Error LMS`, `Sign–Data LMS`, or `Sign–Sign LMS`, the error input through the **Error** port must be real.

Data Types: `single` | `double`

**Mu** — Filter adaptation step size

0.1 (default) | scalar in the range [0,1]

Specify the filter adaptation step size as a scalar in the range [0,1].

**Dependency**

To enable this port, set **Step size source** to `Input` port.

Data Types: `single` | `double`

**Adapt** — Update filter weights

real scalar | vector

The input to this port can be one of these:

- Scalar -- If the number of adaptive filters ( $N$ ) is greater than 1, then the block updates the filter weights for all filters if the value at the port is nonzero and does not update if the value at the port is 0.
- Vector of length  $N$  -- If the number of adaptive filters ( $N$ ) is greater than 1, then the block determines whether to update each filter during run time depending on the value of the corresponding element in the **Adapt** vector input. When the **Adapt** port input element is not 0, the block updates the filter weights. When the input is 0, the filter weights do not change.

For an example, see “Adapt Multiple Filters Using LMS Update block”.

**Dependency**

To enable this port, select the **Enable adapt input** parameter on the block dialog.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

**Reset** — Reset filter weights

real scalar

When the input to this port is not 0, the block resets the filter weights to their initial values. When the input to this port is 0, the filter weights do not change.

**Dependency**

To enable this port, select the **Enable reset input** parameter on the block dialog.

Data Types: `single` | `double` | `Boolean` | `int16` | `int32` | `int64` | `int8` | `uint16` | `uint32` | `uint64` | `uint8`

## Output

**Wts** — Filter weights

row vector | matrix

The block outputs the filter weights as a 1-by- $L$  row vector or a  $N$ -by- $L$  matrix, where  $N$  is the number of adaptive filters, and  $L$  is the length of each filter.

Data Types: `single` | `double`

## Parameters

**Algorithm** — LMS adaptive algorithm

`LMS` (default) | `Normalized LMS` | `Sign-Error LMS` | `Sign-Data LMS` | `Sign-Sign LMS`

The block uses one of the listed algorithms to compute the filter weights. For more details on the algorithms, see “Algorithms” on page 2-896.

**Filter length** — Length of the filter

32 (default) | positive integer

Specify the length of each adaptive filter  $L$  as a positive integer.

When there are  $N$  adaptive filters, the weights vector the block generates through the **Wts** output port is an  $N$ -by- $L$  matrix.

**Number of adaptive filters** — Number of adaptive filters

1 (default) | positive integer

Specify the number of adaptive filters  $N$  the block supports as a positive integer.

When you specify this value to be an integer greater than 1, each filter can be chosen to adapt independently during run time by providing the **Adapt** input as a logical vector of length  $N$ . All filters are assumed to run on the same input and have a common step size, leakage factor, and reset input.

The weights the block generates through the **Wts** output port is an  $N$ -by- $L$  matrix, where  $L$  is the length of each filter.

For an example that shows how to adapt multiple filters, see “Adapt Multiple Filters Using LMS Update block”.

**Step size source** — Method to specify the step size

Property (default) | Input port

- Property — Specify the filter adaptation size using the **Step size (mu)** parameter.
- Input port — Pass filter adaptation size using the **Mu** input port.

**Step size ( $\mu$ )** — Size of the adaptation step

0.1 (default) | nonnegative scalar

**Step size ( $\mu$ )** indicates the amount by which the filter weights are updated in each iteration. Choose an optimal step size so that the filter is stable and the convergence speed is optimal.

This parameter is tunable. You can change its value even during the simulation.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Step size source** to Property.

**Leakage factor (0 to 1)** — Leakage factor

1.0 (default) | real scalar in the range [0,1]

**Leakage factor (0 to 1)** prevents unbounded growth of the filter coefficients by reducing the drift of the coefficients from their optimum values. A leakage factor of 1.0 indicates no leakage. If you encounter coefficient drift, that is, large fluctuation about the optimum solution, decrease the leakage factor until the coefficient fluctuation becomes small.

This parameter is tunable. You can change its value even during the simulation.

**Tunable:** Yes

**Initial value of filter weights** — Initial value of filter weights

0 (default) | real scalar | vector | matrix

Specify the initial value of filter weights as one of the following:

- Scalar
- Vector of size 1-by- $L$  --  $N$  is set to 1
- Matrix of size  $N$ -by- $L$  --  $N > 1$  and  $L > 1$

where  $N$  is the number of adaptive filters specified in **Number of adaptive filters** and  $L$  is the length of each filter specified in **Filter length**.

This parameter specifies the initial value of the filter weights  $\mathbf{w}(n-1)$ . The block uses this value to compute the weights  $\mathbf{w}(n)$ , when  $n = 1$ . For more information, see "Algorithms" on page 2-896.

**Adaptive filter mode** — Adaptive filter mode

Tapped delay-line FIR filter (default) | Adaptive linear combiner

Specify the adaptive filter mode as one of the following:

- **Tapped delay-line FIR filter** -- The block assumes the variable portion of the adaptive filter to be a tapped delay-line FIR filter. In this mode, the input samples are related using this equation:

$$\mathbf{u}(n) = [u(n), u(n-1), \dots, u(n-L+1)]$$

where  $n$  is the current time index and  $L$  is the length of the adaptive filter specified in the **Filter length** parameter.

The block accepts scalar input samples in this mode. The block algorithm buffers the samples to form the  $\mathbf{u}(n)$  vector.

- **Adaptive linear combiner** -- The block does not buffer the input samples, and the input you provide to the block must be a column vector equal in length to the **Filter length** parameter. In this case, there is no relationship between the input samples.

For more details, see “Algorithms” on page 2-896.

**Enable adapt input** — Update the filter weights

off (default) | on

When you select this check box, the **Adapt** input port appears on the block. When the input to this port is greater than 0, the block updates the filter weights. When the input to this port is less than or equal to 0, the filter weights do not change.

**Enable reset input** — Reset the filter weights

off (default) | on

When you select this check box, the **Reset** input port appears on the block. When the input to this port is greater than 0, the block resets the filter weights to their initial values. When the input to this port is less than or equal to 0, the filter weights do not change.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

In a closed loop adaptive filter, the weights or coefficients of the filter are adjusted until the error is minimized. The error is the difference between the filter output and the desired signal. In this block, the error signal is specified through the **Error** input port.

The block computes filter weight estimates using  $\mathbf{w}(n) = \alpha \mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$ .

The function  $f(\mathbf{u}(n), e(n), \mu)$  is defined according to the LMS algorithm you specify through the **Algorithm** parameter:

- **LMS** —  $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \mathbf{u}^*(n)$
- **Normalized LMS** —  $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n) \mathbf{u}(n)}$

In the Normalized LMS algorithm,  $\varepsilon$  is a small positive constant that overcomes the potential numerical instability in the update of weights.

For double-precision floating-point input,  $\varepsilon$  is the output of the `eps` function. For single-precision floating-point input,  $\varepsilon$  is the output of `eps("single")`. For fixed-point input,  $\varepsilon$  is 0.

- **Sign-Error LMS** —  $f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$
- **Sign-Data LMS** —  $f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$ , where  $\mathbf{u}(n)$  is real
- **Sign-Sign LMS** —  $f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$ , where  $\mathbf{u}(n)$  is real

In the equations:

- $n$  — The current time index.
- $\mathbf{u}(n)$  — The vector of input samples at step  $n$ .

When you set the **Adaptive filter mode** parameter to `Tapped delay-line FIR filter`, the input to the block is a scalar value and the block buffers the input samples to generate the  $\mathbf{u}(n)$  vector.

When you set the **Adaptive filter mode** parameter to `Adaptive linear combiner`, the block does not buffer the samples. The input to the block should be in the form of a column vector. In this case, there is no relationship between the input samples.

- $\mathbf{u}^*(n)$  — The complex conjugate of the vector of input samples at step  $n$ .
- $\mathbf{w}(n)$  — The vector of filter weight estimates at step  $n$ .
- $e(n)$  — The estimation error at step  $n$ .
- $\mu$  — The adaptation step size.
- $\alpha$  — The leakage factor ( $0 \leq \alpha \leq 1$ ).

### Multifilter Support

You can update the weights of multiple adaptive filters using the same LMS Update block. To enable this, specify the **Number of adaptive filters** parameter to be a value greater than 1. You can then adapt each filter independently during run time by providing the input at the **Adapt** port as a logical vector of length  $N$ . The block algorithm assumes that all filters run on the same input, adapt using the same algorithm, and have the same filter length, step size, leakage factor, and reset input.

# Lowpass Filter

Design FIR or IIR lowpass filter

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

The Lowpass Filter block independently filters each channel of the input signal over time using the filter design specified by the block parameters. You can control whether the block implements an IIR or FIR lowpass filter using the **Filter type** parameter. You can specify the passband and stopband edge frequencies in Hz or in normalized frequency units.

This block supports ARM Cortex code generation. Under certain conditions, this block also supports SIMD code generation. For details, see “Code Generation” on page 2-903.

## Ports

### Input

**Port\_1** — Input signal to filter

column vector | matrix

Input signal, specified as a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

### Output

**Port\_1** — Filtered signal

vector | matrix

Filtered signal, returned as a vector or matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

### Main

**Filter type** — FIR or IIR filter

FIR (default) | IIR

Specify whether the block implements an FIR lowpass filter or an IIR lowpass filter.

**Design minimum order filter** — Design filter with minimum order

on (default) | off

When you select this check box, the block designs a filter with the minimum order and the specified passband, stopband frequency, passband ripple, and stopband attenuation.

When you clear this check box, you can specify the **Filter order** as a positive integer.

**Filter order** — Order of lowpass filter

50 (default) | positive integer

Specify the filter order of the lowpass filter as a positive integer.

#### Dependencies

To enable this parameter, clear the **Design minimum order filter** check box.

**Passband edge frequency (Hz)** — Passband edge frequency

8e3 (default) | real positive scalar

Specify the passband edge frequency of the lowpass filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the passband edge frequency is in Hz and must be less than half the value of the input sample rate.
- **Use normalized frequency (0 to 1)** -- The value of the passband edge frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Stopband edge frequency (Hz)** — Stopband edge frequency

12e3 (default) | real positive scalar

Specify the stopband edge frequency of the lowpass filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the stopband edge frequency is in Hz and must be less than half the value of the input sample rate.
- **Use normalized frequency (0 to 1)** -- The value of the stopband edge frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

#### Dependencies

To enable this parameter, select the **Design minimum order filter** check box.

**Maximum passband ripple (dB)** — Maximum passband ripple

0.1 (default) | real positive scalar

Specify the maximum ripple of the filter response in the passband as a real positive scalar in dB.

**Minimum stopband attenuation (dB)** — Minimum stopband attenuation

80 (default) | real positive scalar

Specify the minimum attenuation in the stopband as a real positive scalar in dB.

**Sample rate mode** — Mode to specify the input sample rate

Specify on dialog (default) | Inherit from input port | Use normalized frequency (0 to 1)

Specify the input sample rate using one of these options:

- **Specify on dialog** -- Specify the input sample rate in the block dialog box using the **Input sample rate (Hz)** parameter.
- **Inherit from input port** -- The block inherits the sample rate from the input signal.
- **Use normalized frequency (0 to 1)** -- Specify the passband edge and the stopband edge frequencies in normalized frequency units (0 to 1).

**Input sample rate (Hz)** — Input sample rate

44100 (default) | scalar

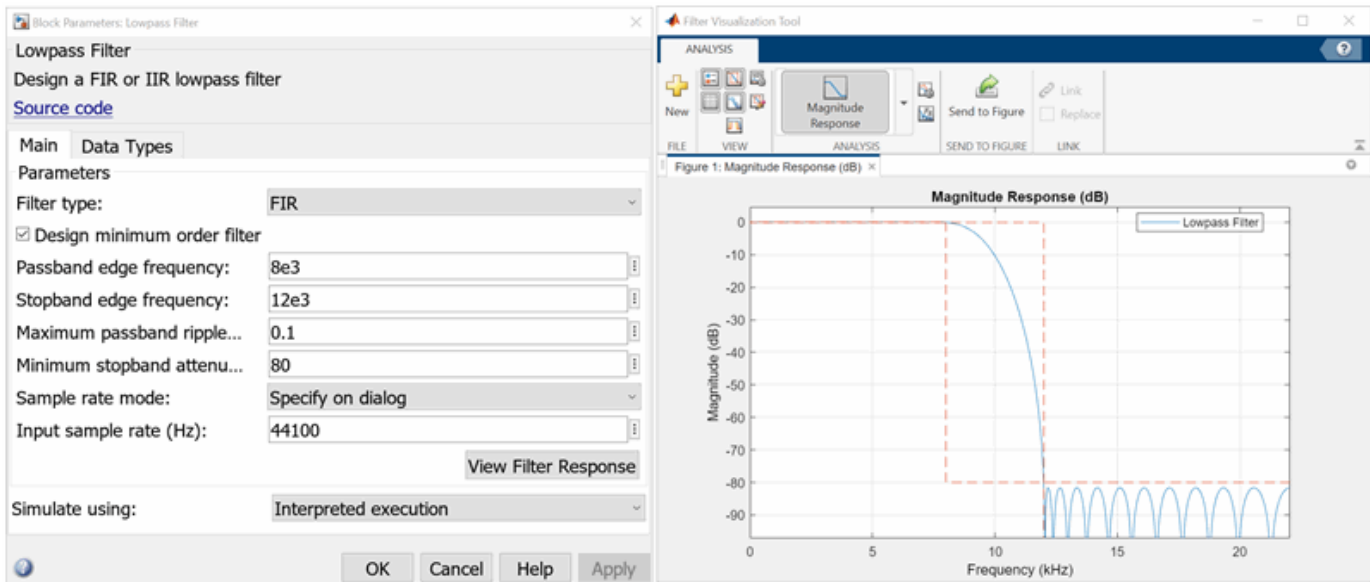

Specify the input sample rate as a scalar in Hz.

### **Dependencies**

To enable this parameter, set the **Sample rate mode** parameter to **Specify on dialog**.

**View Filter Response** — Open Filter Visualization Tool  
button

Opens the Filter Visualization Tool (`fvtool`) and displays the magnitude and phase response of the Lowpass Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

## Data Types

**Rounding mode** — Rounding method

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Rounding method for the output fixed-point operations.

**Coefficients** — Coefficient data type

fixdt(1,16) (default) | fixdt(1,16,0) | <data type expression>

Fixed-point data type of the coefficients, specified as one of the following:

- `fixdt(1,16)` — Signed fixed-point data type of word length 16, with binary point scaling. The block determines the fraction length automatically from the coefficient values in such a way that the coefficients occupy maximum representable range without overflowing.
- `fixdt(1,16,0)` — Signed fixed-point data type of word length 16 and fraction length 0. You can change the fraction length to any other integer value.
- `<data type expression>` — Specify the data type using an expression that evaluates to a data type object, for example, numeric type (`fixdt([ ],16,15)`). Specify the sign mode of this data type as `[ ]` or `true`.
- Refresh Data Type — Refresh to the default data type.

Click the **Show data type assistant** button  to display the data type assistant, which helps you set the data type. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Block Characteristics

|                                 |   |
|---------------------------------|---|

## Algorithms

### FIR Lowpass Filter

For the minimum order design, the algorithm uses generalized Remez FIR filter design algorithm. For the specified order design, the algorithm uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure.

### IIR Lowpass Filter

In the IIR configuration, the algorithm uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The algorithm uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the lowpass filter.

## Version History

### Introduced in R2015b

#### R2023a: Support for normalized frequencies

When you set the **Sample rate mode** parameter to `Use normalized frequency (0 to 1)`, you can specify the passband and stopband edge frequencies in normalized frequency units (0 to 1).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Lowpass Filter block supports ARM Cortex code generation. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

The Lowpass Filter block also supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to FIR.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

## Lowpass Filter (Obsolete)

Design lowpass filter

## Compatibility

---

**Note** The Lowpass Filter (Obsolete) block has been replaced by the Lowpass Filter block. Existing instances of the Lowpass Filter (Obsolete) block will continue to operate. For new models, use the Lowpass Filter block.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Parameters

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select **Minimum** (the default) or **Specify**. Selecting **Specify** enables the **Order** option so you can enter the filter order. When you set the **Impulse response** to **IIR**, you can specify different numerator and denominator orders. To specify a different denominator order, you must select the **Denominator order** check box.

### Order

Enter the filter order. This option is enabled only if you set the **Order mode** to **Specify**.

### Denominator order

Select this check box to specify a different denominator order. This option is enabled only if you set the **Impulse response** to **IIR** and the **Order mode** to **Specify**.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default value is 2.

### Frequency Specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as  $F_{pass}$  and  $F_{stop}$  represent transition regions where the filter response is not constrained.

### Frequency constraints

When **Order mode** is *Specify*, select the filter features that the block uses to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and Stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying the edge of the passband.
- **Stopband frequency** — Define the filter by specifying the edge of the stopband.
- **Halfband power (3dB) frequency** — Define the filter response by specifying the location of the 3 dB point. The 3 dB point is the frequency for the point three decibels below the passband value.
- **Cutoff (6dB) frequency** — For FIR filters, define the filter response by specifying the location of the 6 dB point. The 6 dB point is the frequency for the point six decibels below the passband value.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0–1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

**Input sample rate**, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Half power (3dB) frequency

When **Frequency constraints** is **Half power (3dB) frequency**, specify the frequency of the 3 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Cutoff (6dB) frequency

When **Frequency constraints** is **Cutoff (6dB) frequency**, specify the frequency of the 6 dB point. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude Specifications

Parameters in this group specify the filter response in the passbands and stopbands.

### Magnitude constraints

This option is only available when you specify the order of your filter design. Depending on the setting of the **Frequency constraints** parameter, some combination of the following options will

be available for the **Magnitude constraints** parameter: Unconstrained, and Passband ripple and stopband attenuation.

### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)

### **Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Elliptic, and the default FIR method is Equiripple.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

#### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

#### **Phase constraint**

Specify the phase constraint of the filter as Linear, Maximum, or Minimum.

#### **Minimum order**

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select

Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. The block applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## Filter Implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters (Impulse response: IIR).

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The **Inherited** (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Version History

Introduced in R2006b

## LPC to LSF/LSP Conversion

Convert linear prediction coefficients to line spectral pairs or line spectral frequencies

### Library

Estimation / Linear Prediction

`dsplp`

### Description

The LPC to LSF/LSP Conversion block takes a vector or matrix of linear prediction coefficients (LPCs) and converts it to a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs). When converting LPCs to LSFs, the block outputs match those of the `poly2lsf` function.

The block input must be either a matrix, a column vector, or an unoriented vector. Each channel of the input must have at least two samples.

The input LPCs for each channel,  $1, a_1, a_2, \dots, a_m$ , must be the denominator of the transfer function of a stable all-pole filter with the form given in the first equation of “Requirements for Valid Outputs” on page 2-910. A length- $M+1$  input channel yields a length- $M$  output channel.

See other sections of this reference page to learn about how to ensure that you get valid outputs, how to detect invalid outputs, how the block computes the LSF/LSP values, and more.

### Requirements for Valid Outputs

To get valid outputs, your inputs and the **Root finding coarse grid points** parameter value must meet these requirements:

- The input LPCs for each channel,  $1, a_1, a_2, \dots, a_m$ , must come from the denominator of the following transfer function,  $H(z)$ , of a stable all-pole filter (all roots of  $H(z)$  must be inside the unit circle). Note that the first term in  $H(z)$ 's denominator must be 1. When the input LPCs do not come from a transfer function of the following form, the block outputs are invalid.

$$H(z) = \frac{1}{1 + a_1z^{-1} + a_2z^{-2} + \dots + a_mz^{-m}}$$

- The **Root finding coarse grid points** parameter value must be large enough so that the block can find all the LSP or LSF values. (The output LSFs and LSPs are roots of polynomials related to the input LPC polynomial; the block looks for these roots to produce the output. For details, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-914.) When you do not set **Root finding coarse grid points** to a high enough value relative to the number of LPCs, the block might not find all the LSPs or LSFs and yield invalid outputs as described in “Root Finding Method Limitations: Failure to Find Roots” on page 2-916.

To learn about recognizing invalid inputs and outputs and parameters for dealing with them, see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-912.

### Setting Outputs to LSFs or LSPs

Set the **Output** parameter to one of the following settings to determine whether the block outputs LSFs or LSPs:

- **LSF in radians (0 pi)** — Block outputs the LSF values between 0 and  $\pi$  radians in increasing order. The block does not output the guaranteed LSF values, 0 and  $\pi$ .
- **LSF normalized in range (0 0.5)** — Block outputs normalized LSF values in increasing order, computed by dividing the LSF values between 0 and  $\pi$  radians by  $2\pi$ . The block does not output the guaranteed normalized LSF values, 0 and 0.5.
- **LSP in range (-1 1)** — Block outputs LSP values in decreasing order, equal to the cosine of the LSF values between 0 and  $\pi$  radians. The block does not output the guaranteed LSP values, -1 and 1.

### Adjusting Output Computation Time and Accuracy with Root Finding Parameters

The values  $n$  and  $k$  determine the block's output computation time and accuracy, where

- $n$  is the value of the **Root finding coarse grid points** parameter (choose this value with care; see the note below).
- $k$  is the value of the **Root finding bisection refinement** parameter.
- Decreasing the values of  $n$  and  $k$  decreases the output computation time, but also decreases output accuracy:
  - The upper bound of block's computation time is proportional to  $k \cdot (n - 1)$ .
  - Each LSP output is within  $1/(n \cdot 2^k)$  of the actual LSP value.
  - Each LSF output is within  $\Delta LSF$  of the actual LSF value,  $LSF_{act}$ , where

$$\Delta LSF = \left| \arccos(LSF_{act}) - \arccos\left(LSF_{act} + 1/\left(n \cdot 2^k\right)\right) \right|$$

---

**Note** When the value of the **Root finding coarse grid points** parameter is too small relative to the number of LPCs, the block might output invalid data as described in “Requirements for Valid Outputs” on page 2-910. Also see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-912.

---

### Notable Input and Output Properties

- To get valid outputs, your input LPCs and the value of the **Root finding coarse grid points** parameter must meet the requirements described in “Requirements for Valid Outputs” on page 2-910.
- Length- $L+1$  input channel yields length- $L$  output channel
- **Output** parameter determines the output type (see “Setting Outputs to LSFs or LSPs” on page 2-911):
  - LSFs — frequencies,  $w_k$ , where  $0 < w_k < \pi$  and  $w_k < w_{k+1}$
  - Normalized LSFs —  $w_k / 2\pi$

- LSPs —  $\cos(w_k)$

### Handling and Recognizing Invalid Inputs and Outputs

The block outputs invalid data when your input LPCs and the value of the **Root finding coarse grid points** parameter do not meet the requirements described in “Requirements for Valid Outputs” on page 2-910. The following topics describe what invalid outputs look like, and how to set the block parameters provided for handling invalid inputs and outputs:

- “What Invalid Outputs Look Like” on page 2-912
- “Parameters for Handling Invalid Inputs and Outputs” on page 2-912

### What Invalid Outputs Look Like

The channels of an invalid output have the same dimensions, sizes, and frame statuses as the channels of a valid output. However, invalid output channels do not contain all the LSP or LSF values. Instead, they contain none or some of the LSP and LSF values and the rest of the output is filled with place holder values (-1, 0.5, or  $\pi$ ) depending on the **Output** parameter setting).

In short, all invalid outputs in a channel end in one of the place holder values (-1, 0.5, or  $\pi$ ) as illustrated in the following table. To learn how to use the block's parameters for handling invalid inputs and outputs, see the next section.

| Output Parameter Setting                | Place Holder | Sample Invalid Outputs   |
|---|--------------|--|
| LSF in radians ( $\theta$ $\pi$ )       | $\pi$        | $[w_1 \ w_2 \ w_3 \ \pi \ \pi \ \pi \ \pi \ \pi]$                              |
| LSF normalized in range ( $\theta$ 0.5) | 0.5          | $\begin{bmatrix} w_1 \\ w_2 \\ 0.5 \end{bmatrix}$                              |
| LSP in range (-1 1)                     | -1           | $\begin{bmatrix} \cos(w_{13}) \\ \cos(w_{23}) \\ -1 \\ -1 \\ -1 \end{bmatrix}$ |

### Parameters for Handling Invalid Inputs and Outputs

You must set how the block handles invalid inputs and outputs by setting these parameters:

- **Show output validity status (1=valid, 0=invalid)** — Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; 1 when the output of the corresponding channel is valid, and 0 when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see “Requirements for Valid Outputs” on page 2-910). See the previous section to learn how to recognize invalid outputs.
- **If current output is invalid, overwrite with previous output** — Select this check box to cause the block to overwrite invalid outputs with the previous output. When you set this parameter you also need to consider these parameters:
  - **When first output is invalid, overwrite with user-defined values** — When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state.

- **User-defined LSP/LSF values for overwriting invalid first output** — Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.
- **If first input value is not 1** — The block output in any channel is invalid when the first coefficient in an LPC vector is not 1; this parameter determines what the block does when given such inputs:
  - **Ignore** — Proceed with computations as if the first coefficient is 1.
  - **Normalize** — Divide the input LPCs by the value of the first coefficient before computing the output.
  - **Normalize and warn** — In addition to **Normalize**, display a warning message at the MATLAB command line.
  - **Error** — Stop the simulation and display an error message at the MATLAB command line.

## Parameters

### Output

Specifies whether to convert the input linear prediction polynomial coefficients (LPCs) to LSP in range  $(-1, 1)$ , LSF in radians  $(0, \pi)$ , or LSF normalized in range  $(0, 0.5)$ . See “Setting Outputs to LSFs or LSPs” on page 2-911 for descriptions of the three settings.

### Root finding coarse grid points

The value  $n$ , where the block divides the interval  $(-1, 1)$  into  $n$  subintervals of equal length, and looks for roots (LSP values) in each subinterval. You must pick  $n$  large enough or the block output might be invalid as described in “Requirements for Valid Outputs” on page 2-910. To learn how the block uses this parameter to compute the output, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-914. Also see “Adjusting Output Computation Time and Accuracy with Root Finding Parameters” on page 2-911. Tunable (Simulink).

### Root finding bisection refinement

The value  $k$ , where each LSP output is within  $1/(n \cdot 2^k)$  of the actual LSP value, where  $n$  is the value of the **Root finding coarse grid points** parameter. To learn how the block uses this parameter to compute the output, see “LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding” on page 2-914. Also see “Adjusting Output Computation Time and Accuracy with Root Finding Parameters” on page 2-911. Tunable (Simulink).

### Show output validity status

Set this parameter to activate a second output port that outputs a vector with one Boolean element per channel; 1 when the output of the corresponding channel is valid, and 0 when the output is invalid. The LSF and LSP outputs are invalid when the block fails to find all the LSF or LSP values or when the input LPCs are unstable (for details, see “Requirements for Valid Outputs” on page 2-910).

**If current output is invalid, overwrite with previous output**

Selecting this check box causes the block to overwrite invalid outputs with the previous output. Setting this parameter activates other parameters for taking care of initial overwrite values (when the very first output of the block is invalid). For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-912.

**When first output is invalid, overwrite with user-defined values**

When the first input is unstable, you can overwrite the invalid first output with either

- The default values, by clearing this check box
- Values you specify, by selecting this check box

The default initial overwrite values are the LSF or LSP representations of an all-pass filter. The vector that is used to overwrite invalid output is stored as an internal state. For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-912.

**User-defined LSP/LSF values for overwriting invalid first output**

Specify a vector of values for overwriting an invalid first output if you selected the **When first output is invalid, overwrite with user-defined values** parameter. For multichannel inputs, provide a matrix with the same number of channels as the input, or one vector that will be applied to every channel. The vector or matrix of LSP/LSF values you specify should have the same dimension, size, and frame status as the other outputs.

**If first input value is not 1**

Determines what the block does when the first coefficient of an input is not 1. The block can either proceed with computations as when the first coefficient is 1 (**Ignore**); divide the input LPCs by the value of the first coefficient before computing the output (**Normalize**); in addition to **Normalize**, display a warning message at the MATLAB command line (**Normalize and warn**); stop the simulation and display an error message at the MATLAB command line (**Error**). For more information, see “Parameters for Handling Invalid Inputs and Outputs” on page 2-912.

## Theory

**LSF and LSP Computation Method: Chebyshev Polynomial Method for Root Finding**

---

**Note** To learn the principles on which the block's LSP and LSF computation method is based, see the reference listed in “References” on page 2-917.

---

To compute LSP outputs for each channel, the block relies on the fact that LSP values are the roots of two particular polynomials related to the input LPC polynomial; the block finds these roots using the Chebyshev polynomial root finding method, described next. To compute LSF outputs, the block computes the arc cosine of the LSPs, outputting values ranging from 0 to  $\pi$  radians.

**Root Finding Method**

LSPs, which are the roots of two particular polynomials, always lie in the range (-1, 1). (The guaranteed roots at 1 and -1 are factored out.) The block finds the LSPs by looking for a sign change of the two polynomials' values between points in the range (-1, 1). The block searches a maximum of  $k(n - 1)$  points, where

- $n$  is the value of the **Root finding coarse grid points** parameter.

- $k$  is the value of the **Root finding bisection refinement** parameter.

The block's method for choosing which points to check consists of the following two steps:

- 1 Coarse Root Finding** — The block divides the interval  $[-1, 1]$  into  $n$  intervals, each of length  $2/n$ , and checks the signs of both polynomials' values at the endpoints of the intervals. The block starts checking signs at 1, and continues checking signs at  $1 - 4/n$ ,  $1 - 6/n$ , and so on at steps of length  $2/n$ , outputting any point if it is a root. The block stops searching in these situations:
  - a** The block finds a sign change of a polynomial's values between two adjacent points. An interval containing a sign change is guaranteed to contain a root, so the block further searches the interval as described in Step 2, Root Finding Refinement.
  - b** The block finds and outputs all  $M$  roots (given a length- $M+1$  LPC input).
  - c** The block fails to find all  $M$  roots and yields invalid outputs as described in “Handling and Recognizing Invalid Inputs and Outputs” on page 2-912.
- 2 Root Finding Refinement** — When the block finds a sign change in an interval,  $[a, b]$ , it searches for the root guaranteed to lie in the interval by following these steps:
  - a Check if Midpoint Is a Root** — The block checks the sign of the midpoint of the interval  $[a, b]$ . The block outputs the midpoint if it is a root, and continues Step 1, Coarse Root Finding, at the next point,  $a - 2/n$ . Otherwise, the block selects the half-interval with endpoints of opposite sign (either  $[a, (a + b)/2]$  or  $[(a + b)/2, b]$ ) and executes Step 2b, Stop or Continue Root Finding Refinement.
  - b Stop or Continue Root Finding Refinement** — When the block has repeated Step 2a  $k$  times ( $k$  is the value of the **Root finding bisection refinement** parameter), the block linearly interpolates the root by using the half-interval's endpoints, outputs the result as an LSP value, and returns to Step 1, Coarse Root Finding. Otherwise, the block repeats Step 2a using the half-interval.

**Coarse Root Finding:** LSPs are roots of two particular polynomials related to the input LPCs. Check signs of the two polynomials at evenly-spaced points to find all intervals containing a sign change. Output any roots (LSPs) found.

**Root finding coarse grid points = 5**  
Divide  $[-1, 1]$  into five intervals of equal length and check signs of the polynomials' values at the endpoints of the intervals: 1, 0.6, 0.2, -0.2, -0.6, -1.

**Root Finding Refinement:** Whenever Coarse Root Finding identifies an interval containing a sign change, repeatedly bisect the interval to better approximate the root (LSP value).

**Bisection 1:** Check the sign of the polynomial at the midpoint of the interval and select the half-interval with endpoints of opposite sign:  $[0.2, 0.4]$

**Bisection 2:** Similar to Bisection 1

**Bisection 3:** The last bisection. Since the midpoint of this interval is not the root, linearly interpolate the root and output the result as an LSP value.

**Root finding bisection refinement = 3**  
Bisect all sign change intervals found in the Coarse Root Finding up to three times to find the root. When the root is not found in the last bisection, linearly interpolate the root.

## Coarse Root Finding and Root Finding Refinement

### Root Finding Method Limitations: Failure to Find Roots

The block root finding method described above can fail, causing the block to produce invalid outputs (for details on invalid outputs, see “Handling and Recognizing Invalid Inputs and Outputs” on page 2-912).

In particular, the block can fail to find some roots if the value of the **Root finding coarse grid points** parameter,  $n$ , is too small. If the polynomials oscillate quickly and have roots that are very close together, the root finding might be too coarse to identify roots that are very close to each other, as illustrated in “Fixing a Failed Root Finding” on page 2-917.

For higher-order input LPC polynomials, you should increase the **Root finding coarse grid points** value to ensure the block finds all the roots and produces valid outputs.

**Root Finding Fails:** The root search divides the interval  $[-1, 1]$  into four intervals, but all three roots are in a single interval. The block can only find one root per interval, so two of the roots are never found.

**Fix Root Finding so it Succeeds:** Increasing the value of the **Root finding course grid points** parameter to 15 ensures that each root is in its own interval, so all roots are found.

## Fixing a Failed Root Finding

### Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Supported only by the optional output port that appears when you set the parameter, **Show output validity status (1=valid, 0=invalid)**

# LSF/LSP to LPC Conversion

Convert line spectral frequencies or line spectral pairs to linear prediction coefficients

## Library

Estimation / Linear Prediction

dsplp

## Description

The LSF/LSP to LPC Conversion block takes a vector or matrix of line spectral pairs (LSPs) or line spectral frequencies (LSFs) and converts it to a vector or matrix of linear prediction polynomial coefficients (LPCs). When converting LSFs to LPCs, the block outputs match those of the `lsf2poly` function.

The block input can be an  $N$ -by- $M$  matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel. Each input channel must be in the same format, which you specify in the **Input** parameter:

- LSF in range  $(0 \pi)$  — Vector of LSF values between 0 and  $\pi$  radians in increasing order. Do not include the guaranteed LSF values, 0 and  $\pi$ .
- LSF normalized in range  $(0 0.5)$  — Vector of normalized LSF values in increasing order, (compute by dividing the LSF values between 0 and  $\pi$  radians by  $2\pi$ ). Do not include the guaranteed normalized LSF values, 0 and 0.5.
- LSP in range  $(-1 1)$  — Vector of LSP values in decreasing order, equal to the cosine of the LSF values between 0 and  $\pi$  radians. Do not include the guaranteed LSP values, -1 and 1.

## Parameters

### Input

Specifies whether to convert LSP in range  $(-1 1)$ , LSF in range  $(0 \pi)$ , or LSF normalized in range  $(0 0.5)$  to linear prediction coefficients (LPCs).

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

## LPC to/from Cepstral Coefficients

Convert linear prediction coefficients to cepstral coefficients or cepstral coefficients to linear prediction coefficients

### Library

Estimation / Linear Prediction

dsplp

### Description

The LPC to/from Cepstral Coefficients block either converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs) or cepstral coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to `LPCs to cepstral coefficients` or `Cepstral coefficients to LPCs` to select the domain into which you want to convert your coefficients. The LPC port corresponds to LPCs, and the CC port corresponds to the CCs. For more information, see “Algorithm” on page 2-922.

The block input can be an  $N$ -by- $M$  matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal  $x(n)$  as the input to an FIR analysis filter represented by LPCs. The output of this analysis filter,  $e(n)$ , is known as the prediction error signal. The power of this error signal is denoted by  $P$ , the prediction error power.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can specify the prediction error power in two ways. From the **Specify P** list, choose `via input port` to input the prediction error power using input port  $P$ . The input to the port must be a vector with length equal to the number of input channels. Select `assume P equals 1` to set the prediction error power equal to 1 for all channels.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, the **Output size same as input size** check box appears. When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs. When you do not select this check box, enter a positive scalar for the **Length of output cepstral coefficients** parameter.

When you select `LPCs to cepstral coefficients` from the **Type of conversion** list, you can use the **If first input value is not 1** parameter to specify the behavior of the block when the first coefficient of the LPC vector is not 1. The following options are available:

- `Replace it with 1` — Changes the first value of the coefficient vector to 1. The other coefficient values are unchanged.

- **Normalize** — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1.
- **Normalize and Warn** — Divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — Displays an error telling you that the first coefficient of the LPC vector is not 1.

When you select **Cepstral coefficients to LPCs** from the **Type of conversion** list, the **Output P** check box appears on the block. Select this check box when you want to output the prediction error power from output port P.

## Algorithm

The cepstral coefficients are the coefficients of the Fourier transform representation of the logarithm magnitude spectrum. Consider a sequence,  $x(n)$ , having a Fourier transform  $X(\omega)$ . The cepstrum,  $c_x(n)$ , is defined by the inverse Fourier transform of  $C_x(\omega)$ , where  $C_x(\omega) = \log_e X(\omega)$ . See the Real Cepstrum block reference page for information on computing cepstrum coefficients from time-domain signals.

### LPC to CC

When in this mode, this block uses a recursion technique to convert LPCs to CCs. The LPC vector is defined by  $[a_0 \ a_1 \ a_2 \ \dots \ a_p]$  and the CC vector is defined by  $[c_0 \ c_1 \ c_2 \ \dots \ c_p \ \dots \ c_{n-1}]$ . The recursion is defined by the following equations:

$$c_0 = \log_e P$$

$$c_m = -a_m + \frac{1}{m} \sum_{k=1}^{m-1} [-(m-k) \cdot a_k \cdot c_{(m-k)}], 1 \leq m \leq p$$

$$c_m = \sum_{k=1}^p \left[ \frac{-(m-k)}{m} \cdot a_k \cdot c_{(m-k)} \right], p < m < n$$

### CC to LPC

When in this mode, this block uses a recursion technique to convert CCs to LPCs. The CC vector is defined by  $[c_0 \ c_1 \ c_2 \ \dots \ c_p \ \dots \ c_n]$  and the LPC vector is defined by  $[a_0 \ a_1 \ a_2 \ \dots \ a_p]$ . The recursion is defined by the following equations

$$a_m = -c_m - \frac{1}{m} \sum_{k=1}^{m-1} [(m-k) \cdot c_{(m-k)} \cdot a_k]$$

$$P = \exp(C_0)$$

where  $m = 1, 2, \dots, p$ .

## Parameters

### Type of conversion

Choose **LPCs to cepstral coefficients** or **Cepstral coefficients to LPCs** to specify the domain into which you want to convert your coefficients.

**Specify P**

Choose `via input port` to input the values of prediction error power using input port P. Select `assume P equals 1` to set the prediction error power equal to 1.

**Output size same as input size**

When you select this check box, the length of the input vector of LPCs is equal to the output vector of CCs.

**Length of output cepstral coefficients**

Enter a positive scalar that is the length of each output channel of CCs.

**If first input value is not 1**

Select what you would like the block to do when the first coefficient of the LPC vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Warn`, and `Error`.

**Output P**

Select this check box to output the prediction error power for each channel from output port P.

## LPC to/from RC

Convert linear prediction coefficients to reflection coefficients or reflection coefficients to linear prediction coefficients

## Library

Estimation / Linear Prediction

dsp\lp

## Description

The LPC to/from RC block either converts linear prediction coefficients (LPCs) to reflection coefficients (RCs) or reflection coefficients to linear prediction coefficients. Set the **Type of conversion** parameter to **LPC to RC** or **RC to LPC** to select the domain into which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients. For more information, see “Algorithm” on page 2-925.

The block input can be an  $N$ -by- $M$  matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Consider a signal  $x(n)$  as the input to an FIR analysis filter represented by LPC coefficients. The output of the analysis filter,  $e(n)$ , is known as the prediction error signal. The power of this error signal is denoted by  $P$ . When the zero lag autocorrelation coefficient of  $x(n)$  is one, the autocorrelation sequence and prediction error power are said to be normalized.

Select the **Output normalized prediction error power** check box to enable port P. The normalized prediction error power output at P is a vector with one element per input channel. Each element varies between zero and one.

Select the **Output LPC filter stability** check box to output the stability of the filter represented by the LPCs or RCs. The synthesis filter represented by the LPCs is stable when the absolute value of each of the roots of the LPC polynomial is less than one. The lattice filter represented by the RCs is stable when the absolute value of each reflection coefficient is less than 1. When the filter is stable, the block outputs a Boolean value of 1 for each input channel at the S port. When the filter is unstable, the block outputs a Boolean value of 0 for each input channel at the S port.

If **first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector in any channel is not 1. The following options are available:

- **Replace it with 1** — Changes the first value of the coefficient channel to 1. The other coefficient values are unchanged.
- **Normalize** — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.

- **Normalize and Warn** — Divides the entire channel of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — Displays an error telling you that the first coefficient of the LPC coefficient channel is not 1.

## Algorithm

### LPC to RC

When in this mode, this block uses backward Levinson recursion to convert linear prediction coefficients (LPCs) to reflection coefficients (RCs). For a given Nth order LPC vector  $LPC_N = [1 \ a_{N1} \ a_{N2} \ \dots \ a_{NN}]$ , the block calculates the Nth reflection coefficient value using the formula  $\gamma_N = -a_{NN}$ . The block then finds the lower order LPC vectors,  $LPC_{N-1}, LPC_{N-2}, \dots, LPC_1$ , using the following recursion.

for  $p = N, N - 1, \dots, 2$ ,

$$\gamma_p = a_{pp}$$

$$F = 1 - \gamma_p^2$$

$$a_{p-1,m} = \frac{a_{p,m}}{F} - \frac{\gamma_p a_{p,p-m}}{F}, \quad 1 \leq m < p$$

end

Finally,  $\gamma_1 = -a_{11}$ . The reflection coefficient vector is  $[\gamma_1, \gamma_2, \dots, \gamma_N]$ .

### RC to LPC

When in this mode, this block uses Levinson recursion to convert reflection coefficients (RCs) to linear prediction coefficients (LPCs). In this case, the input to the block is  $RC = [\gamma_1 \ \gamma_2 \ \dots \ \gamma_N]$ . The zeroth order LPC vector term is 1. Starting with this term, the block uses recursion to calculate the higher order LPC vectors,  $LPC_2, LPC_3, \dots, LPC_N$ , until it has calculated the entire LPC matrix.

$$LPC_{matrix} = \begin{bmatrix} LPC_0 \\ LPC_1 \\ LPC_2 \\ \dots \\ LPC_N \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & \dots & 0 \\ 1 & a_{11} & 0 & 0 & \dots & 0 \\ 1 & a_{21} & a_{22} & 0 & \dots & 0 \\ 1 & a_{31} & a_{32} & a_{33} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 1 & a_{N1} & a_{N2} & a_{N3} & \dots & a_{NN} \end{bmatrix}$$

This LPC matrix consists of LPC vectors of order 0 through  $N$  found by using the Levinson recursion. The following are the formulas for the recursion steps, for  $p = 0, 1, \dots, N - 1$ .

$$a_{p+1,m} = a_{p,m} + \gamma_{p+1} a_{p,p+1-m}, \quad 1 \leq m \leq p$$

$$a_{p+1,p+1} = \gamma_{p+1}$$

## Parameters

### Type of conversion

Select `LPC to RC` or `RC to LPC` to select the domain into which you want to convert your coefficients.

### Output normalized prediction error power

Select this check box to output the normalized prediction error power at port P.

### Output LPC filter stability

Select this check box to output the stability of the filter. When the filter represented by the LPCs or RCs is stable, the block outputs a Boolean value of 1 for each input channel at the S port. When the filter represented by the LPCs or RCs is unstable, the block outputs a Boolean value of 0 for each input channel at the S port.

### If first input value is not 1

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose `Replace it with 1`, `Normalize`, `Normalize and Warn`, and `Error`.

# LPC/RC to Autocorrelation

Convert linear prediction coefficients or reflection coefficients to autocorrelation coefficients

## Library

Estimation / Linear Prediction

dsp\lp

## Description

The LPC/RC to Autocorrelation block either converts linear prediction coefficients (LPCs) to autocorrelation coefficients (ACs) or reflection coefficients (RCs) to autocorrelation coefficients (ACs). Set the **Type of conversion** parameter to `LPC to autocorrelation` or `RC to autocorrelation` to select the domain from which you want to convert your coefficients. The A port corresponds to LPC coefficients, and the K port corresponds to the RC coefficients.

The block input can be an  $N$ -by- $M$  matrix or an unoriented vector. Each column of the matrix is treated as a channel. When the input is an unoriented vector, the input is treated as one channel.

Use the **Specify P** parameter to set the value of the prediction error power. You can set this parameter to 1 by selecting `Assume P=1`. When you select `Via input port`, a P port appears on the block. You can use this port to input the value of the actual, non-unity prediction error power for each channel. The length of this vector must equal the number of channels in the input.

The **If first input value is not 1** parameter specifies the behavior of the block when the first coefficient of the LPC coefficient vector is not 1. The following options are available:

- **Replace it with 1** — The block changes the first value of the coefficient vector to 1. The rest of the coefficient values are unchanged.
- **Normalize** — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1.
- **Normalize and Warn** — The block divides the entire vector of coefficients by the first coefficient so that the first coefficient of the LPC coefficient vector is 1. The block displays a warning message telling you that your vector of coefficients has been normalized.
- **Error** — The block displays an error telling you that the first coefficient of the LPC coefficient vector is not 1.

## Parameters

### Type of conversion

From the list select `LPC to autocorrelation` or `RC to autocorrelation` to specify the domain from which you want to convert your coefficients.

**Specify P**

From the list select Assume P=1 or Via input port to specify the value of prediction error power.

**If first input value is not 1**

Select what you would like the block to do when the first coefficient of the LPC coefficient vector is not 1. You can choose Replace it with 1, Normalize, Normalize and Warn, and Error.

# LU Factorization

Factor square matrix into lower and upper triangular components

## Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Factorizations

## Description

The LU Factorization block factors a row-permuted version of the square input matrix  $A$  as  $A_p = L*U$ , where  $L$  is a unit-lower triangular matrix,  $U$  is an upper triangular matrix, and  $A_p$  contains the rows of  $A$  permuted as indicated by the permutation index vector  $P$ . The block uses the pivot matrix  $A_p$  instead of the exact input matrix  $A$  because it improves the numerical accuracy of the factorization.

## Ports

### Input

**A** — Input matrix

$M$ -by- $M$  square matrix

Specify the input matrix as an  $M$ -by- $M$  square matrix through this port. If the input matrix is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

### Output

**LU** — Lower and upper triangular factors

$M$ -by- $M$  square matrix

Composite matrix containing both the lower triangle elements of  $L$  and the upper triangle elements of  $U$ . The composite matrix improves the efficiency of the block. The matrix output is in a different format than the output of the `lu` function, which returns  $L$  and  $U$  as separate matrices. To convert the output from the **LU** port of the block to separate  $L$  and  $U$  matrices, use the following code:

```
L = tril(LU,-1)+eye(size(LU)); U = triu(LU);
```

If you compare the results produced by these equations to the actual output of the `lu` function, you might see slightly different values. These differences are due to a rounding error, and are expected. For more information on the LU factorizations, see the `lu` function page.

This composite matrix has the same size, data type, and complexity as the input matrix  $A$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

**P** — Permutation vector

vector

Permutation vector, returned as a vector of length  $M$ . The block permutes the input square matrix  $A$  using the permutation vector  $P$  and factors the permuted matrix into unit-lower triangular  $L$  and upper triangular matrix  $U$ .

Consider the following input matrix.

$$A = \begin{bmatrix} 1 & -2 & 3 \\ 4 & 0 & 6 \\ 2 & -1 & 3 \end{bmatrix}$$

With a permutation index vector  $P$  that is equal to  $P = \begin{bmatrix} 2 \\ 1 \\ 3 \end{bmatrix}$ , the permuted matrix  $A_p$  becomes:

$$A_p = \begin{bmatrix} 4 & 0 & 6 \\ 1 & -2 & 3 \\ 2 & -1 & 3 \end{bmatrix}$$

The block factors this matrix into upper and lower triangular matrices. For a more detailed version of this example, see “Factorize Matrix Using LU Factorization Block”.

Data Types: `single` | `double` | `uint32`

**S** — Singularity of input matrix  
logical scalar

You can determine the singularity of the input matrix  $A$  by enabling the optional output port **S**. When  $A$  is singular, the block outputs a 1 at port **S**. When  $A$  is nonsingular, the block outputs a 0.

Data Types: `Boolean`

## Parameters

### Main Tab

**Show singularity status** — Show singularity status

`off` (default) | `on`

Select to output the singularity of the input at port **S**, which outputs Boolean data type values of 1 or 0. An output of 1 indicates that the current input is singular, and an output of 0 indicates the current input is nonsingular.

### Data Types Tab

**Rounding mode** — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations as one of the following:

- `Floor`
- `Ceiling`

- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

#### **Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

#### **Product output** — Product output data type

Inherit: `Inherit via internal rule` (default) | Inherit: `Same as input` | `fixdt(1,16,0)`

**Product output** specifies the data type of the output of a product operation in the LU Factorization block. For more information on the product output data type, see “Fixed Point” on page 2-933 and “Multiplication Data Types”.

- `Inherit: Inherit via internal rule` — The block inherits the product output data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the product output data type to be the same as the input data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Accumulator** — Accumulator data type

Inherit: `Inherit via internal rule` (default) | Inherit: `Same as input` | Inherit: `Same as product output` | `fixdt(1,16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the LU Factorization block. For more information on how to use the accumulator data type in this block, see the “Fixed Point” on page 2-933 section.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.

- **Inherit**: Same as product output — The block specifies the accumulator data type to be the same as the product output data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output** — Output data type

**Inherit**: Same as input (default) | `fixdt(1,16,0)`

**Output** specifies the data type of the output of the LU Factorization block. For more information on the output data type, see the “Fixed Point” on page 2-933 section.

- **Inherit**: Same as input — The block specifies the output data type to be the same as the input data type.
- `fixdt(1,16,0)` — The block specifies a signed, binary-point scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

#### **Output Minimum** — Minimum value the block can output

`[]` (default) | scalar

Specify the minimum value the block can output. Simulink software uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

#### **Output Maximum** — Maximum value block can output

`[]` (default) | scalar

Specify the maximum value the block can output. Simulink software uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

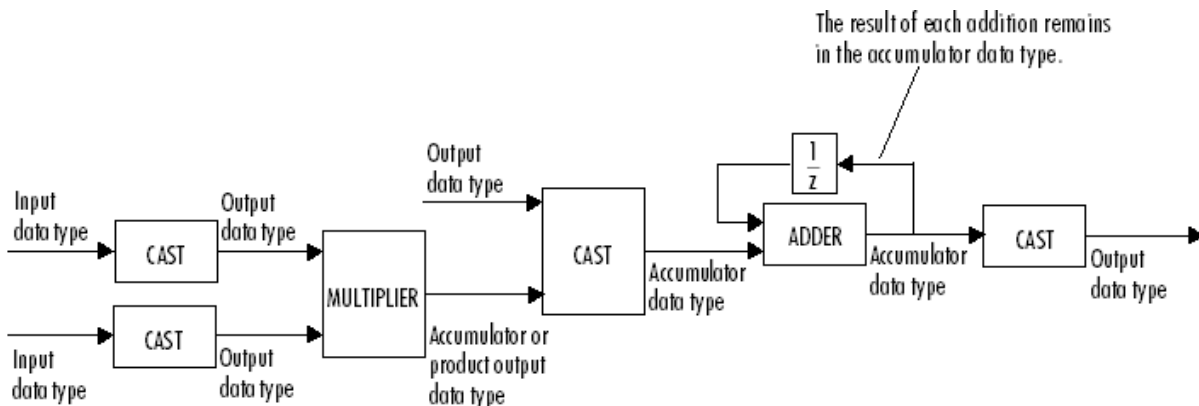

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The following diagram shows the data types used within the LU Factorization block for fixed-point signals.

You can set the product output, accumulator, and output data types in the block dialog as discussed below.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

# LU Inverse

Compute inverse of square matrix using LU factorization

## Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Inverses

## Description

The LU Inverse block computes the inverse of the square input matrix  $A$  by factoring and inverting its row-pivoted variant  $A_p$ .

$$A_p^{-1} = (LU)^{-1}$$

$L$  is a lower triangular square matrix with unity diagonal elements, and  $U$  is an upper triangular square matrix. The block outputs the inverse matrix  $A^{-1}$ .

## Ports

### Input

**Input** — Input square matrix  
square matrix

Specify the input as an  $M$ -by- $M$  square matrix.

Data Types: `single` | `double`

### Output

**Output** — Matrix inverse  
square matrix

Matrix inverse, returned as an  $M$ -by- $M$  square matrix.

Data Types: `single` | `double`

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | <code>double</code>   <code>single</code> |
| <b>Direct Feedthrough</b>       | no  |

### Topics

“Matrix Inverses”

# LU Solver

Solve  $AX = B$  when  $A$  is a square matrix

## Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

## Description

The LU Solver block solves the linear system  $AX = B$  by applying LU factorization, where:

- $A$  is an  $M$ -by- $M$  square matrix input through the **A** port.
- $B$  is an  $M$ -by- $N$  matrix input through the **B** port.
- $X$  is the  $M$ -by- $N$  output matrix and is the unique solution to the equations.

## Ports

### Input

**A** — Input  $A$  matrix  
 $M$ -by- $M$  matrix

Specify the input  $M$ -by- $M$  square matrix  $A$  through this port. Inputs  $A$  and  $B$  must have the same number of rows.

Data Types: `single` | `double`

**B** —  $B$  matrix  
 $M$ -by- $N$  matrix |  $M$ -by-1 vector

Specify the  $B$  matrix in the  $AX = B$  equation as an  $M$ -by- $N$  matrix or an  $M$ -by-1 vector.

When you specify an  $M$ -by-1 vector, the block treats the length- $M$  unoriented vector input at port **B** as an  $M$ -by-1 matrix. Inputs  $A$  and  $B$  must have the same number of rows.

Data Types: `single` | `double`

### Output

**X** — Solution to system of equations  
 $M$ -by- $N$  matrix |  $M$ -by-1 matrix

The block returns the output as an  $M$ -by- $N$  matrix or a  $M$ -by-1 matrix. The size of  $X$  matrix is same as the size of the  $B$  matrix.

Data Types: `single` | `double`

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

The LU algorithm factors a row-permuted variant ( $A_p$ ) of the square input matrix  $A$  as

$$A_p = LU$$

where  $L$  is a lower triangular square matrix with unity diagonal elements, and  $U$  is an upper triangular square matrix.

The matrix factors are substituted for  $A_p$  in

$$A_p X = B_p$$

where  $B_p$  is the row-permuted variant of  $B$ , and the resulting equation

$$LUX = B_p$$

is solved for  $X$  by substituting  $Y = UX$ , and solving two triangular systems.

$$LY = B_p$$

$$UX = Y$$

# Magnitude FFT

Compute nonparametric estimate of spectrum using periodogram method

## Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation  
 DSP System Toolbox / Transforms

## Description

The Magnitude FFT block computes a nonparametric estimate of the spectrum using the periodogram method.

## Ports

### Input

**Input** — Input  
 vector | matrix

Specify the input  $u$  to the block as a vector or a matrix of size  $M$ -by- $N$ .

The block treats an  $M$ -by- $N$  matrix input as  $M$  sequential time samples from  $N$  independent channels.

The Magnitude FFT block supports real and complex floating-point inputs. The block also supports real fixed-point inputs in the `Magnitude` and `Magnitude squared` modes, and complex fixed-point inputs in the `Magnitude squared` mode.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

### Output

**Output** — Magnitude FFT output  
 vector | matrix

Magnitude FFT output, returned as a vector or a matrix.

The block computes a separate estimate for each of the  $N$  independent channels and generates an  $N_{fft}$ -by- $N$  matrix output. Each column of the output matrix contains the estimate of the power spectral density of the corresponding input column at  $N_{fft}$  equally spaced frequency points in the range  $[0, F_s)$ , where  $F_s$  represents the sample rate of the signal.

When you set the **Output** parameter to `Magnitude squared`, the block output for an  $M$ -by- $N$  input  $u$  is equivalent to:

```
y = abs(fft(u,nfft)).^2    % M ≤ nfft
```

When you set the **Output** parameter to `Magnitude`, the block output for an input  $u$  is equivalent to:

```
y = abs(fft(u,nfft))      % M ≤ nfft
```

When  $M > N_{fft}$ , the block wraps the input to  $N_{fft}$  before computing the FFT using one of the above equations:

```
y(:,k) = datawrap(u(:,k),nfft) % 1 ≤ k ≤ N
```

When  $M > N_{fft}$ , the block can also truncate the input:

```
y(:,k) = abs(fft(u,nfft)) % 1 ≤ k ≤ N
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Parameters

**Output** — Type of output

`Magnitude squared (default)` | `Magnitude`

Specify whether the block computes the magnitude FFT or the magnitude-squared FFT of the input signal. For more details on how this block computes the output based on this setting, see the **Output** port description.

**FFT implementation** — FFT implementation

`Auto (default)` | `Radix-2` | `FFTW`

Set this parameter to one of these values:

- **Auto** -- Use this option to let the block choose the FFT implementation. For transform lengths that are not a power of 2, the block restricts the generated code to MATLAB host computers.
- **Radix-2** -- Use this option for bit-reversed processing, fixed or floating-point data, or for portable C-code generation using Simulink Coder. The first dimension  $M$  of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate the dimensions to powers of two, or if possible choose the FFTW algorithm.
- **FFTW** -- Use this option to support an input signal of arbitrary length. The block restricts the generated code with the FFTW implementation to MATLAB host computers.

**Inherit FFT length from input dimensions** — Inherit FFT length from input frame size

`off (default)` | `on`

Select this parameter to use the input frame size as the number of data points on which to perform the FFT. When you select this check box, the input frame size must be a power of two. When you do not select this check box, the **FFT length** parameter specifies the number of data points.

**FFT length** — FFT length

`256 (default)` | `positive integer`

Enter the number of data points  $N_{fft}$  on which to perform the FFT. When  $N_{fft}$  is larger than the input frame size, the block pads each frame with zeros as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

When you set the **FFT implementation** parameter to `Radix-2`, this value must be a power of 2.

## Dependency

To enable this parameter, clear the **Inherit FFT length from input dimensions** parameter.

**Wrap input data when FFT length is shorter than input length** — Choose to wrap or truncate input

on (default) | off

Choose to wrap or truncate the input depending on the **FFT length**.

When you select this parameter and if the **FFT length** is shorter than the input length, a modulo-length data wrapping occurs before the FFT operation. When you clear this parameter, the block truncates the input data to the FFT length before the FFT operation.

## Block Characteristics

## More About

### Fixed-Point Data Types

This diagram shows the data types used within the Magnitude FFT subsystem block for fixed-point signals.

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- Sine table — Same word length as input
- Integer rounding mode — Floor
- Saturate on integer overflow — Not selected
- Product output — Inherit via internal rule
- Accumulator — Inherit via internal rule
- Output — Inherit via internal rule

The settings for the fixed-point parameters of the Magnitude Squared block in the diagram are as follows:

- Integer rounding mode — Floor
- Saturate on integer overflow — Selected
- Output — Inherit via internal rule

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - You set **FFT implementation** to FFTW.
  - You clear the **Inherit FFT length from input dimensions** parameter and set **FFT length** to a value that is not a power of two.

Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

### Fixed-Point Conversion

## Matrix 1-Norm

Compute 1-norm of matrix

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Matrix Operations

## Description

The Matrix 1-Norm block computes the 1-norm or maximum column-sum of an  $M$ -by- $N$  input matrix  $A$ .

$$y = \|A\|_1 = \max_{1 \leq j \leq N} \sum_{i=1}^M |a_{ij}|$$

Equivalent MATLAB code is given by:

```
y = max(sum(abs(A)))
```

## Ports

### Input

**Port\_1** — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

The block treats length- $M$  unoriented vector input as an  $M$ -by-1 matrix.

The Matrix 1-Norm block supports real and complex floating-point inputs and real fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Complex Number Support: Yes

## Output

**Port\_1** — Output signal  
scalar

Matrix 1-norm or maximum column-sum of the input, returned as a scalar. The output  $y$  is always a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

## Parameters

### Main

There are no parameters on the **Main Tab**.

### Data Types

**Rounding mode** — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see Rounding Modes.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numerical results when all these conditions are met:

- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.
- **Output** data type is `Inherit`: `Same as accumulator`.

With these data-type settings, the block operates in a full-precision mode.

---

**Saturate on integer overflow** — Overflow handling method

`off` (default) | `on`

Select this parameter to saturate the result of the fixed-point operation. Clear this parameter to wrap the result of the fixed-point operation. For details on *saturate* and *wrap*, see Overflow Handling for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data-type settings, the block operates in a full-precision mode.

---

#### **Accumulator** — Accumulator data type

`Inherit: Inherit via internal rule (default) | Inherit: Same as input | fixdt([],16,0)`

**Accumulator** specifies the data type of the output of an accumulation operation in the Matrix 1-Norm block.

- `Inherit: Inherit via internal rule` — The block inherits the accumulator data type based on an internal rule. For more information on this rule, see “Inherit via Internal Rule”.
- `Inherit: Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For illustrations on how to use the accumulator data type in this block, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

#### **Output** — Output data type

`Inherit: Same as accumulator (default) | Inherit: Same as input | fixdt([],16,0)`

**Output** specifies the data type of the output of the Matrix 1-Norm block.

- `Inherit: Same as input` — The block specifies the output data type to be the same as the input data type.
- `Inherit: Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `fixdt([],16,0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink).

For more information on the output data type, see Fixed-Point Conversion in “Extended Capabilities” on page 2-0 .

**Output Minimum** — Minimum value that block can output

[ ] (default) | scalar

Specify the minimum value the block can output. Simulink uses this minimum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value that block can output

[ ] (default) | scalar

Specify the maximum value the block can output. Simulink uses this maximum value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this tab. When inputs are floating point, the block ignores these settings and all internal data types are floating point.

---

## Block Characteristics

Array-Vector Multiply | Product | Matrix Product | Dot Product

# Matrix Product

Multiply matrix elements along rows, columns, or entire input

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

## Description

The Matrix Product block multiplies the elements of an  $M$ -by- $N$  input matrix  $u$  along its rows, its columns, or over all its elements.

When the **Multiply over** parameter is set to **Rows**, the block multiplies across the elements of each row and outputs the resulting  $M$ -by-1 matrix. The block treats length- $N$  unoriented vector input as a 1-by- $N$  matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left( \prod_{j=1}^3 u_{1j} \right) \\ \left( \prod_{j=1}^3 u_{2j} \right) \\ \left( \prod_{j=1}^3 u_{3j} \right) \end{bmatrix}$$

When the **Multiply over** parameter is set to **Columns**, the block multiplies down the elements of each column and outputs the resulting 1-by- $N$  matrix. The block treats length- $M$  unoriented vector input as an  $M$ -by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \\ \Downarrow \\ [y_1 \ y_2 \ y_3] = \left[ \left( \prod_{i=1}^3 u_{i1} \right) \left( \prod_{i=1}^3 u_{i2} \right) \left( \prod_{i=1}^3 u_{i3} \right) \right]$$

When the **Multiply over** parameter is set to **Entire input**, the block multiplies all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = y = \left( \prod_{i=1}^3 \prod_{j=1}^3 u_{ij} \right)$$

## Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Product block for fixed-point signals.

The output of the multiplier is in the product output data type when at least one of the inputs to the multiplier is real. When both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, intermediate product, and output data types in the block dialog as discussed in “Parameters” on page 2-952 below.

## Parameters

### Main Tab

#### Multiply over

Indicate whether to multiply together the elements of each row, each column, or the entire input.

#### Data Types Tab

---

**Note** Floating-point inheritance takes precedence over the data type settings defined on this pane. When inputs are floating point, the block ignores these settings, and all internal data types are floating point.

---

#### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

### Intermediate product

Specify the intermediate product data type. As shown in “Fixed-Point Data Types” on page 2-952, the output of the multiplier is cast to the intermediate product data type before the next element of the input is multiplied into it. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-952 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-952 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A rule that inherits a data type, for example, `Inherit: Same as product output`.
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Output**

Specify the output data type. See “Fixed-Point Data Types” on page 2-952 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`.
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Minimum**

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Maximum**

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools**

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

**Intermediate Product Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Intermediate product** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Intermediate product** data type.

**Scaling**

Specify the **Scaling** for the **Intermediate product** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Intermediate product** data type.

#### **Fraction length**

Specify the **Fraction length** for the **Intermediate product** data type.

#### **Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### **Product Output Data Type Assistant Parameters**

#### **Mode**

Select how you would like to specify the data type properties of the **Product output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

#### **Signedness**

Specify the **Signedness** for the **Product output** data type.

#### **Scaling**

Specify the **Scaling** for the **Product output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### **Word length**

Specify the **Word length** for the **Product output** data type.

**Fraction length**

Specify the **Fraction length** for the **Product output** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

**Scaling**

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Accumulator** data type.

**Fraction length**

Specify the **Fraction length** for the **Accumulator** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

### Output Data Type Assistant Parameters

#### Mode

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

#### Signedness

Specify the **Signedness** for the **Output** data type.

#### Scaling

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

#### Word length

Specify the **Word length** for the **Output** data type.

#### Fraction length

Specify the **Fraction length** for the **Output** data type.

#### Data type override

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

### Functions

prod

### Blocks

Array-Vector Multiply | Matrix Sum

## Matrix Sum (Obsolete)

Sum matrix elements along rows, columns, or entire input

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspobslib`

## Description

The Matrix Sum block sums the elements of an  $M$ -by- $N$  input matrix  $u$  along its rows, its columns, or over all its elements.

When the **Sum over** parameter is set to **Rows**, the block sums across the elements of each row and outputs the resulting  $M$ -by-1 matrix. A length- $N$  1-D vector input is treated as a 1-by- $N$  matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \left( \sum_{j=1}^3 u_{1j} \right) \\ \left( \sum_{j=1}^3 u_{2j} \right) \\ \left( \sum_{j=1}^3 u_{3j} \right) \end{bmatrix}$$

When the **Sum over** parameter is set to **Columns**, the block sums down the elements of each column and outputs the resulting 1-by- $N$  matrix. A length- $M$  1-D vector input is treated as a  $M$ -by-1 matrix.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} \\ \Downarrow \\ [y_1 \ y_2 \ y_3] = \left[ \left( \sum_{i=1}^3 u_{i1} \right) \left( \sum_{i=1}^3 u_{i2} \right) \left( \sum_{i=1}^3 u_{i3} \right) \right]$$

When the **Sum over** parameter is set to **Entire** input, the block sums all the elements of the input together and outputs the resulting scalar.

$$\begin{bmatrix} u_{11} & u_{12} & u_{13} \\ u_{21} & u_{22} & u_{23} \\ u_{31} & u_{32} & u_{33} \end{bmatrix} = y = \left( \sum_{i=1}^3 \sum_{j=1}^3 u_{ij} \right)$$

The output of the Matrix Sum block has the same frame status as the input. This block accepts real and complex fixed-point and floating-point inputs except for complex unsigned fixed-point inputs.

### Fixed-Point Data Types

The following diagram shows the data types used within the Matrix Sum block for fixed-point signals.

You can set the accumulator and output data types in the block dialog as discussed in “Dialog Box” on page 2-960 below.

### Dialog Box

The **Main** pane of the Matrix Sum block dialog appears as follows.

#### Sum over

Indicate whether to sum the elements of each row, each column, or of the entire input.

The **Fixed-point** pane of the Matrix Sum block dialog appears as follows.

### Rounding mode

Select the rounding mode for fixed-point operations.

### Overflow mode

Select the overflow mode for fixed-point operations.

### Accumulator

As depicted above, the elements of the block input are cast to the accumulator data type before they are added together. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate this accumulator word and fraction lengths:

- When you select *Inherit via internal rule*, the accumulator word length and fraction length are calculated automatically. For information about how the accumulator word and fraction lengths are calculated when an internal rule is used, see “*Inherit via Internal Rule*”.
- When you select *Same as input*, these characteristics match those of the input to the block.

- When you select **Binary point scaling**, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

### Output

Choose how you specify the output word length and fraction length:

- When you select **Same as accumulator**, these characteristics match those of the accumulator.
- When you select **Same as input**, these characteristics match those of the input to the block.
- When you select **Binary point scaling**, you can enter the word length and the fraction length of the output, in bits.
- When you select **Slope and bias scaling**, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

### Lock scaling against changes by the autoscaling tool

Select this parameter to prevent any fixed-point scaling you specify in this block mask from being overridden by the autoscaling feature of the Fixed-Point Tool. See the `fxptdlg` reference page for more information.

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |

# Matrix Viewer

(To be removed) Display matrices as color images

---

**Note** The Matrix Viewer block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

---

## Library

Sinks

dspsnks4

## Description

The Matrix Viewer block displays an  $M$ -by- $N$  matrix input by mapping the matrix element values to a specified range of colors. The display is updated as each new input is received. This block treats an unoriented length  $M$  vector input as an  $M$ -by-1 matrix.

You can use the Matrix Viewer block in models running in Normal or Accelerator simulation modes. The software does not support this block in models running in Rapid Accelerator or External mode. For more information about these modes, see “How Acceleration Modes Work” (Simulink) in the *Simulink User's Guide*.

## Image Properties

Select the **Image Properties** tab to show the image property parameters, which control the colormap and display.

You specify the mapping of matrix element values to colors in the **Colormap matrix**, **Minimum input value**, and **Maximum input value** parameters. For a colormap with  $L$  colors, the colormap matrix has dimension  $L$ -by-3, with one row for each color and one column for each element of the RGB triple that defines the color. Examples of RGB triples are

```
[ 1  0  0 ] (red)
[ 0  0  1 ] (blue)
[0.8 0.8 0.8] (light gray)
```

MATLAB provides a number of functions for generating predefined colormaps, such as `hot`, `cool`, `bone`, and `autumn`. Each of these functions accepts the colormap size as an argument, and can be used in the **Colormap matrix** parameter. For example, when you specify `gray(128)` for the **Colormap matrix** parameter, the matrix is displayed in 128 shades of gray. The color in the first row of the colormap matrix represents the value specified by the **Minimum input value** parameter, and the color in the last row represents the value specified by the **Maximum input value** parameter.

Values between the minimum and maximum are quantized and mapped to the intermediate rows of the colormap matrix.

The documentation for the MATLAB `colormap` function provides complete information about specifying colormap matrices, and includes a complete list of the available colormap functions.

### Axis Properties

Select the **Axis Properties** tab to show the axis property parameters, which control labeling and positioning.

The **Axis origin** parameter determines where the first element of the input matrix,  $U(1,1)$ , is displayed. When you specify `Upper left corner`, the matrix is displayed in matrix orientation, with  $U(1,1)$  in the upper-left corner.

$$\begin{bmatrix} U_{11} & U_{12} & U_{13} & U_{14} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{41} & U_{42} & U_{43} & U_{44} \end{bmatrix}$$

When you specify `Lower left corner`, the matrix is flipped vertically to image orientation, with  $U(1,1)$  in the lower-left corner.

$$\begin{bmatrix} U_{41} & U_{42} & U_{43} & U_{44} \\ U_{31} & U_{32} & U_{33} & U_{34} \\ U_{21} & U_{22} & U_{23} & U_{24} \\ U_{11} & U_{12} & U_{13} & U_{14} \end{bmatrix}$$

**Axis zoom**, when selected, causes the image display to completely fill the figure window. Axis titles are not displayed. This option can also be selected from the pop-up menu that is displayed when you right-click in the figure window. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the image axes.

To customize the axis tick range, set **Axis tick mode** to `User-defined` and specify a two-element row vector, `[Minvalue Maxvalue]`, in **X-tick range** and **Y-tick range**. The matrix data does not change even when the axes ticks change. For example, consider displaying a matrix on axes with ticks ranging from 0 to 10. When you set **X-tick range** and **Y-tick range** to `[0 1]`, the range of ticks changes from `[0 10]` to `[0 1]`.

### Figure Window

The image title in the figure title bar is the same as the block title. The axis tick marks reflect the size of the input matrix; the x-axis is numbered from 1 to  $N$  (number of columns), and the y-axis is numbered from 1 to  $M$  (number of rows).

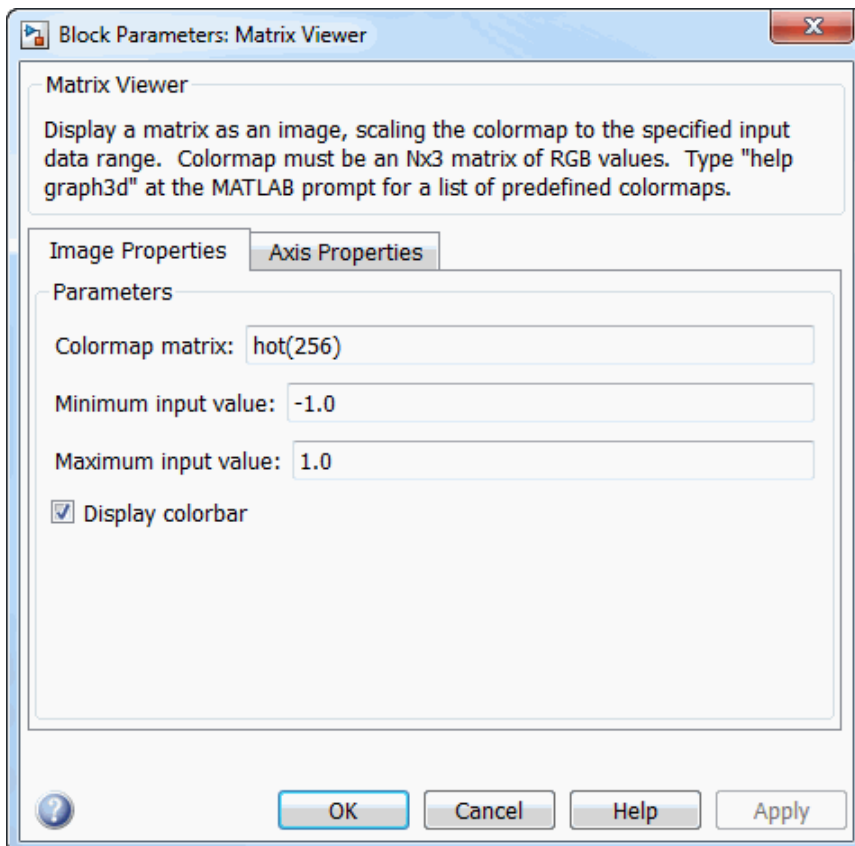

Right-click the image in the figure window to access the following menu items:

- **Refresh** erases all data on the scope display except for the most recent image.
- **Autoscale** recomputes the minimum and maximum input values to fit the range of values observed in a series of 10 consecutive inputs. The numerical limits selected by the autoscale feature are shown in the **Minimum input value** and **Maximum input value** parameters, where you can make further adjustments to them manually.

- **Axis zoom**, when selected, causes the image to completely fill the figure window. Axis titles are not displayed. When **Axis zoom** is cleared, the axis labels and titles are displayed in a gray border surrounding the scope axes. This option can also be set in the Axis Properties pane of the parameter dialog box.
- **Colorbar**, when selected, displays a bar with the specified colormap to the right of the image axes.
- **Save Position** automatically updates the **Figure position** parameter in the **Axis Properties** pane to reflect the figure window's current position and size on the screen. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Position**. The parameter dialog box must be closed when you select **Save Position** for the **Figure position** parameter to be updated.

## Dialog Box

The **Image Properties** pane of the Matrix Viewer block appears as follows.

### Colormap matrix

A 3-column matrix defining the colormap as a set of RGB triples, or a call to a colormap-generating function such as `hot` or `spring`.

- See the `colormap` function for a list of colormap-generating functions.
- A color name or a short name: 'red' (or 'r'), 'green' (or 'g'), 'blue' (or 'b'), 'cyan' (or 'c'), 'magenta' (or 'm'), 'yellow' (or 'y'), 'black' (or 'k'), 'white' (or 'w').

- An RGB triplet specified as a 1-by-3 vector whose elements are the intensities of the red, green, and blue components of a color. The intensities must be in the range [0, 1]. For example, [0.7 0.8 1] specifies light blue.

Tunable (Simulink).

### Minimum input value

The input value to be mapped to the color defined in the first row of the colormap matrix. Right-click in the figure window and select `Autoscale` from pop-up menu to set this parameter to the minimum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

### Maximum input value

The input value to be mapped to the color defined in the last row of the colormap matrix. Right-click in the figure window and select `Autoscale` from the pop-up menu to set this parameter to the maximum value observed in a series of 10 consecutive matrix inputs. Tunable (Simulink).

### Display colorbar

Select to display a bar with the selected colormap to the right of the image axes. Tunable (Simulink).

The **Axis Properties** pane of the Matrix Viewer block appears as follows.

### Axis origin

The position within the axes where the first element of the input matrix,  $U(1,1)$ , is plotted; bottom left or top left. Tunable (Simulink).

**Axis tick mode**

The mode used to specify the axis tick range. When you select **Auto**, the x-axis tick range and y-axis tick range are chosen based on the input signal. When you select **User-defined**, the axis tick range is set based on the values you specify in **X-tick range** and **Y-tick range**. The default is **Auto**.

**X-tick range**

x-axis tick range, specified as a two-element row vector of real scalars,  $[X_{\min} \ X_{\max}]$ . This parameter applies only when you set **Axis tick mode** to **User-defined**. When you change **X-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is  $[0 \ 1]$ .

**Y-tick range**

y-axis tick range, specified as a two-element row vector of real scalars,  $[Y_{\min} \ Y_{\max}]$ . This parameter applies only when you set **Axis tick mode** to **User-defined**. When you change **Y-tick range** during simulation, the axis range on the Matrix Viewer block updates in real time. The default is  $[0 \ 1]$ .

**X-axis title**

The text to be displayed below the x-axis. Tunable (Simulink).

**Y-axis title**

The text to be displayed to the left of the y-axis. Tunable (Simulink).

**Colorbar title**

The text to be displayed to the right of the color bar, when **Display colorbar** is currently selected. Tunable (Simulink).

**Figure position, [x y width height]**

A 4-element vector of the form  $[x \ y \ width \ height]$  specifying the position of the figure window, where  $(0, 0)$  is the lower-left corner of the display. Tunable (Simulink).

**Axis zoom**

Resizes the image to fill the figure window. Tunable (Simulink).

**Supported Data Types**

| Port  | Supported Data Types   |
|-------|--|
| Input | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |

**Version History**

**Introduced before R2006a**

**R2020b: Matrix Viewer block will be removed**

*Not recommended starting in R2020b*

The Matrix Viewer block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

## **Extended Capabilities**

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

### **Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

## **See Also**

Spectrum Analyzer | [colormap](#) | [image](#)

# Maximum

Maximum values of input or sequence of inputs

## Libraries:

DSP System Toolbox / Statistics

DSP System Toolbox HDL Support / Statistics

## Description

The Maximum block identifies the value and position of the largest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input. The Maximum block can also track the maximum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- **Value** — The block outputs the maximum values in the specified dimension.
- **Index** — The block outputs the index array of the maximum values in the specified dimension.
- **Value and Index** — The block outputs the maximum values and the corresponding index array in the specified dimension.
- **Running** — The block tracks the maximum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the maximum value over** parameter.

---

**Note** The **Running** mode in the Maximum block will be removed in a future release. To compute the running maximum in Simulink, use the Moving Maximum block instead.

---

## Ports

### Input

**In** — Data input

vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Rst** — Reset port

scalar

Specify the reset event that causes the block to reset the running maximum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

### Dependencies

To enable this port, set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `Boolean`

### Output

**Val** — Maximum values along the specified dimension

`scalar` | `vector` | `matrix` | *N-D array*

The data type of the maximum value matches the data type of the input.

When the **Mode** parameter is set to either **Value and Index** or **Value**, the following applies:

- The size of the dimension for which the block computes the maximum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an *M*-by-*N*-by-*P* array, with the dimension set to 1, the block outputs a 1-by-*N*-by-*P* array. When the dimension is set to 3, the block outputs a two-dimensional *M*-by-*N* matrix.
- When the input is an *M*-by-*N* matrix, with the dimension set to 1, the block outputs a 1-by-*N* matrix.

If you specify the block to compute the maximum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set **Running**, the block tracks the maximum value of each channel in a time sequence of *M*-by-*N* inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each  $y_{ijk}$  element of the output contains the maximum value observed in element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running maximum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an *N*-dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element  $y_{ij}$  of the output contains the maximum value observed in the *j*th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

### Dependencies

To enable this port, set the **Mode** parameter to either **Value and Index** or **Value**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Idx** — Index of the maximum values along the specified dimension  
 scalar | vector | matrix | *N*-D array

When the input is `double`, the index values are also `double`. Otherwise, the index values are `uint32`.

### Dependencies

To enable this port, set the **Mode** parameter to either `Value` and `Index` or `Index`.

Data Types: `double` | `uint32`

## Parameters

### Main Tab

**Mode** — Mode in which the block operates  
`Value` and `Index` (default) | `Value` | `Index` | `Running`

When the **Mode** parameter is set to:

- **Value** — The block computes the maximum value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the maximum value of the entire input at each sample time, and outputs the array, *y*. Each element in the output is the maximum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the maximum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the maximum value over** to:
  - **Each row** — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the maximum value of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
  - **Each column** — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the maximum value of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- **Entire input** — The output *y* at each sample time is a scalar that contains the maximum value in the *M*-by-*N*-by-*P* input matrix.
- **Specified dimension** — The output *y* at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the maximum value of each vector over the third dimension of the input.

### Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the maximum magnitude squared as shown in the following figure. For complex value  $u = a + bi$ , the magnitude squared is  $a^2 + b^2$ .

- **Index** — The block computes the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array  $I$ . Each element in  $I$  is an integer indexing the maximum value in the corresponding column, row, vector, or entire input. The output  $I$  depends on the setting of the **Find the maximum value over** parameter. Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ :
  - **Each row** — The output  $I$  at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the index of the maximum value of each vector over the second dimension of the input. For an input that is an  $M$ -by- $N$  matrix, the output at each sample time is an  $M$ -by-1 column vector.
  - **Each column** — The output  $I$  at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the index of the maximum value of each vector over the first dimension of the input. For an input that is an  $M$ -by- $N$  matrix, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Entire input** — The output  $I$  at each sample time is a 1-by-3 vector that contains the location of the maximum value in the  $M$ -by- $N$ -by- $P$  input matrix. For an input that is an  $M$ -by- $N$  matrix, the output is a 1-by-2 vector.
- **Specified dimension** — The output  $I$  at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the indices of the maximum values of each vector over the third dimension of the input.

When a maximum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector  $[3 \ 2 \ 1 \ 2 \ 3]'$ , the computed one-based index of the maximum value is 1, rather than 5 when **Each column** is selected.

- **Value and Index** — The block outputs the maximum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array  $I$ .
- **Running** — The block tracks the maximum value of each channel in a time sequence of  $M$ -by- $N$  inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:
  - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each  $y_{ijk}$  element of the output contains the maximum value observed in element  $u_{ijk}$  for all inputs since the last reset.
 

When a reset event occurs, the running maximum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .
  - **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ .

For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the maximum value observed in the  $j$ th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

### Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to **Running**, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
  - When the input size difference is in the number of channels (columns), the state is reset.
  - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

**Index base** — Base of the maximum value index

One (default) | Zero

Specify whether the index of the maximum value is reported using one-based or zero-based numbering.

### Dependencies

To enable this parameter, set **Mode** to either **Index** or **Value** and **Index**.

**Find the maximum value over** — Dimension over which the block computes the maximum value

Each column (default) | Each row | Entire input | Specified dimension

- **Each column** — The block outputs the maximum value over each column.
- **Each row** — The block outputs the maximum value over each row.
- **Entire input** — The block outputs the maximum value over the entire input.
- **Specified dimension** — The block outputs the maximum value over the dimension, specified in the **Dimension** parameter.

### Dependencies

To enable this parameter, set **Mode** to **Value** and **Index**, **Value**, or **Index**.

**Dimension** — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the maximum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

### Dependencies

To enable this parameter, set **Find the maximum value over** to Specified dimension.

**Input processing** — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the maximum value observed in the  $j$ th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running maximum for each channel becomes the maximum value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each  $y_{ijk}$  element of the output contains the maximum value observed in element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running maximum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

### Dependencies

To enable this parameter, set **Mode** to Running.

**Reset port** — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running maximum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer, which is a multiple of the input sample time.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

---

**Note** When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, set **Mode** to `Running`.

### Data Types Tab

---

**Note** To use these parameters, the data input must be complex and fixed-point.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Product output** — Product output data type  
Inherit: Same as input (default) | fixdt([],16,0)

**Product output** specifies the data type of the output of a product operation in the Maximum block. For more information on the product output data type, see “Multiplication Data Types”.

- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type  
Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

**Accumulator** specifies the data type of the output of an accumulation operation in the Maximum block.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.

- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

### Maximum

When you set **Mode** to one of **Value**, **Index**, or **Value and Index**, and specify a dimension, the block produces results identical to the MATLAB `max` function, when it is called as `[y, I] = max(u, [], D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the maximum value.
- `I` is the index of the maximum value.

The maximum value along the entire input is identical to calling the `max` function as `[y, I] = max(u(:))`.

### Running Maximum

When you set **Mode** to **Running**, and **Input processing** to **Columns as channels (frame based)**, the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the maximum value over each channel since the last reset. At  $t = 2$ , the reset event occurs. The maximum value in the second column changes to 6, even though 6 is less than 9, which was the maximum value since the previous reset event.

When you set **Mode** to Running, and **Input processing** to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each  $y_{ij}$  element of the output contains the maximum value observed in element  $u_{ij}$  for all inputs since the last reset. The reset event occurs at  $t = 2$ . When a reset event occurs, the running maximum,  $y_{ij}$ , in the current frame is reset to element  $u_{ij}$ .

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

| Architecture    | Additional cycles of latency                  | Description  |
|-----------------|---|--|
| default<br>Tree | 0   | Generates a tree structure of comparators.   |
| Cascade         | 1, when block has a single vector input port. | This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder). |

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |
| <b>InstantiateStages</b>         | Generate a VHDL® entity or Verilog® module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).   |
| <b>SerialPartition</b>           | Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).                                       |

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-971. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

**Blocks**

Minimum | Moving Maximum | Moving Minimum | Mean

# Mean

Find mean value of input or sequence of inputs

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Mean block computes the mean of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input. You can specify the dimension using the **Find the mean value over** parameter. The Mean block can also track the mean value in a sequence of inputs over a period of time. To track the mean value in a sequence of inputs, select the **Running mean** parameter.

---

**Note** The **Running** mode in the Mean block will be removed in a future release. To compute the running mean in Simulink, use the Moving Average block instead.

---

## Ports

### Input

**I** — Data input  
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point with power-of-two slope and zero bias.

This port is unnamed until you select the **Running mean** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Rst** — Reset port  
scalar

Specify the reset event that causes the block to reset the running mean. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

### Dependencies

To enable this port, select the **Running mean** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

**Port\_1** — Mean value along the specified dimension

scalar | vector | matrix |  $N$ -D array

The data type of the output matches the data type of the input.

When you do not select the **Running mean** parameter, the block computes the mean value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the mean of the entire input at each individual sample time. Each element in the output array  $y$  is the mean value of the corresponding column, row, or entire input. The output array  $y$  depends on the setting of the **Find the mean value over** parameter. Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ . When you set **Find the mean value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the mean value of the  $M$ -by- $N$ -by- $P$  input matrix.
- **Each row** — The output at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the mean value of each vector over the second dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is an  $M$ -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the mean value of each vector over the first dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the mean value of each vector over the third dimension of the input.

When you select **Running mean**, the block tracks the mean value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the mean value of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running mean  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the mean of the values in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

### Main Tab

**Running mean** — Option to select running mean  
off (default) | on

When you select the **Running mean** parameter, the block tracks the mean value of each channel in a time sequence of inputs.

**Find the mean value over** — Dimension over which the block computes the mean value  
Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the mean value over each column.
- **Each row** — The block outputs the mean value over each row.
- **Entire input** — The block outputs the mean value over the entire input.
- **Specified dimension** — The block outputs the mean value over the dimension, specified in the **Dimension** parameter.

### Dependencies

To enable this parameter, clear the **Running mean** parameter.

**Dimension** — Custom dimension  
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the mean is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

### Dependencies

To enable this parameter, set **Find the mean value over** to **Specified dimension**.

**Input processing** — Method to process the input in running mode  
Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the mean of the values in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the mean value of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running mean  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

**Variable-Size Inputs**

When your inputs are of variable size, and you select the **Running mean** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
  - When the input size difference is in the number of channels (number of columns), the state is reset.
  - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

**Dependencies**

To enable this parameter, select the **Running mean** parameter.

**Reset port** — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running mean whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to **Elements as channels (sample based)**, the running mean for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to **Columns as channels (frame based)**, the running mean for each channel becomes the mean value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

---

**Note** When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, select the **Running mean** parameter.

### Data Types Tab

---

**Note** To use these parameters, the data input must be fixed-point. For all other inputs, the parameters on the **Data Types** tab are ignored.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest

- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Accumulator** — Accumulator data type  
Inherit: Same as input (default) | fixdt([],16,0)

**Accumulator** specifies the data type of the output of an accumulation operation in the Mean block. See “Fixed Point” on page 2-990 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output** — Output data type  
Inherit: Same as accumulator (default) | fixdt([],16,0)

**Output** specifies the data type of the output of the Mean block. See “Fixed Point” on page 2-990 for illustrations depicting the use of the output data type in this block. You can set it to:

- **Inherit: Same as accumulator** — The block specifies the output data type to be the same as the accumulator data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output Minimum** — Minimum value the block can output  
[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum value the block can output  
[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

### Mean

When you clear the **Running mean** parameter and specify a dimension, the block produces results identical to the MATLAB mean function, when it is called as  $y = \text{mean}(u, D)$ .

- $u$  is the data input.
- $D$  is the dimension.
- $y$  is the mean value.

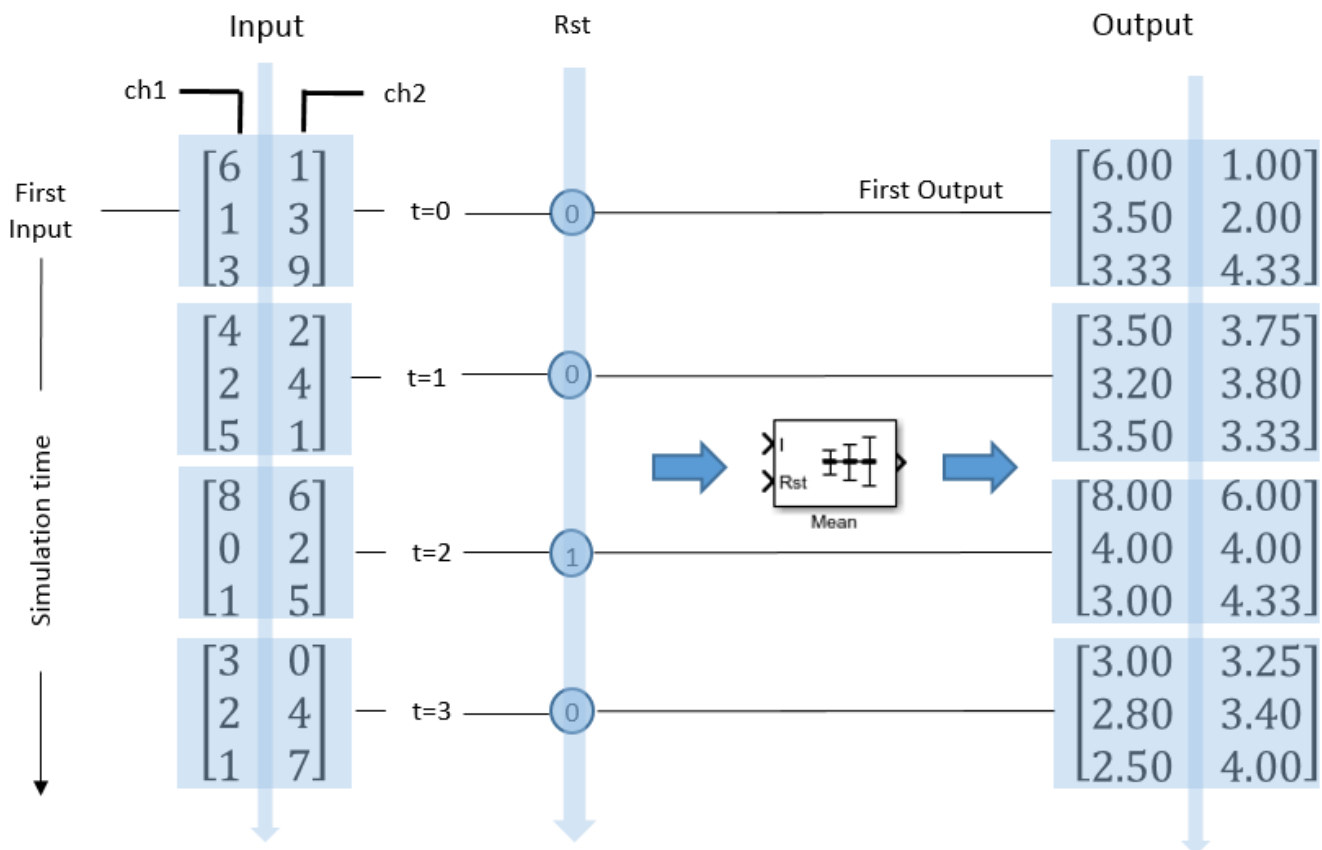

The mean value along the entire input is identical to calling the mean function as  $y = \text{mean}(u(:))$ .

The mean of a complex input is computed independently for the real and imaginary components.

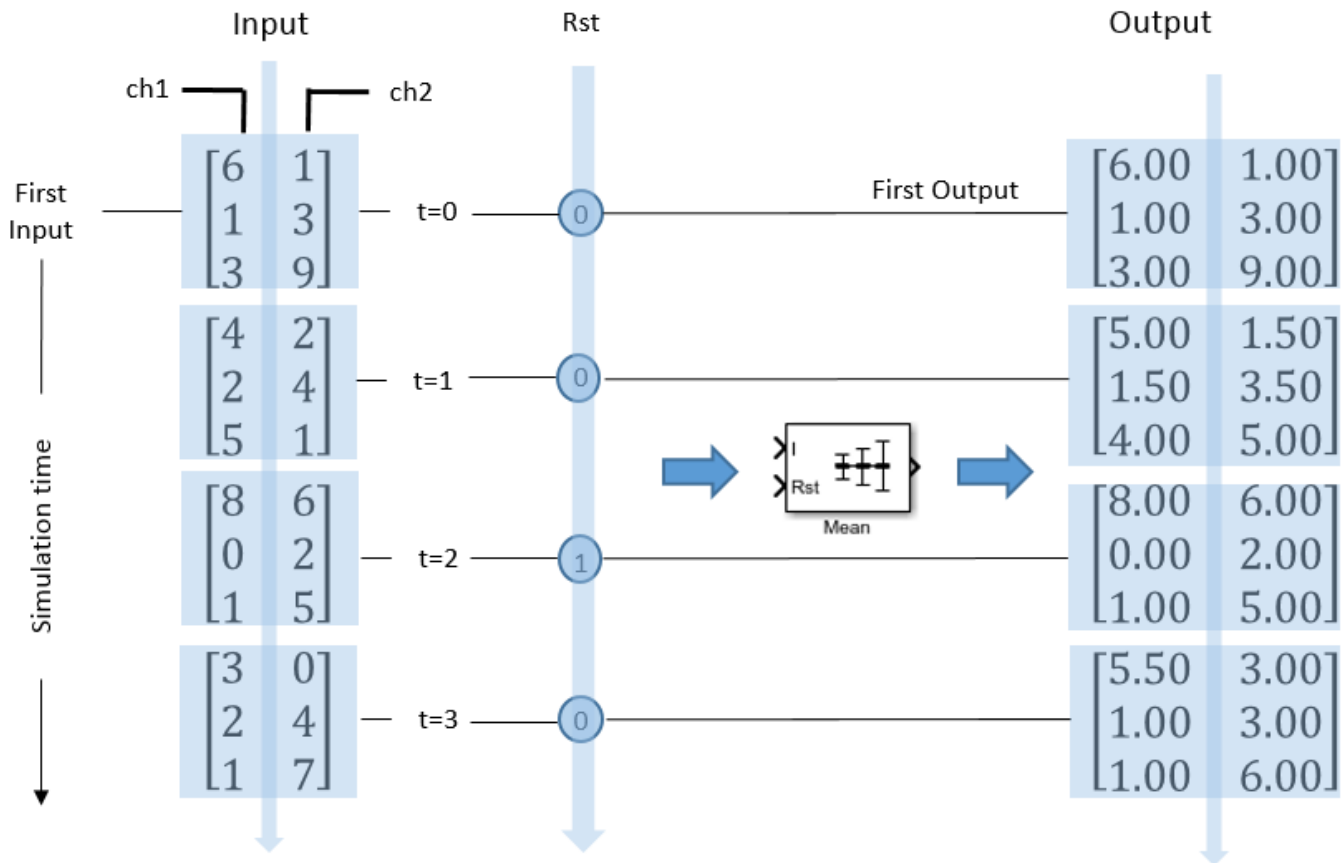

### Running Mean

When you select the **Running mean** parameter, and set the **Input processing** parameter to Columns as channels (frame based), the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the mean value over each channel since the last reset. At  $t = 2$ , the reset event occurs. The window of data in the second column now contains only 6.

When you select the **Running mean** parameter, and set the **Input processing** parameter to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each  $y_{ij}$  element of the output contains the mean value observed in element  $u_{ij}$  for all inputs since the last reset. The reset event occurs at  $t = 2$ . When a reset event occurs, the running mean,  $y_{ij}$ , in the current frame is reset to element  $u_{ij}$ .

Moving Average | Maximum | Median | Median Filter | Minimum

# Median

Median value of input

## Libraries:

DSP System Toolbox / Statistics

## Description

The Median block computes the median of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. You can specify the dimension using the **Find the median value over** parameter. While computing the median, the block first sorts the input values. If the number of values is odd, the median is the middle value. If the number of values is even, the median is the average of the two middle values. To sort the data, you can specify the **Sort algorithm** parameter as either `Quick sort` or `Insertion sort`. The block sorts complex inputs according to their magnitude.

## Ports

### Input

**Port\_1** — Data input

vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

### Output

**Port\_1** — Median value along specified dimension

vector | matrix |  $N$ -D array

The block computes the median value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the median of the entire input. Each element in the output array  $y$  is the median value of the corresponding column, row, or entire input. The output array  $y$  depends on the setting of the **Find the median value over** parameter.

Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ . When you set **Find the median value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the median value of the  $M$ -by- $N$ -by- $P$  input matrix.
- **Each row** — The output at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the median value of each vector over the second dimension of the input. For an  $M$ -by- $N$  matrix input, the output is an  $M$ -by-1 column vector.

- **Each column** — The output at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the median value of each vector over the first dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the median value of each vector over the third dimension of the input.

The data type of the output matches the data type of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Parameters

### Main Tab

**Sort algorithm** — Sort method

`Quick sort` (default) | `Insertion sort`

Specify the sorting algorithm as either `Quick sort` or `Insertion sort`.

**Find the median value over** — Dimension over which the median is computed

`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- **Each column** — The block outputs the median value over each column.
- **Each row** — The block outputs the median value over each row.
- **Entire input** — The block outputs the median value over the entire input.
- **Specified dimension** — The block outputs the median value over the dimension specified in the **Dimension** parameter.

**Dimension** — Custom dimension

1 (default) | `scalar`

Specify the dimension (one-based value) of the input signal over which the block computes the median. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

### Dependencies

To enable this parameter, set **Find the median value over** to `Specified dimension`.

### Data Types Tab

---

**Note** To use these parameters, the data input must be `fixed point`. For all other inputs, the parameters on the **Data Types** tab are ignored.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Product output** — Product output data type

Inherit: Same as input (default) | fixdt([],16,0)

Specify the data type of the output of a product operation in the Median block. For more information, see “Fixed Point” on page 2-997 and “Multiplication Data Types”.

You can set this parameter to:

- **Inherit: Same as input** — The product output data type is the same as the input data type.
- **fixdt([],16,0)** — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

Specify the data type of the output of an accumulation operation in the Median block. For more details, see “Fixed Point” on page 2-997.

You can set this parameter to:

- **Inherit: Same as product output** — The accumulator data type is the same as the product output data type.
- **Inherit: Same as input** — The accumulator data type is the same as the input data type.
- **fixdt([],16,0)** — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output** — Output data type

Inherit: Same as accumulator (default) | Inherit: Same as input | Inherit: Same as product output | fixdt([],16,0)

**Output** specifies the data type of the output of the Median block. For more details, see “Fixed Point” on page 2-997.

You can set this parameter to:

- **Inherit: Same as accumulator** — The output data type is the same as the accumulator data type.
- **Inherit: Same as input** — The output data type is the same as the input data type.
- **Inherit: Same as product output** — The output data type is the same as the product output data type.
- **fixdt([],16,0)** — The output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Output** data type by using the **Data Type Assistant**. To use the

assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Output Minimum** — Minimum output value

[] (default) | scalar

Specify the minimum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Output Maximum** — Maximum output value

[] (default) | scalar

Specify the maximum value that the block can output. The default value is [] (unspecified). Simulink uses this value to perform:

- Simulation range checking. See “Specify Signal Ranges” (Simulink).
- Automatic scaling of fixed-point data types.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

### Median

The median of a set of data is calculated using the following steps:

- 1 The values are sorted using the specified sorting algorithm.
- 2 If the number of values is odd, the median is the middle value.
- 3 If the number of values is even, the median is the average of the two middle values.

The block produces results identical to the MATLAB `median` function when called as  $y = \text{median}(u, D)$ , where

- $u$  is the data input.
- $D$  is the dimension.
- $y$  is the median value.

When the block calculates the median value along the entire input, the result is identical to calling the `median` function as  $y = \text{median}(u(:))$ .

When the input is complex, the block sorts the data according to the magnitude of each value. The magnitude in this case is defined as the sum of the squares of the real and imaginary components of the complex input.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For fixed-point inputs, you can specify the **Accumulator**, **Product output**, and **Output** data types in the block dialog box. Not all of these fixed-point parameters are applicable to all types of fixed-point inputs. The table shows when each kind of data type and scaling is used.

$M$  is the length of the sorted data along the specified dimension. X indicates that the particular data type is applicable.

|  | <b>Output data type</b> | <b>Accumulator data type</b> | <b>Product output data type</b> |
|--|-------------------------|------------------------------|---------------------------------|
| <b>Even <math>M</math></b>             | X                       | X                            | Not Applicable                  |
| <b>Odd <math>M</math></b>              | X                       | Not Applicable               | Not Applicable                  |
| <b>Odd <math>M</math> and complex</b>  | X                       | X                            | X                               |
| <b>Even <math>M</math> and complex</b> | X                       | X                            | X                               |

When  $M$  is even, the **Accumulator** and **Output** data types and scalings are used for fixed-point signals. While calculating the average of the two central rows of the input matrix, the result of the sum is stored in the **Accumulator** data type and scaling. The total result of the average, which is the median of the data, is stored in the **Output** data type and scaling.

When the fixed-point inputs are complex, both the **Accumulator** and the **Product output** data types are used in addition to the **Output** data type. Before sorting the data, the block computes the sum of the squares of the real and imaginary components of the complex input. The results of the squares are stored in the **Product output** data type and scaling. The result of the sum of the squares is stored in the **Accumulator** data type and scaling.

For fixed-point inputs that are both complex and have even  $M$ , the **Accumulator** data type also stores the sum of the two central rows of the input matrix. The average of the two central rows, which is the median of the data, is stored in the **Output** data type.

# Median Filter

Median filter

## Libraries:

DSP System Toolbox / Filtering / Filter Designs  
 DSP System Toolbox / Statistics

## Description

The Median Filter block computes the moving median of the input signal along each channel independently over time. The block uses the sliding window method to compute the moving median. In this method, a window of specified length moves over each channel sample by sample, and the block computes the median of the data in the window. This block performs median filtering on the input data over time. For more details, see “Algorithms” on page 2-999.

## Input/Output Ports

### Input

**Port\_1** — Data input

column vector | row vector | matrix

Data over which the block computes moving median. The block accepts real-valued or complex-valued multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$ , and  $n \geq 1$ . The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: single | double

### Output

**Port\_1** — Moving median output

column vector | row vector | matrix

The size of the moving median output matches the size of the input. The block uses the sliding window method to compute the moving median. For more details, see “Algorithms” on page 2-999.

Data Types: single | double

## Parameters

**Window length** — Length of the sliding window

5 (default) | positive scalar integer

**Window length** specifies the length of the sliding window in samples.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

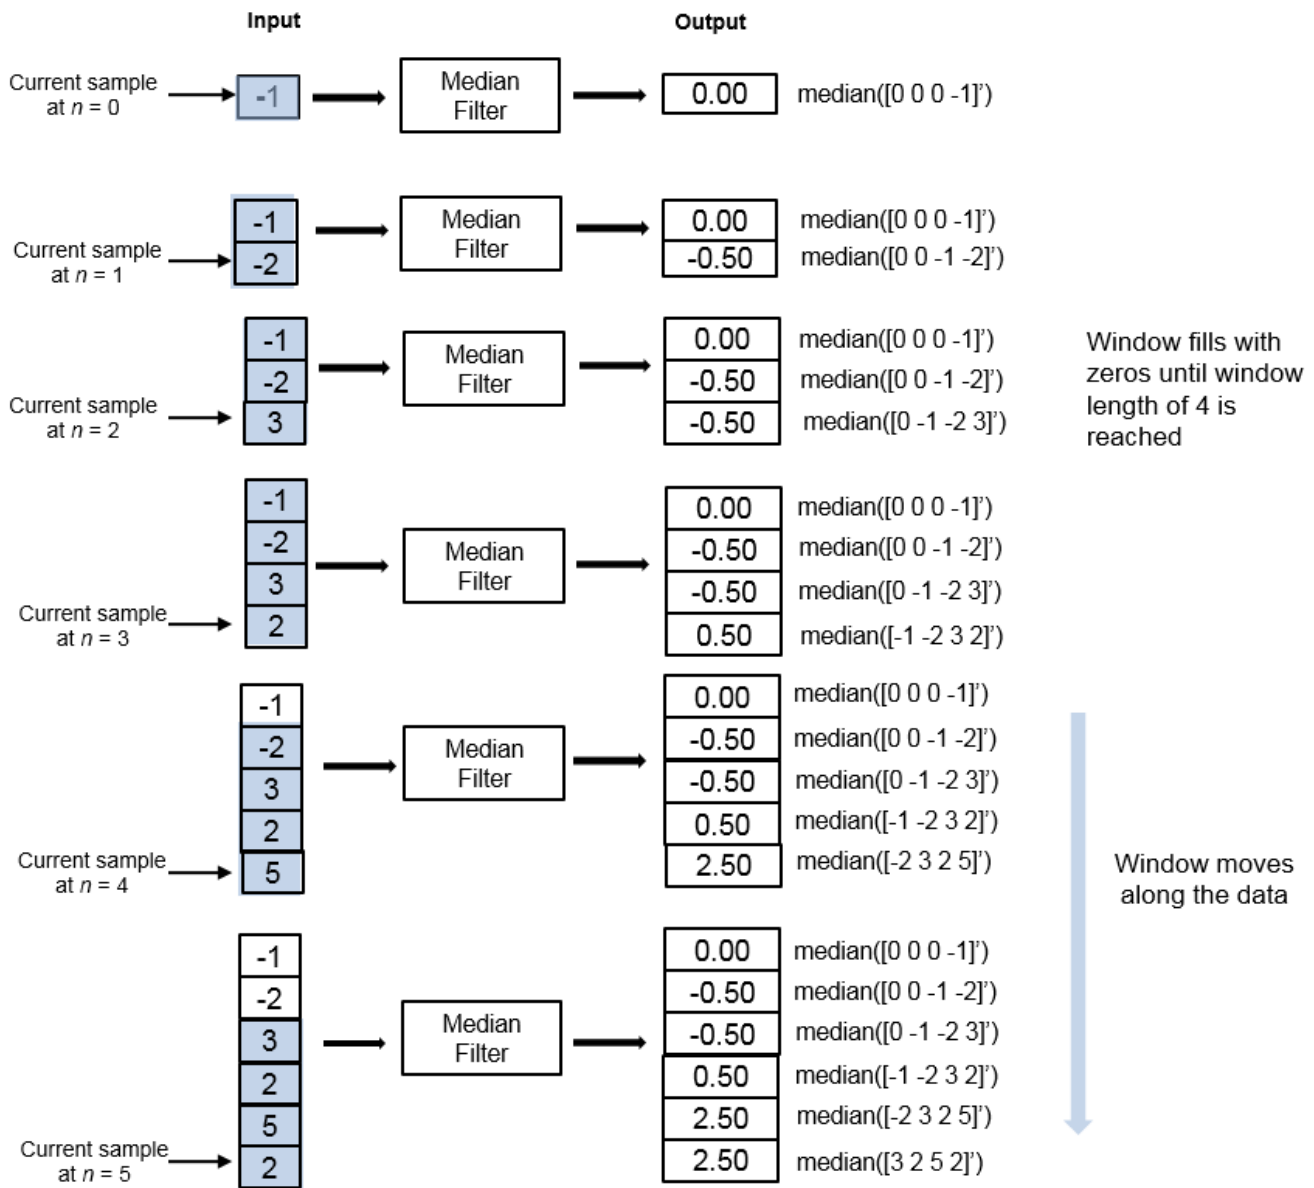

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first  $Len - 1$  outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with  $Len - 2$  zeros. The data vector,  $x$ , is then the two data samples followed by  $Len - 2$  zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

## MIDI Controls

Output values from controls on MIDI control surface

---

**Note** In a future release, the MIDI Controls block will require Audio Toolbox.

---

### Library

Sources

dspsrcs4

### Description

The MIDI Controls block outputs values from controls on a MIDI control surface in real time.

Use the **MIDI device** parameter to specify the name of the MIDI control surface device from which to receive control values. You can choose:

- Default
- Specify other

If you choose **Default**, the block looks for a MATLAB preference with a group named `midi` and preference named `DefaultDevice`. You can set this preference using the MATLAB `setpref` function. For example, if the desired device is named `BCF2000`, you can type the following command at the MATLAB command line:

```
>> setpref('midi', 'DefaultDevice', 'BCF2000');
```

If the block does not find this preference, it then attempts to choose a device using an algorithm that is unspecified and platform dependent.

If you choose **Specify other**, then a **MIDI device name** edit box appears for you to enter a MATLAB expression for the device name. Enter any MATLAB expression that can evaluate to a string. Literal names must be enclosed in quotes, (for example, `'BCF2000'`).

You can determine the name of your MIDI device using `midiid`, discussed in “Identifying MIDI Device Names and Control Numbers” on page 2-1003.

Use the **MIDI controls** parameter to specify the controls on the MIDI device to which the block should respond. This parameter also determines the size of the block output port. You can choose:

- Respond to any control

- Respond to specified controls

If you choose **Respond to any control**, then the block output will be a scalar. This scalar outputs the value from any and all controls that are manipulated on the MIDI device. Use this option in simple cases when you need only a single control value and the control to which it responds is unimportant.

If you choose **Respond to specified controls**, then a **MIDI control numbers** edit box opens. In this box, enter a MATLAB expression for the device control numbers. Enter any MATLAB expression that can evaluate to a row vector of real double-precision values. The block outputs a 1-D vector with one element corresponding to the output of each specified control.

Use the **Initial values** parameter to specify the value of the block output when simulation starts. The MIDI protocol transmits control values only when a control changes. This protocol provides no means for the block to query the current value of a control. Thus, the block must have some initial value to output until it receives a control change from the device.

Use the **Send initial values to device at start** check box to synchronize the device controls with the block outputs when simulation starts. Some MIDI control surfaces are bidirectional, meaning that they not only send control values but can also receive them. For example, some devices have motorized controls that move to the appropriate position when they receive a control value. If you have such a bidirectional device, select this check box. The block attempts to send the initial values to the device when the simulation starts. No diagnostic message appears if the attempt fails.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy. However you must account for these extra .dll files when doing so. The packNGo function creates a single .zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

## Output Port

The MIDI Controls block output is a vector whose width is determined by the **MIDI controls** and **MIDI control numbers** parameters previously described. The output data type can be either real double-precision floating point, or uint8 integer if the output mode is 'Raw MIDI'. The output values range from 0.0 to 1.0, inclusively, and in the raw mode, they range from 0 to 127, inclusively. The output port back inherits its sample time.

## Identifying MIDI Device Names and Control Numbers

To specify a particular control on a particular MIDI device, you must know the name assigned to the device by the operating system. In addition, a number is always associated with the control. You can interactively discover this information using the MATLAB function, `midiid`. To use `midiid`, note that you will need to have the Audio Toolbox installed. Follow these steps to identify device names and control numbers:

- 1 Verify that MIDI control surface device is correctly connected to the host computer running MATLAB.

---

**Note** For the most consistent behavior, MathWorks recommends that you connect your MIDI control surface device to your computer before starting MATLAB. In some circumstances MATLAB may not be able to find your device if you connect it after starting your MATLAB session. Also, it may not find your device if you disconnect it and reconnect it during your MATLAB session.

---

- 2 Type the following command at the MATLAB command line.

```
>> [ctlnum devname] = midiid
```

You are prompted to move the control in which you are interested.

```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ...
```

- 3 Move the control. `midiid` detects the movement and returns the device name and control number.

```
>> [ctlnum devname] = midiid
Move the control you wish to identify; type ^C to abort.
Waiting for control message ... done

```

- 4 Use the device name in the block dialog, or set it as the default device using `setpref`. Then, enter the control number in the block dialog. Concatenate the number with other control numbers as needed.

## Parameters

### MIDI device

Specify whether to use a default MIDI device, or specify a particular device by name.

### MIDI device name

Specify the name of a particular MIDI control surface device from which to receive control values.

### MIDI controls

Specify whether to respond to any control on the MIDI device or respond to particular specified controls.

### MIDI control numbers

Specify particular controls to which the block should respond.

### Initial values

Specify initial values to output when simulation starts.

### Send initial values to device at start

Select this check box to attempt to synchronize a bidirectional MIDI device with block initial values when simulation starts.

### Output mode

Specify the mode in which the control values are generated. When you set **Output mode** to **Normalized (0-1)**, the block generates control values in the range [0 1]. In this mode, control values are represented as a fraction of a full-scale. Hence, you can easily scale this range to your particular application. When you set **Output mode** to **RAW MIDI (0-127)**, the block generates byte-oriented MIDI control values in the range [0 127]. By default, this parameter is set to **Normalized (0-1)**.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Output | <ul style="list-style-type: none"><li>• Double-precision floating point, uint8 integer</li></ul> |

## Version History

Introduced in R2012a

Generate C and C++ code using Simulink® Coder™.

Host computer only. Excludes Simulink Desktop Real-Time code generation.

# Minimum

Minimum values of input or sequence of inputs

## Libraries:

DSP System Toolbox / Statistics

DSP System Toolbox HDL Support / Statistics

## Description

The Minimum block identifies the value and position of the smallest element in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the minimum value of the entire input. The Minimum block can also track the minimum values in a sequence of inputs over a period of time. The **Mode** parameter specifies the block's mode of operation and can be set to one of the following:

- **Value** — The block outputs the minimum values in the specified dimension.
- **Index** — The block outputs the index array of the minimum values in the specified dimension.
- **Value and Index** — The block outputs the minimum values and the corresponding index array in the specified dimension.
- **Running** — The block tracks the minimum values in a sequence of inputs over a period of time.

You can specify the dimension using the **Find the minimum value over** parameter.

---

**Note** The **Running** mode in the Minimum block will be removed in a future release. To compute the running minimum in Simulink, use the Moving Minimum block instead.

---

## Ports

### Input

**In** — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be floating-point, fixed-point, or Boolean. Real fixed-point inputs can be either signed or unsigned. Complex fixed-point inputs must be signed.

This port is unnamed until you set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Rst** — Reset port

scalar

Specify the reset event that causes the block to reset the running minimum. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

## Dependencies

To enable this port, set the **Mode** parameter to **Running** and the **Reset port** parameter to any option other than **None**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

## Output

**Val** — Minimum values along the specified dimension

`scalar` | `vector` | `matrix` | *N-D array*

The data type of the minimum value matches the data type of the input.

When the **Mode** parameter is set to either **Value and Index** or **Value**, the following applies:

- The size of the dimension for which the block computes the minimum value is 1. The sizes of all other dimensions match those of the input array. For example, when the input is an *M*-by-*N*-by-*P* array, with the dimension set to 1, the block outputs a 1-by-*N*-by-*P* array. When the dimension is set to 3, the block outputs a two-dimensional *M*-by-*N* matrix.
- When the input is an *M*-by-*N* matrix, with the dimension set to 1, the block outputs a 1-by-*N* matrix.

If you specify the block to compute the minimum value over the entire input, the block outputs a scalar.

When the **Mode** parameter is set **Running**, the block tracks the minimum value of each channel in a time sequence of *M*-by-*N* inputs. In this mode, you must also specify the **Input processing** parameter as one of the following:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each  $y_{ijk}$  element of the output contains the minimum value observed in element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running minimum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an *N*-dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element  $y_{ij}$  of the output contains the minimum value observed in the *j*th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

## Dependencies

To enable this port, set the **Mode** parameter to either **Value and Index** or **Value**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Idx** — Index of the minimum values along the specified dimension  
 scalar | vector | matrix | *N*-D array

When the input is double, the index values are also double. Otherwise, the index values are uint32.

### Dependencies

To enable this port, set the **Mode** parameter to either Value and Index or Index.

Data Types: double | uint32

## Parameters

### Main Tab

**Mode** — Mode in which the block operates  
 Value and Index (default) | Value | Index | Running

When the **Mode** parameter is set to:

- **Value**— The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input at each sample time, and outputs the array *y*. Each element in *y* is the minimum value in the corresponding column, row, vector, or entire input. The output *y* depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size *M*-by-*N*-by-*P*. Set **Find the minimum value over** to:
  - **Each row** — The output *y* at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the minimum value of each vector over the second dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is an *M*-by-1 column vector.
  - **Each column** — The output *y* at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the minimum value of each vector over the first dimension of the input. For an input that is an *M*-by-*N* matrix, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-*M* unoriented vector inputs as *M*-by-1 column vectors.

- **Entire input** — The output *y* at each sample time is a scalar that contains the minimum value in the *M*-by-*N*-by-*P* input matrix.
- **Specified dimension** — The output *y* at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an *M*-by-*N* matrix containing the minimum value of each vector over the third dimension of the input.

### Complex Inputs

For complex inputs, the block selects the value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input that has the minimum magnitude squared in the following figure. For complex value  $u = a + bi$ , the magnitude squared is  $a^2 + b^2$ .

- **Index** — The block computes the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and outputs the index array  $I$ . Each element in  $I$  is an integer indexing the minimum value in the corresponding column, row, vector, or entire input. The output  $I$  depends on the setting of the **Find the minimum value over** parameter. Consider a three dimensional input signal of size  $M$ -by- $N$ -by- $P$ :
  - **Each row** — The output  $I$  at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the index of the minimum value of each vector over the second dimension of the input. For an input that is an  $M$ -by- $N$  matrix, the output at each sample time is an  $M$ -by-1 column vector.
  - **Each column** — The output  $I$  at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the index of the minimum value of each vector over the first dimension of the input. For an input that is an  $M$ -by- $N$  matrix, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Entire input** — The output  $I$  at each sample time is a 1-by-3 vector that contains the location of the minimum value in the  $M$ -by- $N$ -by- $P$  input matrix. For an input that is an  $M$ -by- $N$  matrix, the output is a 1-by-2 vector.
- **Specified dimension** — The output  $I$  at each sample time depends on **Dimension**. If **Dimension** is set to 1, the output is the same as when you select **Each column**. If **Dimension** is set to 2, the output is the same as when you select **Each row**. If **Dimension** is set to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the indices of the minimum values of each vector over the third dimension of the input.

When a minimum value occurs more than once, the computed index corresponds to the first occurrence. For example, when the input is the column vector  $[3 \ 2 \ 1 \ 2 \ 3]'$ , the computed one-based index of the minimum value is 1, rather than 5 when **Each column** is selected.

- **Value and Index** — The block outputs the minimum value in each row or column of the input, along vectors of a specified dimension of the input, or of the entire input, and the corresponding index array  $I$ .
- **Running** — The block tracks the minimum value of each channel in a time sequence of  $M$ -by- $N$  inputs. The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time. In this mode, you must also specify the **Input processing** parameter as one of the following:
  - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each  $y_{ijk}$  element of the output contains the minimum value observed in element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running minimum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the minimum value observed in the  $j$ th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

### Running Mode for Variable-Size Inputs

When the input is a variable-size signal, and you set the **Mode** to **Running**, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
  - When the input size difference is in the number of channels (columns), the state is reset.
  - When the input size difference is in the length of channels (rows), there is no reset and the running operation is carried out as usual.

**Index base** — Base of the minimum value index  
One (default) | Zero

Specify whether the index of the minimum value is reported using one-based or zero-based numbering.

### Dependencies

To enable this parameter, set **Mode** to either **Index** or **Value** and **Index**.

**Find the minimum value over** — Dimension over which the block computes the minimum value  
Each column (default) | Each row | Entire input | Specified dimension

- **Each column** — The block outputs the minimum value over each column.
- **Each row** — The block outputs the minimum value over each row.
- **Entire input** — The block outputs the minimum value over the entire input.
- **Specified dimension** — The block outputs the minimum value over the dimension specified in the **Dimension** parameter.

### Dependencies

To enable this parameter, set **Mode** to **Value** and **Index**, **Value**, or **Index**.

**Dimension** — Custom dimension  
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the block computes the minimum. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

#### Dependencies

To enable this parameter, set **Find the minimum value over** to Specified dimension.

**Input processing** — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support an  $N$ -dimensional input signal, where  $N > 2$ . For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the minimum value observed in the  $j$ th column of all inputs since the last reset, up to and including element  $u_{ij}$  of the current input.

When a reset event occurs, the running minimum for each channel becomes the minimum value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each  $y_{ijk}$  element of the output contains the minimum value observed in element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running minimum  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

#### Dependencies

To enable this parameter, set **Mode** to Running.

**Reset port** — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running minimum whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer which is a multiple of the input sample time.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

---

**Note** When running simulations in the Simulink `MultiTasking` mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, set **Mode** to `Running`.

### Data Types Tab

---

**Note** To use these parameters, the data input must be complex fixed-point.

---

**Rounding mode** — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Product output** — Product output data type  
Inherit: Same as input (default) | fixdt([],16,0)

**Product output** specifies the data type of the output of a product operation in the Minimum block. For more information on the product output data type, see “Multiplication Data Types”.

- **Inherit: Same as input** — The block specifies the product output data type to be the same as the input data type.
- **fixdt([],16,0)** — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type  
Inherit: Same as product output (default) | Inherit: Same as input | fixdt([],16,0)

**Accumulator** specifies the data type of the output of an accumulation operation in the Minimum block.

- **Inherit: Same as product output** — The block specifies the accumulator data type to be the same as the product output data type.
- **Inherit: Same as input** — The block specifies the accumulator data type to be the same as the input data type.

- `fixdt([], 16, 0)` — The block specifies an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |

## Algorithms

### Minimum

When you set **Mode** to one of Value, Index, or Value and Index, and specify a dimension, the block produces results identical to the MATLAB `min` function, when it is called as `[y, I] = min(u, [], D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the minimum value.
- `I` is the index of the minimum value.

The minimum value along the entire input is identical to calling the `min` function as `[y, I] = min(u(:))`.

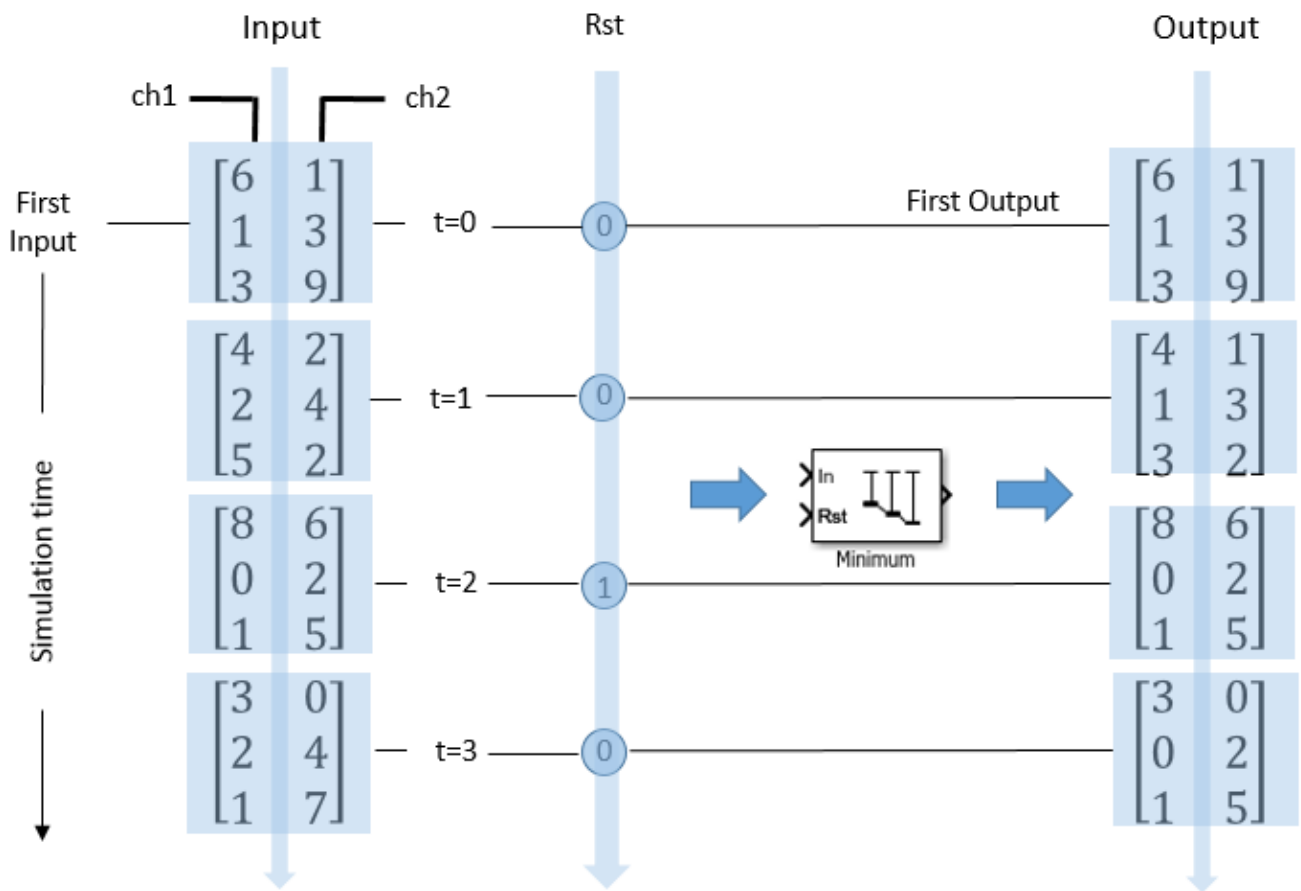

### Running Minimum

When you set **Mode** to Running, and **Input processing** to Columns as channels (frame based), the block treats each column of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

The block outputs the minimum value over each channel since the last reset. At  $t = 2$ , the reset event occurs. The minimum value in the second column changes to 6, and then 2, even though these values are greater than 1, which was the minimum value since the previous reset event.

When you set **Mode** to Running, and **Input processing** to Elements as channels (sample based), the block treats each element of the input as a separate channel. In this example, the block processes a two-channel signal with a frame size of three under these settings.

Each element  $y_{ij}$  of the output contains the minimum value observed in element  $u_{ij}$  for all inputs since the last reset. The reset event occurs at  $t = 2$ . When a reset event occurs, the running minimum,  $y_{ij}$ , in the current frame is reset to the element  $u_{ij}$ .

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

## HDL Architecture

This block has multi-cycle implementations that introduce additional latency in the generated code. To see the added latency, view the generated model or validation model. See “Generated Model and Validation Model” (HDL Coder).

| Architecture    | Additional cycles of latency                  | Description  |
|-----------------|---|--|
| default<br>Tree | 0   | Generates a tree structure of comparators.   |
| Cascade         | 1, when block has a single vector input port. | This implementation is optimized for latency * area, with medium speed. See “Cascade Architecture Best Practices” (HDL Coder). |

## HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |
| <b>InstantiateStages</b>         | Generate a VHDL entity or Verilog module for each cascade stage. The default is off. See also “InstantiateStages” (HDL Coder).   |
| <b>SerialPartition</b>           | Specify partitions for Cascade-serial implementations as a vector of the lengths of each partition. The default setting uses the minimum number of stages. See also “SerialPartition” (HDL Coder).                                       |

## Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types Tab** of the block are used only for complex fixed-point inputs. The sum of the squares of the real and imaginary parts of such an input are formed before a comparison is made, as described under the 'Mode' parameter in “Main Tab” on page 2-1008. The results of the squares of the real and imaginary parts are placed into the product output data type. The result of the sum of the squares is placed into the accumulator data type. These parameters are ignored for other types of inputs.

# Modified Covariance AR Estimator

Compute estimate of autoregressive (AR) model parameters using modified covariance method

## Libraries:

DSP System Toolbox / Estimation / Parametric Estimation

## Description

The Modified Covariance AR Estimator block uses the modified covariance method to fit an autoregressive (AR) model to the input data. This method minimizes the forward and backward prediction errors in the least squares sense.

## Ports

### Input

#### Input — Input

column vector | unoriented vector

Specify the input data as a column vector or an unoriented vector. The block assumes that the input data is the output of an AR system driven by white noise and represents a frame of consecutive time samples from a single-channel signal.

Data Types: single | double

### Output

#### A — Normalized estimate of the AR model polynomial coefficients

column vector

Normalized estimate of the AR model polynomial coefficients  $A(z)$ , returned as a column vector of length  $p+1$  in descending powers of  $z$ .

The block computes the estimate of these coefficients independently for each successive input frame.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: single | double

#### G — Model gain

scalar

Gain of the estimated AR model, returned as a scalar.

$$H(z) = \frac{G}{A(z)} = \frac{G}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Scalar gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: `single` | `double`

## Parameters

**Estimation order** — Order of AR model

4 (default) | positive integer

Specify the estimation order  $p$  of the AR model (all-pole model) as a positive integer. To guarantee a nonsingular output, you must set the **Estimation order** parameter to be less than or equal to two thirds the input vector length. Otherwise, the output might be singular.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | <code>double</code>   <code>single</code> |
| <b>Multidimensional Signals</b> | No  |
| <b>Variable-Size Signals</b>    | No  |

## More About

### AR(p) Model

In an AR model of order  $p$ , the current output is a linear combination of the past  $p$  outputs plus a white noise input. The weights on the  $p$  past outputs minimize the mean squared prediction error of the autoregression.

Let  $y(n)$  be a wide-sense stationary random process obtained by filtering white noise of variance  $e$  with the system function  $A(z)$ . If  $P_y(e^{j\omega})$  is the power spectral density of  $y(n)$ , then

$$P_y(e^{j\omega}) = \frac{e}{|A(e^{j\omega})|^2} = \frac{e}{\left|1 + \sum_{k=1}^p a(k)e^{-j\omega k}\right|^2}.$$

Because the modified covariance method characterizes the input data using an all-pole model, the correct choice of the model order  $p$  is important.

## Compare AR Model Parameter Estimation Methods

This table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and the Yule-Walker AR Estimator blocks.

The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

|                                      | <b>Burg AR Estimator</b>   | <b>Covariance AR Estimator</b>                                    | <b>Modified Covariance AR Estimator</b>   | <b>Yule-Walker AR Estimator</b>  |
|--------------------------------------|--|---|---|--|
| <b>Characteristics</b>               | Does not apply window to data  | Does not apply window to data                                     | Does not apply window to data   | Applies window to data   |
|                                      | Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion | Minimizes the forward prediction error in the least squares sense | Minimizes the forward and backward prediction errors in the least squares sense | Minimizes the forward prediction error in the least squares sense (also called "autocorrelation method")         |

# Modified Covariance Method

Power spectral density estimate using modified covariance method

## Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

## Description

The Modified Covariance Method block estimates the power spectral density (PSD) of the input using the modified covariance method. This method fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors in the least squares sense.

The block computes the spectrum from the FFT of the estimated AR model parameters.

## Ports

### Input

#### Input — Input

column vector | unoriented vector

Specify the input as a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

### Output

#### Output — Power spectral density estimate

column vector

Power spectral density estimate of the signal at  $N_{fft}$  equally spaced frequency points, returned as a column vector. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling rate of the signal.

Data Types: `single` | `double`

## Parameters

### Estimation order — Order of AR model

6 (default) | positive integer

Specify the estimation order of the AR model (all-pole model) as a positive integer. The block computes the spectrum from the FFT of the estimated AR model parameters. To guarantee a nonsingular output, the value of the **Estimation order** parameter must be less than or equal to 2/3 of the input vector length.

**Inherit FFT length from estimation order** — Inherit FFT length from estimation order

off (default) | on

When you select the **Inherit FFT length from estimation order** parameter, the FFT length  $N_{fft}$  is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** parameter. You can then specify a power-of-two FFT length using the **FFT length** parameter. The block zero-pads or wraps the input to  $N_{fft}$  before computing the FFT.

**FFT length** — FFT length

256 (default) | positive integer greater than or equal to 2

Enter the number of data points  $N_{fft}$  on which to perform the FFT as a positive integer greater than or equal to 2. When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

**Dependencies**

To enable this parameter, clear the **Inherit FFT length from estimation order** parameter.

**Inherit sample time from input** — Inherit sample time from input

on (default) | off

When you select the **Inherit sample time from input** parameter, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

**Sample time of original time series** — Sample time of original time-domain signal

1 (default) | positive scalar

Specify the sample time of the original time-domain signal as a positive scalar.

**Dependencies**

To enable this parameter, clear the **Inherit sample time from input** parameter.

**Block Characteristics**

# Moving Average

Moving average

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Moving Average block computes the moving average of the input signal along each channel independently over time. The block uses the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the average over the data in the window. In the exponential weighting method, the block multiplies the data samples with a set of weighting factors and then sums the weighted data to compute the average. For more details on these methods, see “Algorithms” on page 2-1031.

## Input/Output Ports

### Input

**x** — Data input  
vector | matrix

The block computes the moving average of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size  $m$ -by- $n$ , where  $m \geq 1$  and  $n \geq 1$ .

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

**lambda** — Forgetting factor  
positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

### Dependencies

This port appears when you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

## Output

**Port\_1** — Moving average output

`vector` | `matrix`

Moving average, returned as a vector or a matrix. The block computes the moving average based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-1031.

This table provides more details on the dimensions of the output signal.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is a multiple of the hop size (window length – overlap length)     | $(m/\text{hop size})$ -by- $n$  | $m$ -by- $n$   |
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(m/\text{hop size})$ -by- $n$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $m$ -by- $n$   |
| Variable-size signal | $m$ -by- $n$  | $\text{ceil}(m/\text{hop size})$ -by- $n$   | $m$ -by- $n$   |

When the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving Average of Noisy Step Signal”.

Data Types: `single` | `double`

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Method** — Averaging method

`Sliding window` (default) | `Exponential weighting`

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves over, the block computes the average over the data in the window.

- **Exponential weighting** — The block multiplies the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero. To compute the average, the algorithm sums the weighted data.

**Specify window length** — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the average of the current sample and all previous samples in the channel.

#### Dependencies

To enable this parameter, set **Method** to `Sliding window`.

**Window length** — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

#### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Overlap length** — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range  $[0, \mathbf{Window\ length} - 1]$ .

#### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of

the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.

- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

#### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Specify forgetting factor from input port** — Flag to specify forgetting factor  
off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

#### Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

**Forgetting factor** — Exponential weighting factor  
0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

**Tunable:** Yes

#### Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

## Block Characteristics

|                                 |     |
|---------------------------------|-----|
| <b>Multidimensional Signals</b> | No  |
| <b>Variable-Size Signals</b>    | Yes |

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

### Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x_N$$

- $\bar{x}_{N,\lambda}$  — Moving average at the current sample
- $x_N$  — Current data input sample
- $\bar{x}_{N-1,\lambda}$  — Moving average at the previous sample
- $\lambda$  — Forgetting factor
- $w_{N,\lambda}$  — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda}$  — Effect of the previous data on the average

For the first sample, where  $N = 1$ , the algorithm chooses  $w_{N,\lambda} = 1$ . For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

## Version History

Introduced in R2016b

### R2022b: New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

### R2022b: Support for arbitrary input frame length

Moving Average block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation). If **Allow arbitrary frame length for fixed-size input signals** is enabled, select the parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

# Moving Maximum

Moving maximum

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Moving Maximum block determines the moving maximum of the input signal along each channel independently over time. The block uses the sliding window method to determine the moving maximum. In this method, a window of specified length moves over each channel sample by sample, and the block determines the maximum over the data in the window. For more details, see “Algorithms” on page 2-1034.

## Input/Output Ports

### Input

**Port\_1** — Data input

column vector | row vector | matrix

Data over which the moving maximum is determined using the sliding window method. The block accepts real-valued or complex-valued multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$  and  $n \geq 1$ . The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: single | double

### Output

**Port\_1** — Moving maximum output

column vector | row vector | matrix

Moving maximum output, determined using the sliding window method. The size of the output matches the size of the input. The window slides column-wise along each channel, and the block determines the maximum of the data in the window. For more details, see “Algorithms” on page 2-1034.

Data Types: single | double

## Parameters

**Specify window length** — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify through the **Window length** parameter. When you clear this check box, the length of the sliding

window is infinite. In this mode, the block determines the maximum of the current sample and all previous samples in the channel.

**Window length** — Length of the sliding window

4 (default) | positive scalar integer

**Window length** specifies the length of the sliding window in samples.

#### Dependencies

This parameter appears when you select the **Specify window length** check box.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. When the algorithm computes the first  $Len - 1$  outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

## Description

The Moving Minimum block determines the moving minimum of the input signal along each channel independently over time. The block uses the sliding window method to determine the moving minimum. In this method, a window of specified length moves over each channel sample by sample, and the block determines the minimum over the data in the window. For more details, see “Algorithms” on page 2-1038.

## Input/Output Ports

### Input

**Port\_1** — Data input  
column vector | row vector | matrix

Data over which the moving minimum is determined using the sliding window method. The block accepts real-valued or complex-valued multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$  and  $n \geq 1$ . The block also accepts variable-size inputs. During simulation, you can change the size of each input channel. However, the number of channels cannot change.

Data Types: `single` | `double`

### Output

**Port\_1** — Moving minimum output  
column vector | row vector | matrix

Moving minimum output, determined using the sliding window method. The size of the output matches the size of the input. The window slides column-wise along each channel, and the block determines the minimum of the data in the window. For more details, see “Algorithms” on page 2-1038.

Data Types: `single` | `double`

## Parameters

**Specify window length** — Flag to specify window length  
on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify through the **Window length** parameter. When you clear this check box, the length of the sliding

window is infinite. In this mode, the block determines the minimum of the current sample and all the previous samples in the channel.

**Window length** — Length of the sliding window  
4 (default) | positive scalar integer

**Window length** specifies the length of the sliding window in samples.

#### Dependencies

This parameter appears when you select the **Specify window length** check box.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the minimum of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. When the algorithm computes the first  $Len - 1$  outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the minimum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving minimum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Window moves along the data

# Moving RMS

Moving RMS

## Libraries:

DSP System Toolbox / Statistics

## Description

The Moving RMS block computes the moving root mean square (RMS) of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the RMS over the data in the window. In the exponential weighting method, the block squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The block then computes the RMS by taking the square root of the sum. For more details on these methods, see “Algorithms” on page 2-1045.

## Input/Output Ports

### Input

**x** — Data input  
vector | matrix

The block computes the moving RMS of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size  $m$ -by- $n$ , where  $m \geq 1$  and  $n \geq 1$ .

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

**lambda** — Forgetting factor  
positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

## Dependencies

This port appears when you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

## Output

**Port\_1** — Moving RMS output  
vector | matrix

Moving RMS output, returned as a vector or a matrix. The block computes the moving RMS based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-1045.

This table provides more details on the dimensions of the output signal.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is a multiple of the hop size (window length – overlap length)     | $(m/\text{hop size})$ -by- $n$  | $m$ -by- $n$   |
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(m/\text{hop size})$ -by- $n$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $m$ -by- $n$   |
| Variable-size signal | $m$ -by- $n$  | $\text{ceil}(m/\text{hop size})$ -by- $n$   | $m$ -by- $n$   |

When the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving RMS of Noisy Step Signal”.

Data Types: single | double

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Method** — Moving RMS method  
Sliding window (default) | Exponential weighting

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves over, the block computes the RMS over the data in the window.
- **Exponential weighting** — The block multiplies the squares of the samples by a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero. To compute the RMS, the algorithm sums the weighted data and takes a square root of the sum.

**Specify window length** — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the RMS of the current sample and all the previous samples in the channel.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window**.

**Window length** — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Overlap length** — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range  $[0, \mathbf{Window\ length} - 1]$ .

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Specify forgetting factor from input port** — Flag to specify forgetting factor  
off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

### Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

**Forgetting factor** — Exponential weighting factor  
0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

**Tunable:** Yes

### Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

**Simulate using** — Type of simulation to run  
`Code generation` (default) | `Interpreted execution`

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$x_{rmsN,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rmsN-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N^2}$$

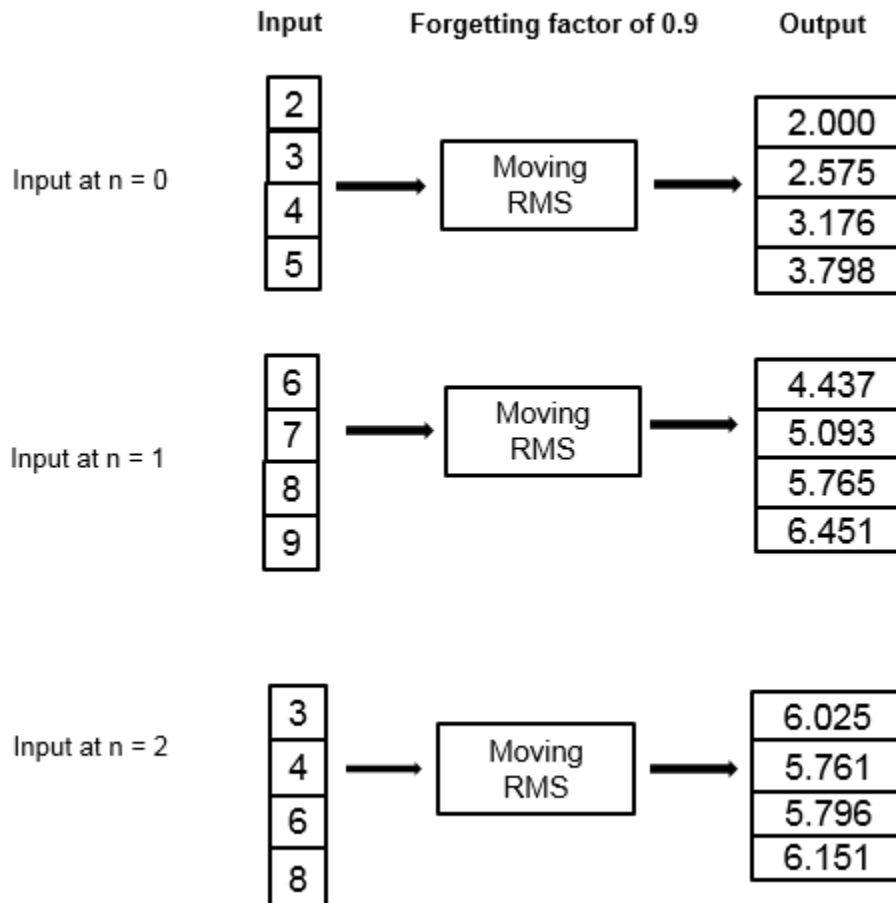

- $x_{rmsN,\lambda}$  – Moving RMS at the current sample
- $x_N^2$  – Square of the current input data sample

- $x_{rms_{N-1,\lambda}}$  – Moving RMS at the previous sample
- $\lambda$  – Forgetting factor
- $w_{N,\lambda}$  – Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rms_{N-1,\lambda}}$  – Effect of the previous data on the RMS

For the first sample, where  $N = 1$ , the algorithm chooses  $w_{N,\lambda} = 1$ . For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

## Version History

Introduced in R2016b

### R2022b: New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

### R2022b: Support for arbitrary input frame length

Moving RMS block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

# Moving Variance

Moving variance

## Libraries:

DSP System Toolbox / Statistics

## Description

The Moving Variance block computes the moving variance of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the variance over the data in the window. In the exponential weighting method, the block subtracts each sample of the data from the average, squares the difference, and multiplies the squared result by a weighting factor. The block then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 2-1053.

## Input/Output Ports

### Input

**x** — Data input  
vector | matrix

The block computes the moving variance of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size  $m$ -by- $n$ , where  $m \geq 1$  and  $n \geq 1$ .

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to `Exponential weighting` and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

**lambda** — Forgetting factor  
positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

## Dependencies

This port appears when you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

## Output

**Port\_1** — Moving variance output  
column vector | row vector | matrix

Moving variance output, returned as a vector or a matrix. The block computes the moving variance based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-1053.

This table provides more details on the dimensions of the output signal.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is a multiple of the hop size (window length – overlap length)     | $(m/\text{hop size})$ -by- $n$  | $m$ -by- $n$   |
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(m/\text{hop size})$ -by- $n$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $m$ -by- $n$   |
| Variable-size signal | $m$ -by- $n$  | $\text{ceil}(m/\text{hop size})$ -by- $n$   | $m$ -by- $n$   |

When the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving Variance of Noisy Square Wave Signal”.

Data Types: single | double

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Method** — Moving variance method  
Sliding window (default) | Exponential weighting

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves over, the block computes the variance over the data in the window.
- **Exponential weighting** — The block subtracts each sample of the data from the average, squares the difference, and multiplies the squared result by a weighting factor. The block then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero.

For more details on these methods, see “Algorithms” on page 2-1053.

**Specify window length** — Flag to specify window length

on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the variance of the current sample with respect to all the previous samples in the channel.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window**.

**Window length** — Length of sliding window

4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Overlap length** — Overlap length between windows

3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range [0, **Window length** – 1].

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop

size is defined as **Window length – Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

#### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Specify forgetting factor from input port** — Flag to specify forgetting factor  
off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

#### Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

**Forgetting factor** — Exponential weighting factor  
0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

**Tunable:** Yes

#### Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

**Simulate using** — Type of simulation to run  
`Code generation` (default) | `Interpreted execution`

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent

simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

## Algorithms

### Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

To compute the moving variance, the algorithm implements these equations recursively.

- $s_{N,\lambda}^2$  — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$  — Moving average at the current sample. For details on computing the moving average, see `dsp.MovingAverage`.
- $[x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$  — Weighting factor applied to the sum.
- $\lambda$  — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

## Version History

Introduced in R2016b

### R2022b: New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

### R2022b: Support for arbitrary input frame length

Moving Variance block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

# Moving Standard Deviation

Moving standard deviation

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Moving Standard Deviation block computes the moving standard deviation of the input signal along each channel independently over time. The block uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length moves over the data sample by sample, and the block computes the standard deviation over the data in the window. In the exponential weighting method, the block computes the exponentially weighted moving variance and takes the square root. For more details on these methods, see “Algorithms” on page 2-1062.

## Input/Output Ports

### Input

**x** — Data input  
vector | matrix

The block computes the moving standard deviation of the data specified at this input port. Specify real- or complex-valued multichannel inputs of the size  $m$ -by- $n$ , where  $m \geq 1$  and  $n \geq 1$ .

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

This port is unnamed until you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: single | double

**lambda** — Forgetting factor  
positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory – all previous samples are given an equal weight.

### Dependencies

This port appears when you set **Method** to Exponential weighting and select the **Specify forgetting factor from input port** parameter.

Data Types: `single` | `double`

## Output

**Port\_1** — Moving standard deviation output  
vector | matrix

Moving standard deviation output, returned as a vector or a matrix. The block computes the moving standard deviation based on the **Method** parameter settings using either the sliding window method or the exponential weighting method. For more details, see “Algorithms” on page 2-1062.

This table provides more details on the dimensions of the output signal.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is a multiple of the hop size (window length – overlap length)     | $(m/\text{hop size})$ -by- $n$  | $m$ -by- $n$   |
| Fixed-size signal    | $m$ -by- $n$ , where $m$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(m/\text{hop size})$ -by- $n$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $m$ -by- $n$   |
| Variable-size signal | $m$ -by- $n$  | $\text{ceil}(m/\text{hop size})$ -by- $n$   | $m$ -by- $n$   |

When the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ , during simulation, the size of the first dimension varies within this bound and the size of the second dimension remains constant. For an example that shows this behavior, see “Compute Moving Standard Deviation of Noisy Square Wave Signal”.

Data Types: `single` | `double`

## Parameters

If a parameter is listed as tunable, then you can change its value during simulation.

**Method** — Moving standard deviation method  
Sliding window (default) | Exponential weighting

- **Sliding window** — A window of length **Window length** moves over the input data along each channel. For every sample the window moves by, the block computes the standard deviation over the data in the window.
- **Exponential weighting** — The block computes the exponentially weighted moving standard deviation and takes the square root. The magnitude of the weighting factors decreases exponentially as the age of the data increases, but the magnitude never reaches zero.

For more details on these methods, see “Algorithms” on page 2-1062.

**Specify window length** — Flag to specify window length  
on (default) | off

When you select this check box, the length of the sliding window is equal to the value you specify in **Window length**. When you clear this check box, the length of the sliding window is infinite. In this mode, the block computes the standard deviation of the current sample with respect to all the previous samples in the channel.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window**.

**Window length** — Length of sliding window  
4 (default) | positive scalar integer

Specifies the length of the sliding window in samples.

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Overlap length** — Overlap length between windows  
3 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range  $[0, \mathbf{Window\ length} - 1]$ .

#### Dependencies

To enable this parameter, set **Method** to **Sliding window** and select the **Specify window length** check box.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the hop size. Hop size is defined as **Window length** – **Overlap length**. The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

### Dependencies

To enable this parameter, set **Method** to `Sliding window` and select the **Specify window length** check box.

**Specify forgetting factor from input port** — Flag to specify forgetting factor

off (default) | on

When you select this check box, the forgetting factor is input through the **lambda** port. When you clear this check box, the forgetting factor is specified on the block dialog through the **Forgetting factor** parameter.

### Dependencies

To enable this parameter, set **Method** to `Exponential weighting`.

**Forgetting factor** — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

The forgetting factor determines how much weight past data is given. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory - all previous samples are given an equal weight.

**Tunable:** Yes

### Dependencies

To enable this parameter, set **Method** to `Exponential weighting` and clear the **Specify forgetting factor from input port** check box.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

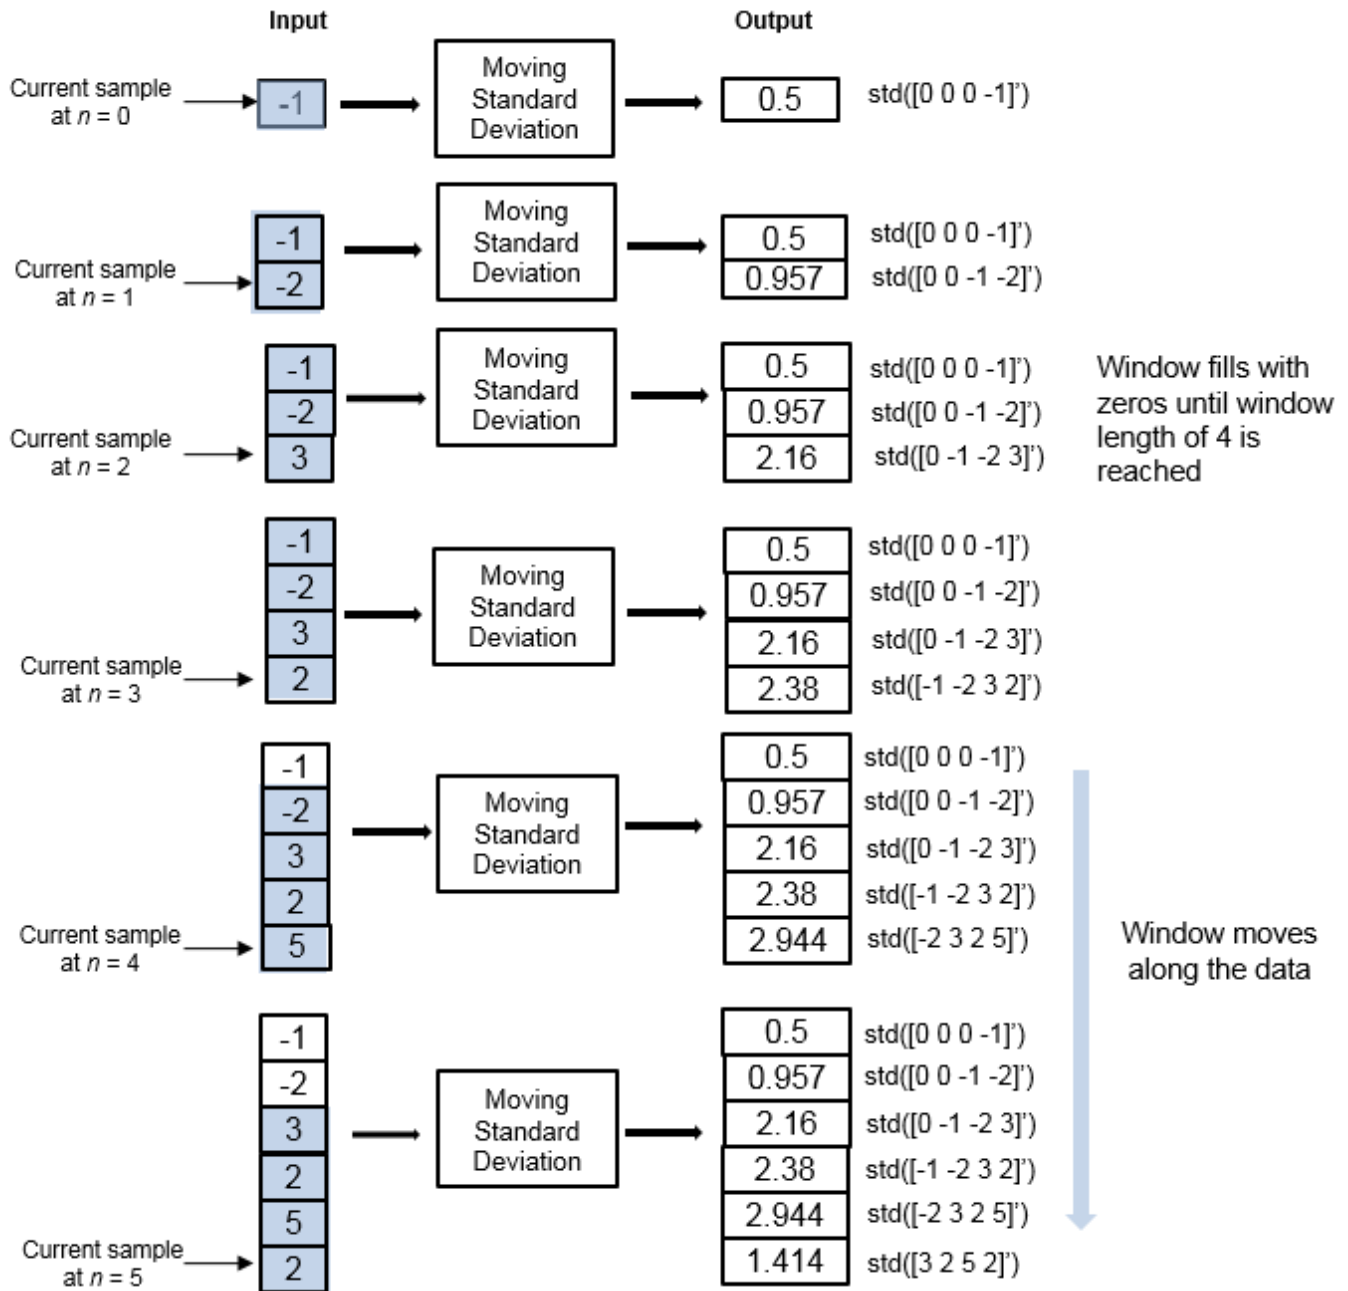

## Algorithms

### Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2}$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

- $s_{N,\lambda}$  — Moving standard deviation of the current data sample with respect to the rest of the data.
- $[x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$  — Weighting factor applied to the sum.
- $\lambda$  — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

## Version History

Introduced in R2016b

### R2022b: New Overlap length parameter

Starting in R2022b, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

### R2022b: Support for arbitrary input frame length

Moving Standard Deviation block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

## Multiphase Clock

Generate multiple binary clock signals

### Libraries:

DSP System Toolbox / Signal Management / Switches and Counters  
 DSP System Toolbox / Sources

### Description

The Multiphase Clock block generates a 1-by- $N$  vector of clock signals, where you specify the integer  $N$  in the **Number of phases** parameter. Each of the  $N$  phases has the same frequency,  $f$ , specified in hertz by the **Clock frequency** parameter.

The clock signal indexed by the **Starting phase** parameter is the first to become active, at  $t=0$ . The other signals in the output vector become active in turn, each one lagging the preceding signal's activation by  $1/(Nf)$  seconds, the phase interval. The period of the output is therefore  $1/(Nf)$  seconds.

The active level can be either high (1) or low (0), as specified by the **Active level (polarity)** parameter. You specify the duration of the active level,  $D$ , as an integer between 1 and  $N-1$  using the **Number of phase intervals over which the clock is active** parameter. This value specifies the number of phase intervals that each signal remains in the active state after becoming active. The active duty cycle of the signal is  $D/N$ .

### Ports

#### Output

**Port\_1** — Vector of clock signals  
 vector

1-by- $N$  vector of clock signals, where you specify  $N$  using the **Number of phases** parameter. For more information, see “Description” on page 2-1066.

Data Types: single | double | Boolean

### Parameters

**Clock frequency (Hz)** — Frequency of all clock signals

1 (default) | positive scalar

The frequency of all output clock signals, specified as a positive scalar.

**Number of phases, N** — Number of phases in output vector

4 (default) | positive integer

The number of different phases,  $N$ , in the output vector, specified as a positive integer scalar.

**Starting phase (1 to N)** — Vector index for starting phase

1 (default) | integer from 1 to  $N$

The vector index of the output signal to first become active, specified as a scalar integer from 1 to  $N$ .

**Number of phase intervals over which clock is active (1 to N-1)** — Duration of active level for each output

3 (default) | integer from 1 to  $N-1$

The duration of the active level,  $D$ , for every output signal specified as a scalar integer from 1 to  $N-1$ . The value you specify determines the number of phase intervals that each signal remains in the active state after becoming active. The active duty cycle of the signal is  $D/N$ .

**Active level (polarity)** — Active level

High (1) (default) | Low (0)

The active level of the output, specified as High (1) or Low (0).

**Output data type** — Output data type

Logical (default) | Boolean

The output data type, specified as Logical or Boolean.

## Multiport Selector

Distribute arbitrary subsets of input rows or columns to multiple output ports

## Library

Signal Management / Indexing

dspindex

## Description

The Multiport Selector block extracts multiple subsets of rows or columns from  $M$ -by- $N$  input matrix  $u$ , and propagates each new submatrix to a distinct output port. The block treats an unoriented length- $M$  vector input as an  $M$ -by-1 matrix.

The **Indices to output** parameter is a cell array whose  $k$ th cell contains a one-dimensional indexing expression specifying the subset of input rows or columns to be propagated to the  $k$ th output port. The total number of cells in the array determines the number of output ports on the block.

When you set the **Select** parameter to **Rows**, the block uses the one-dimensional indices you specify to select matrix rows, and all elements on the chosen rows are included. When you set the **Select** parameter to **Columns**, the block uses the one-dimensional indices you specify to select matrix columns, and all elements on the chosen columns are included. A given input row or column can appear any number of times in any of the outputs, or not at all.

When an index references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

## Examples

### Example 1

Consider the following **Indices to output** cell array:

```
{4, [1:2 5], [7;8], 10:-1:6}
```

This is a four-cell array, which requires the block to generate four independent outputs (each at a distinct port). The table below shows the dimensions of these outputs when **Select** = **Rows** and the input dimension is  $M$ -by- $N$ .

| Cell | Expression | Description               | Output Size |
|------|------------|---------------------------|-------------|
| 1    | 4          | Row 4 of input            | 1-by- $N$   |
| 2    | [1:2 5]    | Rows 1, 2, and 5 of input | 3-by- $N$   |
| 3    | [7;8]      | Rows 7 and 8 of input     | 2-by- $N$   |

| Cell | Expression | Description                      | Output Size    |
|------|------------|----------------------------------|----------------|
| 4    | 10:-1:6    | Rows 10, 9, 8, 7, and 6 of input | 5-by- <i>N</i> |

## Parameters

### Select

Specify the dimension of the input to select, Rows or Columns.

### Indices to output

A cell array specifying the row- or column-subsets to propagate to each of the output ports. The number of cells in the array determines the number of output ports on the block.

### Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

For example, if the block receives a 64-by-4 input and the **Select** parameter is set to Rows, the block clips an index of 72 to 64. For the same input, if the **Select** parameter is set to Columns, the block clips an index of 72 to 4. In both cases, the block clips an index of -2 to 1.

- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

## Supported Data Types

| Port    | Supported Data Types   |
|---------|--|
| Input   | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Enumerated</li> </ul> |
| Outputs | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Enumerated</li> </ul> |

# N-Sample Enable

Output ones or zeros for specified number of sample times

## Libraries:

DSP System Toolbox / Sources

DSP System Toolbox / Signal Management / Switches and Counters

## Description

The N-Sample Enable block outputs the inactive value (0 or 1, whichever is not selected in the **Active level** parameter) during the first  $N$  sample times, where  $N$  is the **Trigger count** value. Beginning with output sample  $N+1$ , the block outputs the active value (1 or 0, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

The output of the block is always a scalar.

The **Reset input** check box enables the **Rst** input port. At any time during the count, a trigger event at the input port resets the counter to its initial state. You specify the type of trigger event using the **Trigger type** parameter. This block supports triggered subsystems when you select the **Reset input** check box.

## Ports

### Input

**Rst** — Reset signal  
scalar

Reset input signal, specified as a scalar. At any time during the count, a trigger event at the input port resets the counter to its initial state.

---

**Tip** The N-Sample Enable block supports triggered subsystems when you select the **Reset input** check box to enable the **Rst** input port.

---

### Dependencies

To enable this input port, select the **Reset input** check box.

Data Types: Boolean

### Output

**Port\_1** — Output signal  
scalar

Scalar output containing the inactive value (0 or 1, whichever is not selected in the **Active level** parameter) during the first  $N$  sample times, where  $N$  is the **Trigger count** value. Beginning with output sample  $N+1$ , the block outputs the active value (1 or 0, whichever you select in the **Active level** parameter) until a reset event occurs or the simulation terminates.

Data Types: Boolean

## Parameters

**Trigger count, N** — Number of samples to output the active value

8 (default) | scalar integer

Specify the number of samples for which the block outputs the active value as a scalar integer, greater than or equal to zero.

**Tunable:** Yes

**Active level** — Active level

Low (0) (default) | High (1)

Specify the value to output after the first *N* sample times as 0 or 1.

**Tunable:** Yes

**Reset input** — Enable reset input port

off (default) | on

To enable the reset (**Rst**) input port, select this check box. When you clear this check box, the **Rst** input port is disabled.

---

**Tip** When you select the **Reset input** check box, the N-Sample Enable block supports triggered subsystems.

---

**Trigger type** — Type of triggering event

Rising edge (default) | Falling edge | Either edge | Non-zero sample

Select type of event that triggers a reset when the **Rst** port is enabled.

You can specify the triggering event as:

- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time that the **Rst** input is not zero.

### Dependencies

To enable this parameter, select the **Reset input** check box.

### Sample time — Output sample period

1 (default) | positive scalar

Specify the sample period,  $T_s$ , for the block's counter as a positive finite scalar. The block switches from the active value to the inactive value at  $t=T_s(N+1)$ .

### Output data type — Output data type

Logical (default) | Boolean

Specify the output data type as Logical or Boolean.

## Block Characteristics

## See Also

### Blocks

Counter | N-Sample Switch

# N-Sample Switch

Switch between two inputs after specified number of sample periods

## Library

Signal Management / Switches and Counters

dspswit3

## Description

The N-Sample Switch block outputs the signal connected to the top input port during the first  $N$  sample times after the simulation begins or the block is reset, where you specify  $N$  in the **Switch count** parameter. Beginning with output sample  $N+1$ , the block outputs the signal connected to the bottom input until the next reset event or the end of the simulation.

You specify the sample period of the output in the **Sample time** parameter (that is, the output sample period is not inherited from the sample period of either input). The block applies a zero-order hold at the input ports, so the value the block reads from a given port between input sample times is the value of the most recent input to that port.

Both inputs must have the same dimension, except in the following two cases:

- When one input is a scalar, the block expands the scalar input to match the size of the other input.
- When one input is an unoriented vector and the other input is a row or column vector with the same number of elements, the block reshapes the unoriented vector to match the dimension of the other input.

The **Reset input** check box enables the Rst input port. At any time during the count, a trigger event at the Rst port resets the counter to zero. The reset sample time must be a positive integer multiple of the input sample time. This block supports triggered subsystems when you select the **Reset input** check box.

You specify the triggering event in the **Trigger type** pop-up menu, and can be one of the following:

- **Rising edge** — Triggers a reset operation when the Rst input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers a reset operation when the Rst input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers a reset operation when the Rst input is a Rising edge or Falling edge (as described above).
- **Non-zero sample** — Triggers a reset operation at each sample time that the Rst input is not zero.

## Parameters

### Switch count

The number of sample periods,  $N$ , for which the output is connected to the top input before switching to the bottom input. Tunable (Simulink).

### Reset input

Enables the Rst input port when selected. The rate of the reset signal must be a positive integer multiple of the rate of the data signal input.

### Trigger type

The type of event at the Rst port that resets the block's counter. This parameter is enabled when you select **Reset input**. Tunable (Simulink).

### Sample time

The sample period,  $T_s$ , for the block's counter. The block switches inputs at  $t=T_s*(N+1)$ .

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- Boolean — The block accepts Boolean inputs to the Rst port, which is enabled when you set the **Reset input** parameter.
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## NCO

Generate real or complex sinusoidal signals

### Libraries:

DSP System Toolbox / Signal Operations  
 DSP System Toolbox / Sources

## Description

The NCO block generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel. The amplitude of the created signal is always 1. The NCO block supports real inputs only. All outputs are real except for the output signal in **Complex exponential** mode. For more information on how the block computes the output, see “Algorithms” on page 2-1084.

To produce a multichannel output, specify a vector quantity for the **Phase increment** and **Phase offset** parameters. Both parameters must have the same length, which defines the number of output channels. Each element of each vector is applied to a different output channel.

## Ports

### Input

**inc** — Phase increment  
 scalar | vector

Phase increment signal, specified as a real-valued scalar or vector. The input must have an integer data type, or a fixed-point data type with zero fraction length. The dimensions of the phase increment signal depend on how you choose to specify the **Phase offset** parameter:

- When you specify the **Phase offset** on the block dialog box, the **Phase increment** must be a scalar or a vector with the same length as the **Phase offset** value. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.
- When you specify the **Phase offset** via the an input port, the **offset** port treats each column of the input as an independent channel. The **Phase increment** length must equal the number of columns in the input to the **offset** port.

### Dependencies

To enable this port, set **Phase increment source** to **Input** port.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

**offset** — Phase offset  
 scalar | vector | matrix

Phase offset signal, specified as a real-valued scalar, vector, or a full matrix. The input must have an integer data type, or a fixed-point data type with zero fraction length. The block treats each column of

the input to the offset port as an independent channel. The number of channels in the phase offset must match the number of channels in the data input. For each frame of the input, the block can apply different phase offsets to each sample and channel.

### Dependencies

To enable this port, set **Phase offset source** to `Input port`.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

### Output

**sin** — Sine output

`scalar` | `vector` | `matrix`

Sinusoidal output signal specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output** data type parameter.

### Dependencies

To enable this port, set **Output signal** to `Sine` or `Sine and cosine`.

Data Types: `single` | `double` | `fixed point`

**cos** — Cosine output

`scalar` | `vector` | `matrix`

Cosinusoidal output signal specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output Data Type** parameter.

### Dependencies

To enable this port, set **Output signal** to `Cosine` or `Sine and cosine`.

Data Types: `single` | `double` | `fixed point`

**exp** — Complex exponential

`scalar` | `vector` | `matrix`

Complex exponential output, specified as a scalar, vector, or matrix. You can specify the data type of the signal using the **Output Data Type** parameter.

### Dependencies

To enable this port, set **Output signal** to `Complex exponential`.

Data Types: `single` | `double` | `fixed point`

Complex Number Support: Yes

**Qerr** — Phase quantization error

`scalar` | `vector` | `matrix`

Phase quantization error specified as a scalar, vector, or matrix.

### Dependencies

To enable this port, select the **Show phase quantization error port** check box.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixed point`

## Parameters

### Main

#### Phase adder parameters

**Phase increment source** — Source of phase increment value

`Specify via dialog` | `Input port`

Choose how you specify the phase increment. The phase increment can come from an input port or from the dialog box parameter.

- If you select `Input port`, the **inc** input port appears on the block icon.
- If you select `Specify via dialog`, the **Phase increment** parameter appears.

#### Dependencies

When the block comes from the Signal Operations library, the default value of the **Phase increment Source** parameter is `Input port`.

When the block comes from the Sources library, the default value of the **Phase increment Source** parameter is `Specify via dialog`.

**Phase increment** — Phase increment value

100 (default) | scalar | vector

Specify the phase increment as an integer-valued scalar or vector. Only integer data types, including fixed-point data types with zero fraction length, are allowed. The dimensions of the phase increment depend on those of the phase offset:

- When you specify the phase offset on the block dialog box, the phase increment must be a scalar or a vector with the same length as the phase offset. The block applies each element of the vector to a different channel, and therefore the vector length defines the number of output channels.
- When you specify the phase offset via an input port, the offset port treats each column of the input as an independent channel. The phase increment length must equal the number of columns in the input to the offset port.

#### Dependencies

To enable this parameter, set **Phase increment source** to `Specify via dialog`.

**Phase offset source** — Source of phase offset

`Specify via dialog (default)` | `Input port`

Choose how you specify the phase offset. The phase offset can come from an input port or from the dialog box.

- If you select `Input port`, the **offset** port appears on the block icon.
- If you select `Specify via dialog`, the **Phase offset** parameter appears.

**Phase offset** — Phase offset value

0 (default) | scalar | vector

Specify the phase offset as an integer-valued scalar or vector. Only integer data types, including fixed-point data types with zero fraction length, are allowed. When you specify the phase offset using this dialog box parameter, it must be a scalar or vector with the same length as the phase increment. Scalars are expanded to a vector with the same length as the phase increment. Each element of the phase offset vector is applied to a different channel of the input, and therefore the vector length defines the number of output channels.

#### Dependencies

To enable this parameter, set **Phase offset source** to *Specify via dialog*.

#### Add internal dither — Add internal dithering

on (default) | off

Select to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications Toolbox™ product.

#### Number of dither bits — Number of dither bits

4 (default) | positive integer

Specify the number of dither bits as a positive integer.

#### Dependencies

To enable this port, select the **Add internal dither** check box.

#### Quantize phase — Enable quantization of accumulated phase

on (default) | off

To enable quantization of the accumulated phase, select this check box.

#### Number of quantized accumulator bits — Number of quantized accumulator bits

12 (default) | integer scalar

Specify the number of quantized accumulator bits as a scalar integer greater than one, and less than the accumulator word length. This value determines the number of entries in the lookup table.

#### Dependencies

To enable this port, select the **Quantize phase** check box.

#### Show phase quantization error port — Output quantization error

off (default) | on

Select to output the phase quantization error. When you select this check box, the **Qerr** port appears on the block icon.

#### Dependencies

To enable this parameter, select the **Quantize phase** check box.

**Output Parameters****Output signal** — Output signal

Sine (default) | Cosine | Complex exponential | Sine and cosine

Choose whether the block outputs a Sine, Cosine, Complex exponential, or both Sine and cosine signals. If you select Sine and cosine, the two signals output on different ports.

**Sample time** — Output sample period

1 (default) | positive scalar

When the block is acting as a source, specify the sample time in seconds as a positive scalar.

**Dependencies**

To enable this parameter, both **Phase increment source** and **Phase offset source** must be set to **Specify via dialog**. When either the phase increment or phase offset come in via a block input port, the sample time is inherited and this parameter is not visible.

**Samples per frame** — Samples per frame

1 (default) | positive integer

Specify the number of samples per frame as a positive integer. When the value is greater than one, the phase increment and phase offset can vary from channel to channel and from frame to frame, but they are constant along each channel in a given frame.

When the phase offset input port exists, it has the same frame status as any output port present. When the phase increment input port exists, it does not support frames.

**Dependencies**

To enable this parameter set **Phase increment source** and/or **Phase offset source** to **Specify via dialog**.

**Data Types****Rounding mode** — Rounding method

Floor (default)

This parameter is read-only.

When the input is fixed point, the NCO block always uses the rounding mode Floor.

**Overflow mode** — Overflow method

Wrap (default)

This parameter is read-only.

When the input is fixed point, the NCO block always uses the overflow mode Wrap.

**Accumulator Word Length** — Accumulator word length

16 (default) | integer from 2 to 128

Specify a **Word length** for the **Accumulator** as a positive integer from 2 to 128. The **Data Type** is always `Binary point scaling`, and the **Fraction length** is always 0.

**Output Data Type** — Output data type  
`double (default) | single | Binary point scaling`

Specify a **Data Type** for the block **Output**.

- Choose `double` or `single` for a floating-point implementation.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.

---

**Note** The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

---

**Output Word Length** — Output word length  
`16 (default) | integer from 2 to 128`

Specify a **Word length** for the block **Output** as a positive integer from 2 to 128.

#### Dependencies

To enable this parameter, set the **Data Type** for the **Output** to `Binary point scaling`.

**Output Fraction Length** — Output fraction length  
`14 (default) | integer`

Specify a **Fraction length** for the block **Output** as a scalar integer.

#### Dependencies

To enable this parameter, set the **Data Type** for the **Output** to `Binary point scaling`.

#### NCO Characterization

The **NCO Characterization** pane provides you with read-only details on the NCO signal currently being implemented by the block:

**Number of data points for lookup table** — Number of points in lookup table  
`no default`

The lookup table is implemented as a quarter-wave sine table. The number of lookup table data points is defined by

$$2^{\text{number of quantized accumulator bits}-2} + 1$$

Example: 1025

**Quarter wave sine lookup table size** — Size of quarter wave sine lookup table  
`no default`

The quarter wave sine lookup table size is defined by

$$\frac{(\text{number of data points for lookup table}) \cdot (\text{output word length})}{8} \text{ bytes}$$

Example: 2050 bytes

**Theoretical spurious free dynamic range** — Spurious free dynamic range  
no default

The spurious free dynamic range (SFDR) is calculated as follows for a lookup table with  $2^P$  entries:

$$SFDR = (6P) \text{ dB} \quad \text{without dither}$$

$$SFDR = (6P + 12) \text{ dB} \quad \text{with dither}$$

Example: 84 dBc

**Frequency resolution** — Frequency resolution  
no default

The frequency resolution is the smallest possible incremental change in frequency and is defined by:

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{ Hz}$$

Example: 15.2588 uHz

### Dependencies

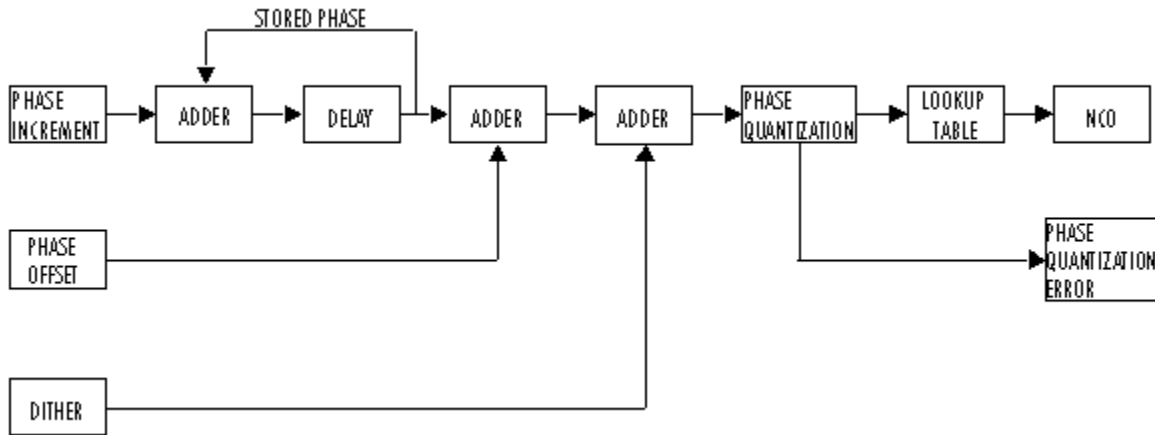

The frequency resolution only appears when you set **Phase increment source** and **Phase offset source** to Specify via dialog.

## Block Characteristics

|                                 |                       |
|---------------------------------|-----------------------|
| <b>Data Types</b>               | fixed point   integer |
| <b>Direct Feedthrough</b>       | no                    |
| <b>Multidimensional Signals</b> | no                    |
| <b>Variable-Size Signals</b>    | no                    |
| <b>Zero-Crossing Detection</b>  | no                    |

## Algorithms

The block implements the algorithm as shown in the following diagram:

The implementation of a numerically controlled oscillator (NCO) has two distinct parts. First, a phase accumulator accumulates the phase increment and adds in the phase offset. In this stage, an optional internal dither signal can also be added. The NCO output is then calculated by quantizing the results of the phase accumulator section and using them to select values from a lookup table. Since the lookup table contains a finite set of entries, in its normal mode of operation, the NCO block allows the adder's numeric values to overflow and wrap around. The Fixed-Point infrastructure then causes overflow warnings to appear on the command line. This overflow is of no consequence.

Given a desired output frequency  $F_0$ , calculate the value of the **Phase increment** block parameter with

$$phaseincrement = \left( \frac{F_0 \cdot 2^N}{F_s} \right)$$

where  $N$  is the accumulator word length and

$$F_s = \frac{1}{T_s} = \frac{1}{sampletime}$$

The frequency resolution of an NCO is defined by

$$\Delta f = \frac{1}{T_s \cdot 2^N} \text{Hz}$$

Given a desired phase offset (in radians), calculate the **Phase offset** block parameter with

$$phaseoffset = \frac{2^N \cdot desiredphaseoffset}{2\pi}$$

The spurious free dynamic range (SFDR) is estimated as follows for a lookup table with  $2^P$  entries, where  $P$  is the number of quantized accumulator bits:

$$SFDR = (6P) \text{ dB} \quad \text{without dither}$$

$$SFDR = (6P + 12) \text{ dB} \quad \text{with dither}$$

The NCO block uses a quarter-wave lookup table technique that stores table values from 0 to  $\pi/2$ . The block calculates other values on demand using the accumulator data type, then casts them into the

output data type. This can lead to quantization effects at the range limits of a given data type. For example, consider a case where you would expect the value of the sine wave to be  $-1$  at  $\pi$ . Because the lookup table value at that point must be calculated, the block might not yield exactly  $-1$ , depending on the precision of the accumulator and output data types.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### HDL Code Generation

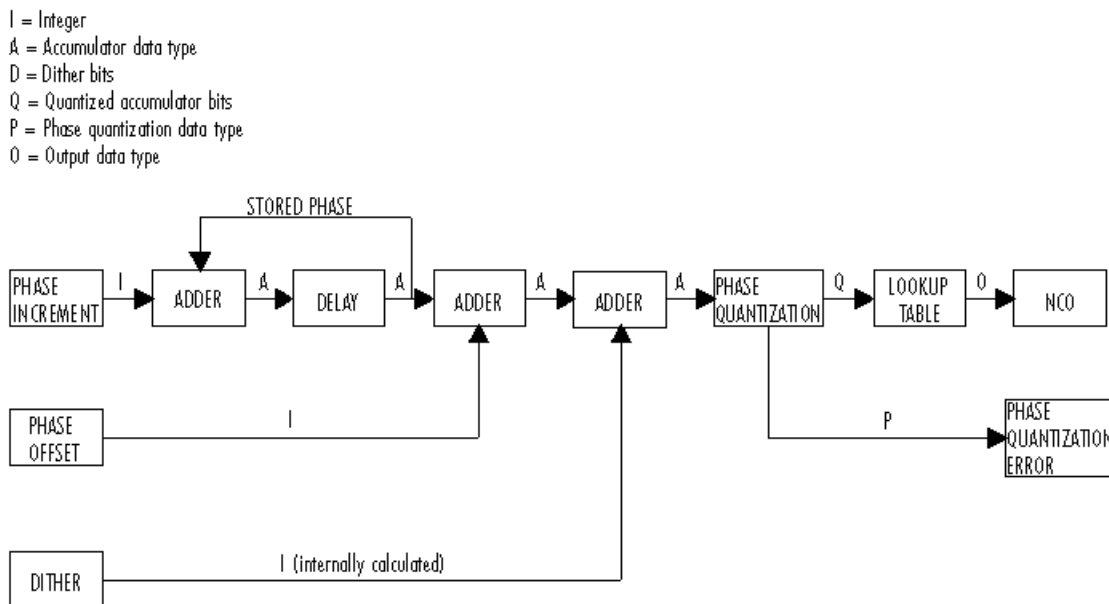

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL support for the NCO block will be removed in a future release. Use the NCO block instead. The DSP HDL Toolbox block provides an HDL-optimized algorithm with hardware-friendly control signals and simulates the latency of the HDL algorithm in Simulink.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the NCO block.

- You can set the accumulator and output data types in the block dialog box as discussed in “Data Types” on page 2-1082.

**Note** The lookup table for this block is constructed from double-precision floating-point values. Thus, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** data type to values greater than 53 bits does not improve the precision of your output.

- The phase increment and phase offset inputs must be integers or fixed-point data types with zero fraction length.
- You specify the number of quantized accumulator bits in the **Number of quantized accumulator bits** parameter.
- The phase quantization error word length is equal to the accumulator word length minus the number of quantized accumulator bits, and the fraction length is zero.

## Normalization

Perform vector normalization along rows, columns, or specified dimension

## Library

Math Functions / Math Operations

dspmathops

## Description

The Normalization block independently normalizes each row, column, or vector of the specified dimension of the input. The block accepts both fixed- and floating-point signals in the squared 2-norm mode, but only floating-point signals in the 2-norm mode. The output always has the same dimensions as the input.

This block treats an arbitrarily dimensioned input  $U$  as a collection of vectors oriented along the specified dimension. The block normalizes these vectors by either their norm or the square of their norm.

For example, consider a 3-dimensional input  $U(i,j,k)$  and assume that you want to normalize along the second dimension. First, define the 2-dimensional intermediate quantity  $V(i,k)$  such that each element of  $V$  is the norm of one of the vectors in  $U$ :

$$V(i, k) = \left( \sum_{j=1}^J U^2(i, j, k) \right)^{1/2}$$

Given  $V$ , the output of the block  $Y(i, j, k)$  in 2-norm mode is

$$Y(i, j, k) = \frac{U(i, j, k)}{V(i, k) + b}$$

In squared 2-norm mode, the block output is

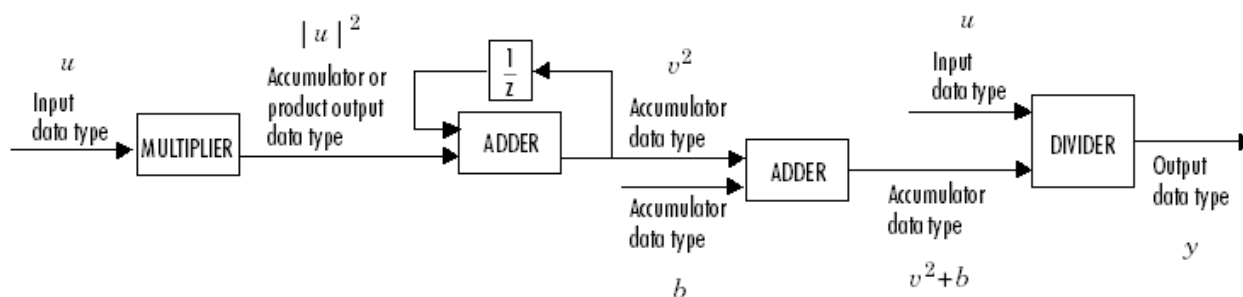

$$Y(i, j, k) = \frac{U(i, j, k)}{V(i, k)^2 + b}$$

The normalization bias,  $b$ , is typically chosen to be a small positive constant (for example, 1e-10) that prevents potential division by zero.

### Fixed-Point Data Types

The following diagram shows the data types used within the Normalization block for fixed-point signals (squared 2-norm mode only).

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”. You can set the accumulator, product output, and output data types in the block dialog as discussed in “Parameters” on page 2-1089.

## Examples

See “Zero Algorithmic Delay” in the *DSP System Toolbox User's Guide* for an example.

## Parameters

### Main Tab

#### Norm

Specify the type of normalization to perform, 2-norm or Squared 2-norm. 2-norm mode supports floating-point signals only. Squared 2-norm supports both fixed-point and floating-point signals.

#### Normalization bias

Specify the real value  $b$  to be added in the denominator to avoid division by zero. Tunable (Simulink).

#### Normalize over

Specify whether to normalize along rows, columns, or the dimension specified in the **Dimension** parameter.

#### Dimension

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This parameter is only visible if Specified dimension is selected for the **Normalize over** parameter.

### Data Types Tab

---

**Note** The parameters on this pane are only applicable to fixed-point signals when the block is in squared 2-norm mode. See “Fixed-Point Data Types” on page 2-1088 for a diagram of how the product output, accumulator, and output data types are used in this case.

---

### Rounding mode

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

### Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

### Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1088 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1088 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([], 16, 0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1088 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as product output`
- A rule that inherits a data type, for example, `Inherit: Same as input`

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

### Output Minimum

Specify the minimum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

### Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

### Product Output Data Type Assistant Parameters

#### Mode

Select how you would like to specify the data type properties of the **Product output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

#### Signedness

Specify the **Signedness** for the **Product output** data type.

#### Scaling

Specify the **Scaling** for the **Product output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Product output** data type.

**Fraction length**

Specify the **Fraction length** for the **Product output** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Accumulator Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Accumulator** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, **Inherit via internal rule**
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Accumulator** data type.

**Scaling**

Specify the **Scaling** for the **Accumulator** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Accumulator** data type.

**Fraction length**

Specify the **Fraction length** for the **Accumulator** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Output Data Type Assistant Parameters****Mode**

Select how you would like to specify the data type properties of the **Output** data type. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via internal rule`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

**Signedness**

Specify the **Signedness** for the **Output** data type.

**Scaling**

Specify the **Scaling** for the **Output** data type.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Output** data type.

**Fraction length**

Specify the **Fraction length** for the **Output** data type.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li><li>• Fixed point (signed and unsigned)</li><li>• 8-, 16-, and 32-bit signed integers</li><li>• 8-, 16-, and 32-bit unsigned integers</li></ul> |
| Output | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li><li>• Fixed point (signed and unsigned)</li><li>• 8-, 16-, and 32-bit signed integers</li><li>• 8-, 16-, and 32-bit unsigned integers</li></ul> |

# Notch-Peak Filter

Design second-order tunable notching and peaking IIR filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

The Notch-Peak Filter block filters each channel of the input signal over time using a specified center frequency and 3 dB bandwidth. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

## Algorithms

This block brings the capabilities of the `dsp.NotchPeakFilter` System object to the Simulink environment.

The filter uses a coupled allpass structure to optimize joint computation of the peak and notch response. For information on the algorithms used by the Notch-Peak filter block, see the “Algorithms” on page 4-908 section of `dsp.NotchPeakFilter`.

## Parameters

### Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- Bandwidth and center frequency (default) — Design the filter using **3 dB bandwidth (Hz)** and **Notch/Peak center frequency (Hz)**.

- **Coefficients** — Design the filter using **Bandwidth coefficient** and **Center frequency coefficient**.
- **Quality factor and center frequency** — Design the filter using **Quality factor** and **Notch/Peak center frequency (Hz)**.

This parameter is nontunable.

#### **Specify bandwidth from input port**

When you select this check box, the 3 dB bandwidth is input through the **BW** port. When you clear this check box, the 3 dB bandwidth is specified on the block dialog through the **3 dB bandwidth (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency.

#### **3 dB bandwidth (Hz)**

3 dB bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency, and clear the **Specify bandwidth from input port** parameter. The default is 2205. This parameter is tunable.

#### **Specify center frequency from input port**

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Notch/Peak center frequency (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

#### **Notch/Peak center frequency (Hz)**

Center frequency of the notch and peak of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify center frequency from input port** parameter. The default is 11025. This parameter is tunable.

#### **Specify bandwidth coefficient from input port**

When you select this check box, the bandwidth coefficient is input through the port, **BWCoeff**. When you clear this check box, the bandwidth coefficient is specified on the block dialog through the **Bandwidth coefficient** parameter.

This parameter applies when you set **Filter specification** to Coefficients.

#### **Bandwidth coefficient**

Coefficient that determines the 3 dB bandwidth of the filter, specified as a finite numeric scalar in the range  $[-1 \ 1]$ .

- -1 corresponds to the maximum 3 dB bandwidth (one-fourth the sample rate of the input signal).
- 1 corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to Coefficients and clear the **Specify bandwidth coefficient from input port** parameter. The default is 0.72654. This parameter is tunable.

**Specify center frequency coefficient from input port**

When you select this check box, the center frequency coefficient is input through the **FcCoeff** port. When you clear this check box, the center frequency coefficient is specified on the block dialog through the **Center frequency coefficient** parameter.

This parameter applies when you set **Filter specification** to Coefficients.

**Center frequency coefficient**

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to Coefficients and clear the **Specify center frequency coefficient from input port** parameter. The default is 0, which corresponds to quarter the sample rate of the input signal. This parameter is tunable.

**Specify quality factor from input port**

When you select this check box, the quality factor is input through the **Q** port. When you clear this check box, the quality factor is specified on the block dialog through the **Quality factor** parameter.

This parameter applies when you set **Filter specification** to Quality factor and center frequency.

**Quality factor**

Quality factor of the notch and peak filter, specified as a real positive scalar. The quality factor is defined as **Notch/Peak center frequency (Hz) / 3 dB bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to Quality factor and center frequency and clear the **Specify quality factor from input port** parameter. The default is 5. This parameter is tunable.

**Output**

Output of the filter block, specified as one of the following:

- Notch and Peak (default) — The block outputs the notch and peak responses of the filter.
- Notch — The block outputs the notch response of the filter.
- Peak — The block outputs the peak response of the filter.

This parameter is nontunable.

**Inherit sample rate from input**

When you select this check box, the block sample rate is computed as  $N/T_s$ , where  $N$  is the frame size of the input signal, and  $T_s$  is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

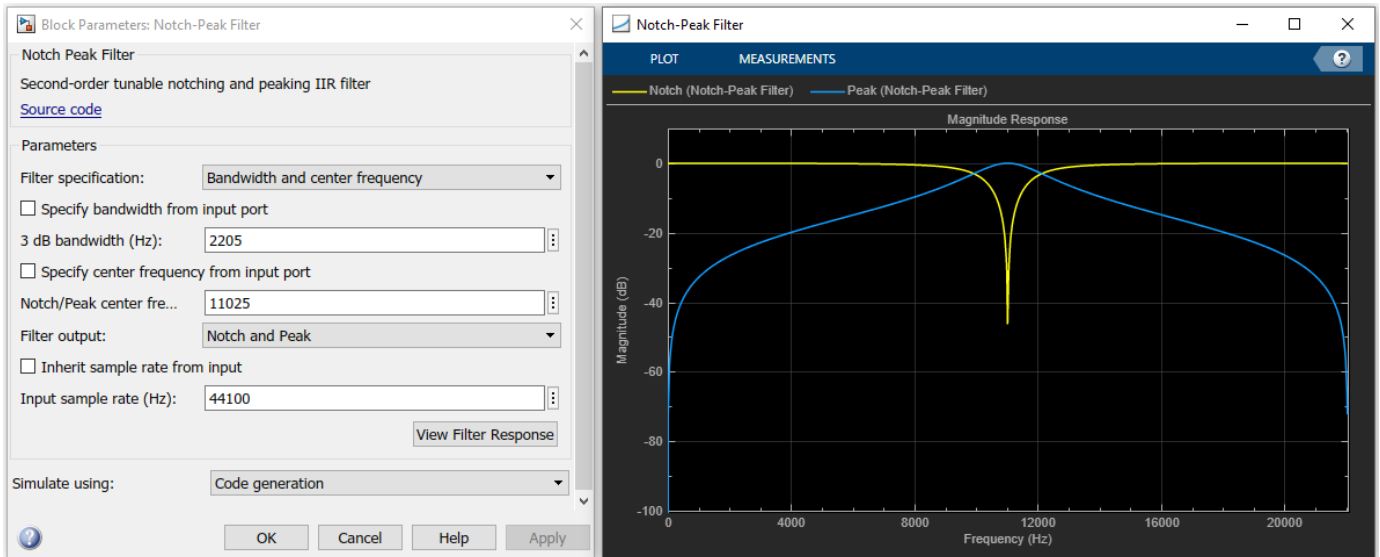

**Input sample rate (Hz)**

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

**View Filter Response**

Opens the Dynamic Filter Visualizer window and displays the magnitude and phase response of the notch-peak filter. The response is based on the parameters you select in the Block Parameters

dialog box. To update the response while the visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the frequency response measurements from the interface of the visualizer.

On the **Plot** tab, you can enable the legend, specify to plot both magnitude and phase responses of the filter, modify the plot settings, generate a script to re-create the plot, and even save or share the settings.

On the **Measurements** tab, you can enable data cursors, and display the peak values of the filter response.

For more details on the Dynamic Filter Visualizer interface and its tools, see “Configure Filter Visualizer”.

### Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

Parametric EQ Filter

# Nyquist Filter

Design Nyquist filter

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-1104.

## Dialog Box

See “Nyquist Filter Design — Main Pane” on page 5-634 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify your filter format, such as the impulse response and the filter order.

#### Band

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region,  $F_c$ , is calculated using the value for **Band**:

$$F_c = F_s / (2 \cdot \mathbf{Band}).$$

The default value, 2, corresponds to a halfband filter.

### Impulse response

Select either FIR or IIR from the drop-down list. FIR is the default. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. These options are both available only when **Band** is 2. For values of **Band** greater than 2, only FIR designs are supported.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Filter order mode

Select either Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, the block specifies a single-rate filter.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Filter order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default value is 2.

## Frequency Specifications

The parameters in this group allow you to specify your filter response curve.

### Frequency constraints

Select the filter features that the block uses to define the frequency response characteristics.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select Normalized (0–1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the

specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Transition width**

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

**Magnitude Specifications**

Parameters in this group specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. From the drop-down list, select one of the following options:

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

**Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure of your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is Butterworth, and the default FIR method is Kaiser window.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 20 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Minimum order

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select **Any**, **Even**, or **Odd** from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. The block applies that slope to the stopband.
- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. The block applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## Filter Implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Input processing

Specify how the block should process the input. The available options may vary depending on he settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## Version History

Introduced in R2006b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Nyquist Filter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- **Filter type** is set to **Single-rate**, **Decimator**, or **Interpolator**.
- For **Filter type** that is set to **Single-rate**, **Structure** is set to **Direct-form FIR** or **Direct-form FIR transposed**.
- For **Filter type** that is set to **Decimator**, **Structure** is set to **Direct-form FIR polyphase decimator** and **Rate options** is set to **Enforce single-rate processing**.
- For **Filter type** that is set to **Interpolator**:

- **Interpolation Factor** cannot be equal to 1.
- **Rate options** is set to Enforce single-rate processing.
- **Input processing** is set to Columns as channels (frame based).
- Input signal has a data type of single or double.
- Input port dimensions cannot be equal to [1 1].

The SIMD technology significantly improves the performance of the generated code.

## Octave Filter

Design octave filter

## Compatibility

---

**Note** The Octave Filter block will be removed from DSP System Toolbox in a future release. Existing instances of the block continue to run. For new code, use the Octave Filter block from Audio Toolbox instead.

---

## Library

Filtering / Filter Designs

dspfdesign

## Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

## Dialog Box

See “Octave Filter Design — Main Pane” on page 5-638 for more information about the parameters of this block. The **Data Types** and **Code Generation** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

## Filter Specifications

### Order

Specify filter order. Possible values are: 4, 6, 8, 10.

### Bands per octave

Specify the number of bands per octave. Possible values are: 1, 3, 6, 12, 24.

### Frequency units

Specify frequency units as Hz or kHz.

### Input sample rate

Specify the input sampling frequency in the frequency units specified previously.

### Center Frequency

Select from the drop-down list of available center frequency values.

## Algorithm

### Design Method

Butterworth is the design method used for this type of filter.

### Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

## Filter Implementation

### Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use variable names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Version History

Introduced in R2007a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

# Offset

Truncate vectors by removing or keeping beginning or ending values

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Offset block removes or keeps values from the beginning or end of the input vectors. The number of values to remove or keep is determined by the offset value that you specify through the **O** ports (**O1**, **O2**, ...). The length of the truncated vector is determined by the **Output port length** and **Output length** parameters. The **Number of input data-offset pairs** parameter determines the number of input data-offset pairs.

## Ports

### Input

**In1** — First input data

scalar | vector

Specify the first input data as a scalar or a vector. The inputs to the **In** ports (**In1**, **In2**, ...) must be of the same size and data type.

When the input is fixed-point, it is signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

**O1** — First offset value

integer

Specify the offset value that the block uses to truncate the first input data as an integer. The offset value determines the number of samples the block removes or keeps at the beginning or at the end of the first data.

The inputs to the **O** ports (**O1**, **O2**, ...) must have the same data type. The block rounds any offset value that is a noninteger value to the nearest integer value. If the offset value is out of the  $[0 N]$  range, then the **Action for out of range offset value** parameter determines how the block behaves.  $N$  is the input vector length.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**In2** — Second input data

scalar | vector

Specify the second input data as a scalar or a vector. The inputs to the **In** ports (**In1**, **In2**, ...) must be of the same size and data type.

When the input is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

### **O2** — Second offset value

integer

Specify the offset value that the block uses to truncate the second input data as an integer. The offset value determines the number of samples the block removes or keeps at the beginning or at the end of the second data.

The inputs to the **O** ports (**O1**, **O2**, ...) must have the same data type. The block rounds any offset value that is a noninteger value to the nearest integer value. If the offset value is out of the  $[0 N]$  range, then the **Action for out of range offset value** parameter determines how the block behaves.  $N$  is the input vector length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### **Output**

#### **Out1** — First truncated data

scalar | vector

The block returns the truncated data as a scalar or a vector. The length of the truncated data depends on the **Output port length** and the **Output length** parameters. If **Output port length** is set to `Same as input`, the truncated data has the same size as the input data. If **Output port length** is set to `User-defined`, then the **Output length** parameter determines the length of the output data.

There is one output port for each pair of **In** and **O** ports.

The truncated output has the same data type as the input data. When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

#### **Out2** — Second truncated data

scalar | vector

The block returns the truncated data as a scalar or a vector. The length of the truncated data depends on the **Output port length** and the **Output length** parameters. If **Output port length** is set to `Same as input`, the truncated data has the same size as the input data. If **Output port length** is set to `User-defined`, then the **Output length** parameter determines the length of the output data.

There is one output port for each pair of **In** and **O** ports.

The truncated output has the same data type as the input data. When the output is fixed-point, it is signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## **Parameters**

**Mode** — Specify which values to discard and which values to keep

`Remove beginning samples (default)` | `Remove ending samples` | `Keep beginning samples` | `Keep ending samples`

Use this parameter to specify which values the block discards and which values the block keeps from the input vector.

Select from the following:

- **Remove beginning samples** -- Discard the initial values of a vector.
- **Remove ending samples** -- Discard the final values of a vector.
- **Keep beginning samples** -- Retain the initial values of a vector.
- **Keep ending samples** -- Retain the final values of a vector.

**Number of input data-offset pairs** — Number of input data-offset pairs

2 (default) | positive integer

Use the **Number of input data-offset pairs** parameter to specify the number of inputs to the block. The number of input ports is twice the scalar value you specify in this parameter. For example, if you enter 3, input ports **In1**, **O1**, **In2**, **O2**, **In3**, and **O3** appear on the block.

**Output port length** — Mode to specify output port length

Same as input (default) | User-defined

Use this parameter to specify the length of the output vectors. If you select **Same as input**, the output vectors have the same length as the input vectors. If you select **User-defined**, you can enter the desired length in the **Output length** parameter.

**Output length** — Desired length of output vectors

9 (default) | positive integer

Enter a scalar that represents the desired length of the output vectors. If the desired output length that you specify is greater than the number of values that the block extracts from the input vector, the block zero-pads the end of the vector to reach the length that you specify.

### Dependencies

This parameter is visible only if you set the **Output port length** parameter to **User-defined**.

**Action for out of range offset value** — Action for out of range offset value

Clip (default) | Clip and warn | Error

Use this parameter to determine how the block behaves when an offset value is not in the range such that  $0 \leq \text{offset value} \leq N$ , where  $N$  is the input vector length.

- **Clip** -- Offset values less than 0 are set to 0 and offset values greater than  $N$  are set to  $N$ .
- **Clip and warn** -- Offset values less than 0 are set to 0 and offset values greater than  $N$  are set to  $N$ . In addition, the block displays a warning message.
- **Error** -- Simulation stops and the block displays an error when the offset values are out of range.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |

## Overlap-Add FFT Filter (Obsolete)

Implement overlap-add method of frequency-domain filtering

### Library

Filtering / Filter Implementations

dsparch4

### Description

---

**Note** The Overlap-Add FFT Filter block has been replaced with the Frequency-Domain FIR Filter block. Existing instances of the Overlap-Add FFT Filter block continue to run.

---

The Overlap-Add FFT Filter block uses an FFT to implement the *overlap-add method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is  $M$  times faster than its data input rate, where  $M$  is the length of the columns in the input (frame-size).

The block breaks the scalar input sequence  $u$ , of length  $nu$ , into length- $L$  nonoverlapping data sections,

which it linearly convolves with the filter's FIR coefficients,

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_{n+1}z^{-n}$$

The numerator coefficients for  $H(z)$  are specified as a vector by the **FIR coefficients** parameter. The coefficient vector,  $\mathbf{b} = [b(1) \ b(2) \ \dots \ b(n+1)]$ , can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to `Complex`. Otherwise, the default **Output** setting, `Real`, instructs the block to take only the real part of the solution.

The block's overlap-add operation is equivalent to

$$y = \text{ifft}(\text{fft}(u(i:i+L-1), \text{nfft}) .* \text{fft}(b, \text{nfft}))$$

where you specify `nfft` in the **FFT size** parameter as a power-of-two value greater (typically *much* greater) than  $n+1$ . Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The block overlaps successive output sections by  $n$  points and sums them.

The first  $L$  samples of each summation are output in sequence. The block chooses the parameter  $L$  based on the filter order and the FFT size.

$$L = \text{nfft} - n$$

### Latency

In *single-tasking* operation, the Overlap-Add FFT Filter block has a latency of  $\text{nfft} - n + 1$  samples. The first  $\text{nfft} - n + 1$  consecutive outputs from the block are zero; the first filtered input value appears at the output as sample  $\text{nfft} - n + 2$ .

In *multitasking* operation, the Overlap-Add FFT Filter block has a latency of  $2 * (\text{nfft} - n) + 1$  samples. The first  $2 * (\text{nfft} - n) + 1$  consecutive outputs from the block are zero; the first filtered input value appears at the output as sample  $2 * (\text{nfft} - n) + 3$ .

---

**Note** For more information on latency and the Simulink software tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Parameters

### FFT size

The size of the FFT, which should be a power-of-two value greater than the length of the specified FIR filter.

### FIR coefficients

The filter numerator coefficients.

### Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

## Overlap-Save FFT Filter (Obsolete)

Implement overlap-save method of frequency-domain filtering

### Library

Filtering / Filter Implementations

dsparch4

### Description

---

**Note** The Overlap-Save FFT Filter block has been replaced with the Frequency-Domain FIR Filter block. Existing instances of the Overlap-Save FFT Filter block continue to run.

---

The Overlap-Save FFT Filter block uses an FFT to implement the *overlap-save method*, a technique that combines successive frequency-domain filtered sections of an input sequence.

The block accepts vector or matrix inputs, and treats each column of the input as an individual channel. The block unbuffers the input data into row vectors such that the length of the output vector is equal to the number of channels in the input. The data output rate of the block is  $M$  times faster than its data input rate, where  $M$  is the length of the columns in the input (frame-size).

Overlapping sections of input  $u$  are circularly convolved with the FIR filter coefficients

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_{n+1}z^{-n}$$

The numerator coefficients for  $H(z)$  are specified as a vector by the **FIR coefficients** parameter. The coefficient vector,  $\mathbf{b} = [b(1) \ b(2) \ \dots \ b(n+1)]$ , can be generated by one of the filter design functions in the Signal Processing Toolbox product, such as `fir1`. All filter states are internally initialized to zero.

When either the filter coefficients or the inputs to the block are complex, the **Output** parameter should be set to **Complex**. Otherwise, the default **Output** setting, **Real**, instructs the block to take only the real part of the solution.

The circular convolution of each section is computed by multiplying the FFTs of the input section and filter coefficients, and computing the inverse FFT of the product.

```
y = ifft(fft(u(i:i+(L-1))),nfft) .* fft(b,nfft)
```

where you specify `nfft` in the **FFT size** parameter as a power of two value greater (typically *much* greater) than  $n+1$ . Values for **FFT size** that are not powers of two are rounded upwards to the nearest power-of-two value to obtain `nfft`.

The first  $n$  points of the circular convolution are invalid and are discarded. The Overlap-Save FFT Filter block outputs the remaining  $n_{\text{fft}} - n$  points, which are equivalent to the linear convolution.

### Latency

In *single-tasking* operation, the Overlap-Save FFT Filter block has a latency of  $n_{\text{fft}} - n + 1$  samples. The first  $n_{\text{fft}} - n + 1$  consecutive outputs from the block are zero; the first filtered input value appears at the output as sample  $n_{\text{fft}} - n + 2$ .

In *multitasking* operation, the Overlap-Save FFT Filter block has a latency of  $2 * (n_{\text{fft}} - n + 1)$  samples. The first  $2 * (n_{\text{fft}} - n + 1)$  consecutive outputs from the block are zero; the first filtered input value appears at the output as sample  $2 * (n_{\text{fft}} - n) + 3$ .

---

**Note** For more information on latency and the Simulink environment tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Parameters

### FFT size

The size of the FFT, which should be a power of two value greater than the length of the specified FIR filter.

### FIR coefficients

The filter numerator coefficients.

### Output

The complexity of the output; `Real` or `Complex`. When the input signal or the filter coefficients are complex, this should be set to `Complex`.

## Overwrite Values

Overwrite submatrix or subdiagonal of input

## Library

- Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtx3`

- Signal Management / Indexing

`dspindex`

## Description

The Overwrite Values block overwrites a contiguous submatrix or subdiagonal of an input matrix. You can provide the overwriting values by typing them in a block parameter, or through an additional input port, which is useful for providing overwriting values that change at each time step.

The block accepts scalars, vectors and matrices. The output always has the same size as the original input signal, not necessarily the same size as the signal containing the overwriting values. The input(s) and output of this block must have the same data type.

### Specifying the Overwriting Values

The **Source of overwriting value(s)** parameter determines how you must provide the overwriting values, and has the following settings.

- Specify via dialog** — You must provide the overwriting value(s) in the **Overwrite with** parameter. The block uses the same overwriting values to overwrite the specified portion of the input at each time step. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 2-1120.
- Second input port** — You must provide overwriting values through a second block input port, *V*. Use this setting to provide different overwriting values at each time step. The output inherits its size and rate from the input signal, *not* the overwriting values.

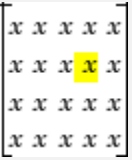

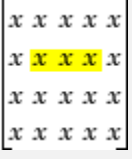

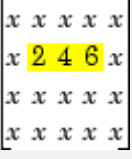

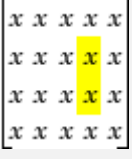

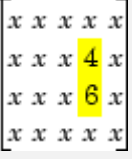

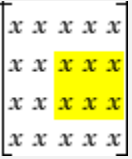

The rate at which you provide the overwriting values through input port V must match the rate at which the block receives each input matrix at input port A. In other words, the input signals must have the same Simulink sample time.

**Valid Overwriting Values**
