The overwriting values can be a single constant, vector, or matrix, depending on the portion of the input you are overwriting, regardless of whether you provide the overwriting values through an input port or by providing them in the **Overwrite with** parameter.

**Valid Overwriting Values**

| Portion of Input to Overwrite  | Valid Overwriting Values  | Example   |
|--|---|---|
| <p>A single element in the input</p>                    | <p>Any constant value, <math>v</math></p>                             | <p><math>v = 9</math></p>   |
| <p>A length-<math>k</math> portion of the diagonal</p>  | <p>Any length-<math>k</math> column or row vector, <math>v</math></p> | <p><math>k = 3 \quad v = [2 \ 4 \ 6] \quad \text{or} \quad \begin{bmatrix} 2 \\ 4 \\ 6 \end{bmatrix}</math></p>         |
| <p>A length-<math>k</math> portion of a row</p>        | <p>Any length-<math>k</math> row vector, <math>v</math></p>           | <p><math>k = 3 \quad v = [2 \ 4 \ 6]</math></p>    |
| <p>A length-<math>k</math> portion of a column</p>    | <p>Any length-<math>k</math> column vector, <math>v</math></p>        | <p><math>k = 2 \quad v = \begin{bmatrix} 4 \\ 6 \end{bmatrix}</math></p>    |
| <p>An <math>m</math>-by-<math>n</math> submatrix</p>  | <p>Any <math>m</math>-by-<math>n</math> matrix, <math>v</math></p>    | <p><math>m = 2 \quad n = 3 \quad v = \begin{bmatrix} 4 &amp; 5 &amp; 6 \\ 7 &amp; 8 &amp; 9 \end{bmatrix}</math></p>  |

This block supports Simulink virtual buses.

## Parameters

---

**Note** Only some of the following parameters are visible in the dialog box at any one time.

---

### Overwrite

Determines whether to overwrite a specified submatrix or a specified portion of the diagonal.

### Source of overwriting value(s)

Determines where you must provide the overwriting values: either through an input port, or by providing them in the **Overwrite with** parameter. For more information, see “Specifying the Overwriting Values” on page 2-1119.

### Overwrite with

The value(s) with which to overwrite the specified portion of the input matrix. Enabled only when **Source of overwriting value(s)** is set to *Specify via dialog*. To learn how to specify valid overwriting values, see “Valid Overwriting Values” on page 2-1120.

### Row span

The range of input rows to be overwritten. Options are *All rows*, *One row*, or *Range of rows*. For descriptions of these options, see “Parameters” on page 2-1122.

### Row/Starting row

The input row that is the first row of the submatrix that the block overwrites. For a description of the options for the **Row** and **Starting row** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row** is enabled when **Row span** is set to *One row*, and **Starting row** when **Row span** is set to *Range of rows*.

### Row index/Starting row index

Index of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row index** is enabled when **Row** is set to *Index*, and **Starting row index** when **Starting row** is set to *Index*.

### Row offset/Starting row offset

The offset of the input row that is the first row of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Row offset** is enabled when **Row** is set to *Offset from middle* or *Offset from last*, and **Starting row offset** is enabled when **Starting row** is set to *Offset from middle* or *Offset from last*.

### Ending row

The input row that is the last row of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Row span** is set to *Range of rows*, and **Starting row** is set to any option but *Last*.

### Ending row index

Index of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to *Index*.

**Ending row offset**

The offset of the input row that is the last row of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. Enabled when **Ending row** is set to `Offset from middle` or `Offset from last`.

**Column span**

The range of input columns to be overwritten. Options are `All columns`, `One column`, or `Range of columns`. For descriptions of the analogous row options, see “Parameters” on page 2-1122.

**Column/Starting column**

The input column that is the first column of the submatrix that the block overwrites. For a description of the options for the **Column** and **Starting column** parameters, see Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column** is enabled when **Column span** is set to `One column`, and **Starting column** when **Column span** is set to `Range of columns`.

**Column index/Starting column index**

Index of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column index** is enabled when **Column** is set to `Index`, and **Starting column index** when **Starting column** is set to `Index`.

**Column offset/Starting column offset**

The offset of the input column that is the first column of the submatrix that the block overwrites. See how to use these parameters in Settings for Row, Column, Starting Row, and Starting Column Parameters. **Column offset** is enabled when **Column** is set to `Offset from middle` or `Offset from last`, and **Starting column offset** is enabled when **Starting column** is set to `Offset from middle` or `Offset from last`.

**Ending column**

The input column that is the last column of the submatrix that the block overwrites. For a description of this parameter's options, see Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Column span** is set to `Range of columns`, and **Starting column** is set to any option but `Last`.

**Ending column index**

Index of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Index`.

**Ending column offset**

The offset of the input column that is the last column of the submatrix that the block overwrites. See how to use this parameter in Settings for Ending Row and Ending Column Parameters. This parameter is enabled when **Ending column** is set to `Offset from middle` or `Offset from last`.

**Diagonal span**

The range of diagonal elements to be overwritten. Options are `All elements`, `One element`, or `Range of elements`. For descriptions of these options, see “Overwriting a Subdiagonal” on page 2-1127.

**Element/Starting element**

The input diagonal element that is the first element in the subdiagonal that the block overwrites. For a description of the options for the **Element** and **Starting element** parameters, see Element

and Starting Element Parameters. **Element** is enabled when **Element span** is set to One element, and **Starting element** when **Element span** is set to Range of elements.

#### **Element index/Starting element index**

Index of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters.

**Element index** is enabled when **Element** is set to Index, and **Starting element index** when **Starting element** is set to Index.

#### **Element offset/Starting element offset**

The offset of the input diagonal element that is the first element of the subdiagonal that the block overwrites. See how to use these parameters in Element and Starting Element Parameters.

**Element offset** is enabled when **Element** is set to Offset from middle or Offset from last, and **Starting element offset** is enabled when **Starting element** is set to Offset from middle or Offset from last.

#### **Ending element**

The input diagonal element that is the last element of the subdiagonal that the block overwrites. For a description of this parameter's options, see Ending Element Parameters. This parameter is enabled when **Element span** is set to Range of elements, and **Starting element** is set to any option but Last.

#### **Ending element index**

Index of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to Index.

#### **Ending element offset**

The offset of the input diagonal element that is the last element of the subdiagonal that the block overwrites. See how to use this parameter in Ending Element Parameters. This parameter is enabled when **Ending element** is set to Offset from middle or Offset from last.

## **Examples**

### **Overwriting a Submatrix**

To overwrite a submatrix, follow these steps:

- 1 Set the **Overwrite** parameter to Submatrix.
- 2 Specify the overwriting values as described in “Specifying the Overwriting Values” on page 2-1119.
- 3 Specify which rows and columns of the input matrix are contained in the submatrix that you want to overwrite by setting the **Row span** parameter to one of the following options and the **Column span** to the analogous column-related options:
  - All rows — The submatrix contains all rows of the input matrix.
  - One row — The submatrix contains only one row of the input matrix, which you must specify in the **Row** parameter, as described in the following table.
  - Range of rows — The submatrix contains one or more rows of the input, which you must specify in the **Starting Row** and **Ending row** parameters, as described in the following tables.
- 4 When you set **Row span** to One row or Range of rows, you need to further specify the row(s) contained in the submatrix by setting the **Row** or **Starting row** and **Ending row** parameters.

Likewise, when you set **Column span** to One column or Range of columns, you must further specify the column(s) contained in the submatrix by setting the **Column** or **Starting column** and **Ending column** parameters. For descriptions of the settings for these parameters, see the following tables.

#### Settings for Row, Column, Starting Row, and Starting Column Parameters

| Settings for Specifying the Submatrix's First Row or Column | First Row of Submatrix<br>(Only row for Row span = One row)   | First Column of Submatrix<br>(Only row for Row span = One row)   |
|---|---|--|
| First   | First row of the input  | First column of the input  |
| Index   | Input row specified in the <b>Row index</b> parameter   | Input column specified in the <b>Column index</b> parameter  |
| Offset from last  | Input row with the index $M - \text{rowOffset}$ where $M$ is the number of input rows, and $\text{rowOffset}$ is the value of the <b>Row offset</b> or <b>Starting row offset</b> parameter                     | Input column with the index $N - \text{colOffset}$ where $N$ is the number of input columns, and $\text{colOffset}$ is the value of the <b>Column offset</b> or <b>Starting column offset</b> parameter                        |
| Last  | Last row of the input   | Last column of the input   |
| Offset from middle  | Input row with the index $\text{floor}(M/2 + 1 - \text{rowOffset})$ where $M$ is the number of input rows, and $\text{rowOffset}$ is the value of the <b>Row offset</b> or <b>Starting row offset</b> parameter | Input column with the index $\text{floor}(N/2 + 1 - \text{colOffset})$ where $N$ is the number of input columns, and $\text{colOffset}$ is the value of the or <b>Column offset</b> or <b>Starting column offset</b> parameter |
| Middle  | Input row with the index $\text{floor}(M/2 + 1)$ where $M$ is the number of input rows  | Input columns with the index $\text{floor}(N/2 + 1)$ where $N$ is the number of input columns  |

## Settings for Ending Row and Ending Column Parameters

| Settings for Specifying the Submatrix's Last Row or Column | Last Row of Submatrix  | Last Column of Submatrix  |
|--|--|---|
| Index  | Input row specified in the <b>Ending row index</b> parameter   | Input column specified in the <b>Ending column index</b> parameter  |
| Offset from last   | Input row with the index $M - \text{rowOffset}$ where $M$ is the number of input rows, and $\text{rowOffset}$ is the value of the <b>Ending row offset</b> parameter                     | Input column with the index $N - \text{colOffset}$ where $N$ is the number of input columns, and $\text{colOffset}$ is the value of the <b>Ending column offset</b> parameter                     |
| Last   | Last row of the input  | Last column of the input  |
| Offset from middle   | Input row with the index $\text{floor}(M/2 + 1 - \text{rowOffset})$ where $M$ is the number of input rows, and $\text{rowOffset}$ is the value of the <b>Ending row offset</b> parameter | Input column with the index $\text{floor}(N/2 + 1 - \text{colOffset})$ where $N$ is the number of input columns, and $\text{colOffset}$ is the value of the <b>Ending column offset</b> parameter |
| Middle   | Input row with the index $\text{floor}(M/2 + 1)$ where $M$ is the number of input rows   | Input columns with the index $\text{floor}(N/2 + 1)$ where $N$ is the number of input columns   |

For example, to overwrite the lower-right 2-by-3 submatrix of a 3-by-5 input matrix with all zeros, enter the following set of parameters:

- **Overwrite** = Submatrix
- **Source of overwriting value(s)** = Specify via dialog
- **Overwrite with** = 0
- **Row span** = Range of rows
- **Starting row** = Index
- **Starting row index** = 2
- **Ending row** = Last
- **Column span** = Range of columns
- **Starting column** = Offset from last
- **Starting column offset** = 2
- **Ending column** = Last

The following figure shows the block with the above settings overwriting a portion of a 3-by-5 input matrix.

There are often several possible parameter combinations that select the *same* submatrix from the input. For example, instead of specifying Last for **Ending column**, you could select the same submatrix by specifying

- **Ending column** = Index
- **Ending column index** = 5

### Overwriting a Subdiagonal

To overwrite a subdiagonal, follow these steps:

- 1 Set the **Overwrite** parameter to **Diagonal**.
- 2 Specify the overwriting values as described in “Specifying the Overwriting Values” on page 2-1119.
- 3 Specify the subdiagonal that you want to overwrite by setting the **Diagonal span** parameter to one of the following options:
  - All elements — Overwrite the entire input diagonal.
  - One element — Overwrite one element in the diagonal, which you must specify in the **Element** parameter (described below).
  - Range of elements — Overwrite a portion of the input diagonal, which you must specify in the **Starting element** and **Ending element** parameters, as described in the following table.
- 4 When you set **Diagonal span** to One element or Range of elements, you need to further specify which diagonal element(s) to overwrite by setting the **Element** or **Starting element** and **Ending element** parameters. See the following tables.

### Element and Starting Element Parameters

| Settings for Element and Starting Element Parameters | First Element in Subdiagonal<br>(Only element when Diagonal span = One element)  |
|--|--|
| First  | Diagonal element in first row of the input   |
| Index  | $k$ th diagonal element, where $k$ is the value of the <b>Element index</b> or <b>Starting element index</b> parameter   |
| Offset from last                                     | Diagonal element in the row with the index $M - \text{offset}$<br>where $M$ is the number of input rows, and $\text{offset}$ is the value of the <b>Element offset</b> or <b>Starting element offset</b> parameter                           |
| Last   | Diagonal element in the last row of the input  |
| Offset from middle                                   | Diagonal element in the input row with the index $\text{floor}(M/2 + 1 - \text{offset})$<br>where $M$ is the number of input rows, and $\text{offset}$ is the value of the <b>Element offset</b> or <b>Starting element offset</b> parameter |
| Middle   | Diagonal element in the input row with the index $\text{floor}(M/2 + 1)$<br>where $M$ is the number of input rows  |

### Ending Element Parameters

| Settings for Ending Element Parameter | Last Element in Subdiagonal  |
|---------------------------------------|--|
| Index                                 | $k$ th diagonal element, where $k$ is the value of the <b>Ending element index</b> parameter   |
| Offset from last                      | Diagonal element in the row with the index $M - \text{offset}$ where $M$ is the number of input rows, and $\text{offset}$ is the value of the <b>Ending element offset</b> parameter                           |
| Last                                  | Diagonal element in the last row of the input  |
| Offset from middle                    | Diagonal element in the input row with the index $\text{floor}(M/2 + 1 - \text{offset})$ where $M$ is the number of input rows, and $\text{offset}$ is the value of the <b>Ending element offset</b> parameter |
| Middle                                | Diagonal element in the input row with the index $\text{floor}(M/2 + 1)$ where $M$ is the number of input rows   |

### Supported Data Types

The input(s) and output of this block must have the same data type.

| Port | Supported Data Types  |
|------|---|
| A    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Bus</li> </ul> |
| V    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Bus</li> </ul> |

| Port | Supported Data Types  |
|------|---|
| B    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> <li>• Bus</li> </ul> |

reshape

### Blocks

Reshape | Selector | Submatrix | Variable Selector

## Pad

Pad or truncate specified dimension(s)

### Libraries:

DSP System Toolbox / Signal Operations

## Description

The Pad block extends or crops the dimensions of an input signal by padding or truncating along its columns, rows, columns and rows, or along any other dimension(s) that you specify. The block truncates the input when you specify output dimensions that are shorter than the corresponding input dimensions. If the input and output lengths are the same, the block acts as a pass-through.

You can enter the pad value in the block mask or via an input port. You can enter output sizes in the block mask, or have the block pad the specified dimensions until their length is the next highest power of two. The **Pad signal at** parameter controls whether the block pads or truncates the input signal dimensions at the beginning, end, or both. For odd pad or truncation lengths, the extra pad or truncation value is applied at the end of the signal. When the block is in the **Specified dimensions** mode, you can specify either the output size or the pad size.

You can configure the block to warn or error when an input signal is truncated using the **Action when truncation occurs** parameter.

## Ports

### Input

#### Input 1 — Data input

scalar | vector | matrix | *N*-D array

Specify the input as a scalar, vector, matrix, or an *N*-D array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

### Output

#### Output 1 — Padded or truncated output

scalar | vector | matrix | *N*-D array

Output of the Pad block. The size and dimension of the output depends on whether the block has padded or truncated the input along the specified dimension. The data type and complexity of the output matches that of the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | bus

## Parameters

**Pad over** — Dimension over which to pad or truncate

Columns (default) | Rows | Columns and rows | None | Specified dimensions

Specify the dimensions over which to pad or truncate:

- Columns
- Rows
- Columns and rows
- None
- Specified dimensions

**Dimensions to pad** — Specify dimension over which to pad or truncate

1 (default) | scalar | vector

Specify the one-based dimension(s) over which to pad or truncate. The value for this parameter can be a scalar or a vector. For example, specify 1 to pad columns. Specify [1 2] to pad columns and rows. Specify [1 3 5] to pad the first, third, and fifth dimensions.

### Dependencies

This parameter appears only when you set **Pad over** to Specified dimensions.

**Pad value source** — Source of pad value

Specify via dialog (default) | Input port

Choose how you specify the pad value. The pad value can come from the dialog or from an input port:

- If you select Specify via dialog, the **Pad value** parameter appears.
- If you select Input port, the PVal port appears on the block icon.

**Pad value** — Pad value

0 (default) | scalar

Specify the constant scalar value with which to pad the input.

**Tunable:** Yes

### Dependencies

This parameter appears only when you set **Pad value source** to Specify via dialog.

**Output column mode** — Mode of specifying column length

User-specified | Next power of two

Choose how you specify the column length of the output:

- If you select User-specified, the **Column size** parameter appears.

- If you select `Next power of two`, the block pads the output columns until their length is the next highest power of two. If the column length is already a power of two, the block does not pad the columns.

**Dependencies**

This parameter appears only when you set **Pad over** to `Columns` or `Columns and rows`.

**Column size** — Column length of output

1 | scalar

Specify the column length of the output. If the specified column length is longer than the input column length, the block pads the columns. If the specified column length is shorter than the input column length, the block truncates the columns.

**Dependencies**

This parameter appears only when you set **Output column mode** to `User-specified`.

**Output row mode** — Mode of specifying row length

`User-specified (default)` | `Next power of two`

Choose how you specify the row length of the output:

- If you select `User-specified`, the **Row size** parameter appears.
- If you select `Next power of two`, the block pads the output rows until their length is the next highest power of two. If the row length is already a power of two, the block does not pad the rows.

**Dependencies**

This parameter appears only when you set **Pad over** to `Rows` or `Columns and rows`.

**Row size** — Row length of output

1 | scalar

Specify the row length of the output. If the specified row length is longer than the input row length, the block pads the rows. If the specified row length is shorter than the input row length, the block truncates the rows.

**Dependencies**

This parameter appears only when you set **Output row mode** to `User-specified`.

**Specify** — Specify output size or pad size

`Output size (default)` | `Pad size`

Choose whether you want to control the output length of the specified dimensions by specifying the output size or the pad size.

**Dependencies**

This parameter appears only when you set **Pad over** to `Specified dimensions`.

**Output size mode** — Mode of specifying output length

User-specified | Next power of two

Choose how you specify the output length of the specified dimensions:

- If you select **User-specified**, the **Output size** parameter appears.
- If you select **Next power of two**, the block pads the specified dimensions until their length is the next highest power of two. If the dimension length is already a power of two, the block does not pad in that dimension.

**Dependencies**

This parameter appears only when you set **Pad over** to **Specified dimensions** and the **Specify** parameter to **Output size**.

**Output size** — Output length along specified dimension

1 | scalar | vector

Specify the output length of the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Output size** vector gives the output length for the corresponding dimension in the **Dimensions to pad** vector. If the specified length is longer than the input length for a given dimension, the block pads that dimension. If the specified length is shorter than the input length for a given dimension, the block truncates that dimension.

**Dependencies**

This parameter appears only when you set **Pad over** to **Specified dimensions** and the **Specify** parameter to **Output size**.

**Pad size at beginning** — Specify number of values to add to beginning of input signal

0 | scalar | vector

Specify how many values to add to the beginning of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at beginning** parameter gives the pad length at the beginning of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be nonnegative integers.

**Dependencies**

This parameter appears only when you set **Pad over** to **Specified dimensions** and the **Specify** parameter to **Pad size**.

**Pad size at end** — Specify number of values to add to end of input signal

0 | scalar | vector

Specify how many values to add to the end of the input signal along the specified dimension(s). This parameter must be a scalar or a vector with the same number of elements as the **Dimensions to pad** parameter. Each element in the **Pad size at end** parameter gives the pad length at the end of the corresponding dimension in the **Dimensions to pad** parameter. Values of this parameter must be nonnegative integers.

**Dependencies**

This parameter appears only when you set **Pad over** to `Specified dimensions` and the **Specify** parameter to `Pad size`.

**Pad signal at** — Specify where to pad or truncate signal

End (default) | Beginning | Beginning and end

Specify whether to pad or truncate the signal at the `Beginning`, `End`, or `Beginning and end` of the specified dimension(s). When you select `Beginning and end`, half the pad length is added to the beginning of the signal and the other half is added to the end of the signal. For an odd pad length, the extra value is added to the end of the signal. When you specify to truncate the signal in this mode, an equal number of values are truncated from the beginning and the end of the signal. In the case of an odd truncation length, the extra value is removed from the end of the signal.

**Dependencies**

This parameter appears only when you set **Pad over** to `Columns`, `Rows`, and `Columns and rows`.

**Action when truncation occurs** — Action to take when truncation occurs

None | Warning | Error

Specify the action the block takes when it truncates the input.

- `None` -- The block does not notify when the input is truncated.
- `Warning` -- The block displays a warning when the input is truncated.
- `Error` -- The block displays an error message and terminates the simulation when the input is truncated.

**Dependencies**

This parameter appears only when you set **Pad over** to `Columns`, `Rows`, and `Columns and rows`.

**Block Characteristics**

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | Boolean   double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no  |
| <b>Multidimensional Signals</b> | no  |
| <b>Variable-Size Signals</b>    | no  |
| <b>Zero-Crossing Detection</b>  | no  |

**View filter response**

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

**Filter Specifications****Order mode**

Select **Minimum** to design a minimum order filter that meets the design specifications, or **Specify** to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a **Minimum** order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width
- Center frequency, bandwidth, stopband width

If you select **Specify**, the available frequency constraints are:

- Center frequency, bandwidth
- Center frequency, quality factor
- Shelf type, cutoff frequency, quality factor
- Shelf type, cutoff frequency, shelf slope parameter
- Low frequency, high frequency

**Order**

Specify the filter order. This parameter is enabled only if the **Order mode** is set to **Specify**.

**Frequency specifications**

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

**Frequency constraints**

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)
- Center frequency, bandwidth, stopband width (available for minimum order only)
- Center frequency, bandwidth (available for a specified order only)
- Center frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, shelf slope parameter (available for a specified order only)

- Low frequency, high frequency (available for a specified order only)

### Frequency units

Select the frequency units from the available drop down list (Normalized, Hz, kHz, MHz, GHz). If Normalized is selected, then the **Input Fs** box is disabled for input.

### Input Fs

Enter the input sampling frequency. This input box is disabled for input if Normalized is selected in the **Frequency units** input box.

### Center frequency

Enter the center frequency in the units specified by the value in **Frequency units**.

### Bandwidth

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to  $\text{db}(\text{sqrt}(.5))$ , or -3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: Center frequency, bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

### Passband width

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

### Stopband width

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

### Low frequency

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

### High frequency

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

## Gain Specifications

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

### Gain constraints

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband

- Reference, center frequency, bandwidth, passband, stopband
- Reference, center frequency, bandwidth

**Gain units**

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

**Reference gain**

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

**Bandwidth gain**

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

**Center frequency gain**

Specify the center frequency in **Gain units**

**Passband gain**

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

**Stopband gain**

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are Center frequency, bandwidth, stopband width.

**Boost/cut gain**

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the **Shelf** type parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

**Algorithm****Design method**

Select the design method from the drop-down list. Different methods are available depending on the chosen filter constraints.

**Scale SOS filter coefficients to reduce chance of overflow**

Select the check box to scale the filter coefficients.

**Filter Implementation****Structure**

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS

- Direct-form II transposed SOS

### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed – see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types  |
|--------|---|
| Input  | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |
| Output | <ul style="list-style-type: none"><li>• Double-precision floating point</li><li>• Single-precision floating point</li></ul> |

## Version History

Introduced in R2007a

## Parametric EQ Filter (Obsolete)

(Removed) Model second-order parametric equalizer filter

---

**Note** The Parametric EQ Filter block requires Audio Toolbox. Existing models using the Parametric EQ Filter block continue to run. For new models, use the Parametric EQ block from Audio Toolbox.

---

### Library

dspobslib

### Description

The Parametric EQ Filter block filters each channel of the input signal over time using a specified center frequency, bandwidth, and peak (dip) gain. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

### Parameters

#### Filter specification

Parameters or coefficients used to design the filter, specified as one of the following:

- Bandwidth and center frequency (default) — Design the filter using **Filter bandwidth (Hz)**, **Equalizer center frequency (Hz)**, and **Gain (dB)**.
- Coefficients — Design the filter using **Bandwidth coefficient**, **Center frequency coefficient**, and **Gain (Linear Units)**.
- Quality factor and center frequency — Design the filter using **Equalizer center frequency (Hz)**, **Gain (dB)**, and **Quality factor**.

This parameter is nontunable.

**Specify bandwidth from input port**

When you select this check box, the filter bandwidth is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency.

**Filter bandwidth (Hz)**

Bandwidth of the filter, specified as a finite positive numeric scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency and clear the **Specify bandwidth from input port** parameter. The default is 2205. This parameter is tunable.

**Specify center frequency from input port**

When you select this check box, the equalizer center frequency is input through the **Fc** port. When you clear this check box, the equalizer center frequency is specified on the block dialog through the **Equalizer center frequency (Hz)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

**Equalizer center frequency (Hz)**

Center frequency of the filter, specified as a finite positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify center frequency from input port** parameter. The default is 11025. This parameter is tunable.

**Specify gain (dB) from input port**

When you select this check box, the peak or dip gain of the filter in dB is input through the **PGaindB** port. When you clear this check box, the filter gain is specified on the block dialog through the **Gain (dB)** parameter.

This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency.

**Gain (dB)**

Peak or dip gain of the filter, specified as a real scalar in dB. A value greater than zero corresponds to a peak. A value less than zero corresponds to a dip. This parameter applies when you set **Filter specification** to Bandwidth and center frequency or Quality factor and center frequency, and clear the **Specify gain (dB) from input port** parameter. The default is 6.0206. This parameter is tunable.

**Specify bandwidth coefficient from input port**

When you select this check box, the bandwidth coefficient is input through the **BWCoeff** port. When you clear this check box, the bandwidth coefficient is specified on the block dialog through the **Bandwidth coefficient** parameter.

This parameter applies when you set **Filter specification** to Coefficients.

**Bandwidth coefficient**

Coefficient that determines the filter bandwidth, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the maximum bandwidth (one-fourth the sample rate of the input signal).
- 1 corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify bandwidth coefficient from input port** parameter. The default is 0.72654. This parameter is tunable.

#### **Specify center frequency coefficient from input port**

When you select this check box, the center frequency coefficient is input through the **FcCoeff** port. When you clear this check box, the center frequency coefficient is specified on the block dialog through the **Center frequency coefficient** parameter.

This parameter applies when you set **Filter specification** to **Coefficients**.

#### **Center frequency coefficient**

Coefficient that determines the center frequency of the filter, specified as a finite numeric scalar in the range [-1 1].

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (half the sample rate of the input signal).

This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify center frequency coefficient from input port** parameter. The default is 0, which corresponds to one-fourth the sample rate of the input signal. This parameter is tunable.

#### **Specify gain from input port**

When you select this check box, the peak or dip gain of the filter in linear units is input through the **PGain** port. When you clear this check box, the filter gain is specified on the block dialog through the **Gain (Linear Units)** parameter.

This parameter applies when you set **Filter specification** to **Coefficients**.

#### **Gain (Linear Units)**

Peak or dip gain of the filter, specified as a real positive scalar in linear units. A value greater than one boosts the input signal. A value less than one attenuates the input signal. This parameter applies when you set **Filter specification** to **Coefficients** and clear the **Specify gain from input port** parameter. The default is 2. This parameter is tunable.

#### **Specify quality factor from input port**

When you select this check box, the quality factor is input through the **Q** port. When you clear this check box, the quality factor is specified on the block dialog through the **Quality factor** parameter.

This parameter applies when you set **Filter specification** to **Quality factor** and center frequency.

#### **Quality factor**

Quality factor of the filter, specified as a real positive scalar. The quality factor is defined as **Equalizer center frequency (Hz) / Filter bandwidth (Hz)**. A higher quality factor corresponds to a narrower peak or dip. This parameter applies when you set **Filter specification** to **Quality factor** and center frequency and clear the **Specify quality factor from input port** parameter. The default is 5. This parameter is tunable.

#### **Inherit sample rate from input**

When you select this check box, the block's sample rate is computed as  $N/T_s$ , where  $N$  is the frame size of the input signal, and  $T_s$  is the sample time of the input signal. When you clear this

check box, the block sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

### Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar value. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

### View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Parametric EQ Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

### Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## References

[1] Orfanidis, Sophocles J. *Introduction to Signal Processing*. Upper Saddle River, NJ: Prentice-Hall, 1996.

## Algorithms

The parametric equalizer is formed by a linear combination of a peak and a notch filter. See the **Algorithm** section of `dsp.NotchPeakFilter` for details.

$$H(z) = H_{notch}(z) + GH_{peak}(z)$$

Here is a graph of the two cases (boost and cut) of the magnitude squared of the transfer functions:

The transfer function can be written as:

$$H(z) = \frac{\left(\frac{1+G\gamma}{1+\gamma}\right) - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-G\gamma}{1+\gamma}\right)z^{-2}}{1 - 2\left(\frac{\cos\omega_0}{1+\gamma}\right)z^{-1} + \left(\frac{1-\gamma}{1+\gamma}\right)z^{-2}}$$

where

$$\gamma = \tan\left(\frac{\Delta\omega}{2}\right)$$

and

$$G_B^2 = \frac{1+G^2}{2}$$

$G$  is the parametric equalizer gain, and  $G_B$  is the bandwidth gain, that is, the gain level at which the bandwidth  $\Delta\omega$  is measured.

The `dsp.NotchPeakFilter` that does most of the work is implemented in a decoupled way so that the center frequency can be tuned independently from the bandwidth. Note that the  $Q$  factor is defined as center frequency/bandwidth.

#### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

# Peak Finder

Determine whether each value of input signal is local minimum or maximum

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Peak Finder block counts the number of local extrema in each column of a real-valued input signal. The block outputs the number of local extrema at the **Cnt** port. You can also configure the block to output the extrema indices, the extrema values, and a binary value indicating if the extrema are maxima or minima. To qualify as an extremum, a point has to be larger (or smaller) than both its neighboring points, so the block does not consider end points when counting extrema.

## Ports

### Input

#### Port\_1 — Data input

column vector of at least three rows | matrix with at least three rows

The Peak Finder blocks accepts real-valued vector or matrix inputs with at least three rows.

Example: [9 6 10 3 5 5 0 12; 9 6 1 13 4 1 0 12]'

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

### Output

#### Cnt — Number of peak values

scalar | row vector

Number of peak values the block detects in the input signal, returned as a scalar or a row vector of length equal to the number of channels in the data input.

Example: [4 3]

Data Types: uint32

#### Idx — Indices of the peak values

column vector | matrix

Indices of the peak values in the input signal, returned as a column vector or matrix. The size of the peak indices output is the same as that of the input. All nonzero elements represent peak indices.

If you set **Index base** to Zero, the block outputs zero-based extrema indices. If you set **Index base** to One, the block outputs one-based extrema indices.

Example: [1 2 3 6 0 0 0 0 0 0; 2 3 6 0 0 0 0 0 0 0]'

### Dependencies

To enable this output port, select the **Output peak indices** parameter.

Data Types: uint32

### Val — Peak values

column vector | matrix

Peak values in the input signal, returned as a column vector or matrix.

Example: [6 10 3 0 0 0 0 0 0 0; 1 13 0 0 0 0 0 0 0 0]'

### Dependencies

To enable this output port, select the **Output peak values** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

### Pol — Peak value polarity

column vector | matrix

Peak value polarity in input signal, returned as a column vector or a matrix of logical 1s and 0s. If the signal value is a maximum, the block outputs 1 at this port. If the signal value is a minimum, the block outputs 0 at this port.

Example: [0 1 0 0 0 0 0 0 0 0; 0 1 0 0 0 0 0 0 0 0]'

### Dependencies

To enable this port, select either **Output peak indices** or **Output peak values**, and set the **Peak type(s)** parameter to Maxima and Minima.

Data Types: Boolean

## Parameters

**Peak type(s)** — Type of peaks to identify

Maxima and Minima (default) | Maxima | Minima

Specify the type of peaks to identify as one of these:

- **Maxima** -- If you select **Ignore peaks within threshold of neighboring values**, the block identifies the current value as a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . Specify *threshold* in the **Threshold** parameter. If you do not select **Ignore peaks within threshold of neighboring values**, the block identifies a maxima if the current value is larger than both its neighboring points.
- **Minima** -- If you select **Ignore peaks within threshold of neighboring values**, the block identifies the current value as a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ . If you do not select **Ignore peaks within threshold of neighboring values**, the block identifies a minima if the current value is smaller than both its neighboring points.
- **Maxima and Minima** -- The block identifies the maxima and the minima points.

**Index base** — Index base

Zero (default) | One

Specify the base of the extrema indices as either:

- Zero -- The first index starts with 0. For example, consider an input vector  $[-1.5, 0.5, 0]$ . The peak value of this vector is 0.5 and the index of this peak value is 1.
- One -- In this setting, the first index starts with 1. The index of the peak value in  $[-1.5, 0.5, 0]$  is 2.

**Output peak indices** — Enable output of peak indices

off (default) | on

Select this check box if you want the block to output the extrema indices at the **Idx** port.**Output peak values** — Enable output of peak values

off (default) | on

Select this parameter if you want the block to output the extrema values at the **Val** port.**Maximum number of peaks to find** — Maximum number of peak values to identify

10 (default) | integer greater than or equal to 1

Enter the number of extrema to look for in each input signal as an integer greater than or equal to 1. The block stops searching the input signal for extrema once the maximum number of extrema has been found.

**Ignore peaks within threshold of neighboring values** — Ignore peaks below a threshold

off (default) | on

Select this parameter if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. This feature allows the block to ignore noise by focusing on values above the specified threshold.

When you clear this parameter, the block identifies the current value as a peak if the current value is larger (or smaller) than both its neighboring points. When you select this parameter, the block identifies the current value as a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . The block identifies the current value as a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ .

**Threshold** — Threshold below which peaks are ignored

0 (default) | positive real scalar | vector

Specify the threshold below which peaks are ignored as a real scalar greater than or equal to 0 or a vector with all elements greater than or equal to 0. The length of the vector must be equal to the number of channels.

This property identifies the current input value to be a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . The current value is a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ .

### Dependencies

To enable this parameter, select the **Ignore peaks within threshold of neighboring values** parameter.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operations. When you clear this parameter, the block wraps the result of its fixed-point operations. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

### Dependencies

To enable this parameter, select the **Ignore peaks within threshold of neighboring values** parameter.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.

- Impulse response and step response in the time domain.
- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### **Filter Specifications**

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

#### **Response**

Select **Peak** or **Notch** from the drop-down list. The rest of the parameters that specify are equivalent for either filter type.

#### **Order**

Enter the filter order. The order must be even.

### **Frequency Specifications**

This group of parameters allows you to specify frequency constraints and units.

#### **Frequency Constraints**

Select the frequency constraints for filter specification. There are two choices as follows:

- Center frequency and quality factor
- Center frequency and bandwidth

#### **Frequency units**

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

#### **Input Fs**

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

#### **Center frequency**

Enter the center frequency in the units specified previously.

#### **Quality Factor**

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

#### **Bandwidth**

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

### **Magnitude Specifications**

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

### Magnitude Constraints

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation
- Passband ripple and stopband attenuation

### Magnitude units

Select the magnitude units: either dB or squared.

### Apass

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

### Astop

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

### Algorithm

The parameters in this group allow you to specify the design method and structure of your filter.

### Design Method

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Filter Implementation

#### Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

#### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The **Inherited (this choice will be removed – see release notes)** option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port  | Supported Data Types   |
|-------|--|
| Input | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

| Output | <ul style="list-style-type: none"><li data-bbox="418 300 834 331">• Double-precision floating point</li><li data-bbox="418 338 824 369">• Single-precision floating point</li></ul> |

## Version History

Introduced in R2007a

## Periodogram

Power spectral density or mean-square spectrum estimate using periodogram method

### Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

## Description

The Periodogram block estimates the power spectral density (PSD) or mean-square spectrum (MSS) of the input. The block uses the periodogram method and Welch's averaged, modified periodogram method. The block averages the squared magnitude of the FFT function computed over windowed sections of the input. It then normalizes the spectral average by the square of the sum of the window samples. For more information, see “Periodogram” and “Welch's Method”.

## Ports

### Input

**Port\_1** — Input signal

vector | matrix

Input signal, specified as a vector or a matrix.

The block treats  $M$ -by- $N$  matrix input as  $M$  sequential time samples from  $N$  independent channels.

Data Types: single | double

### Output

**Port\_1** — Output signal

vector | matrix

Output signal, returned as a vector or a matrix.

Each column of the output matrix contains the estimate of the power spectral density of the corresponding input column at  $N_{fft}$  equally spaced frequency points. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling frequency of the signal.

The block computes a separate estimate for each of the  $N$  independent channels and generates an  $N_{fft}$ -by- $N$  matrix output.

Data Types: single | double

## Parameters

### Measurement — Measurement type

Power spectral density (default) | Mean-square spectrum

Specify the type of measurement for the block to perform: Power spectral density or Mean-square spectrum.

**Tunable:** No

### Window — Window type

Hamming (default) | Bartlett | Blackman | Boxcar | Chebyshev | Hann | Hanning | Kaiser | Triang

Select the type of window to apply.

For details, see the Window Function block reference page.

**Tunable:** Yes

### Beta — Beta

5 (default) | scalar

Enter the  $\beta$  parameter for the Kaiser window. Increasing **Beta** widens the mainlobe and decreases the amplitude of the sidelobes in the displayed frequency magnitude response.

For more details, see the Window Function block reference page.

**Tunable:** Yes

### Dependencies

This parameter becomes visible if, for the Window parameter, you chose Kaiser.

### Window sampling — Window sampling

Symmetric (default) | Periodic

From the list, choose Symmetric or Periodic.

See the Window Function block reference page for more details.

**Tunable:** Yes

### Dependencies

This parameter becomes visible only if you set the Window parameter to one of Blackman, Hamming, Hann, or Hanning.

### FFT implementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Set this parameter to `FFTW` to support an arbitrary length input signal. The block restricts generated code with an FFTW implementation to MATLAB host computers.

Set this parameter to `Radix-2` for bit-reversed processing, fixed or floating-point data, or for portable C-code generation by using Simulink Coder. The first dimension  $M$  of the input matrix must be a power of two. To work with other input sizes, use the Pad block to pad or truncate these dimensions to powers of two, or if possible, choose the FFTW implementation.

Set this parameter to `Auto` to enable the block choose the FFT implementation. For non-power-of-two transform lengths, the block restricts generated code to MATLAB host computers.

**Tunable:** No

**Stopband attenuation in dB** — Stopband attenuation in dB

50 (default) | scalar

Enter the level, in decibels (dB), of stopband attenuation,  $R_s$ , for the Chebyshev window.

**Tunable:** Yes

**Dependencies**

This parameter becomes visible if, for the `Window` parameter, you choose `Chebyshev`.

**Inherit FFT length from input dimensions** — Inherit FFT length

off (default) | on

When you select this check box, the block uses the input frame size as the number of data points,  $N_{fft}$ , on which to perform the FFT. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from input dimensions** check box. You can then specify a power of two FFT length by using the “FFT length” on page 2-0 parameter.

**Tunable:** No

**FFT length** — Number of data points

256 (default) | scalar

Enter the number of data points on which to perform the FFT,  $N_{fft}$ . When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

When you set the `FFT implementation` parameter to `Radix-2`, this value must be a power of two.

**Tunable:** No

**Dependencies**

This parameter becomes visible only when you clear the “Inherit FFT length from input dimensions” on page 2-0 check box.

**Number of spectral averages** — Number of spectral averages

4 (default) | scalar

Specify the number of spectral to average. When you set this value to 1, the block computes the periodogram of the input. When you set this value greater 1, the block implements “Welch's Method” to compute a modified periodogram of the input.

**Tunable:** No

**Inherit sample time from input** — Inherit sample time from input

on (default) | off

If you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time by using the `Sample time of original time series` parameter.

#### Dependencies

This parameter becomes visible only if you set the `Measurement` parameter to `Power spectral density`.

**Sample time of original time series** — Sample time of original time series

1 (default) | scalar

Specify the sample time of the original time-domain signal.

**Tunable:** No

#### Dependencies

This parameter becomes visible only when you clear the `Inherit sample time from input` check box.

### Block Characteristics

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the following conditions apply, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - **FFT implementation** is set to FFTW.
  - **Inherit FFT length from input dimensions** is cleared and **FFT length** is set to a value that is not a power of two.

Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

# Phase Extractor

Extract the unwrapped phase of a complex input

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Phase Extractor block extracts the unwrapped phase of a complex input.

## Ports

### Input

**Input 1** — Input signal  
vector | matrix

Specify the input signal as a vector or a matrix. When the input is a matrix, the block treats each column of the signal as an independent channel. The first dimension is the length of the channel. The second dimension is the number of channels. The block treats one dimensional inputs as one channel.

Data Types: single | double

### Output

**Output 1** — Unwrapped phase  
vector | matrix

The block returns the unwrapped phase of the signal.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Data Types: single | double

## Parameters

**Unwrap phase only within the frame** — Unwrap phase only within the frame

off (default) | on

When you clear this check box, the block ignores boundaries between the input frames. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame.

**Simulate using** — Type of simulation to run  
Code generation (default) | Interpreted execution

Specify the type of simulation to run as one of the following:

- **Code generation** -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

Consider an input frame of length  $N$ :

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here,  $i$  runs from 1 to  $N$ . The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - $\Phi_0$  is 0.

- $x_0$  is 1.
- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - $\Phi_0$  is the last unwrapped phase from the previous frame.
  - $x_0$  is the last sample from the previous frame.

# Polynomial Evaluation

Evaluate polynomial expression

## Library

Math Functions / Polynomial Functions

dsppolyfun

## Description

The Polynomial Evaluation block applies a polynomial function to the real or complex input at the In port.

`y = polyval(u)` % Equivalent MATLAB code

The Polynomial Evaluation block performs these types of operation more efficiently than the equivalent construction using Simulink Sum and Math Function blocks.

When you select the **Use constant coefficients** check box, you specify the polynomial expression in the **Constant coefficients** parameter. When you do not select **Use constant coefficients**, a variable polynomial expression is specified by the input to the **Coeffs** port. In both cases, the polynomial is specified as a vector of real or complex coefficients in order of descending exponents.

The table below shows some examples of the block's operation for various coefficient vectors.

| Coefficient Vector | Equivalent Polynomial Expression               |
|--------------------|--|
| [1 2 3 4 5]        | $y = u^4 + 2u^3 + 3u^2 + 4u + 5$               |
| [1 0 3 0 5]        | $y = u^4 + 3u^2 + 5$                           |
| [1 2+i 3 4-3i 5i]  | $y = u^4 + (2 + i)u^3 + 3u^2 + (4 - 3i)u + 5i$ |

Each element of a vector or matrix input to the In port is processed independently, and the output size is the same as the input.

## Parameters

### Use constant coefficients

Select to enable the **Constant coefficients** parameter and disable the **Coeffs** input port.

### Constant coefficients

Specify the vector of polynomial coefficients to apply to the input, in order of descending exponents. This parameter is enabled when you select the **Use constant coefficients** check box.

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

## Polynomial Stability Test

Use Schur-Cohn algorithm to determine whether all roots of input polynomial are inside unit circle

### Library

Math Functions / Polynomial Functions

dsppolyfun

### Description

The Polynomial Stability Test block uses the Schur-Cohn algorithm to determine whether all roots of a polynomial are within the unit circle.

```
y = all(abs(roots(u)) < 1) % Equivalent MATLAB code
```

Each column of the M-by-N input matrix  $u$  contains M coefficients from a distinct polynomial,

$$f(x) = u_1x^{M-1} + u_2x^{M-2} + \dots + u_M$$

arranged in order of descending exponents,  $u_1, u_2, \dots, u_M$ . The polynomial has order M-1 and positive integer exponents.

Inputs to the block represent the polynomial coefficients as shown in the previous equation. The block always treats length-M unoriented vector input as an M-by-1 matrix.

The output is a 1-by-N matrix with each column containing the value 1 or 0. The value 1 indicates that the polynomial in the corresponding column of the input is stable; that is, the magnitudes of all solutions to  $f(x) = 0$  are less than 1. The value 0 indicates that the polynomial in the corresponding column of the input might be unstable; that is, the magnitude of at least one solution to  $f(x) = 0$  is greater than or equal to 1.

### Applications

This block is most commonly used to check the pole locations of the denominator polynomial,  $A(z)$ , of a transfer function,  $H(z)$ .

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}}{a_1 + a_2z^{-1} + \dots + a_nz^{-(n-1)}}$$

The poles are the  $n-1$  roots of the denominator polynomial,  $A(z)$ . When any poles are located outside the unit circle, the transfer function  $H(z)$  is unstable. As is typical in DSP applications, the transfer function above is specified in descending powers of  $z^{-1}$  rather than  $z$ .

## Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Boolean — Block outputs are always Boolean.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

## Power Meter

Measure power and the CCDF of the power of voltage signal in Simulink

**Libraries:**  
DSP System Toolbox / Statistics

### Description

The Power Meter block computes the power measurements of a voltage signal. When you select the **Compute CCDF** parameter, the block also calculates the complementary cumulative distribution function (CCDF) of the power of a voltage signal. The CCDF measurements that the block outputs are relative power and probability (in percentage). The power measurements include average power, peak power, and peak-to-average power ratio.

For more details on how the block computes the power measurements and the CCDF measurements, see “Algorithms” on page 2-1182.

### Ports

#### Input

**Port\_1** — Input signal  
vector | matrix

Specify the input signal in volts as a vector or a matrix. If  $x$  is a matrix, the block treats each column as an independent channel and computes the power measurement along each channel.

When the **Allow arbitrary frame length for fixed-size input signals** parameter appears and is not selected, and you input a fixed-size signal, the frame length must be a multiple of the hop size (window length – overlap length). In all other cases, the input frame length can be arbitrary.

The block accepts variable-size inputs (frame length changes during simulation). When you input a variable-size signal, the frame length of the signal can be arbitrary.

Data Types: single | double

**Rst** — Reset port  
scalar

Specify the boolean reset signal as a scalar. If the input on the **Rst** port is `true`, the block clears the internal histograms and statistics before processing the current input. If the input on the **Rst** port is `false`, the block computes the measurements from the start of the simulation or from the last reset.

#### Dependencies

To enable this port, select the **Compute CCDF** and **Reset port** parameters.

Data Types: Boolean

## Output

### Avg — Average power

scalar | vector | matrix

Average power of the voltage signal from the start of the simulation or from the last reset, returned as a scalar, vector, or a matrix. The block computes the average power along each channel in the units specified in the **Output power units** parameter. For details on how the block computes the average power, see “Average Power” on page 2-1183.

If you clear the **Compute CCDF** parameter, the block computes the moving average power using the “Sliding Window Method” on page 2-1182.

See this table for details on the output signal dimensions.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is a multiple of the hop size (window length – overlap length)     | $(P/\text{hop size})$ -by- $M$  | $P$ -by- $M$   |
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(P/\text{hop size})$ -by- $M$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $P$ -by- $M$   |
| Variable-size signal | $P$ -by- $M$  | $\text{ceil}(P/\text{hop size})$ -by- $M$   | $P$ -by- $M$   |

When the output has an upper bound size of  $\text{ceil}(P/\text{hop size})$ -by- $M$ , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary average power of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels (columns) in the input signal.

### Dependencies

To enable this port, set **Measurement** to Average power or All.

Data Types: single | double

### Peak — Peak power

scalar | vector | matrix

Peak power of the voltage signal from the start of the simulation or from the last reset, returned as a scalar, vector, or a matrix. The block computes the peak power along each channel in the units specified in the **Output power units** parameter. For details on how the block computes the peak power, see “Peak Power” on page 2-1183.

If you clear the **Compute CCDF** parameter, the block computes the moving peak power using the “Sliding Window Method” on page 2-1182.

See this table for details on the output signal dimensions.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is a multiple of the hop size (window length – overlap length)     | $(P/\text{hop size})$ -by- $M$  | $P$ -by- $M$   |
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(P/\text{hop size})$ -by- $M$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $P$ -by- $M$   |
| Variable-size signal | $P$ -by- $M$  | $\text{ceil}(P/\text{hop size})$ -by- $M$   | $P$ -by- $M$   |

When the output has an upper bound size of  $\text{ceil}(P/\text{hop size})$ -by- $M$ , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary peak power of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels (columns) in the input signal.

#### Dependencies

To enable this port, set **Measurement** to Peak power or All.

Data Types: single | double

**PAPR** — Peak-to-average power ratio  
scalar | vector | matrix

Ratio of the peak power to the average power (PAPR) of the voltage signal, returned as a scalar, vector, or a matrix. The block computes the peak-to-average power ratio along each channel. For details on how the block computes this measurement, see “Peak-to-Average Power Ratio” on page 2-1184.

If you clear the **Compute CCDF** parameter, the block computes the moving peak-to-average power ratio using the “Sliding Window Method” on page 2-1182.

See this table for details on the output signal dimensions.

| Input Signal         | Input Dimensions  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Appears  | Output Dimensions When Allow arbitrary frame length for fixed-size input signals Does Not Appear |
|----------------------|---|---|--|
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is a multiple of the hop size (window length – overlap length)     | $(P/\text{hop size})$ -by- $M$  | $P$ -by- $M$   |
| Fixed-size signal    | $P$ -by- $M$ , where $M$ is not a multiple of the hop size (window length – overlap length) | $\text{ceil}(P/\text{hop size})$ -by- $M$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b><br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. | $P$ -by- $M$   |
| Variable-size signal | $P$ -by- $M$  | $\text{ceil}(P/\text{hop size})$ -by- $M$   | $P$ -by- $M$   |

When the output has an upper bound size of  $\text{ceil}(P/\text{hop size})$ -by- $M$ , during simulation, the size of the first dimension varies within this bound, while the size of the second dimension remains constant.

If you select the **Compute CCDF** parameter, the block computes the stationary peak-to-average power ratio of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels (columns) in the input signal.

PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, the block shows only the highest 100 dB power levels.

### Dependencies

To enable this port, set **Measurement** to Peak-to-average power ratio or All.

Data Types: single | double

**RelPwr** — Relative power

$N$ -by- $M$  matrix

Relative power (dB above average power), returned as an  $N$ -by- $M$  matrix, where:

- $M$  is the number of channels (columns) in the input signal.
- When you set **CCDF output** to Relative power (dB above average power),  $N$  equals the length of the column vector that you specify in the **Specify probability (%) for relative power output** parameter.

- When you set **CCDF output** to Relative power and probability (whole CCDF curve),  $N$  equals  $\text{ceil}(\text{Power range (dB)}/\text{Power resolution (dB)}) + 1$ .

Relative power is the power in dB by which the instantaneous signal power is above the average signal power with a probability of **Prob**, expressed as a percentage. For details on how the block computes relative power, see “Relative Power” on page 2-1184.

### Dependencies

To enable this port, select the **Compute CCDF** parameter and then set the **CCDF output** parameter to Relative power (dB above average power) or Relative power and probability (whole CCDF curve).

Data Types: single | double

**Prob** — Probability in percentage  
*N*-by-*M* matrix

Probability in percentage, returned as an *N*-by-*M* matrix, where:

- $M$  is the number of channels (columns) in the input signal.
- When you set **CCDF output** to Probability (%),  $N$  equals the length of the column vector that you specify in the **Specify relative power (dB) for probability output** parameter.
- When you set **CCDF output** to Relative power and probability (whole CCDF curve),  $N$  equals  $\text{ceil}(\text{Power range (dB)}/\text{Power resolution (dB)}) + 1$ .

**Prob**(*i*)/100 is the probability that the instantaneous signal power of the  $j^{\text{th}}$  channel is above its average signal power by **RelPwr**(*i,j*) in dB.

### Dependencies

To enable this port, select the **Compute CCDF** parameter and then set the **CCDF output** parameter to Probability (%) or Relative power and probability (whole CCDF curve).

Data Types: single | double

## Parameters

**Measurement** — Desired power measurement  
 Average power (default) | Peak power | Peak-to-average power ratio | All

Specify the desired power measurement as one of the following:

- Average power (default)
- Peak power
- Peak-to-average power ratio
- All

For details on how the block computes these measurements, see “Algorithms” on page 2-1182.

**Reference load (ohms)** — Reference load in ohms  
 1 (default) | positive scalar in ohms

Specify the reference load that the power meter uses to compute power values as a real, positive scalar in ohms.

**Tunable:** Yes

Data Types: single | double

**Output power units** — Units of measured power values  
dBm (default) | dBW | Watts

Specify the units of the measured power values as one of the following:

- dBm
- dBW
- Watts

**Compute CCDF** — Enable CCDF computations  
off (default) | on

Select the **Compute CCDF** parameter to enable the block to compute the CCDF of the power of voltage signals. CCDF measurements include the relative power and the probability (in percentage). Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

These measurements provide a qualitative way to view the power distribution between the amplitude values of an input signal over time. The CCDF curves (plot of probability in percentage against relative power in dB) are useful indicators of the dynamic range of a signal.

When you select **Compute CCDF**:

- The block uses all the input samples from the start of the simulation or from a reset signal on the **Rst** port to compute the statistics. The power measurements are stationary.
- You can specify variable-size input signals.

When you clear **Compute CCDF**,

- The block does not calculate the CCDF measurements and computes the power measurements using the “Sliding Window Method” on page 2-1182.
- The block accepts input signals of arbitrary frame length only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

**Window length** — Window length  
256 (default) | positive integer

Specify the window length over which the block computes the measurement as a positive integer.

#### Dependencies

To enable this parameter, clear the **Compute CCDF** check box. When you select **Compute CCDF**, **Window length** becomes Inf.

Data Types: `single` | `double`

**Overlap length** — Overlap length between windows  
255 (default) | nonnegative integer

Specify the overlap length between sliding windows as a nonnegative integer. The value of overlap length varies in the range  $[0, \mathbf{Window\ length} - 1]$ .

#### Dependencies

To enable this parameter, clear the **Compute CCDF** check box. When you select **Compute CCDF**, **Overlap length** becomes 0.

Data Types: `single` | `double`

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be multiple of the hop size. Hop size is defined as  $\mathbf{Window\ length} - \mathbf{Overlap\ length}$ . The block uses this parameter setting only for fixed-size input signals and ignores this parameter if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the hop size.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the hop size. If the input is not a multiple of the hop size, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the hop size.

#### Dependencies

To enable this parameter, clear the **Compute CCDF** parameter.

**Power range (dB)** — Power range in dB  
50 (default) | positive scalar

Specify the x-axis range of the CCDF curves as a positive scalar in dB. The CCDF curves end at the maximum relative power, namely, the PAPR of the signal, and start at  $\text{PAPR} - \mathbf{Power\ range\ (dB)}$ . In the CCDF capability of the Power Meter block, relative power is the power in dB by which the instantaneous signal power is above the average signal power.

#### Dependencies

To enable this parameter, select the **Compute CCDF** check box.

Data Types: `single` | `double`

**Power resolution (dB)** — Power Resolution in dB

0.1 (default) | positive scalar

Specify the x-axis resolution of the CCDF curves as a positive scalar in dB.

**Dependencies**

To enable this parameter, select the **Compute CCDF** check box.

Data Types: single | double

**CCDF output** — CCDF output

Relative power (dB above average power) (default) | Probability (%) | Relative power and probability (whole CCDF curve)

Specify the block to output:

- **RelPwr** -- Relative power (dB above average power). This is the amount of power in dB by which the instantaneous signal power is above the average power.
- **Prob** -- Probability in percentage. This is the probability that the instantaneous signal power is above the average signal power by the value of the relative power in dB.
- Both the **RelPwr** and the **Prob**.

**Dependencies**

To enable this parameter, select the **Compute CCDF** check box.

**Specify probability (%) for relative power output** — Specify probability for relative power output

[10;1;0.1;0.01;0.001;0.0001] (default) | column vector

Specify the probability (in percentage) for the relative power output as a column vector. The length of this vector determines the number of rows in the relative power output at the **RelPwr** port.

**Dependencies**

To enable this parameter, select the **Compute CCDF** check box and set the **CCDF output** parameter to Relative power (dB above average power).

This also enables the **RelPwr** output port.

Data Types: single | double

**Specify relative power (dB) for probability output** — Specify relative power for probability output

[0;3;6;9;12] (default) | column vector

Specify the relative power (in dB) for the probability output as a column vector. The length of this vector determines the number of rows in the probability output at the **Prob** port.

**Dependencies**

To enable this parameter, select the **Compute CCDF** check box and set the **CCDF output** parameter to Probability (%).

This also enables the **Prob** output port.

Data Types: `single` | `double`

**Reset port** — Enable reset port  
`off` (default) | `on`

Select this parameter to enable the input port **Rst** that accepts a boolean signal. If the value at the **Rst** port is `true`, then the block clears the internal histograms and statistics before processing the current input.

### Dependencies

To enable this parameter, select the **Compute CCDF** check box.

**Simulate using** — Type of simulation to run  
`Code generation` (default) | `Interpreted execution`

Specify the type of simulation to run as one of the following:

- `Code generation` -- Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution` -- Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

## Block Characteristics

## Algorithms

### Sliding Window Method

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving power measurements using the sliding window method.

In the sliding window method, the block computes the power measurement over a finite duration of the signal. The window length defines the length of the data over which the algorithm computes the power value. The window moves as new data comes in. The output for each input sample is the measurement over the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the sliding window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining

samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

For a more detailed example, see “Sliding Window Method”.

If the window is large, the power that the block computes is closer to the stationary power of the data. For data that does not change rapidly, use a long window to get a smoother measurement. For data that changes fast, use a smaller window.

When you configure the power meter to compute the CCDF measurements, the algorithm computes the stationary power of the data. It sets the window length to `Inf` and the overlap length to `0`, making both the parameters read-only.

### Average Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving average power of the voltage signal across each channel using the Sliding Window Method on page 2-1182. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary average power of the voltage signal across each channel.

These equations give the average power in dBm, dBW, and in Watts units.

$$AvgPower_{dBm} = 10\log_{10}(Avg(|x|^2)/R) + 30$$

$$AvgPower_{dBW} = 10\log_{10}(Avg(|x|^2)/R)$$

$$AvgPower_{Watts} = Avg(|x|^2)/R$$

where,

- $x$  is the input voltage signal.
- $R$  is the reference load (in ohms) that the block uses to compute the power value.
- $Avg$  represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements,  $Avg$  represents the stationary average power across each channel.

### Peak Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak power of the voltage signal across each channel using the Sliding Window Method on page 2-1182. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak power of the voltage signal across each channel.

These equations give the peak power in dBm, dBW, and in Watts units.

$$PeakPower_{dBm} = 10\log_{10}(Max(|x|^2)/R) + 30$$

$$PeakPower_{dBW} = 10\log_{10}(Max(|x|^2)/R)$$

$$PeakPower_{Watts} = Max(|x|^2)/R$$

where,

- $x$  is the input voltage signal.
- $R$  is the reference load (in ohms) that the block uses to compute the power value.
- $Max$  represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements,  $Max$  represents the stationary peak power across each channel.

### Peak-to-Average Power Ratio

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak-to-average power ratio of the voltage signal across each channel using the Sliding Window Method on page 2-1182. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak-to-average power ratio of the voltage signal across each channel.

These equations give the peak-to-average power ratio in dBm, dBW, and in Watts units.

$$pkAvgPwr_{dBm} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{dBW} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{Watts} = Max(|x|^2)/Avg(|x|^2)$$

where,

- $x$  is the input voltage signal.
- $Avg$  represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements,  $Avg$  represents the stationary average power across each channel.

- $Max$  represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements,  $Max$  represents the stationary peak power across each channel.

### Relative Power

The power meter computes the relative power only when you configure the algorithm to compute the CCDF measurements. The algorithm uses a window of infinite duration to compute the relative power.

Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. The block calculates the relative power using these equations:

If output power is in dBm,

$$relPower = 10\log_{10}(|x|^2/R) + 30 - AvgPower_{dBm}$$

If output power is in dBW,

$$relPower = 10\log_{10}(|x|^2/R) - AvgPower_{dBW}$$

If output power is in Watts,

$$relPower = (|x|^2/R) - AvgPower_{Watts}$$

where,

- $x$  is the input voltage signal.
- $R$  is the reference load (in ohms) that the block uses to compute the power value.
- $|x|^2/R$  is the instantaneous signal power in Watts.
- $AvgPower$  is the average power of the voltage signal. For more details on how the algorithm computes this measurement, see “Average Power” on page 2-1183.

### Probability

The power meter computes the probability only when you configure the algorithm to compute the CCDF measurements. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

## Version History

### Introduced in R2021a

#### R2022b: New Overlap length parameter

Starting in R2022b, when the block is not computing the CCDF measurements, you can specify the overlap length between sliding windows using the **Overlap length** parameter.

#### R2022b: Support for arbitrary input frame length

Power Meter block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter (if enabled).
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an arbitrary frame length input signal, the input frame length does not have to be a multiple of the hop size.

# Pseudoinverse

Compute Moore-Penrose pseudoinverse of matrix

## Library

Math Functions / Matrices and Linear Algebra / Matrix Inverses

dspinverses

## Description

The Pseudoinverse block computes the Moore-Penrose pseudoinverse of input matrix  $A$ .

`[U,S,V] = svd(A,0)` % Equivalent MATLAB code

The pseudoinverse of  $A$  is the matrix  $A^\dagger$  such that

$$A^\dagger = VS^\dagger U^*$$

where  $U$  and  $V$  are orthogonal matrices, and  $S$  is a diagonal matrix. The pseudoinverse has the following properties:

- $AA^\dagger = (AA^\dagger)^*$
- $A^\dagger A = (A^\dagger A)^*$
- $AA^\dagger A = A$
- $A^\dagger AA^\dagger = A^\dagger$

## Parameters

### Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The pseudoinverse calculation converges.
- 1 — The pseudoinverse calculation does not converge.

If the pseudoinverse calculation fails to converge, the output at port X is an undefined matrix of the correct size.

### Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time. For this block, the simulation speed in this mode is faster than in Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but the simulation speed increases with subsequent simulations.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

## Pulse Shaping Filter (Obsolete)

(Removed) Design pulse shaping filter

### Compatibility

---

**Note** The Pulse Shaping Filter block has been removed from DSP System Toolbox block library. Existing instances of the Pulse Shaping Filter block will continue to operate. For new models, use the Raised Cosine Receive Filter and Raised Cosine Transmit Filter blocks from the Communications Toolbox library. These blocks replace the functionality of Pulse Shaping Filter block, when **Filter Type** is set to Decimator and Interpolator, respectively.

---

### Library

Filtering / Filter Designs

dspfdesign

### Description

This block brings the filter design capabilities of the `filterBuilder` function to the Simulink environment.

### Dialog Box

See “Pulse-shaping Filter Design —Main Pane” on page 5-644 for more information about the parameters of this block. The **Data Types** and **Code** panes are not available for blocks in the DSP System Toolbox Filter Designs library.

Parameters of this block that do not change filter order or structure are tunable.

### View filter response

This button opens the Filter Visualization Tool (**FVTool**) from the Signal Processing Toolbox product. You can use the tool to display:

- Magnitude response, phase response, and group delay in the frequency domain.
- Impulse response and step response in the time domain.

- Pole-zero information.

The tool also helps you evaluate filter performance by providing information about filter order, stability, and phase linearity. For more information on FVTool, see the Signal Processing Toolbox documentation.

### Filter Specifications

In this group, you specify the shape and length of the filter.

#### Pulse shape

Select the shape of the impulse response from the following options:

- Raised Cosine
- Square Root Raised Cosine
- Gaussian

#### Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- **Minimum**— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- **Specify order**—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be  $\text{Order}+1$ .
- **Specify symbols**—This option enables the user to specify the length of the impulse response in an alternative manner. If **Specify symbols** is chosen, the **Order** input box changes to the **Number of symbols** input box.

#### Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be  $\text{Number of symbols} * \text{Samples per symbol} + 1$ . The product  $\text{Number of symbols} * \text{Samples per symbol}$  must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product  $\text{Number of symbols} * \text{Samples per symbol}$  must be an even number. The filter length will be  $\text{Number of symbols} * \text{Samples per symbol} + 1$ .

### Frequency specifications

In this group, you specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

#### Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

#### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

For a Gaussian pulse shape, the available frequency specifications are:

#### Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

#### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, the block assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

#### Magnitude specifications

If the **Order mode** is specified as minimum, the magnitude units may be selected from:

- dB — Specify the magnitude in decibels (default).
- Linear — Specify the magnitude in linear units.

#### Algorithm

The only design method available for FIR pulse-shaping filters is the window method.

#### Filter Implementation

##### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. FIR filters use direct-form structure.

##### Use basic elements to enable filter customization

Select this check box to implement the filter as a subsystem of basic Simulink blocks. Clear the check box to implement the filter as a high-level subsystem. By default, this check box is cleared.

The high-level implementation provides better compatibility across various filter structures, especially filters that would contain algebraic loops when constructed using basic elements. On the other hand, using basic elements enables the following optimization parameters:

- **Optimize for zero gains** — Terminate chains that contain Gain blocks with a gain of zero.
- **Optimize for unit gains** — Remove Gain blocks that scale by a factor of one.
- **Optimize for delay chains** — Substitute delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for negative gains** — Use subtraction in Sum blocks instead of negative gains in Gain blocks.

##### Optimize for unit-scale values

Select this check box to scale unit gains between sections in SOS filters. This parameter is available only for SOS filters.

##### Input processing

Specify how the block should process the input. The available options may vary depending on the settings of the **Filter Structure** and **Use basic elements for filter customization** parameters. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The **Inherited (this choice will be removed – see release notes)** option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Rate options

When the **Filter type** parameter specifies a multirate filter, select the rate processing rule for the block from following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the sample rate of the input.
- **Allow multirate processing** — When you select this option, the block adjusts the rate at the output to accommodate an increased or reduced number of samples. To select this option, you must set the **Input processing** parameter to **Elements as channels (sample based)**.

### Use symbolic names for coefficients

Select this check box to enable the specification of coefficients using MATLAB variables. The available coefficient names differ depending on the filter structure. Using symbolic names allows tuning of filter coefficients in generated code. By default, this check box is cleared.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

## QR Factorization

Factor arbitrary matrix into unitary and upper triangular components

## Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfactors

## Description

The QR Factorization block uses a sequence of Householder transformations to triangularize the input matrix  $A$ . The block factors a column permutation of the  $M$ -by- $N$  input matrix  $A$  as

$$A_e = QR$$

The column-pivoted matrix  $A_e$  contains the columns of  $A$  permuted as indicated by the contents of length- $N$  permutation vector  $E$ .

```
A_e = A(:,E) % Equivalent MATLAB code
```

The block selects a column permutation vector  $E$ , which ensures that the diagonal elements of matrix  $R$  are arranged in order of decreasing magnitude.

$$|r_{i+1,j+1}| < |r_{i,j}| \quad i = j$$

The size of matrices  $Q$  and  $R$  depends on the setting of the **Output size** parameter:

- When you select **Economy** for the output size,  $Q$  is an  $M$ -by- $\min(M,N)$  unitary matrix, and  $R$  is a  $\min(M,N)$ -by- $N$  upper-triangular matrix.

```
[Q R E] = qr(A,0) % Equivalent MATLAB code
```

- When you select **Full** for the output size,  $Q$  is an  $M$ -by- $M$  unitary matrix, and  $R$  is a  $M$ -by- $N$  upper-triangular matrix.

```
[Q R E] = qr(A) % Equivalent MATLAB code
```

The block treats length- $M$  unoriented vector input as an  $M$ -by-1 matrix.

QR factorization is an important tool for solving linear systems of equations because of good error propagation properties and the invertibility of unitary matrices:

$$Q^{-1} = Q'$$

where  $Q'$  is the complex conjugate transpose of  $Q$ .

Unlike LU and Cholesky factorizations, the matrix  $A$  does not need to be square for QR factorization. However, QR factorization requires twice as many operations as LU Factorization (Gaussian elimination).

## Parameters

### Output size

Specify the size of output matrices  $Q$  and  $R$ :

- **Economy** — When this output size is selected, the block outputs an  $M$ -by- $\min(M,N)$  unitary matrix  $Q$  and a  $\min(M,N)$ -by- $N$  upper-triangular matrix  $R$ .
- **Full** — When this output size is selected, the block outputs an  $M$ -by- $M$  unitary matrix  $Q$  and a  $M$ -by- $N$  upper-triangular matrix  $R$ .

### Simulate using

- **Interpreted execution (default)**

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed compared to **Code generation**.

- **Code generation**

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

# QR Solver

Find minimum-norm-residual solution to  $AX=B$

## Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dsp solvers

## Description

The QR Solver block solves the linear system  $AX=B$ , which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying QR factorization to the M-by-N matrix, A, at the A port. The input to the B port is the right side M-by-L matrix, B. The block treats length-M unoriented vector input as an M-by-1 matrix.

The output at the x port is the N-by-L matrix, X. X is chosen to minimize the sum of the squares of the elements of  $B-AX$ . When B is a vector, this solution minimizes the vector 2-norm of the residual ( $B-AX$  is the residual). When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems  $AX_k=B_k$ , where  $B_k$  is the kth column of B, and  $X_k$  is the kth column of X.

X is known as the minimum-norm-residual solution to  $AX=B$ . The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the QR Solver is applied to an underdetermined system, the output X is chosen such that the number of nonzero entries in X is minimized.

## Parameters

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed compared to Code generation.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Algorithm

QR factorization factors a column-permuted variant ( $A_e$ ) of the M-by-N input matrix A as

$$A_e = QR$$

where Q is a M-by-min(M,N) unitary matrix, and R is a min(M,N)-by-N upper-triangular matrix.

The factored matrix is substituted for  $A_e$  in

$$A_e X = B_e$$

and

$$QRX = B_e$$

is solved for X by noting that  $Q^{-1} = Q^*$  and substituting  $Y = Q^* B_e$ . This requires computing a matrix multiplication for Y and solving a triangular system for X.

$$RX = Y$$

## Supported Data Types

- Double-precision floating point
- Single-precision floating point

# Queue

Store inputs in FIFO register

## Libraries:

DSP System Toolbox / Signal Management / Buffers

## Description

The Queue block stores a sequence of input samples in a first-in first-out (FIFO) register. Depending on the inputs at the ports, the block can push, pop, or empty the queue.

When the block receives a trigger event at the **Push** port, it pushes the input at the **In** port to the end of the queue. When the block receives a trigger event at the **Pop** port, it pops the first element off the queue and holds the **Out** port at that value. The first input to be pushed onto the queue is always the first to be popped off.

## Input/Output Ports

### Input

**In** — Input to FIFO register

scalar | vector | matrix

Specify the input to the FIFO register as a scalar, vector, or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

**Push** — Trigger signal to push queue  
scalar

Specify the trigger signal to push the queue as a real scalar.

Input to the **Push** port must have the same data type as the input to the **Pop** and **Rst** ports.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

**Pop** — Trigger signal to pop queue  
scalar

Specify the trigger signal to pop the queue as a real scalar.

Input to the **Pop** port must have the same data type as the inputs to the **Push** and **Rst** ports.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

**Rst** — Trigger signal to empty queue  
scalar

Specify the trigger signal to empty the queue as a real scalar.

Input to the **Rst** port must have the same data type as the inputs to the **Push** and **Pop** ports.

### **Dependencies**

To enable this port, select **Show reset port (Rst) to clear internal stack buffer**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

### **Output**

**Out** — Output of FIFO register  
scalar | vector | matrix

Output of the FIFO register, returned as a scalar, vector, or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

**Empty** — Indicates if queue is empty  
1 | 0

The block returns 1 at this port to indicate an empty queue and 0 otherwise.

### **Dependencies**

To enable this port, select **Show empty register indicator port (Empty)**.

Data Types: `double` | `Boolean`

**Full** — Indicates if queue is full  
1 | 0

The block returns 1 at this port to indicate a full queue and 0 otherwise.

If you select `Dynamic` reallocation in the **Push onto full register** parameter, the **Full** port remains 0.

#### Dependencies

To enable this port, select **Show full register indicator port (Full)**.

Data Types: `double` | `Boolean`

**Num** — Track number of elements in queue  
scalar

Track the number of elements in the queue at any given time.

If the data type at the **In** port is `double`, the data type at the **Num** port is `double`. Otherwise, the data type at the **Num** port is `uint32`.

#### Dependencies

To enable this port, select **Show number of register entries port (Num)**.

Data Types: `double` | `uint32`

## Parameters

**Register size** — Number of entries FIFO register can hold

8 (default) | positive integer

The number of entries that the FIFO register can hold, specified as a positive integer.

**Trigger type** — Type of trigger event for Push, Pop, and Rst ports

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero sample`

The type of event that triggers the execution of the block. Select one of these options:

| Trigger Type    | Description  |
|-----------------|--|
| Rising edge     | <p>Triggers execution of the block when the trigger input does one of the following:</p> <ul style="list-style-type: none"> <li>• Rises from a negative value to zero or a positive value.</li> <li>• Rises from zero to a positive value but is not a continuing rise.</li> </ul> |
| Falling edge    | <p>Triggers execution of the block when the trigger input does one of the following:</p> <ul style="list-style-type: none"> <li>• Falls from a positive value to zero or a negative value.</li> <li>• Falls from zero to a negative value but is not a continuing fall.</li> </ul> |
| Either edge     | Triggers execution of the block when the trigger input type is Rising edge or Falling edge (as described above).   |
| Non-zero sample | Triggers execution of the block at each sample time that the trigger input is not zero.  |

The rate of the trigger signal must be the same as the rate of the data signal input.

**Push onto full register** — Specify block behavior to push request when register is full

Dynamic reallocation (default) | Ignore | Warning | Error

Specify the block behavior when it receives a trigger at the **Push** port but the register is full. The available options are:

- **Dynamic reallocation** — Dynamically resize the register to accept as many additional inputs as memory permits.

To use this option, set the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box to `grt_malloc.tlc – Generic Real-Time Target` with dynamic memory allocation.

---

**Note** If your model contains any referenced models that use a Queue block with the **Push onto full register** parameter set to **Dynamic reallocation**, you cannot simulate your top-level model in the accelerator mode in Simulink.

---

- **Ignore** — Ignore the trigger event and continue the simulation.
- **Warning** — Ignore the trigger event but display a warning message in the MATLAB Command Window.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** The **Push onto full register** is a diagnostic parameter. Like all diagnostic parameters in the Configuration Parameters dialog box, this parameter is set to **Ignore** in the code generated for this block by the Simulink Coder code generation software.

---

**Pop empty register** — Specify block behavior to pop request when register is empty

Warning (default) | Ignore | Error

Specify the block behavior when it receives a trigger at the **Pop** port but the register is empty. The available options are:

- **Ignore** — Ignore the trigger event and continue the simulation.
- **Warning** — Ignore the trigger event but display a warning message in the MATLAB Command Window.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** The **Pop empty register** is a diagnostic parameter. Like all diagnostic parameters in the Configuration Parameters dialog box, this parameter is set to **Ignore** in the code generated for this block by the Simulink Coder code generation software.

---

**Show empty register indicator port (Empty)** — Enable Empty output port

off (default) | on

Select to enable the **Empty** output port to indicate an empty register.

**Show full register indicator port (Full)** — Enable Full output port

off (default) | on

Select to enable the **Full** output port to indicate a full register.

**Show number of register entries port (Num)** — Enable Num output port

off (default) | on

Select to enable the **Num** output port to show the number of register entries.

**Show reset port (Rst) to clear internal stack buffer** — Enable Rst input port

off (default) | on

Select to enable the **Rst** input port. The block empties the queue when it receives a trigger at this port.

**Clear output port on reset** — Set Out port to 0 when clearing queue

off (default) | on

If you select **Clear output port on reset**, then a trigger event at the **Rst** port empties the queue and sets the value at the **Out** port to 0. This setting also applies when a disabled subsystem containing the Queue block is re-enabled.

#### Dependencies

To enable this parameter, select the **Show reset port (Rst) to clear internal stack buffer** parameter.

**Allow direct feedthrough** — Allow input data to be readily available at Out port

on (default) | off

Select to allow the input data to be available immediately at the **Out** port of the block. Clear to delay the input data by an extra frame.

When you select the **Allow direct feedthrough** parameter and trigger two or more of the control input ports at the same time step, the block executes the operations in the following order:

- 1 Reset
- 2 Push
- 3 Pop

When you clear the **Allow direct feedthrough** parameter and trigger two or more of the control input ports at the same time step, the block executes the operations in the following order:

- 1 Reset
- 2 Pop
- 3 Push

The rate of the trigger signal must be the same as the rate of the data signal input.

### Block Characteristics

|                           |   |
|---------------------------|---|
| <b>Data Types</b>         | Boolean   double   fixed point   integer   single |
| <b>Direct Feedthrough</b> | no  |

|                                 |    |
|---------------------------------|----|
| <b>Multidimensional Signals</b> | no |
| <b>Variable-Size Signals</b>    | no |
| <b>Zero-Crossing Detection</b>  | no |

## More About

### Operation of Queue Block

This table shows how the Queue block operates when you set the **Register size** to 4, **Trigger type** to **Either edge**, and enable the **Clear output port on reset** parameter. Because the block triggers on both rising and falling edges, each transition from 1 to 0 or 0 to 1 in the **Push**, **Pop**, and **Rst** columns represents a distinct trigger event. 1 in the **Empty** column indicates an empty queue, while 1 in the **Full** column indicates a full queue.

| In | Push | Pop | Rst | Queue  | Out | Empty | Full | Num |
|----|------|-----|-----|--|-----|-------|------|-----|
| 1  | 0    | 0   | 0   | top  bottom   | 0   | 1     | 0    | 0   |
| 2  | 1    | 0   | 0   | top  bottom   | 0   | 0     | 0    | 1   |
| 3  | 0    | 0   | 0   | top  bottom  | 0   | 0     | 0    | 2   |
| 4  | 1    | 0   | 0   | top  bottom | 0   | 0     | 0    | 3   |
| 5  | 0    | 0   | 0   | top  bottom | 0   | 0     | 1    | 4   |
| 6  | 0    | 1   | 0   | top  bottom | 2   | 0     | 0    | 3   |
| 7  | 0    | 0   | 0   | top  bottom | 3   | 0     | 0    | 2   |
| 8  | 0    | 1   | 0   | top  bottom | 4   | 0     | 0    | 1   |
| 9  | 0    | 0   | 0   | top  bottom | 5   | 1     | 0    | 0   |
| 10 | 1    | 0   | 0   | top  bottom | 5   | 0     | 0    | 1   |
| 11 | 0    | 0   | 0   | top  bottom | 5   | 0     | 0    | 2   |
| 12 | 1    | 0   | 1   | top  bottom | 0   | 0     | 0    | 1   |

In the last time step, there are triggers at the **Push** and **Rst** ports simultaneously. The **Rst** trigger takes precedence: the block first clears the queue and then pushes the value at the In port into the queue.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following limitations apply:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When you select `Dynamic reallocation`, you must set the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box to `grt_malloc.tlc - Generic Real-Time Target with dynamic memory allocation`.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Buffer | Delay Line | Stack

# Random Source

Generate randomly distributed values

**Libraries:**  
DSP System Toolbox / Sources

## Description

The Random Source block generates a frame of  $M$  values drawn from a uniform or Gaussian pseudorandom distribution. Specify  $M$  in the **Samples per frame** parameter.

## Ports

### Output

**Port\_1** — Signal of random values

scalar | vector | matrix

Signal of random values with uniform or Gaussian (normal) distribution.

Data Types: single | double

## Parameters

**Source type** — Uniform or Gaussian

Uniform (default) | Gaussian

The distribution from which to draw the random values, `Uniform` or `Gaussian`.

When you set the **Source type** parameter to `Uniform`, the output samples are drawn from a uniform distribution whose minimum and maximum values are specified by the **Minimum** and **Maximum** parameters, respectively. All values in this range are equally likely to be selected. A length- $N$  vector specified for one or both of these parameters generates an  $N$ -channel output ( $M$ -by- $N$  matrix) containing a unique random distribution in each channel.

For example, specify

- **Minimum** = [0 0 -3 -3]
- **Maximum** = [10 10 20 20]

to generate a four-channel output whose first and second columns contain random values in the range [0, 10], and whose third and fourth columns contain random values in the range [-3, 20]. When you specify only one of the **Minimum** and **Maximum** parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

When you set the **Source type** parameter to `Gaussian`, you must also set the **Method** parameter, which determines the method by which the block computes the output.

**Method** — Method of computing Gaussian random values

Ziggurat (default) | Sum of uniform values

The method by which the block computes the Gaussian random values:

- **Ziggurat** — Produces Gaussian random values by using the ziggurat method.
- **Sum of uniform values** — Produces Gaussian random values by adding and scaling uniformly distributed random signals based on the central limit theorem. This theorem states that the probability distribution of the sum of a sufficiently high number of random variables approaches the Gaussian distribution. You must set the **Number of uniform values to sum** parameter, which determines the number of uniformly distributed random numbers to sum to produce a single Gaussian random value.

For both settings of the **Method** parameter, the output samples are drawn from the normal distribution defined by the **Mean** and **Variance** parameters. A length- $N$  vector specified for one or both of the **Mean** and **Variance** parameters generates an  $N$ -channel output ( $M$ -by- $N$  frame matrix) containing a distinct random distribution in each column. When you specify only one of these parameters as a vector, the block scalar expands the other parameter so it is the same length as the vector.

#### Dependencies

To enable this parameter, set **Source type** to Gaussian. For more information, see “Source type” on page 2-0 .

**Number of uniform values to sum** — Number of uniform values to sum

12 (default)

The number of uniformly distributed random values to sum to compute a single number in a Gaussian random distribution.

#### Dependencies

To enable this parameter, set **Source type** to Gaussian and **Method** to Sum of uniform values. For more information, see “Source type” on page 2-0 .

**Minimum** — Minimum value of uniform distribution

0 (default) | scalar | vector

The minimum value in the uniform distribution specified as a finite scalar or vector.

**Tunable:** Yes

#### Dependencies

To enable this parameter, set **Source type** to Uniform.

#### Limitations

Tunable (Simulink) in Simulation mode only.

**Maximum** — Maximum value of uniform distribution

1 (default) | scalar | vector

The maximum value in the uniform distribution specified as a finite scalar or vector.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Source type** to Uniform.

**Limitations**

Tunable (Simulink) in Simulation mode only.

**Mean** — Mean value of Gaussian distribution

0 (default) | scalar | vector

The mean of the Gaussian (normal) distribution specified as a finite scalar or vector.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Source type** to Gaussian.

**Limitations**

Tunable (Simulink) in Simulation mode only.

**Variance** — Variance of Gaussian distribution

1 (default) | scalar | vector

The variance of the Gaussian (normal) distribution.

**Dependencies**

To enable this parameter, set **Source type** to Gaussian.

**Limitations**

Tunable (Simulink) in Simulation mode only.

**Repeatability** — Repeatability of block output

Specify seed (default) | Repeatable | Not repeatable

The **Repeatability** parameter determines if the block outputs the same signal each time you run the simulation. You can set the parameter to one of the following options:

- **Repeatable** — Outputs the same signal each time you run the simulation. The first time you run the simulation, the block randomly selects an initial seed. The block reuses these same initial seeds every time you rerun the simulation.
- **Specify seed** — Outputs the same signal each time you run the simulation. Every time you run the simulation, the block uses the initial seeds specified in the **Initial seed** parameter. Also see “Initial seed” on page 2-0 .

- **Not repeatable** — Does not output the same signal each time you run the simulation. Every time you run the simulation, the block randomly selects an initial seed.

**Initial seed** — Initial seed for random number generator

1 (default) | scalar | vector

The initial seed(s) to use for the random number generator specified as a finite scalar or vector. The generator produces an identical sequence of pseudorandom numbers each time it is executed with a particular initial seed.

To specify the  $N$  initial seeds for an  $N$ -channel real-valued output, set the **Complexity** parameter to **Real** and provide one of the following in the **Initial seed** parameter:

- Length- $N$  vector of initial seeds — Uses each vector element as an initial seed for the corresponding channel in the  $N$ -channel output.
- Single scalar — Uses the scalar to generate  $N$  random values as the seeds for the  $N$ -channel output.

To specify the initial seeds for an  $N$ -channel complex-valued output, set the **Complexity** parameter to **Complex** and provide one of the following in the **Initial seed** parameter:

- Length- $N$  vector of initial seeds — Uses each vector element as an initial seed for generating  $N$  channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.
- Single scalar — Uses the scalar to generate  $N$  random values as the seeds for generating  $N$  channels of *real* random values. The block uses pairs of adjacent values in each of these channels as the real and imaginary components of the final output, as illustrated in the following figure.

Use  $N$  channels of real random values to create the  $N$ -channel complex random output.

**Tunable:** Yes

**Dependencies**

To enable this parameter, set **Repeatability** to **Specify seed**.

**Limitations**

Tunable (Simulink) in Simulation mode only.

**Inherit output port attributes** — Inherit output port parameters from downstream block

off (default) | on

When you select this check box, the block inherits the sample mode, sample time, output data type, complexity, and signal dimensions of the signal from the downstream block. When you select this check box, the **Sample mode**, **Sample time**, **Samples per frame**, **Output data type**, and **Complexity** parameters are disabled.

Suppose that you want to back propagate a 1-D vector. The output of the Random Source block is a 1-D vector of length  $M$ , where length  $M$  is inherited from the downstream block. When the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter specifies  $N$  channels, the 1-D vector output contains  $M/N$  samples from each channel. An error occurs in this case when  $M$  is not an integer multiple of  $N$ .

Suppose that you want to back propagate a  $M$ -by- $N$  signal. When  $N > 1$ , your signal has  $N$  channels. When  $N = 1$ , your signal has  $M$  channels. The value of the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter can be a scalar or a vector of length equal to the number of channels. You can specify these parameters as either row or column vectors, except when the signal is a row vector. In this case, the **Minimum**, **Maximum**, **Mean**, or **Variance** parameter must also be specified as a row vector.

**Sample mode** — Discrete or continuous

Discrete (default) | Continuous

The sample mode, specified as Continuous or Discrete.

When you set **Sample mode** to Discrete, the **Sample time** parameter value,  $T_s$ , specifies the random sequence sample period. In this mode, the block generates the number of samples specified by the **Samples per frame** parameter value,  $M$ , and outputs this frame with a period of  $MT_s$ .

When you set **Sample mode** to Continuous, the block is configured for continuous-time operation, and the **Sample time** and **Samples per frame** parameters are disabled. Note that many DSP System Toolbox blocks do not accept continuous-time inputs.

#### Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box.

**Sample time** — Output sample period

1 (default) | scalar

The sample period,  $T_s$ , of the random output sequence when the **Sample mode** is Discrete, specified as a positive, finite, scalar. The output frame period is  $MT_s$ .

#### Dependencies

To enable this parameter, clear the **Inherit output port attributes** check box and set **Sample mode** to Discrete.

**Samples per frame** — Samples per output frame

1 (default) | positive integer

The number of samples,  $M$ , in each output frame, specified as a positive integer. The output frame period is  $MT_s$ .

**Dependencies**

To enable this parameter, clear the **Inherit output port attributes** check box and set **Sample mode** to **Discrete**.

**Output data type** — Output data type

Double (default) | Single

The data type of the output, specified as single-precision or double-precision.

**Dependencies**

To enable this parameter, clear the **Inherit output port attributes** check box.

**Complexity** — Complexity of output

Real (default) | Complex

The complexity of the output, specified as **Real** or **Complex**. These settings control all channels of the output, so real and complex data cannot be combined in the same output. For complex output with a **Uniform** distribution, the real and imaginary components in each channel are both drawn from the same uniform random distribution, defined by the **Minimum** and **Maximum** parameters for that channel.

For complex output with a **Gaussian** distribution, the real and imaginary components in each channel are drawn from normal distributions with different means. In this case, the **Mean** parameter for each channel should specify a complex value; the real component of the **Mean** parameter specifies the mean of the real components in the channel, while the imaginary component specifies the mean of the imaginary components in the channel. When either the real or imaginary component is omitted from the **Mean** parameter, a default value of 0 is used for the mean of that component.

For example, a **Mean** parameter setting of  $[5+2i \ 0.5 \ 3i]$  generates a three-channel output with the following means.

|                |                   |                      |
|----------------|-------------------|----------------------|
| Channel 1 mean | <i>real</i> = 5   | <i>imaginary</i> = 2 |
| Channel 2 mean | <i>real</i> = 0.5 | <i>imaginary</i> = 0 |
| Channel 3 mean | <i>real</i> = 0   | <i>imaginary</i> = 3 |

For complex output, the **Variance** parameter,  $\sigma^2$ , specifies the *total variance* for each output channel. This is the sum of the variances of the real and imaginary components in that channel.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

The specified variance is equally divided between the real and imaginary components, so that

$$\sigma_{\text{Re}}^2 = \frac{\sigma^2}{2}$$

$$\sigma_{\text{Im}}^2 = \frac{\sigma^2}{2}$$

**Dependencies**

To enable this parameter, clear the **Inherit output port attributes** check box.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |

### Topics

“Estimate the Transfer Function of an Unknown System”

## Real Cepstrum

Compute real cepstrum of input

**Libraries:**  
DSP System Toolbox / Transforms

### Description

The Real Cepstrum block computes the real cepstrum of the input.

### Ports

#### Input

**Input** — Input  
vector | matrix

Specify the input  $u$  as a vector or a matrix of size  $M$ -by- $N$ . The block treats each column of the input as an independent channel containing  $M$  consecutive samples. The block always processes unoriented vector inputs as a single channel, and returns the result as a length- $M$  column vector. The block does not accept complex-valued inputs.

Data Types: single | double

#### Output

**Output** — Real cepstrum output  
vector | matrix

Real cepstrum output, returned as an  $M_o$ -by- $N$  matrix.

When you clear the **Inherit FFT length from input port dimensions** parameter,  $M_o$  is the value you specify in the **FFT length** parameter. When you select the **Inherit FFT length from input port dimensions** parameter,  $M_o = M$ , where  $M$  is the frame size (number of rows) of the input signal.

Each output column contains the length- $M_o$  real cepstrum of the corresponding input column.

The output port rate is the same as the input port rate.

Data Types: single | double

### Parameters

**Inherit FFT length from input port dimensions** — Match the FFT length to the dimensions of the input port

on (default) | off

When you select this check box, the output frame size  $M_o$  matches the input frame size  $M$ .

**FFT length** — Compute FFT length

64 (default) | positive integer

The number of frequency points at which to compute the FFT, which is also the output frame size  $M_o$ .

**Dependency**

To enable this parameter, clear the **Inherit FFT length from input port dimensions** parameter.

## Block Characteristics

## More About

### Real Cepstrum

The *real cepstrum* is the inverse Fourier transform of the real logarithm of the magnitude of the Fourier transform of a sequence.

Here is the equivalent MATLAB code for computing the real cepstrum.

```
y = real(ifft(log(abs(fft(u,Mo))))))
```

or, more compactly,

```
y = rceps(u,Mo)
```

where,

- $u$  -- Input
- $y$  -- Real cepstrum output
- $M_o$  -- Output frame size

# Repeat

Resample input at higher rate by repeating values

## Libraries:

DSP System Toolbox / Signal Operations  
 Communications Toolbox / Sequence Operations  
 DSP System Toolbox HDL Support / Signal Operations

## Description

The Repeat block upsamples each channel of the  $M_i$ -by- $N$  input to a rate  $L$  times higher than the input sample rate. To do so, the block repeats each consecutive input sample  $L$  times at the output. Specify the integer  $L$  in the **Repetition count**, **L** parameter or through the input port **L**.

You can use the Repeat block in triggered subsystems when you set the **Rate options** parameter to **Enforce single-rate processing**.

## Ports

### Input

**in** — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix.

When you set **Input processing** to **Columns as channels (frame based)** and **Rate options** to **Enforce single-rate processing**, the input can be a variable-size signal. When the input is a variable-size signal, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

This port is unnamed until you set **Repetition count source** to **Input port**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

**L** — Repetition count

positive integer  $\leq L_{max}$

Specify the repetition count  $L$  as a positive integer less than or equal to the value you specify in the **Maximum repetition count**, **L<sub>max</sub>** parameter  $L_{max}$ .

### Dependency

To enable this port, set the **Repetition count source** parameter to **Input port**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

### Output

**Port\_1** — Output signal

scalar | vector | matrix

The Repeat block outputs a signal that has the same data type and complexity as the input signal **in**. The size of the output depends on the value of the repetition count and the option you select in the **Rate options** parameter.

If you set **Repetition count, L** to  $L$  and **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate by increasing the output frame size by a factor of  $L$ .
- **Allow multirate processing** -- The block resamples the signal such that the output sample rate is  $L$  times faster than the input sample rate. The output signal has the same frame size as the input signal.

When you input the repetition count through the input port **L**, the **Rate options** parameter is automatically set to **Enforce single-rate processing**. In this case, the block maintains the input sample rate at the output by increasing the output frame size by a factor of  $L$ .

The output is a variable-size signal when one or both of these conditions are met:

- Input is a variable-size signal.
- Repetition count is input through the port **L**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

## Parameters

**Repetition count source** — Mode of specifying repetition count

Dialog parameter (default) | Input port

Specify the repetition count through one of these options:

- **Dialog parameter** -- The block enables the **Repetition count, L** parameter in the block dialog box.
- **Input port** -- The block enables the input port **L** through which you specify the repetition count.

**Repetition count, L** — Repetition count

5 (default) | positive integer

Specify the repetition count  $L$  as a positive integer. This value is the number of times that the block repeats the input value. This is the factor by which the block increases the output frame size or sample rate.

### Dependency

To enable this parameter, set **Repetition count source** to **Dialog parameter**.

**Maximum repetition factor, Lmax** — Maximum repetition count

16 (default) | positive integer  $\geq 1$

Specify the maximum repetition  $L_{max}$  as a positive integer greater than or equal to 1. The repetition count you specify through the input port **L** must be less than or equal to  $L_{max}$ .

**Dependency**

To enable this parameter, set **Repetition count source** to `Input port`.

**Input processing** — Method to process input signals

`Columns as channels (frame based) (default)` | `Elements as channels (sample based)`

Specify how the block should process the input by setting this parameter to one of these options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

**Dependency**

To enable this parameter, set **Repetition count source** to `Dialog parameter`.

When you set **Repetition count source** to `Input port`, the **Input processing** parameter is automatically set to `Columns as channels (frame based)`.

**Rate options** — Method by which block upsamples input

`Enforce single-rate processing (default)` | `Allow multirate processing`

Specify the method by which the block upsamples the input by selecting one of these options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of  $L$ . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is  $L$  times faster than the input sample rate.

**Dependency**

To enable this parameter, set **Repetition count source** to `Dialog parameter`.

When you set **Repetition count source** to `Input port`, the **Rate options** parameter is automatically set to `Enforce single-rate processing`.

**Initial conditions** — Initial conditions

`0 (default)` | `scalar` | `matrix`

Specify the value with which the block is initialized for cases of nonzero latency as a scalar or a matrix.

**Dependencies**

To enable this parameter, set **Rate options** to `Allow multirate processing`.

## Block Characteristics

## More About

### Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input.

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame size than the input. The block upsamples each channel independently by repeating each row of the input matrix  $L$  times at the output. For upsampling by a factor of  $L$ , the output frame size is  $L$  times larger than the input frame size ( $M_o = M_i * L$ ), but the input and output frame rates are equal.

For an example that shows how the Repeat block operates in the single-rate processing mode, see “Repeat Signal In Single-Rate Frame-Based Processing Mode”.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an  $M_i$ -by- $N$  matrix input as  $N$  independent channels. The block generates the output at the faster (upsampled) rate by using a proportionally shorter frame period at the output port than at the input port. For  $L$  repetitions of the input, the output frame period is  $L$  times shorter than the input frame period ( $T_{fo} = T_{fi}/L$ ). In this mode, the output always has the same frame size as the input.

For an example that shows how the Repeat block operates in the multirate frame-based processing mode, see “Repeat Signal In Multirate Frame-Based Processing Mode”.

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an  $M$ -by- $N$  matrix input as  $M*N$  independent channels, and upsamples each channel over time. The block upsamples each channel over time such that the output sample rate is  $L$  times higher than the input sample rate ( $T_{so} = T_{si}/L$ ). In this mode, the output is always the same size as the input.

### Nonzero Latency

The Repeat block has tasking latency for a multirate multitasking operation:

- In the multirate sample-based processing mode, the block repeats the initial condition for each channel for the first  $L$  output samples. The first element of the input channel appears as output sample  $L+1$ . The **Initial conditions** parameter can be an  $M_i$ -by- $N$  matrix containing one value for each channel, or a scalar value that the block applies to all signal channels.

- In the multirate frame-based processing mode, the block repeats the first row of the initial condition matrix for the first  $L$  output samples, the second row of the initial condition matrix for the next  $L$  output samples, and so on. The first row of the first input matrix appears in the output as sample  $M_1L+1$ . The **Initial conditions** parameter can be an  $M_1$ -by- $N$  matrix, or a scalar value that the block repeats across all elements of the  $M_1$ -by- $N$  matrix.

---

**Note** For more information on latency and Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Zero Latency

The Repeat block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you specify a repetition count of 1 or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Repeat block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block repeats the first input (received at  $t=0$ ) for the first  $L$  output samples, the second input for the next  $L$  output samples, and so on.

## Version History

### Introduced before R2006a

#### R2022b: Support for variable-size input signal

Starting in R2022b, when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

When the input is a variable-size signal, the output is also a variable-size signal.

#### R2023a: Tune repetition count through input port

You can now specify the repetition count through an input port when the Repeat block operates in the single-rate frame-based processing mode. When you specify the repetition count through the input port, you can change the value during simulation.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### Best Practices

The Repeat block uses fewer hardware resources than the Upsample block. If your algorithm does not require zero-padding upsampling, use the Repeat block.

### HDL Architecture

This block has one default HDL architecture.

### HDL Block Properties

## RLS Adaptive Filter (Obsolete)

Compute filter estimates for input using RLS adaptive filter algorithm

### Library

dspobslib

### Description

---

**Note** The RLS Adaptive Filter block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the RLS Filter block.

---

The RLS Adaptive Filter block recursively computes the recursive least squares (RLS) estimate of the FIR filter coefficients.

The corresponding RLS filter is expressed in matrix form as

$$k(n) = \frac{\lambda^{-1}P(n-1)u(n)}{1 + \lambda^{-1}u^H(n)P(n-1)u(n)}$$

$$y(n) = \widehat{w}^H(n-1)u(n)$$

$$e(n) = d(n) - y(n)$$

$$\widehat{w}(n) = \widehat{w}(n-1) + k(n)e^*(n)$$

$$P(n) = \lambda^{-1}P(n-1) - \lambda^{-1}k(n)u^H(n)P(n-1)$$

where  $\lambda^{-1}$  denotes the reciprocal of the exponential weighting factor. The variables are as follows

| Variable         | Description                                    |
|------------------|--|
| $n$              | The current algorithm iteration                |
| $u(n)$           | The buffered input samples at step $n$         |
| $P(n)$           | The inverse correlation matrix at step $n$     |
| $k(n)$           | The gain vector at step $n$                    |
| $\widehat{w}(n)$ | The vector of filter-tap estimates at step $n$ |
| $y(n)$           | The filtered output at step $n$                |
| $e(n)$           | The estimation error at step $n$               |
| $d(n)$           | The desired response at step $n$               |
| $\lambda$        | The exponential memory weighting factor        |

The block icon has port labels corresponding to the inputs and outputs of the RLS algorithm. Note that inputs to the **In** and **Err** ports must be sample-based scalars. The signal at the **Out** port is a scalar, while the signal at the **Taps** port is a sample-based vector.

| Block Ports | Corresponding Variables   |
|-------------|---|
| In          | $u$ , the scalar input, which is internally buffered into the vector $u(n)$ |
| Out         | $y(n)$ , the filtered scalar output   |
| Err         | $e(n)$ , the scalar estimation error  |
| Taps        | $\hat{w}(0)$ , the vector of filter-tap estimates                           |

An optional **Adapt** input port is added when you select the **Adapt input** check box in the dialog box. When this port is enabled, the block continuously adapts the filter coefficients while the **Adapt** input is nonzero. A zero-valued input to the **Adapt** port causes the block to stop adapting, and to hold the filter coefficients at their current values until the next nonzero **Adapt** input.

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse correlation matrix  $P(n)$ . This decreases the total number of computations by a factor of two.

The **FIR filter length** parameter specifies the length of the filter that the RLS algorithm estimates. The **Memory weighting factor** corresponds to  $\lambda$  in the equations, and specifies how quickly the filter “forgets” past sample information. Setting  $\lambda=1$  specifies an infinite memory; typically,  $0.95 \leq \lambda \leq 1$ .

The **Initial value of filter taps** specifies the initial value  $\hat{w}(0)$  as a vector, or as a scalar to be repeated for all vector elements. The initial value of  $P(n)$  is

$$I \frac{1}{\hat{\sigma}^2}$$

where you specify  $\hat{\sigma}^2$  in the **Initial input variance estimate** parameter.

## Parameters

### FIR filter length

The length of the FIR filter.

### Memory weighting factor

The exponential weighting factor, in the range  $[0, 1]$ . A value of 1 specifies an infinite memory. Tunable (Simulink).

### Initial value of filter taps

The initial FIR filter coefficients.

### Initial input variance estimate

The initial value of  $1/P(n)$ .

### Adapt input

Enables the **Adapt** port.

## RLS Filter

Compute filtered output, filter error, and filter weights for given input and desired signal using RLS adaptive filter algorithm

## Library

Filtering / Adaptive Filters

dspadpt3

## Description

The RLS Filter block recursively computes the least squares estimate (RLS) of the FIR filter weights. The block estimates the filter weights, or coefficients, needed to convert the input signal into the desired signal. Connect the signal you want to filter to the Input port. The input signal can be a scalar or a column vector. Connect the signal you want to model to the Desired port. The desired signal must have the same data type, complexity, and dimensions as the input signal. The Output port outputs the filtered input signal. The Error port outputs the result of subtracting the output signal from the desired signal.

The corresponding RLS filter is expressed in matrix form as

$$\mathbf{k}(n) = \frac{\lambda^{-1} \mathbf{P}(n-1) \mathbf{u}(n)}{1 + \lambda^{-1} \mathbf{u}^H(n) \mathbf{P}(n-1) \mathbf{u}(n)}$$

$$y(n) = \mathbf{w}(n-1) \mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^H(n) e(n)$$

$$\mathbf{P}(n) = \lambda^{-1} \mathbf{P}(n-1) - \lambda^{-1} \mathbf{k}(n) \mathbf{u}^H(n) \mathbf{P}(n-1)$$

where  $\lambda^{-1}$  denotes the reciprocal of the exponential weighting factor. The variables are as follows

| Variable        | Description                                      |
|-----------------|--|
| $n$             | The current time index                           |
| $\mathbf{u}(n)$ | The vector of buffered input samples at step $n$ |
| $\mathbf{P}(n)$ | The inverse covariance matrix at step $n$        |
| $\mathbf{k}(n)$ | The gain vector at step $n$                      |
| $\mathbf{w}(n)$ | The vector of filter-tap estimates at step $n$   |

| Variable  | Description                      |
|-----------|----------------------------------|
| $y(n)$    | The filtered output at step $n$  |
| $e(n)$    | The estimation error at step $n$ |
| $d(n)$    | The desired response at step $n$ |
| $\lambda$ | The forgetting factor            |

The implementation of the algorithm in the block is optimized by exploiting the symmetry of the inverse covariance matrix  $P(n)$ . This decreases the total number of computations by a factor of two.

Use the **Filter length** parameter to specify the length of the filter weights vector.

The **Forgetting factor (0 to 1)** parameter corresponds to  $\lambda$  in the equations. It specifies how quickly the filter “forgets” past sample information. Setting  $\lambda=1$  specifies an infinite memory. Typically,  $1 - \frac{1}{2L} < \lambda < 1$ , where  $L$  is the filter length. You can specify a forgetting factor using the input port, Lambda, or enter a value in the **Forgetting factor (0 to 1)** parameter in the Block Parameters: RLS Filter dialog box.

Enter the initial filter weights,  $\hat{w}(0)$ , as a vector or a scalar for the **Initial value of filter weights** parameter. When you enter a scalar, the block uses the scalar value to create a vector of filter weights. This vector has length equal to the filter length and all of its values are equal to the scalar value.

The initial value of  $P(n)$  is

$$\frac{1}{\sigma^2}I$$

where you specify  $\sigma^2$  in the **Initial input variance estimate** parameter.

When you select the **Adapt port** check box, an Adapt port appears on the block. When the input to this port is nonzero, the block continuously updates the filter weights. When the input to this port is zero, the filter weights remain at their current values.

When you want to reset the value of the filter weights to their initial values, use the **Reset input** parameter. The block resets the filter weights whenever a reset event is detected at the Reset port. The reset signal rate must be the same rate as the data signal input.

From the **Reset input** list, select None to disable the Reset port. To enable the Reset port, select one of the following from the **Reset input** list:

- **Rising edge** — Triggers a reset operation when the Reset input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero; see the following figure

- **Falling edge** — Triggers a reset operation when the Reset input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero; see the following figure

- **Either edge** — Triggers a reset operation when the Reset input is a **Rising edge** or **Falling edge**, as described above
- **Non-zero sample** — Triggers a reset operation at each sample time that the Reset input is not zero

Select the **Output filter weights** check box to create a Wts port on the block. For each iteration, the block outputs the current updated filter weights from this port.

## Examples

The `rlsdemo` example illustrates a noise cancellation system built around the RLS Filter block.

## Parameters

### Filter length

Enter the length of the FIR filter weights vector.

### Specify forgetting factor via

Select **Dialog** to enter a value for the forgetting factor in the Block parameters: RLS Filter dialog box. Select **Input port** to specify the forgetting factor using the Lambda input port.

**Forgetting factor (0 to 1)**

Enter the exponential weighting factor in the range  $0 \leq \lambda \leq 1$ . A value of 1 specifies an infinite memory. Tunable (Simulink).

**Initial value of filter weights**

Specify the initial values of the FIR filter weights.

**Initial input variance estimate**

The initial value of  $1/P(n)$ .

**Adapt port**

Select this check box to enable the Adapt input port.

**Reset input**

Select this check box to enable the Reset input port.

**Output filter weights**

Select this check box to export the filter weights from the Wts port.

## RMS

Root mean square value of input or sequence of inputs

**Libraries:**  
DSP System Toolbox / Statistics

### Description

The RMS block computes the root mean square (RMS) value of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input. You can specify the dimension using the **Find the RMS value over** parameter. The RMS block can also track the RMS value in a sequence of inputs over a period of time. To track the RMS value in a sequence of inputs, select the **Running RMS** parameter.

---

**Note** The **Running** mode in the RMS block will be removed in a future release. To compute the running RMS in Simulink, use the Moving RMS block instead.

---

### Ports

#### Input

**In** — Data input  
vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running RMS** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double

**Rst** — Reset port  
scalar

Specify the reset event that causes the block to reset the running RMS. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

#### Dependencies

To enable this port, select the **Running RMS** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

#### Output

**Port\_1** — RMS value along the specified dimension  
scalar | vector | matrix |  $N$ -D array

The data type of the output matches the data type of the input.

When you do not select the **Running RMS** parameter, the block computes the RMS value in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the RMS value of the entire input at each individual sample time. Each element in the output array  $y$  is the RMS value of the corresponding column, row, or entire input. The output array  $y$  depends on the setting of the **Find the RMS value over** parameter. Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ . When you set **Find the RMS value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the RMS value of the  $M$ -by- $N$ -by- $P$  input matrix.
- **Each row** — The output at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the RMS value of each vector over the second dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is an  $M$ -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the RMS value of each vector over the first dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the RMS value of each vector over the third dimension of the input.

When you select **Running RMS**, the block tracks the RMS value of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the RMS value of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running RMS  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the RMS value of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double`

## Parameters

### Main Tab

**Running RMS** — Option to select running RMS  
off (default) | on

When you select the **Running RMS** parameter, the block tracks the RMS value of each channel in a time sequence of inputs.

**Find the RMS value over** — Dimension over which the block computes the RMS value  
Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the RMS value over each column.
- **Each row** — The block outputs the RMS value over each row.
- **Entire input** — The block outputs the RMS value over the entire input.
- **Specified dimension** — The block outputs the RMS value over the dimension specified in the **Dimension** parameter.

#### Dependencies

To enable this parameter, clear the **Running RMS** parameter.

**Dimension** — Custom dimension  
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the RMS value is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

#### Dependencies

To enable this parameter, set **Find the RMS value over** to Specified dimension.

**Input processing** — Method to process the input in running mode  
Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the RMS value of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the RMS value of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running RMS  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

#### Variable-Size Inputs

When your inputs are of variable size, and you select the **Running RMS** parameter, then:

- If you set the **Input processing** parameter to Elements as channels (sample based), the state is reset.

- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
  - When the input size difference is in the number of channels (number of columns), the state is reset.
  - When the input size difference is in the length of channels (number of rows), there is no reset and the running operation is carried out as usual.

### Dependencies

To enable this parameter, select the **Running RMS** parameter.

### Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running RMS whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running RMS for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running RMS for each channel becomes the RMS value of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

**Note** When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

### Dependencies

To enable this parameter, select the **Running RMS** parameter.

### Block Characteristics

### More About

#### Root Mean Square (RMS)

The RMS value of a discrete-time signal is the square root of the arithmetic mean of the squares of the signal sample values.

For an  $M$ -by- $N$  input matrix  $u$ , the RMS value of the  $j$ th column of the input is given by:

$$y_j = \sqrt{\frac{\sum_{i=1}^M |u_{ij}|^2}{M}} \quad 1 \leq j \leq N$$

## Algorithms

### Root Mean Square (RMS)

When you clear the **Running RMS** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `rms` function, when it is called as `y = rms(u,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the RMS value.

The RMS value along the entire input is identical to calling the `rms` function as `y = rms(u(:))`.

When inputs are complex, the block computes the RMS value of the magnitude of the complex input.

# Sample and Hold

Sample and hold input signal

## Libraries:

DSP System Toolbox / Signal Operations

DSP System Toolbox HDL Support / Signal Operations

## Description

The Sample and Hold block acquires the input at the signal port whenever it receives a trigger event at the trigger port (marked by ). The block then holds the output at the acquired input value until the next triggering event occurs.

## Ports

### Input

**In** — Signal port

scalar | vector | matrix

The signal port can accept data in the form of a scalar, vector, or matrix.

### Dependencies

This port is named **In<Lo>** when you select the **Latch (buffer) input** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

**Trigger** — Trigger port

scalar

The trigger input must be a sample-based scalar with sample rate equal to the input frame rate at the signal port. You specify the trigger event using the **Trigger type** parameter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

### Output

**Port\_1** — Sample and hold value

scalar | vector | matrix

Sample and hold output, returned as a scalar, vector, or a matrix. The block acquires input at the signal port whenever it receives a trigger event at the trigger port. The block then holds the acquired data until the next triggering event occurs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

## Parameters

**Trigger type** — Type of trigger

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the block to acquire the input signal:

- **Rising edge** -- The trigger input rises from a negative value or zero to a positive value.
- **Falling edge** -- The trigger input falls from a positive value or zero to a negative value.
- **Either edge** -- The trigger input either rises from a negative value or zero to a positive value or falls from a positive value or zero to a negative value.

**Initial condition** — Block output prior to first trigger event

0 (default) | scalar | vector | matrix

Specify the block's output before the first trigger event using the **Initial condition** parameter. When the acquired input is an  $M$ -by- $N$  matrix, the **Initial condition** can be an  $M$ -by- $N$  matrix or a scalar repeated across all elements of the matrix. When the input is a length- $M$  unoriented vector, the **Initial condition** can be a length- $M$  row or column vector, or a scalar to be repeated across all elements of the vector.

**Latch (buffer) input** — Latch buffer input

off (default) | on

If you select the **Latch (buffer) input** check box, the block outputs the value of the input from the previous time step until the next triggering event occurs. To use this block in a loop, select this check box.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL code for the Sample and Hold block is generated as a Triggered Subsystem. Similar restrictions apply to both blocks. See “Using Triggered Subsystems for HDL Code Generation” (HDL Coder).

### **HDL Block Properties**

For HDL block property descriptions, see “HDL Block Properties: General” (HDL Coder).

### **Best Practices**

When using the Sample and Hold block in models targeted for HDL code generation, consider the following:

- For synthesis results to match Simulink results, drive the trigger port with registered logic (with a synchronous clock) on the FPGA.
- It is good practice to put a unit delay on the output signal. Doing so prevents the code generator from inserting extra bypass registers in the HDL code.
- The use of triggered subsystems, such as the Sample and Hold block, can affect synthesis results in the following ways:
  - In some cases, the system clock speed can drop by a small percentage.
  - Generated code uses more resources, scaling with the number of triggered subsystem instances.

### **Restrictions**

The Sample and Hold block must meet the following conditions:

- The DUT (i.e., the top-level subsystem for which code is generated) must not be the Sample and Hold block.
- The trigger signal must be a scalar.
- The data type of the trigger signal must be either `boolean` or `ufix1`.
- The output of the Sample and Hold block must have an initial value of 0.
- The input, output, and trigger signal of the Sample and Hold block must run at the same rate. If one of the input or the trigger signals is an output of a Signal Editor block, see “Using the Signal Editor Block” (HDL Coder) for how to match rates.

# Sample-Rate Converter

Multistage sample-rate conversion

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Sample-Rate Converter block implements a multistage FIR sample-rate converter. The multistage FIR converter converts the rate of each channel of the input signal from the input sample rate to the output sample rate. Multistage implementations minimize the amount of computation required for the sample-rate conversions by first reducing the sample rate of the input signal. Next, the block determines the optimal number of decimators and interpolators based on the parameters you specify in the block dialog box. The block then accordingly designs filters in the individual stages.

This block supports SIMD code generation. For details, see “Code Generation” on page 2-1246.

## Ports

### Input

**Port 1** — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix.

The block treats each column of a two-dimensional input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size), and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets the signal as having a single channel.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

To determine the decimation factor, click the **View Info** button in the block dialog box.

Data Types: single | double

### Output

**Port 1** — Resampled signal

scalar | vector | matrix

The Sample-Rate Converter block outputs a signal that has the same data type and complexity as the input signal.

The output signal dimensions depend on the input signal dimensions, the overall interpolation and decimation factors of the Sample-Rate Converter block, and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter. You can determine the overall interpolation factor  $L$  and the decimator factor  $M$  by clicking the **View Info** button in the block dialog box.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

### Fixed-Size Input Signal

| Input Signal  | Output Signal Dimensions   |
|---|--|
| $P$ -by-1 column vector, where $P$ is a multiple of the decimation factor $M$     | $(LP/M)$ -by-1, where $L$ is the interpolation factor  |
| $P$ -by-1 column vector, where $P$ is not a multiple of the decimation factor $M$ | $\text{ceil}(LP/M)$ -by-1 when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.    |
| $P$ -by- $Q$ matrix, where $P$ is a multiple of the decimation factor $M$         | $(LP/M)$ -by- $Q$  |
| $P$ -by- $Q$ matrix, where $P$ is not a multiple of the decimation factor $M$     | $\text{ceil}(LP/M)$ -by- $Q$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

This table gives more details on the dimensions of the output signal when you input a variable-size input signal. When you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** parameter is visible in the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

### Variable-Size Input Signal

| Input Signal | Output Signal Dimensions     |
|--------------|------------------------------|
| $P$ -by- $Q$ | $\text{ceil}(LP/M)$ -by- $Q$ |

Data Types: `single` | `double`

## Parameters

**Sample rate of input signal (Hz)** — Sample rate of input signal in Hz

48e3 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

**Sample rate of output signal (Hz)** — Sample rate of output signal in Hz

96e3 (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar in Hz. The output sample rate must be greater than the bandwidth of interest.

**Tolerance for output sample rate** — Maximum tolerance for output sample rate

0 (default) | positive scalar in the range [0,0.5]

Specify the maximum tolerance for the output sample rate as a positive scalar in the range [0,0.5]. The default is 0.

The actual output sample rate varies but is within the specified range. For example, if you set the **Tolerance for output sample rate** to 0.01, then the actual output sample rate is in the range given by sample rate of output signal  $\pm 1\%$ . This flexibility allows for a simpler filter design.

**Two-sided bandwidth of interest (Hz)** — Two-sided bandwidth of interest in Hz

40e3 (default) | positive scalar

Specify the two-sided bandwidth of interest (after the rate of conversion) as a positive scalar in Hz.

**Stopband attenuation (dB)** — Minimum attenuation for aliased components in dB

80 (default) | positive scalar

Specify the minimum amount of attenuation for aliased components in the stopband as a positive scalar in dB. This parameter is the minimum amount by which the block attenuates any aliasing involved in the process.

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter only for fixed-size input signals and ignores it if the input data varies in size during simulation.

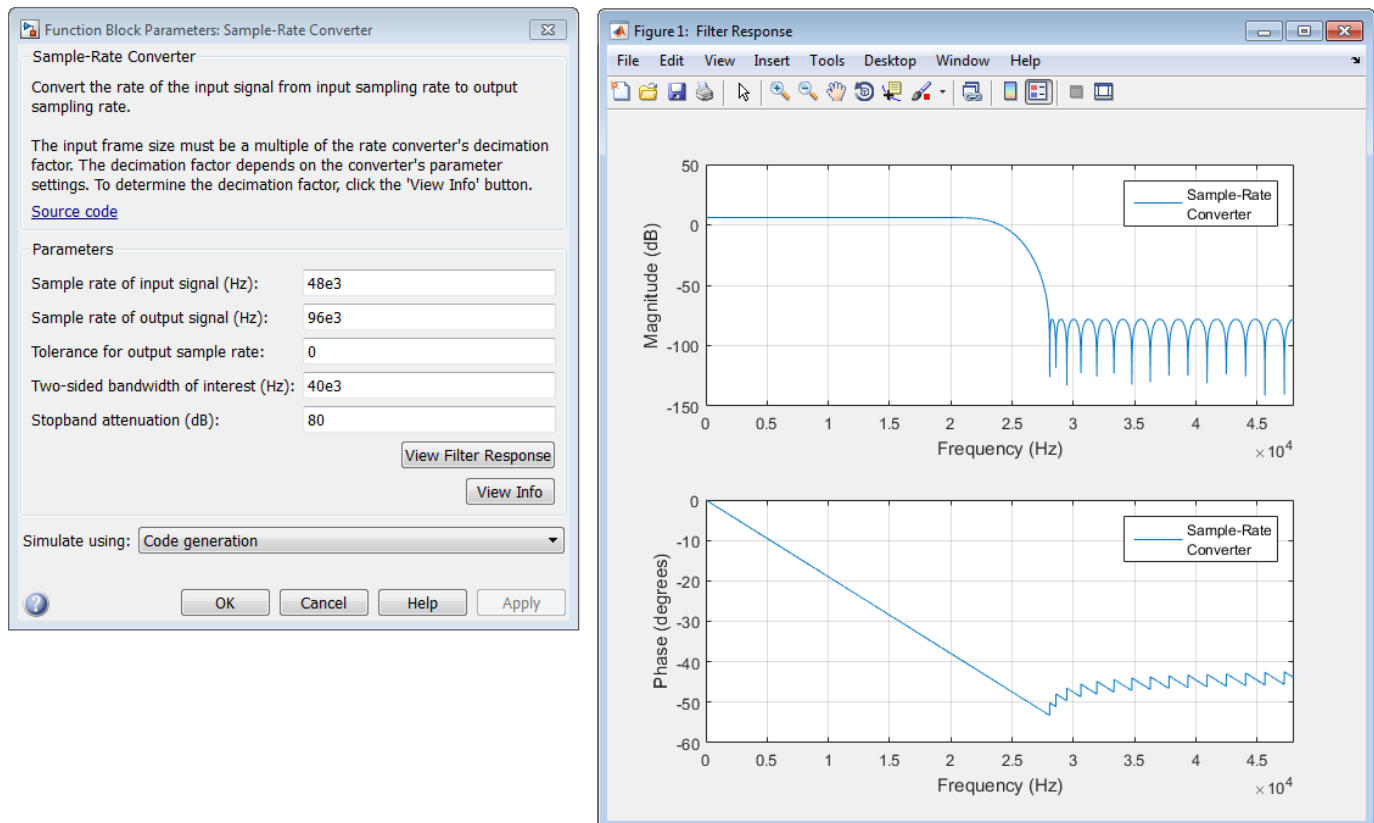

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

### View Filter Response — View Filter Response button

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Sample-Rate Converter. The response is based on the block parameters. FVTool updates when you change the parameters.

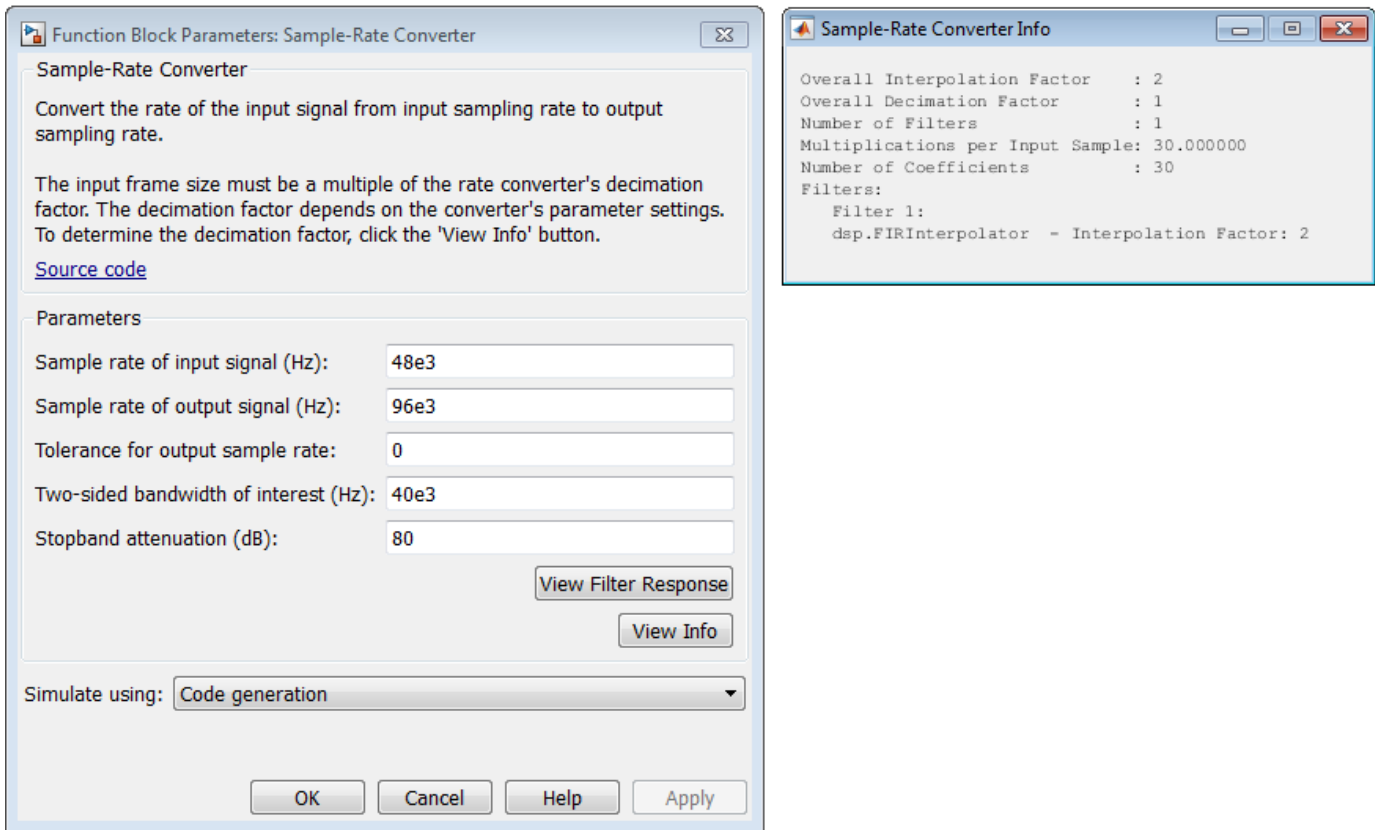

To update the magnitude response while FVTool is running, modify the parameters in the dialog box and click **Apply**.

### View Info — Display information about filter button

Click on the **View Info** button to display the filter information of the Sample-Rate Converter block:

- Overall Interpolation Factor
- Overall Decimation Factor
- Number of Filters
- Multiplication per Input Sample
- Number of Coefficients
- Filters

The button brings the functionality of the `info` function into the Simulink environment.

**Simulate using** — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                           |                 |
|---------------------------|-----------------|
| <b>Data Types</b>         | double   single |
| <b>Direct Feedthrough</b> | no              |

|                                 |     |
|---------------------------------|-----|
| <b>Multidimensional Signals</b> | no  |
| <b>Variable-Size Signals</b>    | yes |
| <b>Zero-Crossing Detection</b>  | no  |

## Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation. Actual designs include at most two of these steps.
- The procedure automatically determines the optimal number of decimation or interpolation stages. In special cases, the algorithm can perform a decimation or interpolation in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step ensures that the intermediate sample rate does not go below the bandwidth of interest and that the block does not filter out any information.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- The algorithm allows transition-band aliasing because it decreases the implementation cost. It keeps the signal within the bandwidth of interest alias free up to the value specified by the `StopbandAttenuation` property.

## Version History

Introduced in R2015b

### R2023a: Support for arbitrary input frame length

This block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an input signal with an arbitrary frame length, the input frame length does not have to be a multiple of the decimation factor.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sample-Rate Converter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- For upsampling, the ratio of output sample rate to input sample rate must be an integer.
- For downsampling, the ratio of input sample rate to output sample rate must be an integer.

- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

## Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal

## Library

dspobslib

## Description

---

**Note** The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Scalar Quantizer Encoder block or the Scalar Quantizer Decoder block.

---

The Scalar Quantizer block has three modes of operation. In **Encoder** mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In **Decoder** mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the **Encoder and Decoder** mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select **Specify via dialog**, type the parameters into the block parameters dialog box. Select **Input ports**, and port B and/or C appears on the block. In **Encoder** and **Encoder and decoder** mode, the input to port B is used as the **Boundary points**. In **Decoder** and **Encoder and decoder** mode, the input to port C is used as the **Codebook**.

In **Encoder** and **Encoder and decoder** mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is  $-\infty$  and your last boundary point is  $\infty$ , your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is  $-\infty$  or  $\infty$ , your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select **Choose the lower index**. To assign the input value with the higher index, select **Choose the higher index**.

In **Decoder** and **Encoder** and **decoder** mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In **Encoder** and **Encoder** and **decoder** mode, the **Searching method** determines how the appropriate quantizer index is found. Select **Linear** and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order  $P$ , where  $P$  is the number of boundary points.

Select **Binary** for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order  $\log_2 P$ , where  $P$  is the number of boundary points. In most cases, the **Binary** option is faster than the **Linear** option.

In **Decoder** mode, the input to this block is a vector of index values, where  $0 \leq \text{index} < N$  and  $N$  is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to  $N$  to be set to  $N - 1$ , select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to  $N$  are set to  $N - 1$ , select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

In **Encoder** and **decoder** mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the **Err** port on this block.

### Data Type Support

In **Encoder** mode, the input data values and the boundary points can be the input to the block at ports **U** and **B**. Similarly, in **Encoder** and **decoder** mode, the codebook values can also be the input to the block at port **C**. The data type of the input data values, boundary points, and codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. In **Decoder** mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port **Idx** can be **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. The data type of the codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**.

In Encoder mode, the output of the block is the index values. In Encoder and decoder mode, the output can also include the quantized output values and the quantization error. In Encoder and Encoder and decoder mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port Idx. The data type of the index output can be uint8, uint16, uint32, int8, int16, or int32. The data type of the quantized output and the quantization error can be double, single, uint8, uint16, uint32, int8, int16, or int32. In Decoder mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the data type of the quantized output values. The data type can be double, single, uint8, uint16, uint32, int8, int16, int32.

---

**Note** The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

---

## Parameters

### Quantizer mode

Specify Encoder, Decoder, or Encoder and decoder as a mode of operation.

### Source of quantizer parameters

Choose Specify via dialog to type the parameters into the block parameters dialog box. Select Input ports to specify the parameters using the block's input ports. In Encoder and Encoder and decoder mode, input the **Boundary points** using port B. In Decoder and Encoder and decoder mode, input the **Codebook** values using port C.

### Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. Tunable (Simulink).

### Codebook

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

### Searching method

Select Linear and the block finds the region in which the input value is located using a linear search. Select Binary and the block finds the region in which the input value is located using a binary search.

### Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select Choose the lower index, the input value is assigned to lower index value. When you select Choose the higher index, the value is assigned to the higher index.

### Action for out of range input

Choose the block's behavior when an input index value is out of range, where  $0 \leq \text{index} < N$  and  $N$  is the length of the codebook vector. Select Clip, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to  $N$  to be set to  $N - 1$ . Select Clip and warn, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to  $N$  are set to  $N - 1$ . Select Error, when you want the simulation to stop and display an error when the index values are out of range.

**Output the quantization error**

In Encoder and decoder mode, select this check box to output the quantization error from the Err port on this block.

**Output index data type**

In Encoder and Encoder and decoder mode, specify the data type of the index output from the block at port Idx. The data type can be uint8, uint16, uint32, int8, int16, or int32.

This parameter becomes visible when you select the **Show additional parameters** check box.

**Output data type**

In Decoder mode, specify the data type of the quantized output. The data type can be uint8, uint16, uint32, int8, int16, int32, single, or double. This parameter becomes visible when you select Specify via dialog for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

**Supported Data Types**

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 2-1249.

## Scalar Quantizer Decoder

Convert each index value into quantized output value

## Library

Quantizers

dspquant2

## Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select *Specify via dialog*, type the codebook values into the block parameters dialog box. When you select *Input port*, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where  $0 \leq \text{index} < N$  and  $N$  is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to  $N$  to be set to  $N - 1$ , select *Clip*. When you want to be warned when clipping occurs, select *Clip and warn*. When you want the simulation to stop and the block to display an error when the index values are out of range, select *Error*.

## Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select *Specify via dialog*, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be *Same as input*, `double`, `single`, `Fixed-point`, or *User-defined*. If, for the **Source of codebook** parameter you select *Input port*, the quantized output values have the same data type as the codebook values input at port C.

## Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.

### Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where  $0 \leq \text{index} < N$  and  $N$  is the length of the codebook vector. Select **Clip**, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to  $N$  to be set to  $N - 1$ . Select **Clip and warn**, when you want to be warned when clipping occurs. Select **Error**, when you want the simulation to stop and the block to display an error when the index values are outside the range.

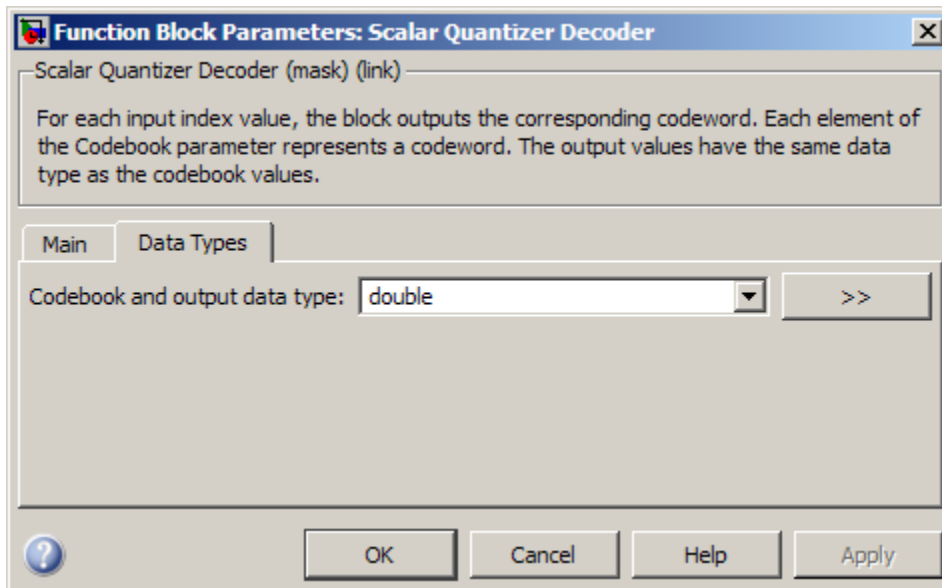

### Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook using input port C.

### Codebook values

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.

### Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

### Codebook and Output Data Type Assistant Parameters

#### Mode

Select how you would like to specify the data type properties of the **Codebook and output data type**. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit: Same as input`
- `Built in`— Lets you specify a built in data type, for example, `double`
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

**Signedness**

Specify the **Signedness** for the **Codebook and output data type**.

**Scaling**

Specify the **Scaling** for the **Codebook and output data type**.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Codebook and output data type**.

**Fraction length**

Specify the **Fraction length** for the **Codebook and output data type**.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

# Scalar Quantizer Design

(Removed) Start Scalar Quantizer Design Tool (SQDTool) to design scalar quantizer using Lloyd algorithm

---

**Note** The Scalar Quantizer Design block and the associated SQDTool have been removed. For more information, see “Compatibility Considerations”.

---

## Library

Quantizers

dspquant2

## Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length  $N$ , where  $N$  is the **Number of levels** parameter. When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. Then, set the **Source of initial boundary points** parameter. You can select **Mid-points** to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose **User defined** and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select **User defined** for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

---

**Note** This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

---

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd

algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select `Binary search` for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

---

**Note** You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

---

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

## Parameters

### Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is  $1e6$ .

### Source of initial codebook

Select **Auto-generate** to have the block choose the initial codebook values. Select **User defined** to enter your own initial codebook values.

### Number of levels

Enter the length of the codebook vector. For a b-bit quantizer, the length should be  $N = 2^b$ .

### Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter.

### Source of initial boundary points

Select **Mid-points** to locate the boundary points at the midpoint between the codebook values. Choose **User defined** to enter your own boundary points. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter.

### Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are  $-\infty$  and  $\infty$ , regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select **User defined** in order to activate this parameter.

### Stopping criteria

Choose **Relative threshold** to enter the maximum acceptable fractional drop in the squared quantization error. Choose **Maximum iteration** to specify the number of iterations at which to stop. Choose **Whichever comes first** and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

### Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

### Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select **Maximum iteration** in order to activate this parameter.

**Searching methods**

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

**Tie-breaking rules**

When a training point lies on a boundary point, choose `Lower indexed codeword` to assign the training point to the lower indexed quantization region. Choose `Higher indexed codeword` to assign the training point to the higher indexed region.

**Design and Plot**

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

**Export Outputs**

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

**Destination**

Choose `Current model` to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

**Block type**

Select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

**Encoder block name**

Enter a name for the Scalar Quantizer Encoder block.

**Decoder block name**

Enter a name for the Scalar Quantizer Decoder block.

**Overwrite target block(s)**

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

**Generate Model**

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

## Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region

## Library

Quantizers

dspquant2

## Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select **Specify via dialog**, type the boundary points into the block parameters dialog box. When you select **Input port**, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let  $N$  be the number of quantization regions. When the codebook is defined as  $[c_1 \ c_2 \ c_3 \ \dots \ c_N]$ , and the **Boundary points** parameter is defined as  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ , then  $p_0 < c_1 < p_1 < c_2 \ \dots \ p_{(N-1)} < c_N < p_N$  for a regular quantizer. When your quantizer is bounded, from the **Partitioning** list, select **Bounded**. You need to specify  $N+1$  boundary points, or  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ . When your quantizer is unbounded, from the **Partitioning** list, select **Unbounded**. You need to specify  $N-1$  boundary points, or  $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$ ; the block sets  $p_0$  equal to  $-\text{inf}$  and  $p_N$  equal to  $\text{inf}$ .

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select **Bounded** and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select Unbounded and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select **Linear**, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order  $P$ , where  $P$  is the number of boundary points.

When you select **Binary** for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order  $\log_2 P$ , where  $P$  is the number of boundary points. In most cases, the Binary option is faster than the Linear option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to be assigned to the lower indexed region, select **Choose the lower index**. To assign the input value with the higher indexed region, select **Choose the higher index**.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose **Specify via dialog**, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose **Input port**, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select **Bounded**, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$  and the possible index values are defined as  $[i_0 \ i_1 \ i_2 \ \dots \ i_{(N-1)}]$ , where  $i_0=0$  and  $i_0 < i_1 < i_2 < \dots < i_{(N-1)}$ . When you want any input value less than  $p_0$  to be assigned to index value  $i_0$  and any input values greater than  $p_N$  to be assigned to index value  $i_{(N-1)}$ , select **Clip**. When you want to be warned

when clipping occurs, select `Clip` and `warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1264 or “Supported Data Types” on page 2-1266.

### Data Type Support

The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or `Fixed-point`.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or `Fixed-point`. The clipping status values output at port S are Boolean values.

---

**Note** The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

---

## Dialog Box

### Main Tab

#### Source of quantizer parameters

Choose `Specify via dialog` to enter the boundary points and codebook values using the block parameters dialog box. Select `Input port` to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

#### Partitioning

When your quantizer is bounded, select `Bounded`. When your quantizer is unbounded, select `Unbounded`.

#### Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list. Tunable (Simulink).

#### Searching method

When you select `Linear`, the block finds the region in which the input value is located using a linear search. When you select `Binary`, the block finds the region in which the input value is located using a binary search.

#### Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower indexed region. When you select `Choose the higher index`, the value is assigned to the higher indexed region.

#### Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

**Output quantization error**

Select this check box to output the quantization error for each input value at port Err.

**Codebook**

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select **Bounded** and your boundary points vector has length  $N$ , then you must specify a codebook of length  $N-1$ . If, for the **Partitioning** parameter, you select **Unbounded** and your boundary points vector has length  $N$ , then you must specify a codebook of length  $N+1$ .

This parameter is visible when you select **Specify** via dialog from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. Tunable (Simulink).

**Output clipping status**

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select **Bounded** from the **Partitioning** list.

**Action for out of range input**

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as  $[p_0 p_1 p_2 p_3 \dots p_N]$  and the index values are defined as  $[i_0 i_1 i_2 \dots i_{(N-1)}]$ . When you want any input value less than  $p_0$  to be assigned to index value  $i_0$  and any input values greater than  $p_N$  to be assigned to index value  $i_{(N-1)}$ , select **Clip**. When you want to be warned when clipping occurs, select **Clip and warn**. When you want the simulation to stop and the block to display an error when the index values are out of range, select **Error**. This parameter is visible when you select **Bounded** from the **Partitioning** list.

**Index output data type**

Specify the data type of the index output from the block at port I. You can choose **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, or **Inherit** via back propagation.

**Data Types Tab****Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Saturate on integer overflow**

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on **saturate** and **wrap**, see overflow mode for fixed-point operations.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## Short-Time FFT

Nonparametric estimate of spectrum using short-time fast Fourier transform (STFT) method

### Libraries:

DSP System Toolbox / Transforms

## Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

## Ports

### Input

**x[n]** — Input signal  
vector | matrix

Specify the time-domain input signal as a vector or a matrix. If the input is a matrix, the block treats each column as an independent channel. The input can be a variable-size signal. That is, the frame size of the signal can change while the simulation is running. The number of channels must remain the same.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

**w[n]** — Analysis window vector  
vector

Connect your single-channel analysis window to the **w[n]** port. For the **Analysis window length** parameter, enter the length of the analysis window  $W$ . The block buffers the input signal such that it has a frame length of  $W$ .

If the window vector is fixed point, it must be a signed integer or signed fixed point with a power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

### Output

**X[nL,k]** — Short-time FFT output  
vector | matrix

The block outputs the complex-valued single-channel or multichannel short-time FFT at this port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Parameters

**Analysis window length** — Length of analysis window

512 (default) | positive integer greater than 1

Specify the frame length of the analysis window as a positive integer greater than 1. The block buffers the input into overlapping window segments using the specified window length and overlap length, and then multiplies each overlapped segment by the window.

**Overlap between consecutive windows (in samples)** — Overlap length

384 (default) | nonnegative integer

Specify the number of samples by which consecutive windows overlap in each frame of the input signal as a nonnegative integer. The window overlap reduces artifacts at the data boundaries.

**FFT length** — FFT length

1024 (default) | positive integer greater than or equal to 2

Enter the length up to which the block pads the input signal as a positive integer greater than or equal to 2. After the block buffers and windows the signal, it zero-pads the signal before computing the FFT. This parameter determines the length of the short-time fast Fourier transform output (number of rows). The FFT length must be greater than or equal to the window length.

## More About

### Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.

The values of the fixed-point parameters of the Array-Vector Multiply block in this diagram are:

- **Rounding Mode** — Floor
- **Saturate on integer overflow** — Wrap
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Same as first input

The values of the fixed-point parameters of the FFT block in this diagram are:

- **Rounding Mode** — Floor
- **Saturate on integer overflow** — Wrap
- **Sine table** — Same word length as input
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Inherit via internal rule

See the FFT and Array-Vector Multiply block reference pages for more information.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

## Signal From Workspace

Import signal from MATLAB workspace

**Libraries:**  
DSP System Toolbox / Sources

### Description

The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Also, the initial signal values are always produced immediately at  $t=0$ .

### Ports

#### Output

**Port\_1** — Signal imported from workspace  
scalar | vector | matrix | 3-D array

Signal imported from workspace, as a scalar, vector, matrix, or 3-D array.

When the **Signal** parameter specifies an  $M$ -by- $N$  matrix ( $M \neq 1$ ), each of the  $N$  columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter,  $M_o$ . The output is an  $M_o$ -by- $N$  matrix containing  $M_o$  consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter,  $T_s$ , and the output frame period is  $M_o T_s$ . For convenience, an imported row vector ( $M=1$ ) is treated as a single channel, so the output dimension is  $M_o$ -by-1.

When the **Signal** parameter specifies an  $M$ -by- $N$ -by- $P$  array, each of the  $P$  pages (an  $M$ -by- $N$  matrix) is output in sequence with period  $T_s$ . The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

### Parameters

**Signal** — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

**Sample time** — Output sample period

1 (default) | scalar | vector

The sample period,  $T_s$ , of the output, specified as a scalar or vector. The output frame period is  $M_o T_s$ .

**Samples per frame** — Samples per frame

1 (default) | positive integer

The number of samples,  $M_o$ , to buffer into each output frame, specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

**Form output after final data value by** — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure that the frame size evenly divides the input signal length.

The block does not extrapolate the imported signal beyond the last sample.

**Warn when frame size does not evenly divide input length** — Warn when input length is not an integer multiple of frame size

off (default) | on

Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size. When the input length is not an integer multiple of the frame size, the model becomes multirate. Use the Model Explorer to turn these warnings on or off model-wide:

- In the **Modeling** tab, click **Model Explorer**.
- In the **Search** bar of the Model Explorer, search by **Property Name** for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.
- Select each of the blocks for which you want to toggle the warning parameter, and select or clear the check box in the `ignoreOrWarnInputAndFrameLengths` column.

### Dependencies

To enable this parameter set **Form output after final data value by** to **Cyclic Repetition**.

# Signal To Workspace

Write data to MATLAB workspace

## Compatibility

**Note** The Signal To Workspace block has been replaced by the To Workspace block in Simulink. Replace existing instances of the Signal To Workspace block with To Workspace block. For new models, use the To Workspace block.

## Library

Sinks

dspsnks4

## Description

The Signal To Workspace block writes data from your simulation into an array or structure in the main MATLAB workspace. You can specify a name for the workspace variable as well as whether the data is saved as an array, structure, or structure with time.

When the **Save format** is set to Array or Structure, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table,  $K$  represents the value of the **Limit data points to last** parameter.

| Input Signal Dimensions | Save 2-D Signals as ...                       | Signal To Workspace Output Dimension   |
|-------------------------|---|--|
| $M$ -by- $N$ matrix     | 2-D array (concatenate along first dimension) | <p><math>K</math>-by-<math>N</math> matrix.</p> <p>If you set the <b>Limit data points to last</b> parameter to <math>\text{inf}</math>, <math>K</math> represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (<math>M</math>) by the total number of <math>M</math>-by-<math>N</math> inputs acquired by the block.</p> |

| Input Signal Dimensions              | Save 2-D Signals as ...                       | Signal To Workspace Output Dimension   |
|--------------------------------------|---|--|
| $M$ -by- $N$ matrix                  | 3-D array (concatenate along third dimension) | $M$ -by- $N$ -by- $K$ array.<br><br>If you set the <b>Limit data points to last</b> parameter to $\text{inf}$ , $K$ represents the total number of $M$ -by- $N$ inputs acquired by the end of the simulation.  |
| Length- $N$ unoriented vector        | Any setting                                   | $K$ -by- $N$ matrix  |
| $N$ -dimensional array where $N > 2$ | Any setting                                   | Array with $N+1$ dimensions, where the size of the last dimension is equal to $K$ . If you set the <b>Limit data points to last</b> parameter to $\text{inf}$ , $K$ represents the total number of $M$ -by- $N$ inputs acquired by the end of simulation |

## Examples

### Example 1: Save 2-D Signals as a 2-D Array

In the `ex_signaltoworkspace_ref2` model, the Signal To Workspace block receives a 2-by-4 matrix input and logs 11 frames (two samples per frame) by the end of the simulation. Because the **Save 2-D signals as** parameter is set to 2-D array (concatenate along first dimension), the block concatenates the input along the first dimension to create a 22-by-4 matrix,  $A$ , in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

In the 2-D output mode, there is no indication of where one frame ends and another begins. To log input frames separately, set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension), as shown in Example 2.

## Example 2: Save 2-D Signals as a 3-D Array

In the `ex_signaltoworkspace_ref1` model, the input to the Signal To Workspace block is a 2-by-4 matrix. The **Save 2-D signals as** parameter is set to 3-D array (concatenate along third dimension), so by the end of the simulation the Signal To Workspace block logs 11 frames of data as a 2-by-4-by-11 array, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

## Parameters

### Variable name

Specify the name of the array or structure into which the block logs the simulation data. The block creates this variable in the MATLAB workspace only after the simulation stops running. When you enter the name of an existing workspace variable, the block overwrites that variable with the simulation data.

### Limit data points to last

Specify the maximum number of samples or frames the block will save. When the simulation generates more than the specified maximum number of samples or frames, the simulation saves only the most recently generated data. To capture all data, set this parameter to `inf`. See the table in the Description on page 2-1275 section for more information on how this parameter affects the dimensions of the logged data.

### Decimation

Specify a positive integer *d* to determine how often the block writes data to the workspace array or structure. The block writes data to the array or structure every *d*th sample. With the default decimation value of 1, the block writes data at every time step.

### Save format

Specify the format in which to save simulation output to the workspace. You can select one of the following options:

- **Array** — Select this option to save the data as an N-dimensional array. If the input signal is an unoriented vector, the resulting workspace array is 2-D. Each input vector is saved in a row of the output matrix, vertically concatenated onto the previous vector. If the input signal is 2-dimensional, the dimensions of the resulting workspace array depend on the setting of the **Save 2-D signals as** parameter.

- **Structure** — Select this option to save the data as a structure consisting of three fields: `time`, `signals` and `blockName`. In this mode, the `time` field is empty, and the `blockName` field contains the name of the Signal To Workspace block. The `signals` field contains a structure with three additional fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values, the `dimensions` field specifies the dimensions of the values array, and the `label` field contains the label of the input line.
- **Structure with time** — This option is the same as **Structure**, except that the `time` field contains a vector of simulation time steps. This is the only output format that can be read directly by a From Workspace block. When you select this option, the **Save 2-D signals as** parameter is not available. In this mode, the block always saves 2-D input arrays as a 3-D array.

The default setting of this parameter is **Array**.

### Save 2-D signals as

Specify whether the block outputs 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- **2-D array (concatenate along first dimension)** — When you select this option, the block saves an  $M$ -by- $N$  input signal as a  $(K*M)$ -by- $N$  matrix, where  $K*M$  is the total number of samples acquired by the end of the simulation. The block vertically concatenates each  $M$ -by- $N$  matrix input with the previous input to produce the 2-D output array. See “Example 1: Save 2-D Signals as a 2-D Array” on page 2-1276 for more information about this mode.
- **3-D array (concatenate along third dimension)** — When you select this option, the block saves an  $M$ -by- $N$  input signal as an  $M$ -by- $N$ -by- $K$  array, where  $K$  is the number of  $M$ -by- $N$  inputs logged by the end of the simulation.  $K$  has an upper bound equal to the value of the **Limit data points to last** parameter. See “Example 2: Save 2-D Signals as a 3-D Array” on page 2-1277 for more information about this mode.

This parameter is visible only when you set the **Save format** parameter to **Array** or **Structure**. When you set the **Save format** parameter to **Structure with time**, the block outputs the 2-D input signal as a 3-D array.

---

**Note** The **Inherit from input** (this choice will be removed - see release notes) option will be removed in a future release. See “Signal To Workspace Block Changes” in the *DSP System Toolbox Release Notes* for more information.

---

### Frames

The output dimensionality for frame-based inputs. **Frames** can be set to **Concatenate frames** (2-D array) or **Log frames separately** (3-D array). This parameter is ignored when inputs are not frame based.

### Log fixed-point data as a fi object

Select this parameter to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

### Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)

- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

## Sine Wave

Generate continuous or discrete sine wave

### Libraries:

DSP System Toolbox / Sources

DSP System Toolbox HDL Support / Sources

### Description

The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. The block supports floating point and signed fixed-point data types.

The block generates a real sinusoidal signal when you set the **Output complexity** parameter to **Real**. The real sinusoidal output is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify  $A$  in the **Amplitude** parameter,  $f$  in hertz in the **Frequency** parameter, and  $\phi$  in radians in the **Phase offset** parameter.

The block generates a complex exponential signal when you set the **Output complexity** parameter to **Complex**. This complex exponential signal is defined by an expression of the type

$$y = Ae^{j(2\pi ft + \phi)} = A\{\cos(2\pi ft + \phi) + j\sin(2\pi ft + \phi)\}$$

### Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values ( $A$ ,  $f$ , and  $\phi$ ) can be scalars or length- $N$  vectors, where  $N$  is the desired number of channels in the output. When you specify at least one of these parameters as a length- $N$  vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the following real sinusoids, set the block parameters as shown:

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \frac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

- **Output complexity** = Real
- **Amplitude** = [1 2 3]
- **Frequency** = [1000 500 250]
- **Phase offset** = [0 0 pi/2]

## Ports

### Output

**Port 1** — Sinusoidal signal

scalar | vector | matrix

Output a sinusoidal signal as a scalar or vector. For more information about output complexity, see “Description” on page 2-1280. For information about multichannel support, see “Generating Multichannel Outputs” on page 2-1280.

---

**Tip** To output fixed-point data types, you must set **Sample mode** to Discrete and **Computation method** to Table lookup.

---

Data Types: single | double | fixed point  
Complex Number Support: Yes

## Parameters

### Main

**Amplitude** — Amplitude of sine waves

1 (default) | scalar | vector

A length- $N$  vector containing the amplitudes of the sine waves in each of  $N$  output channels, or a scalar to be applied to all  $N$  channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters.

---

**Tip** This parameter is tunable (Simulink) only when the **Computation method** is Trigonometric fcn or Differential.

---

**Tunable:** Yes

**Frequency (Hz)** — Frequency of each sine wave

100 (default) | scalar | vector

A length- $N$  vector containing frequencies, in hertz, of the sine waves in each of  $N$  output channels, or a scalar to be applied to all  $N$  channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies.

---

**Tip** This parameter is tunable (Simulink) when you set either:

- **Sample mode** to Continuous.
  - **Sample mode** to Discrete and **Computation method** to Trigonometric fcn.
- 

**Tunable:** Yes

**Phase offset (rad)** — Phase offset

0 (default) | scalar | vector

A length- $N$  vector containing the phase offsets, in radians, of the sine waves in each of  $N$  output channels, or a scalar to be applied to all  $N$  channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters.

---

**Tip** This parameter is tunable (Simulink) when you set either:

- **Sample mode** to Continuous.
  - **Sample mode** to Discrete and **Computation method** to Trigonometric fcn.
- 

**Tunable:** Yes

**Sample mode** — Continuous or discrete sampling mode

Discrete (default) | Continuous

Specify the sampling mode as Continuous or Discrete:

- Continuous

In continuous mode, the sinusoid in the  $i$ th channel,  $y_i$ , is computed as a continuous function,

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

and the block's output is continuous. In this mode, the block operates the same as the Simulink Sine Wave block with **Sample time** set to 0. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Also, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- Discrete

In discrete mode, the block can generate discrete-time output by directly evaluating the trigonometric function, by table lookup, or by a differential method. For more information on these computation methods, see “Algorithms” on page 2-1286.

**Output complexity** — Real or complex waveform

Real (default) | Complex

The type of waveform to generate: Real specifies a real sine wave, Complex specifies a complex exponential.

**Computation method** — Method for computing discrete-time sinusoids

Trigonometric fcn (default) | Table lookup | Differential

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. For more information on each of the available options, see “Algorithms” on page 2-1286.

**Dependencies**

This parameter is only visible when you set the **Sample mode** to `Discrete`.

---

**Note** To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

---

**Optimize table for** — Optimize for speed or memory

Speed (default) | Memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains  $k$  elements, and when optimized for memory, the table contains  $k/4$  elements, where  $k$  is the number of input samples in one full period of the sine wave.

**Dependencies**

This parameter is only visible when you set the **Computation method** parameter to `Table lookup`.

**Sample time** — Sample period

1/1000 (default) | scalar

The period with which the sine wave is sampled,  $T_s$ , as a finite scalar, greater than zero. The output frame period of the block is  $MT_s$ , where you specify  $M$  in the **Samples per frame** parameter.

**Dependencies**

To enable this parameter, set **Sample mode** to `Discrete`.

**Samples per frame** — Samples per frame

1 (default) | positive integer

The number of consecutive samples from each sinusoid to buffer into the output frame,  $M$ , specified as a positive scalar integer. This parameter is not tunable.

The block output is an  $M$ -by- $N$  matrix with frame period  $MT_s$ , where you specify  $T_s$  in the **Sample time** parameter.

**Dependencies**

To enable this parameter, set **Sample mode** to `Discrete`.

**Resetting states when re-enabled** — State behavior inside enabled subsystems

Restart at time zero (default) | Catch up to simulation time

This parameter determines the behavior of the Sine Wave block when an enabled subsystem is reenabled. The block can either reset itself to its starting state (`Restart at time zero`), or resume generating the sinusoid based on the current simulation time (`Catch up to simulation time`).

### Dependencies

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to `reset`.

### Data Types

**Output data type** — Output data type

`double (default) | single | fixdt(1,16) | fixdt(1,16,0) | <data type expression> | Inherit:Inherit via back propagation`

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via back propagation`
- `Built in`— Lets you specify a built in data type, for example, `double`
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

### Data Type Assistant

**Mode** — Data type mode

`Built in (default) | Inherit | Fixed point | Expression`

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- `Inherit` — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via back propagation`
- `Built in`— Lets you specify a built-in data type, for example, `double`
- `Fixed point` — Lets you specify the fixed-point attributes of the data type.
- `Expression` — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Signedness** — Signedness of fixed-point data

`Signed (default)`

Specify the signedness of the fixed-point output. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Limitations**

The Sine Wave only supports Signed data types.

**Scaling** — Method for scaling fixed-point data

Best precision (default) | Binary point

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to Fixed point

**Word length** — Bit size of the word that holds the quantized integer

16 (default) | integer from 2 to 128

Specify the bit size of the word that holds the quantized integer as a positive integer from 2 to 128. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Dependencies**

To enable this parameter, set **Mode** to Fixed point

**Fraction length** — Fraction length for fixed-point data type

0 (default) | integer scalar

Specify the fraction length of the fixed-point data type as a positive or negative integer scalar.

**Dependencies**

To enable this parameter, set **Mode** to Fixed point and **Scaling** to Binary point.

**Data type override** — Data type override mode

Inherit (default) | Off

Select the data type override mode for this signal. You can select:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify.

**Dependencies**

To enable this parameter, set **Mode** to Built in or Fixed point. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

**Block Characteristics**

|                   |   |
|-------------------|---|
| <b>Data Types</b> | double   fixed point   integer   single |
|-------------------|---|

|                                 |    |
|---------------------------------|----|
| <b>Direct Feedthrough</b>       | no |
| <b>Multidimensional Signals</b> | no |
| <b>Variable-Size Signals</b>    | no |
| <b>Zero-Crossing Detection</b>  | no |

## Algorithms

When you select **Discrete** from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid: **Trigonometric fcn**, **Table lookup**, and **Differential**.

### Trigonometric Fcn

The trigonometric function method computes the sinusoid in the  $i$ th channel,  $y_i$ , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

with a period of  $T_s$ , where you specify  $T_s$  in the **Sample time** parameter. This mode of operation has the same benefits and liabilities as the **Continuous** sample mode.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

### Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is,  $1/(f_i T_s) = k_i$  must be an integer value for every channel  $i = 1, 2, \dots, N$ .

When the **Optimize table for** parameter is set to **Speed**, the table constructed for each channel contains  $k_i$  elements. When the **Optimize table for** parameter is set to **Memory**, the table constructed for each channel contains  $k_i/4$  elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, and that therefore must be optimized for execution speed.

---

**Note** The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the `Table` lookup computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

---

**Tip** To generate fixed-point sinusoids, you must select `Table Lookup`.

---

## Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by using the following identities.

$$\sin(t + T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$

$$\cos(t + T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the  $i$ th channel,  $y_i$ , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify  $T_s$  in the **Sample time** parameter. Since  $T_s$  is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of  $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$  is then computed from the values of  $\sin(2\pi f_i t + \phi_i)$  and  $\cos(2\pi f_i t + \phi_i)$  by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

## Version History

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sine Wave block references absolute simulation time when configured in continuous sample mode.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

---

**Note** For a sine wave generator that is optimized for HDL code generation and has hardware-friendly control signals, see NCO (DSP HDL Toolbox), and “Generate Sine Wave” (DSP HDL Toolbox). The DSP HDL Toolbox blocks provide HDL-optimized algorithms with hardware-friendly control signals and simulate the latency of the HDL algorithm in Simulink.

---

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

**HDL Architecture**

This block has one default HDL architecture.

**Restrictions**

For HDL code generation, you must select the following Sine Wave block settings:

- **Computation method:** Table lookup
- **Sample mode:** Discrete

Output:

- The output port cannot have data types `single` or `double`.

**Complex Data Support**

This block supports code generation for complex signals.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# Singular Value Decomposition

Factor matrix using singular value decomposition

## Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfactors

## Description

The Singular Value Decomposition block factors the  $M$ -by- $N$  input matrix  $A$  such that

$$A = U \cdot \text{diag}(S) \cdot V^*$$

where

- $U$  is an  $M$ -by- $P$  matrix
- $V$  is an  $N$ -by- $P$  matrix
- $S$  is a length- $P$  vector
- $P$  is defined as  $\min(M,N)$

When

- $M = N$ ,  $U$  and  $V$  are both  $M$ -by- $M$  unitary matrices
- $M > N$ ,  $V$  is an  $N$ -by- $N$  unitary matrix, and  $U$  is an  $M$ -by- $N$  matrix whose columns are the first  $N$  columns of a unitary matrix
- $N > M$ ,  $U$  is an  $M$ -by- $M$  unitary matrix, and  $V$  is an  $N$ -by- $M$  matrix whose columns are the first  $M$  columns of a unitary matrix

In all cases,  $S$  is an unoriented vector of positive singular values having length  $P$ .

Length- $N$  row inputs are treated as length- $N$  columns.

Note that the first (maximum) element of output  $S$  is equal to the 2-norm of the matrix  $A$ .

## Parameters

### Show singular vector ports

Select to enable the  $U$  and  $V$  output ports.

### Show error status port

Select to enable the  $E$  output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

### Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

## **Version History**

**Introduced before R2006a**

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

## Sort

Sort input elements by value

**Libraries:**  
DSP System Toolbox / Statistics

### Description

The Sort block ranks the values of the input elements along each channel (column) in an **Ascending** or a **Descending** order, based on the **Sort order** you specify. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. You can choose the **Sort algorithm** to be either **Quick sort** or **Insertion sort**. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, use the insertion sort algorithm to avoid recursive function calls.

The **Mode** parameter specifies the block's mode of operation, which you can set to **Value**, **Index**, or **Value and Index**.

### Ports

#### Input

**Port\_1** — Data input

vector | matrix

The block accepts real-valued or complex-valued multichannel inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

#### Output

**Val** — Sorted data

vector | matrix

The block sorts the data along each channel and outputs the sorted data through this port. The size, data type, and complexity of the sorted data matches that of the input data. The block sorts complex inputs according to their magnitude.

#### Dependencies

To enable this port, set the **Mode** parameter to **Value** and **index** or **Value**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Idx** — Index of the sorted data  
vector | matrix

The output at this port contains the indices of the sorted data.

### Dependencies

To enable this port, set the **Mode** parameter to `Value` and `index` or `Index`.

Data Types: `uint32`

## Parameters

### Main Tab

**Mode** — Specify whether block returns values, indices, or both  
`Value` and `Index` (default) | `Value` | `Index`

When the **Mode** parameter is set to:

- `Value` — The block sorts the elements in each channel of the  $M$ -by- $N$  input matrix in an ascending or descending order, based on what you specify in the **Sort order** parameter. The output at each sample time, *Val*, is an  $M$ -by- $N$  matrix that contains the sorted columns of the input.

The block sorts complex inputs according to their magnitude.

- `Index` — The block sorts the elements in each channel of the  $M$ -by- $N$  input matrix, and outputs the index array, *I*. Each element in *I* is an integer of type `uint32` that indexes the sorted value in the corresponding column of the input.
- `Value` and `index` — The block outputs the sorted values of the input data, *Val*, and the corresponding indices in the index array, *I*.

**Sort order** — Order of sorting  
`Ascending` (default) | `Descending`

Specify to sort the input data in either ascending or descending order.

**Sort algorithm** — Sort method  
`Quick sort` (default) | `Insertion sort`

The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

### Data Types Tab

---

**Note** To use these parameters, the data input must be complex and fixedpoint. For all other inputs, the parameters on the **Data Types** tab are ignored.

---

**Rounding mode** — Method of rounding operation  
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

**Product output** — Product output data type

Inherit: Same as input (default) | `fixdt([],16,0)`

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- `Inherit: Same as input` — The product output data type is the same as the input data type.
- `fixdt([],16,0)` — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use

the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Accumulator** — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | `fixdt([],16,0)`

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as product output` — The accumulator data type is the same as the product output data type.
- `Inherit: Same as input` — The accumulator data type is the same as the input data type.
- `fixdt([],16,0)` — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the

assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types  
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | no                                      |
| <b>Zero-Crossing Detection</b>  | no                                      |

## Algorithms

### Sort

The block produces results identical to the MATLAB `sort` function.

The output of the block is equivalent to the following MATLAB code, when **Sort order** is set to:

- Ascending — `[Val,I] = sort(u,'ascend')`
- Descending — `[Val,I] = sort(u,'descend')`

where:

- `u` is the data input.
- `Val` is the sorted output.
- `I` is the index of the sorted output.

When the input is complex, the block sorts the data according to the magnitude. The block computes the magnitude by taking the sum of the squares of the real and imaginary components of the complex input. This is identical to calling the `sort` function as `[Val,I] = sort(u,...,'ComparisonMethod','abs')`.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

DSP System Toolbox / Sinks

DSP System Toolbox HDL Support / Sinks

## Description

The Spectrum Analyzer block, referred to here as the scope, displays frequency-domain signals and the frequency spectrum of time-domain signals. The scope shows the spectrum view and the spectrogram view. The block algorithm performs spectral estimation using the filter bank method and Welch's method of averaged modified periodograms. You can customize the spectrum analyzer display to show the data and the measurement information that you need. For more details, see "Algorithms" on page 2-1335.

You can use the Spectrum Analyzer block in models running in `Normal` or `Accelerator` simulation modes. You can also use the Spectrum Analyzer block in models running in `Rapid Accelerator` or `External` simulation modes with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditionally Executed Subsystems Overview” (Simulink) for more information.

## Measurements

- “Cursor Measurements” on page 2-1330 — Measure signal values using vertical and horizontal cursors.
- “Peak Finder Measurements” on page 2-1330 — Find maxima and show the x-axis values at which they occur.
- “Channel Measurements” on page 2-1333 — Measure the occupied bandwidth or adjacent channel power ratio (ACPR).
- “Distortion Measurements” on page 2-1331 — Measure harmonic distortion and intermodulation distortion.
- “Spectral Mask” on page 2-1334 — Visualize spectrum limits and compare spectrum values to specification values.

## Programmatic Control

You can configure and display the Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

## Ports

### Input

**Signal** — Signals to visualize  
scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals must have these characteristics:

- **Signal Domain** — Frequency or time signals.
- **Type** — Discrete signals.
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — One dimensional (vector), two dimensional (matrix), or multidimensional (array) signals. Input signal must have a fixed number of channels. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Frequency** — Frequencies in Hz  
column vector

Specify the frequencies in Hz. The frequency vector must be a finite, monotonically increasing, column vector with two or more elements. The number of frequency vector points must be equal to the input frame size. You can also specify the frequencies using the **Frequency (Hz)** parameter on the **Estimation** tab.

#### Dependency

To enable this port, set the:

- **Input Domain** parameter on the **Estimation** tab to Frequency.
- **Frequency (Hz)** parameter on the **Estimation** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

#### RBW — RBW Value

positive scalar

Specify the resolution bandwidth in Hz through this port. RBW defines the smallest positive frequency that can be resolved by the scope. You can also specify the RBW value using the **RBW (Hz)** parameter on the **Analyzer** tab.

#### Dependency

To enable this port, set the **RBW (Hz)** parameter on the **Analyzer** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

#### VBW — VBW Value

positive scalar

Specify the video bandwidth in Hz through this port. Video bandwidth is the bandwidth of the lowpass filter that the scope uses to average or smooth the noise in the signal before displaying it. You can also specify the VBW value using the **VBW (Hz)** parameter on the **Estimation** tab.

#### Dependency

To enable this port, set the:

- **Input Domain** parameter on the **Estimation** tab to Time.
- **Averaging Method** parameter on the **Estimation** tab to VBW.
- **VBW (Hz)** parameter on the **Estimation** tab to Input port.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

## Parameters

### Analyzer Tab

#### Views

#### Spectrum — Type of spectrum to display

Power (default) | Power Density | RMS

Set the type of spectrum to display as one of these values:

- **Power** — Spectrum Analyzer shows the power spectrum.
- **Power Density** — Spectrum Analyzer shows the power spectral density. The power spectral density is the squared magnitude of the spectrum normalized to a bandwidth of 1 Hz.
- **RMS** — Spectrum Analyzer shows the root mean squared spectrum. Use this option to view the frequency of voltage or current signals.

**Tunable:** Yes

**Dependency**

To enable this parameter, set the **Input Domain** parameter on the **Estimation** tab to Time.

**Programmatic Use**

**Block Parameter:** SpectrumType

**Type:** character vector or string scalar

**Spectrogram** — Type of spectrogram to display

Power (default) | Power Density | RMS

Set the type of spectrogram to display as one of these values:

- **Power** — Spectrum Analyzer shows the power spectrogram.
- **Power Density** — Spectrum Analyzer shows the power density of the spectrogram. The power spectrogram density is the squared magnitude of the spectrogram normalized to a bandwidth of 1 Hz.
- **RMS** — Spectrum Analyzer shows the root mean square of the spectrogram. The root-mean-square shows the square root of the mean square. Use this option to view the frequency of voltage or current signals.

**Tunable:** Yes

**Dependency**

To enable this parameter, set the **Input Domain** parameter on the **Estimation** tab to Time.

**Programmatic Use**

**Block Parameter:** SpectrumType

**Type:** character vector or string scalar

**Bandwidth**

**Sample Rate (Hz)** — Sample rate the scope uses in Hz

Inherited (default) | positive scalar

Specify the sample rate the scope uses in Hz as one of the following:

- **Inherited** -- Use this option to specify the same sample rate as the input signal.
- **Positive scalar** -- The sample rate you specify must be at least twice the sample rate of the input signal. Otherwise, you might see unexpected behavior when visualizing your signal in the scope due to aliasing.

To display this property on the status bar, right-click the status bar at the bottom of the Spectrum Analyzer window and select **Sample Rate**.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** SampleRate, SampleRateSource

**Type:** double

**RBW (Hz)** — Resolution bandwidth in Hz  
Auto (default) | Input port | positive scalar

Specify the resolution bandwidth in Hz. This parameter defines the smallest positive frequency that can be resolved by the scope. By default, this parameter is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span.

If you set this parameter to **Input port**, you can specify the RBW value through an input port on the block.

If you set this parameter to a numeric value, the value must allow at least two RBW intervals over the specified frequency span. In other words, the ratio of the overall frequency span to RBW must be greater than two:

$$\frac{\text{span}}{\text{RBW}} > 2$$

To display this property on the status bar, right-click the status bar at the bottom of the Spectrum Analyzer window and select **RBW**.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** RBWSource, RBW

**Type:** character vector, string scalar, double

**Offset (Hz)** — Offset to apply to frequency axis  
0 (default) | scalar | vector

Specify the offset to apply to the frequency axis (x-axis) in units of Hz as one of the following:

- **Scalar** — Apply the same frequency offset to all channels.
- **Vector** — Apply a specific frequency offset for each channel. The vector length must be equal to the number of input channels.

The overall span must fall within the “Nyquist Frequency Interval” on page 2-1340. You can control the overall span in different ways based on how you set the **Span (Hz)** parameter.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** FrequencyOffset

**Type:** double

**Configuration > Spectrum Analyzer Settings ( )**

**Num Inputs** — Number of input ports  
1 (default) | integer between 1 and 96

The number of input ports to the block, specified as an integer between 1 and 96. To change the number of input ports, drag a new input signal line to the block and the block automatically creates new ports.

**Programmatic Use**

**Block Parameter:** NumInputPorts  
**Type:** character vector or string scalar  
**Values:** scalar between 1 and 96

**Open at Simulation Start** — Automatically open scope when simulation starts  
on (default) | off

Select this parameter to automatically open the Spectrum Analyzer window when you run the simulation.

**Programmatic Use**

**Block Parameter:** OpenAtSimulationStart  
**Type:** logical

**Font Size** — Font size of labels  
Small (default) | Medium | Large | Extra Large

Specify the font size of labels in the display as Small, Medium, Large, and Extra Large.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** -  
**Type:** character vector or string scalar

**Plot Type** — Plot type  
Line (default) | Stem

Specify whether to display a Line or Stem plot in the Spectrum display.

**Tunable:** Yes

**Dependency**

To enable this parameter:

- Select **Spectrum** in the **Analyzer** tab.
- Select the **Normal Trace** check box in the **Spectrum** tab.

**Programmatic Use**

**Block Parameter:** PlotType  
**Type:** character vector or string scalar

**Y-Label** — y-axis label

character vector | string scalar

Specify the y-axis label in the Spectrum display as a character vector or a string scalar. To display signal units, add (%<SignalUnits>) to the label. When simulation starts, Simulink replaces (%SignalUnits) with the units associated with the signals.

For example, for a velocity signal with units of m/s enter

Velocity (%<SignalUnits>)

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** YLabel

**Type:** character vector or string scalar

**Y-Axis Limits** — y-axis limits

[-80 20] | [ymin ymax]

Specify the y-axis limits in the Spectrum Analyzer display as a two-element numeric vector of the form [ymin ymax]. The units of the y-axis limits depend on the **Spectrum Unit** in the **Spectrum** tab.

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** YLimits

**Type:** double

**Title** — Display title

character vector | string

Specify the display title. Enter %<SignalLabel> to use the signal labels in the Simulink model as the axes titles.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** Title

**Type:** character vector or string

**Show Grid** — Show internal grid lines

on (default) | off

Select this check box to show the grid in the Spectrum Analyzer display.

**Tunable:** Yes

**Programmatic Use****Block Parameter:** ShowGrid**Type:** logical**Color Map** — Spectrogram colormap

jet (default) | hot | bone | cool | copper | gray | parula | three-column matrix

Select a valid colormap name for the spectrogram, or enter a three-column matrix with values in the range [0,1] defining RGB triplets. For more information about colormaps, see `colormap`.

**Tunable:** Yes**Dependency**

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

**Programmatic Use****Block Parameter:** Colormap**Type:** character vector or string scalar**Color Limits** — Color limits of spectrogram

[-80, 20] (default) | [colorMin colorMax]

Specify the color limits of the spectrogram as a two-element numeric vector of the form [colorMin colorMax]. The units of the color limits directly depend upon the **Spectrum Unit** in the **Spectrogram** tab.

**Tunable:** Yes**Dependencies**

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

**Programmatic Use****Block Parameter:** ColorLimits**Type:** double**Preserve colors for copy to clipboard** — Preserve colors when copying to clipboard

off (default) | on

When you select this parameter, the scope preserves the colors when you copy the display to the clipboard using the **Copy Display** and the **Print** options in the **Analyzer** tab > **Share** section.

**Tunable:** Yes**Background** — Window background

black (default) | color picker

Specify the background color in the scope figure.

**Tunable:** Yes**Axes** — Axes background color

black (default) | color picker

Specify the background color of the axes.

**Tunable:** Yes

**Labels** — Color of labels  
gray (default) | color picker

Specify the color of the labels, grid, and the channel names in the legend.

**Tunable:** Yes

**Line** — Channel for line property settings  
channel names

Specify the channel for which you want to modify the visibility, line color, style, width, and marker properties.

**Tunable:** Yes

**Visible** — Channel visibility  
on (default) | off

Select this check box to display the channel you have selected. If you clear this check box, the selected channel is no longer visible. You can also click the signal name in the legend to control its visibility. For more details, see “Legend” on page 2-0 .

**Tunable:** Yes

**Style** — Line style  
- (default) | : | -. | -- | None

Specify the line style for the selected channel.

**Tunable:** Yes

**Width** — Line width  
1.5 (default) | 0.5 | 1 | 2 | ...

Specify the line width for the selected channel.

**Tunable:** Yes

**Marker** — Data point markers  
None (default) | + | x | ...

Specify a data point marker for the selected channel. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the drop-down list.

**Tunable:** Yes

**Color** — Line color  
yellow (default) | color picker

Specify the line color for the selected channel.

**Tunable:** Yes

## Configuration

**Legend** — Show or hide signal legend  
button

Click the **Legend** button to enable the Spectrum Analyzer to display the signal legend. The legend displays the signal names from the model. For signals with multiple channels, the scope appends a channel index after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

You can control which signals are visible using the legend. To hide a signal, in the scope legend, click the signal name. To display the signal, click the signal name again. Alternatively, you can control

which signal is visible using the **Visible** parameter in the **Spectrum Analyzer Settings** () .

To display only one signal and hide all other signals, right-click the name of the signal you want the scope to display. To show all signals, press **Esc**.

---

**Note** The legend displays only the first 20 signals. You cannot view or control any additional signals from the legend.

---

**Tunable:** Yes

### Dependency

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

### Programmatic Use

**Block Parameter:** ShowLegend  
**Type:** logical

**Colorbar** — Show or hide color bar  
button

When you select the **Colorbar** button, the Spectrum Analyzer shows the color bar.

**Tunable:** Yes

### Dependencies

To enable the **Colorbar** button, select **Spectrogram** in the **Analyzer** tab.

### Programmatic Use

**Block Parameter:** ShowColorbar  
**Type:** logical

**Layout** — Stack axes vertically or horizontally  
vertical layout (default) | horizontal layout

Stack axes vertically or horizontally by selecting the appropriate configuration in the layout grid.

**Tunable:** Yes

**Dependencies**

To enable the **Layout**, select **Spectrum** and **Spectrogram** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** AxesLayout

**Type:** character vector or string scalar

**Share**

**Copy Display** — Send display to clipboard  
button

Click this button to copy the scope display to the clipboard. You can preserve the color in the display by selecting the “Preserve colors for copy to clipboard” on page 2-0 parameter.

**Print** — Print display  
button

Click this button to save the scope display as an image or a PDF or to print the display.

**Estimation Tab****Domain**

**Input Domain** — Domain of the input signal

Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the scope transforms the signal to the frequency spectrum based on the algorithm you specify in the **Method** parameter.

**Programmatic Use**

**Block Parameter:** InputDomain

**Type:** character vector or string scalar

**Frequency (Hz)** — Frequency vector

Auto (default) | Input port | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display to one of these values:

- Auto — The scope calculates the frequency vector from the length of the input. For more details, see “Frequency Vector” on page 2-1341.
- Input port — You specify the frequency vector at the **Frequency** input port on the block.
- Custom vector — You specify a custom vector as the frequency vector. The length of the custom vector must be equal to the frame size of the input signal.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Input Domain** to Frequency.

**Programmatic Use****Block Parameter:** FrequencyVectorSource, FrequencyVector**Type:** character vector, string scalar, double**Input Unit** — Units of frequency input

dBm (default) | dBV | dBW | Vrms | Watts | None

Select the units of the frequency-domain input. This parameter enables the Spectrum Analyzer to scale frequency data when you select a different display unit in the **Spectrum Unit** parameter in the **Estimation** tab.

**Tunable:** Yes**Dependency**

To enable this parameter, set **Input Domain** to Frequency.

**Programmatic Use****Block Parameter:** InputUnits**Type:** character vector or string scalar**Frequency Resolution****Method** — Spectrum estimation method

Filter Bank (default) | Welch

Select the spectrum estimation method as one of the following:

- **Filter Bank** -- Use an analysis filter bank to estimate the power spectrum. Compared to Welch's method, this method has a lower noise floor, better frequency resolution, lower spectral leakage, and requires fewer samples per update.
- **Welch** -- Use Welch's method of averaged modified periodograms.

For more details on these methods, see "Algorithms" on page 2-1335.

**Tunable:** Yes**Dependency**

To use this parameter, set **Input Domain** to Time.

**Programmatic Use****Block Parameter:** Method**Type:** character vector or string scalar**Sharpness** — Sharpness of lowpass filter

0.5 (default) | nonnegative scalar in the range [0,1]

Specify the sharpness of the prototype lowpass filter as a real nonnegative scalar in the range [0,1].

Increasing the filter sharpness decreases the spectral leakage and gives a more accurate power reading.

**Tunable:** Yes

**Dependencies**

To enable this property, set **Method** to `Filter bank`.

**Programmatic Use**

**Block Parameter:** `FilterSharpness`

**Type:** `double`

**Averaging**

**Averaging Method** — Smoothing method

`VBW (default)` | `Exponential`

Specify the smoothing method as one of the following:

- **VBW** — Video bandwidth method. The block uses a lowpass filter to smooth the trace and decrease the noise. Use the **VBW (Hz)** parameter to specify the video bandwidth (VBW) value.
- **Exponential** — Weighted average of samples. The block computes the average over samples weighted by an exponentially decaying forgetting factor. Use the **Forgetting Factor** parameter to specify the weighted forgetting factor.

For more information on the averaging methods, see “Averaging Method” on page 2-1343.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Input Domain** to `Time`.

**Programmatic Use**

**Block Parameter:** `AveragingMethod`

**Type:** `character vector` or `string scalar`

**VBW (Hz)** — Video bandwidth

`Auto (default)` | `Input port` | `positive scalar`

Specify the video bandwidth as one of the following:

- `Auto` -- The Spectrum Analyzer adjusts the VBW such that the equivalent forgetting factor is 0.9.
- `Input port` -- You specify the frequency vector at the **VBW** input port on the block.
- `Positive scalar` -- You specify a positive scalar. The Spectrum Analyzer adjusts the VBW using this value. The value you specify must be less than or equal to **Sample Rate (Hz)/2**.

For more details on the video bandwidth method, see “Averaging Method” on page 2-1343.

The Spectrum Analyzer shows the VBW value in the status bar at the bottom of the display. To display the VBW value, right-click the status bar and select **VBW**.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- Averaging Method to VBW.

#### Programmatic Use

**Block Parameter:** VBWSource, VBW

**Type:** double

**Forgetting Factor** — Forgetting factor of weighted average method

0.9 (default) | scalar in the range [0,1]

Specify the forgetting factor of the exponential weighted averaging method as a scalar in the range [0,1].

**Tunable:** Yes

#### Dependency

To enable this parameter, set:

- **Input Domain** to Time.
- **Averaging Method** to Exponential.

#### Programmatic Use

**Block Parameter:** ForgettingFactor

**Type:** double

#### Frequency Options

**Frequency Span** — Frequency span mode

Full (default) | Span and Center Frequency | Start and Stop Frequencies

Specify the frequency span mode as one of the following:

- **Full** -- The Spectrum Analyzer computes and plots the spectrum over the entire “Nyquist Frequency Interval” on page 2-1340.
- **Span and Center Frequency** -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the **Span (Hz)** and **Center Frequency (Hz)** parameters.
- **Start and Stop Frequencies** -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the **Start Frequency (Hz)** and **Stop Frequency (Hz)** parameters.

**Tunable:** Yes

#### Dependency

To enable this parameter, set **Input Domain** to Time.

#### Programmatic Use

**Block Parameter:** FrequencySpan

**Type:** character vector or string scalar

**Span (Hz)** — Frequency span to compute spectrum in Hz

10e3 (default) | real positive scalar

Specify the frequency span in Hz over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this parameter and the **Center Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 2-1340. This parameter defines the range of the values shown on the Frequency axis in the Spectrum Analyzer window.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Span and Center Frequency.

**Programmatic Use**

**Block Parameter:** Span

**Type:** double

**Center Frequency (Hz)** — Center of frequency span in Hz  
0 (default) | real scalar

Specify the center of the frequency span in Hz over which the Spectrum Analyzer computes and plots the spectrum. Use this parameter with the **Span (Hz)** parameter to define the frequency span around a center frequency. This parameter defines the midpoint of the Frequency axis in the Spectrum Analyzer window.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Span and Center Frequency.

**Programmatic Use**

**Block Parameter:** CenterFrequency

**Type:** double

**Start Frequency (Hz)** — Start frequency in Hz  
-5e3 (default) | scalar

Specify the starting frequency in Hz of the frequency interval over which the Spectrum Analyzer computes and plots the spectrum. The overall span, which is defined by this parameter and the **Stop Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 2-1340. This parameter defines the leftmost value on the Frequency axis in the Spectrum Analyzer window.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.

- **Frequency Span** to Start and Stop Frequencies.

**Programmatic Use****Block Parameter:** StartFrequency**Type:** double**Stop Frequency (Hz)** — Stop frequency in Hz  
5e3 (default) | scalar

Specify the stop frequency in Hz of the frequency interval over which the Spectrum Analyzer computes and plots the spectrum. The overall span, which is defined by this parameter and the **Start Frequency (Hz)** parameter, must fall within the “Nyquist Frequency Interval” on page 2-1340. This parameter defines the rightmost value on the Frequency axis in the Spectrum Analyzer window.

**Tunable:** Yes**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Frequency Span** to Start and Stop Frequencies.

**Programmatic Use****Block Parameter:** StopFrequency**Type:** double**Window Options****Window** — Windowing method

Hann (default) | Blackman-Harris | Chebyshev | Flat Top | Hamming | Kaiser | Rectangular | custom window function name

Specify the windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows”.

You can use your own spectral estimation window by directly specifying a custom window function name in the **Window** parameter.

**Tunable:** Yes**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Method** to Welch.

**Programmatic Use****Block Parameter:** Window, CustomWindow**Type:** character vector or string scalar

**Attenuation (dB)** — Sidelobe attenuation in dB  
60 (default) | scalar greater than or equal to 45

Specify the sidelobe attenuation in dB as a scalar greater than or equal to 45.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Window** to Chebyshev or Kaiser.

**Programmatic Use**

**Block Parameter:** SidelobeAttenuation  
**Type:** double

**Overlap (%)** — Percentage of overlap  
0 (default) | scalar in the range [0 100)

Specify the percentage of overlap between the previous and the current buffered data segments as a scalar in the range [0 100). The overlap creates a window segment that the scope uses to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Input Domain** to Time.
- **Method** to Welch.

**Programmatic Use**

**Block Parameter:** OverlapPercent  
**Type:** double

**Measurements Tab**

**Channel**

**Channel** — Channel for which to obtain measurements  
1 (default) | positive integer

The channel for which you need to obtain measurements, specified as a positive integer in the range [1  $N$ ], where  $N$  is the number of input channels.

**Tunable:** Yes

**Dependency**

To enable this parameter, pass some data through the scope.

**Programmatic Use**

See MeasurementChannel.

**Cursors**

**Data Cursors** — Enable cursor measurements  
button

Click the **Data Cursors** button to enable data cursor measurements. Each cursor tracks a vertical line along the signal. The scope displays the difference between x- and y-values of the signal at the two cursors in the box between the cursors.

**Tunable:** Yes

**Programmatic Use**

See Enabled.

**Snap to data** — Snap cursors to data  
off (default) | on

Select this parameter to position the cursors on the signal data points.

**Tunable:** Yes

**Programmatic Use**

See SnapToData.

**Lock cursor spacing** — Lock cursor spacing  
off (default) | on

Select this parameter to lock the frequency difference between the two cursors.

**Tunable:** Yes

**Programmatic Use**

See LockSpacing.

**Peaks**

**Peak Finder** — Enable peak finder measurements  
button

Click the **Peak Finder** button to enable peak finder measurements. An arrow appears on the plot at each maxima and a Peaks panel appears at the bottom of the scope window.

**Tunable:** Yes

**Programmatic Use**

See Enabled.

**Num Peaks** — Maximum number of peaks to show  
3 (default) | positive integer less than 100

Specify the maximum number of peaks to show as a positive integer less than 100.

**Tunable:** Yes

**Programmatic Use**

See NumPeaks.

**Min Height** — Level above which scope detects peaks

-Inf (default) | real scalar value

Specify the level above which the scope detects peaks as a real scalar.

**Tunable:** Yes

**Programmatic Use**

See MinHeight.

**Min Distance** — Minimum number of samples between adjacent peaks

1 (default) | positive integer

Specify the minimum number of samples between adjacent peaks as a positive integer.

**Tunable:** Yes

**Programmatic Use**

See MinDistance.

**Threshold** — Minimum difference between height of peak and its neighboring samples

0 (default) | nonnegative scalar

Specify the minimum difference between the height of the peak and its neighboring samples as a nonnegative scalar.

**Tunable:** Yes

**Programmatic Use**

See Threshold.

**Label Peaks** — Label peaks

button

Click the **Label Peaks** button to label the peaks. The scope displays the labels (**P1**, **P2**, ...) above the arrows in the plot.

**Tunable:** Yes

**Programmatic Use**

See LabelPeaks.

**Distortion**

**Distortion** — Enable distortion measurements

button

Click the **Distortion** button to enable distortion measurements. A Distortion panel appears at the bottom of the scope window when you click this button.

**Tunable:** Yes

**Programmatic Use**

See Enabled.

**Distortion Type** — Type of measurement to display

Harmonic (default) | Intermodulation

Specify the type of measurement data to display as **Harmonic** or **Intermodulation**. For more details, see “Distortion Measurements” on page 2-1331.

**Tunable:** Yes

**Programmatic Use**

See Type.

**Num Harmonics** — Number of harmonics to measure

6 (default) | positive integer

Specify the number of harmonics to measure as a positive integer less than or equal to 99.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Distortion Type** to **Harmonic**.

**Programmatic Use**

See NumHarmonics.

**Label Harmonics** — Label harmonics

off (default) | on

When you select this parameter, the Spectrum Analyzer adds numerical labels to harmonics in the spectrum display.

**Tunable:** Yes

**Programmatic Use**

See LabelValues.

**Label Frequencies** — Label frequencies

off (default) | on

When you select this parameter, the Spectrum Analyzer adds numerical labels to the first-order intermodulation product and third-order frequencies in the Spectrum Analyzer display.

**Tunable:** Yes

**Programmatic Use**

See LabelValues.

## Spectrum Tab

---

**Note** This tab appears when you select **Spectrum** in the **Analyzer** tab.

---

### Trace Options

**Two-Sided Spectrum** — Enable two-sided spectrum view  
on (default) | off

Select this check box to enable a two-sided spectrum view. In this view, the Spectrum Analyzer shows both negative and positive frequencies. When the input signal is complex-valued, you must select this parameter. If you clear this check box, the Spectrum Analyzer shows a one-sided spectrum with positive frequencies only. In this case, the input signal data must be real valued.

When you clear this check box, the Spectrum Analyzer uses power folding. The y-axis values are twice the amplitude that they would be if you were to select this parameter, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

**Tunable:** Yes

### Programmatic Use

**Block Parameter:** `PlotAsTwoSidedSpectrum`  
**Type:** logical

**Normal Trace** — Normal trace view  
on (default) | off

When you select this check box, the Spectrum Analyzer calculates and plots the power spectral estimates. The Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates and continues its spectral computations even when you clear this parameter.

**Tunable:** Yes

### Dependencies

To clear this check box, first select either the **Max-Hold Trace** or the **Min-Hold Trace** parameters.

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

### Programmatic Use

**Block Parameter:** `PlotNormalTrace`  
**Type:** logical

**Max-Hold Trace** — Maximum hold trace view  
off (default) | on

Select this check box to enable the Spectrum Analyzer to plot the maximum spectral values of all the estimates. The Spectrum Analyzer computes the maximum-hold spectrum at each frequency bin by keeping the maximum value of all the power spectrum estimates. When you clear this check box, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** PlotMaxHoldTrace

**Type:** logical

**Min-Hold Trace** — Minimum hold trace view  
off (default) | on

Select this check box to enable the Spectrum Analyzer to plot the minimum spectral values of all the estimates. The Spectrum Analyzer computes the minimum-hold spectrum at each frequency bin by keeping the minimum value of all the power spectrum estimates. When you clear this check box, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrum** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** PlotMinHoldTrace

**Type:** logical

**Scale**

**Frequency Scale** — Scale of frequency axis  
Linear (default) | Log

Specify the scale to display frequencies as Linear or Log. When the frequency span contains negative frequency values, you cannot choose the logarithmic option.

**Tunable:** Yes

**Dependency**

To set the **Frequency Scale** to Log, clear the **Two-Sided Spectrum** check box in the **Trace Options** section in the **Spectrum** or the **Spectrogram** tab (if enabled). If you select the **Two-Sided Spectrum** check box, then the **Frequency Scale** parameter is set to Linear.

**Programmatic Use**

**Block Parameter:** FrequencyScale

**Type:** character vector or string scalar

**Reference load ( $\Omega$ )** — Reference load in  $\Omega$   
1 (default) | positive real scalar

Specify the reference load in ohms that the Spectrum Analyzer uses as a reference to compute the power values.

**Tunable:** Yes

**Dependency**

To enable this parameter, set:

- **Spectrum** type to Power or Power Density.
- **Spectrum Unit** to any option other than dBFS or dBFS/Hz.

**Programmatic Use**

**Block Parameter:** ReferenceLoad

**Type:** double

**Spectrum Unit** — Units of the spectrum

dBm (default) | dBFS | dBV | dBW | Vrms | Watts | dBm/Hz | dBW/Hz | dBFS/Hz | Watts/Hz | Auto

Specify the units in which the Spectrum Analyzer displays the power values as one of the following:

- dBm
- dBFS
- dBV
- dBW
- Vrms
- Watts
- dBm/Hz
- dBW/Hz
- dBFS/Hz
- Watts/Hz
- Auto

**Tunable:** Yes

**Dependency**

The units available depend on the value you choose for the **Spectrum** parameter in the **Analyzer** tab.

| Estimation tab > Input Domain parameter | Analyzer tab > Spectrum option | Available Units                   |
|---|--------------------------------|-----------------------------------|
| Time                                    | Power                          | dBm, dBW, dBFS, Watts             |
|   | Power Density                  | dBm/Hz, dBW/Hz, dBFS/Hz, Watts/Hz |
|   | RMS                            | dBV, Vrms                         |
| Frequency                               | —                              | Auto, dBm, dBV, dBW, Vrms, Watts  |

If you set the **Input Domain** parameter to Frequency and the **Spectrum Unit** parameter to Auto, the Spectrum Analyzer assumes the spectrum units to be equal to input units specified in the **Estimation tab > Input Unit** parameter. If you set the **Input Domain** parameter to Time and the **Spectrum Unit** parameter to any option other than Auto, the Spectrum Analyzer converts the units specified in the **Input Unit** parameter to the units specified in the **Spectrum Unit** parameter.

**Programmatic Use****Block Parameter:** SpectrumUnits**Type:** character vector or string scalar**Full Scale** — Full scale for dBFS units

Auto (default) | positive real scalar

The full scale used for the decibel full scale (dBFS) units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

**Tunable:** Yes**Dependencies**

To enable this parameter:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

**Programmatic Use****Block Parameter:** FullScale**Type:** double**Spectrogram Tab**

---

**Note** This tab appears when you select **Spectrogram** in the **Analyzer** tab.

---

**Channel****Channel** — Channel for which spectrogram is plotted

1 (default) | character vector of a positive integer | string scalar of a positive integer

Select the signal channel for which the spectrogram settings apply.

**Tunable:** Yes**Dependency**To enable this parameter, select **Spectrogram** in the **Analyzer** tab.**Programmatic Use****Block Parameter:** SpectrogramChannel**Type:** character vector, string scalar, double**Time Options****Time Resolution (s)** — Time resolution in seconds

Auto (default) | positive scalar

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current Spectrum Analyzer settings.

When you set **RBW (Hz)** and **Time Resolution (s)** to **Auto**, then the Spectrum Analyzer adjusts the RBW value such that there are 1024 RBW intervals in one frequency span and sets the time resolution is set to  $1/\text{RBW}$ .

When you set **RBW (Hz)** to **Auto** and **Time Resolution (s)** to a positive scalar, then time resolution becomes the main control and RBW is set to  $1/\text{Time Resolution (s)}$  Hz.

When you set **RBW (Hz)** to a positive scalar and **Time Resolution (s)** to **Auto**, then RBW becomes the main control and the time resolution is set  $1/\text{RBW (Hz)}$  s.

When you set **RBW (Hz)** and **Time Resolution (s)** to a positive value, then time resolution must be equal to or larger than the minimum attainable time resolution defined by  $1/\text{RBW (Hz)}$ . Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of  $1/\text{RBW (Hz)}$ .

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** TimeResolutionSource, TimeResolution

**Type:** character vector, string scalar, double

**Time Span (s)** — Time span in seconds

Auto (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified as a positive scalar in seconds. The time span is the product of the desired number of spectral lines and the time resolution. When you set this parameter to **Auto**, the spectrogram displays 100 spectrogram lines at any given time. Otherwise, the spectrogram uses the time duration you specify in this parameter. The time span that you specify must be at least two times larger than the duration of the number of samples required for a spectral update.

**Tunable:** Yes

**Dependency**

To enable this parameter, select **Spectrogram** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** TimeSpanSource, TimeSpan

**Type:** character vector, string scalar, double

**Trace Options**

**Two-Sided Spectrum** — Enable two-sided spectrum view

on (default) | off

Select this check box to enable a two-sided spectrum view. In this view, the Spectrum Analyzer shows both negative and positive frequencies. When the input signal is complex-valued, you must select this

parameter. If you clear this check box, the Spectrum Analyzer shows a one-sided spectrum with positive frequencies only. In this case, the input signal data must be real valued.

When you clear this check box, the Spectrum Analyzer uses power folding. The y-axis values are twice the amplitude that they would be if you were to select this parameter, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

**Tunable:** Yes

**Programmatic Use**

**Block Parameter:** `PlotAsTwoSidedSpectrum`

**Type:** logical

**Spectral Mask Tab**

---

**Note** This tab appears when you select **Spectrum** in the **Analyzer** tab and set the **Spectrum** type to be Power or Power Density.

---

**Views**

**Upper Mask** — Enable upper spectral mask  
button

Select **Upper Mask** to display the upper mask in the spectrum plot. The **Spectral Mask** panel appears at the bottom of the Spectrum Analyzer window and displays mask details, such as number of times a mask succeeded, number of times a mask failed, channels causing the mask failure, and so on.

Use the **Upper Limits** parameter to specify the upper mask. If the entire spectrum plot is below the upper mask, the upper mask looks green. In all other cases, the upper mask looks red.

**Tunable:** Yes

**Programmatic Use**

See `EnabledMasks`.

**Lower Mask** — Enable lower spectral mask  
button

Select **Lower Mask** to display the lower mask in the spectrum plot. The **Spectral Mask** panel appears at the bottom of the Spectrum Analyzer window and displays mask details, such as number of times a mask succeeded, number of times a mask failed, channels causing the mask failure, and so on.

Use the **Lower Limits** parameter to specify the lower mask. If the entire spectrum plot is above the lower mask, the lower mask looks green. In all other cases, the lower mask looks red.

**Tunable:** Yes

**Programmatic Use**

See `EnabledMasks`.

## Configuration

**Upper Limits** — Limit for upper spectral mask

Inf (default) | scalar | two-column matrix

Specify the limit for the upper spectral mask as a scalar or a two-column matrix.

If **UpperMask** is a scalar, the upper limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If you specify a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **Reference Level (dBr)** and the **Frequency Offset (Hz)** parameters.

**Tunable:** Yes

### Programmatic Use

See **UpperMask**.

**Lower Limits** — Limit for lower spectral mask

-Inf (default) | scalar | two-column matrix

Specify the limit for the lower spectral mask as a scalar or a two-column matrix.

If **LowerMask** is a scalar, the lower limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If you specify a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **Reference Level (dBr)** and the **Frequency Offset (Hz)** parameters.

**Tunable:** Yes

### Programmatic Use

See **LowerMask**.

**Reference Level (dBr)** — Reference level for mask power values

0 (default) | real scalar | **Spectrum peak**

Specify the reference level for mask power values as a numeric scalar or set it to **Spectrum peak**.

When you set **Reference Level (dBr)** to a scalar value, the Spectrum Analyzer uses this value as the reference to the power values (in dBr) for the upper mask and the lower mask of the Spectrum Analyzer. The reference level should have the same units as the **Spectrum Unit** parameter in the **Spectrum** tab.

When you set **Reference Level (dBr)** to **Spectrum peak**, the Spectrum Analyzer uses the peak value of the current spectrum of the **Channel** in the **Spectral Mask** tab as the reference power value.

**Tunable:** Yes

**Programmatic Use**

See `ReferenceLevel` and `CustomReferenceLevel`.

**Channel** — Input channel with peak spectrum

1 (default) | integer

Select the input channel which the Spectrum Analyzer uses to determine the mask reference level. The peak value of the spectrum in this channel becomes the mask reference level when you set the **Reference Level (dBr)** parameter to `Spectrum peak`.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Reference Level (dBr)** to `Spectrum peak` and display some data on the scope.

**Programmatic Use**

See `SelectedChannel`.

**Frequency Offset (Hz)** — Frequency offset in Hz

0 (default) | finite numeric scalar

Specify the frequency offset in Hz as a finite numeric scalar. Using this value, the Spectrum Analyzer offsets the frequency values in the **Upper Mask** and the **Lower Mask** parameters.

**Tunable:** Yes

**Programmatic Use**

See `MaskFrequencyOffset`.

**Channel Measurements Tab**

---

**Note** This tab appears when you select **Spectrum** in the **Analyzer** tab.

---

**Channel**

**Channel** — Channel for computing occupied bandwidth and adjacent channel power ratio

1 (default) | positive integer

Specify the channel over which the Spectrum Analyzer computes and displays the occupied bandwidth and adjacent channel power ratio as a positive integer in the range [1 *N*], where *N* is the number of input channels.

**Tunable:** Yes

**Dependency**

To enable this parameter, pass data through the scope.

**Programmatic Use**

See MeasurementChannel.

**Channel Measurements**

**Channel Measurements** — Enable channel measurements  
button

Click **Channel Measurements** to enable channel measurements.

**Tunable:** Yes

**Programmatic Use**

See Enabled.

**Type** — Type of measurement data to display  
Occupied BW (default) | ACPR

Specify the type of measurement data to display as Occupied BW or ACPR.

**Tunable:** Yes

**Programmatic Use**

See Type.

**Occupied BW (%)** — Percentage of power to compute occupied bandwidth  
99 (default) | positive scalar

Specify the percentage of power over which the Spectrum Analyzer computes the occupied bandwidth as a positive scalar.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to Occupied BW.

**Programmatic Use**

See PercentOccupiedBW.

**Frequency Options**

**Frequency Span** — Frequency span mode  
Span and Center Frequency (default) | Start and Stop Frequencies

Specify the frequency span mode as one of the following:

- Span and Center Frequency -- Measure over a frequency range specified in **Span (Hz)** and around the frequency value specified in **Center Frequency (Hz)**.
- Start and Stop Frequencies -- Measure over the frequency range [**Start Frequency (Hz)**, **Stop Frequency (Hz)**].

**Tunable:** Yes

**Programmatic Use**

See FrequencySpan.

**Span (Hz)** — Frequency span in Hz

2000 (default) | positive scalar

Specify the frequency span over which the Spectrum Analyzer computes the channel measurements as a positive scalar in Hz.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Frequency Span** to Span and Center Frequency.

**Programmatic Use**

See Span.

**Center Frequency (Hz)** — Center frequency of span in Hz

0 (default) | real scalar

Center frequency of the span over which the object computes the channel measurements, specified as a real scalar in Hz.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Frequency Span** to Span and Center Frequency.

**Programmatic Use**

See CenterFrequency.

**Start Frequency (Hz)** — Start frequency in Hz

-1000 (default) | real scalar

Specify the start frequency in Hz over which the Spectrum Analyzer computes the channel measurements.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Frequency Span** to Start and Stop Frequencies.

**Programmatic Use**

See StartFrequency.

**Stop Frequency (Hz)** — Stop frequency in Hz

1000 (default) | real scalar

Specify the stop frequency in Hz over which the Spectrum Analyzer computes the channel measurements.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Frequency Span** to Start and Stop Frequencies.

**Programmatic Use**

See StopFrequency.

**Adjacent Channels**

**Num Pairs** — Number of adjacent channel pairs

2 (default) | positive integer in range [1, 12]

Specify the number of adjacent channel pairs as a positive integer in the range [1, 12].

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR.

**Programmatic Use**

See NumOffsets.

**Offsets (Hz)** — ACPR offsets in Hz

[2000 3500] (default) | vector

Specify the frequency of the adjacent channel relative to the center frequency of the main channel as a real vector of length equal to the number of offset pairs specified in **Num Pairs**.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR.

**Programmatic Use**

See ACPROffsets.

**Adjacent BW (Hz)** — Adjacent channel bandwidth in Hz

1000 (default) | positive scalar

Specify the adjacent channel bandwidth in Hz as a positive scalar.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR.

**Programmatic Use**

See AdjacentBW.

**Filter Shape** — Filter shape

None (default) | RRC | Gaussian

Specify the filter shape for the main and adjacent channels as None, RRC, or Gaussian.

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR.

**Programmatic Use**

See `FilterShape`.

**Roll-off Factor** — Roll-off factor

0.5 (default) | real scalar in range [0, 1]

Specify the roll-off factor as a real scalar in the range [0, 1].

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR and **Filter Shape** to RRC.

**Programmatic Use**

See `FilterCoeff`.

**BT Product** — BT product

0.5 (default) | real scalar in range [0, 1]

Specify the BT product as a real scalar in the range [0, 1].

**Tunable:** Yes

**Dependency**

To enable this parameter, set **Type** to ACPR and **Filter Shape** to Gaussian.

**Programmatic Use**

See `FilterCoeff`.

**Property Inspector Only**

**Channel Names** — Input channel names

[] (default) | character vector | string | array of strings or character vectors.

Input channel names, specified as a character vector, string, or array. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify the names, the scope labels the channels as Channel 1, Channel 2, etc.

Example: ["A","B"]

**Dependency**

To see channel names, select **Legend** in the **Analyzer** tab.

**Programmatic Use**

**Block Parameter:** ChannelNames

**Type:** cell array of character vectors or string array

**Maximize Axes** — Maximize size of plots

Auto (default) | Off | On

- Auto — If you have not specified **Title** and **Y-Label**, the scope maximizes all plots.
- On — The scope maximizes all plots and hides all values in **Title** and **Y-label**.
- Off — The scope does not maximize plots.

Hover over the Spectrum Analyzer to see the maximize axes button .

**Tunable:** Yes**Programmatic Use****Block Parameter:** MaximizeAxes**Type:** character vector or string scalar**Axes Scaling** — Y-axis scaling mode

OnceAtStop (default) | Manual | Auto | Updates

- OnceAtStop — Scale y-axis after simulation completes.
- Manual — Manually scale y-axis range with the **Scale Y-axis Limits** toolbar button.
- Auto — Scale y-axis range during and after simulation.
- Updates — Scale y-axis after the number of time steps specified in the “Number of Updates” on page 2-0 text box (100 by default). Scaling occurs only once during each run.

**Tunable:** Yes**Programmatic Use****Block Parameter:** AxesScaling**Type:** character vector or string scalar**Number of Updates** — Number of updates before scaling

100 (default) | integer

Set this property to delay auto scaling the y-axis.

**Tunable:** Yes**Dependency**

To enable this property, set “Axes Scaling” on page 2-0 to Updates.

**Programmatic Use****Block Parameter:** AxesScalingNumUpdates**Type:** character vector or string scalar**Values:** scalar**Block Characteristics**

## More About

### Cursor Measurements

Measure signal values using vertical waveform cursors that track along the signal.

When you click the **Data Cursors** button in the **Measurements** tab of the Spectrum Analyzer, the spectrum display shows vertical cursors on each signal. Each cursor tracks a vertical line along the signal. The scope displays the difference between  $x$ - and  $y$ -values of the signal at the two cursors in the box between the cursors.

To enable cursor measurements, click the **Data Cursors** button in the **Measurements** tab. The cursors appear only when the Spectrum Analyzer has at least one signal in its display.

You can use the mouse to move the vertical cursors left and right.

In the **Measurements** tab, click the **Data Cursors** drop-down arrow to select one of these options:

- **Snap to Data** — To position the cursors on the signal data points.
- **Lock Cursor Spacing** — To lock the frequency difference between the two cursors.

For modifying the cursor measurements programmatically, see the `CursorMeasurementsConfiguration` object.

### Peak Finder Measurements

Compute and display peak values in the scope display.

When you click on the **Peak Finder** button in the **Measurements** tab of the Spectrum Analyzer, an arrow appears on the plot at each maxima and a **Peaks** panel appears at the bottom of the scope window. The Spectrum Analyzer computes peaks from the portion of the input signal that is currently on display in the scope, and the **Peaks** panel shows the peak values and the frequencies at which they occur.

The **Peaks** section in the **Measurements** tab allows you to specify the number of peaks you want the scope to display, the minimum height above which you want the scope to detect peaks, the minimum distance between peaks, and label the peaks.

The Spectrum Analyzer algorithm defines a peak as a local maximum with lower values present on either side of the peak. It does not consider end points as peaks. For more information on the algorithm, see the `findpeaks` function.

The peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

For modifying the peak finder measurements programmatically, see the `PeakFinderConfiguration` object. For more information on these settings in the UI, see “Peaks” on page 2-0 .

## Distortion Measurements

Measure harmonic distortion and intermodulation distortion.

When you click the **Distortion** button in the **Distortion** section of the **Measurements** tab, a distortion panel opens at the bottom of the Spectrum Analyzer window. This panel shows the harmonic and distortion measurement values for the input signal currently on display in the scope. The **Distortion** section in the **Measurements** tab allows you to specify the distortion type, number of harmonics, and even label the harmonics.

---

**Note** For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the Spectrum Analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious noise content. In general, you should set the RBW value such that there is at least a 10 dB separation between the peaks of the sinusoids and the noise floor. You also might need to select a different spectral window to obtain a valid measurement.

---

You can set the **Distortion Type** parameter to one of these values:

- **Harmonic** -- Select **Harmonic** if your input is a single sinusoid.
- **Intermodulation** -- Select **Intermodulation** if your input is two equal-amplitude sinusoids. Intermodulation can help you determine distortion when the scope uses only a small portion of the available bandwidth.

See “Distortion Measurements” on page 2-1341 for information on how distortion measurements are calculated.

### Harmonic Distortion

When you set the **Distortion Type** to **Harmonic**, these fields appear in the **Harmonic Distortion** panel at the bottom of the Spectrum Analyzer window.

- **H1** — Fundamental frequency in Hz and its power in decibels of the measured power referenced to 1 milliwatt (dBm).
- **H2, H3, ...** — Harmonics frequencies in Hz and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — Total harmonic distortion. This value represents the ratio of the power in the harmonics  $D$  to the power in the fundamental frequency  $S$ . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of the power in the fundamental frequency  $S$  to the power of all nonharmonic content  $N$ , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total nonharmonic content of your signal is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion ratio. This value represents the ratio of the power in the fundamental frequency  $S$  to all other content (including noise  $N$  and harmonic distortion  $D$ ) in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N + D}\right)$$

- **SFDR** — Spurious-free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency  $S$  to power of the largest spurious signal  $R$  regardless of where it falls in the frequency spectrum. The worst spurious signal might or might not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal and ignores any DC component. The measurement does not include any harmonics that are outside the Spectrum Analyzer frequency span. Adjust your frequency span so that it includes all the desired harmonics.

**Note** To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. The noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

### Intermodulation Distortion

When you set the **Distortion Type** to **Intermodulation**, the following fields appear in the **Intermodulation Distortion** panel at the bottom of the Spectrum Analyzer window.

- **F1** — Lower fundamental first-order frequency.
- **F2** — Upper fundamental first-order frequency.
- **2F1 - F2** — Lower intermodulation product from third-order harmonics.

- **2F2 - F1** — Upper intermodulation product from third-order harmonics.
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

The intermodulation distortion measurement automatically locates the fundamental and the first-order frequencies ( $F1$  and  $F2$ ). It then computes the frequencies of the third-order intermodulation products ( $2F1 - F2$  and  $2F2 - F1$ ).

For modifying the distortion measurements programmatically, see the `DistortionMeasurementsConfiguration` object. For more information on these settings in the UI, see “Distortion” on page 2-0 .

## Channel Measurements

Measure the occupied bandwidth or adjacent channel power ratio (ACPR).

When you click the **Channel Measurements** button in the **Channel Measurements** tab, a channel measurements panel opens at the bottom of the Spectrum Analyzer window. This panel displays the occupied bandwidth or the adjacent channel power ratio measurements. In the **Channel Measurements** tab, you can specify the occupied bandwidth or the ACPR settings, frequency span, center frequency, and start and stop frequencies.

You can select the channel measurements **Type** to:

- **Occupied BW** -- Occupied bandwidth
- **ACPR** -- Ratio of the power of the main channel to the power of the adjacent channel

For more details on how the Spectrum Analyzer calculates the occupied bandwidth, see “Occupied BW” on page 2-1341.

## Occupied Bandwidth

When you set the **Type** of channel measurement to compute and display to **Occupied BW**, these fields appear in the measurements panel at the bottom of the scope window.

- **Channel Power** — Total power in the channel
- **Occupied BW** — Bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum.
- **Frequency Error** — Difference between the center of the occupied band and the center frequency (**Center Frequency (Hz)**) of the channel

## ACPR

When you set the **Type** of channel measurement to compute and display to ACPR, these fields appear in the measurements panel at the bottom of the scope window.

- **Lower (Rel Power (dBc))** — Ratio of the power of the lower sideband to the power of the main channel
- **Upper (Rel Power (dBc))** — Ratio of the power of the upper sideband to the power of the main channel

To modify the channel measurements programmatically, see the `ChannelMeasurementsConfiguration` object. For more information on these settings in the UI, see “Channel Measurements” on page 2-0 .

## Spectral Mask

Visualize spectrum limits and compare spectrum values to specification values.

Add upper and lower masks to the Spectrum Analyzer to visualize spectrum limits and compare spectrum values to specification values. To enable the **Spectral Mask** tab, select **Spectrum** in the **Analyzer** tab. When you click the **Upper Mask** and **Lower Mask** buttons in the **Spectral Mask** tab, a **Spectral Mask** panel opens at the bottom of the Spectrum Analyzer window. This panel provides information on pass-fail statistics of masks, names of masks currently failing or passing, and names of channels causing the failure.

You can modify the mask settings in the **Spectral Mask** tab. For more information on these settings in the UI, see Spectral Mask on page 2-1322. For modifying the channel measurements programmatically, see the `SpectralMaskConfiguration` object.

### Check Spectral Masks

You can check the status of the spectral mask using the `getSpectralMaskStatus` function. This function gives details on the number of times a mask succeeded or failed, names of channels causing mask failure, and so on.

You can even use the `MaskTestFailed` event to perform an action every time the mask fails. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger it. For more details about using events, see “Events”.

### Customize Visualization

Set configuration and style settings in the Spectrum Analyzer.

To control the settings of the display and labels, color and styling, click on **Settings** () in the **Analyzer** tab of the Spectrum Analyzer toolbar.

In the dialog box that opens, you can customize the font size, plot type, y-axis properties of the spectrum plot, and color map properties of the spectrogram plot. You can change the color of the spectrum plot, background, axes, and labels and also change the line properties.

When you view the spectrum or the spectrogram, you see only the relevant options. For more details about these options, see Configuration > Spectrum Settings on page 2-0 .

### Display Controls

Zoom and pan axes using display controls.

To scale the plot axes, use the mouse to pan around the axes and the scroll button on your mouse to zoom in and out of the plot. Additionally, you can use the buttons that appear when you hover over the plot window.

-  — Maximize the axes, hide all labels and inset the axes values.

-  — Zoom in on the plot.
-  — Pan the plot.
-  — Autoscale the axes to fit the shown data.

## Algorithms

### Spectrum Estimation — Filter Bank

When you choose the `Filter Bank` method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal  $x(n)$ , of sample rate  $fs$ , into multiple narrow band signals  $y_0(m)$ ,  $y_1(m)$ , ...,  $y_{M-1}(m)$ , of sample rate  $fs/M$ .

The variable  $M$  represents the number of frequency bands in the filter bank. In the Spectrum Analyzer,  $M$  is equal to the number of data points needed to achieve the specified RBW value or 1024, whichever is larger. For more information on the analysis filter bank and its implementation, see the “More About” on page 4-198 and the “Algorithm” on page 4-200 sections in the `dsp.Channelizer` object.

After the Spectrum Analyzer splits the broadband input signal into multiple narrow bands, it computes the power in each narrow frequency band using the following equation. Each  $Z_i$  value is the power estimate over that narrow frequency band.

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

$L$  is length of the narrowband signal  $y_i(m)$  and  $i = 1, 2, \dots, M-1$ .

The power values in all the narrow frequency bands (denoted by  $Z_i$ ) form the  $Z$  vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The Spectrum Analyzer averages the current  $Z$  vector with the previous  $Z$  vectors using one of the two moving average methods: video bandwidth or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 2-1343.

The Spectrum Analyzer uses the value you specify in the **RBW (Hz)** parameter to determine the input frame length. To view the **RBW (Hz)** parameter in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth property **RBW (Hz)**.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to Auto, the Spectrum Analyzer calculates RBW using this equation.

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- The Spectrum Analyzer calculates the number of samples  $N_{samples}$  using this equation.

$$N_{samples} = \frac{F_s}{RBW}$$

$F_s$  is the sample rate of the input signal as specified in the **Sample Rate (Hz)** property. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

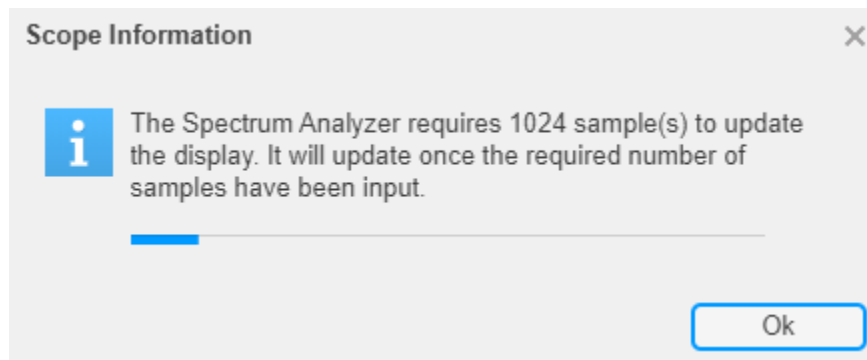

When you specify a resolution bandwidth using the **RBW (Hz)** parameter, you must specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two.

$$\frac{span}{RBW} > 2$$

$span$  is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Frequency Options** section. To enable this property, set **Frequency Span** to Span and Center Frequency.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

### Spectrum Estimation – Welch's Method

When you select the Welch method, the power spectrum estimate is the averaged modified periodograms.

The algorithm in the Spectrum Analyzer consists of these steps:

- 1 The block buffers the input into  $N$ -point data segments. Each data segment is split into  $P$  overlapping data segments, each of length  $M$ , overlapping by  $D$  points. The data segments can be represented as:

$$x_i(n) = x(n + iD), \quad n = 0, 1, \dots, M - 1$$

$$i = 0, 1, \dots, P - 1$$

- If  $D = M/2$ , the overlap is 50%.
- If  $D = 0$ , the overlap is 0%.

- 2 Apply a window to each of the  $P$  overlapping data segments in the time domain.

The Spectrum Analyzer uses **RBW (Hz)** in the **Analyzer** tab to determine the data window length  $N_{window}$  internally. Then, it partitions the input signal into a number of windowed data segments.

Most window functions afford more influence to the data at the center of the set than to the data at the edges, which represents a loss of information. To mitigate that loss, the individual data sets are commonly overlapped in time. For each windowed segment, compute the periodogram by computing the discrete Fourier transform. Then compute the squared magnitude of the result and divide the result by  $M$ .

$$P_{xx}^i(f) = \frac{1}{MU} \left| \sum_{n=0}^{M-1} x_i(n)w(n)e^{-j2\pi fn} \right|^2, \quad i = 0, 1, \dots, P - 1$$

where  $U$  is the normalization factor for the power in the window function and is given by

$$U = \frac{1}{M} \sum_{n=0}^{M-1} w^2(n)$$

You can specify the window using the **Window** parameter in the **Estimation** tab of the Spectrum Analyzer toolstrip.

- 3 The Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS using the modified Periodogram estimator. For more information about the Periodogram method, see [periodogram](#).

To determine the power spectrum estimate for Welch's method, the Spectrum Analyzer averages the result of the periodograms for the last  $P$  data segments. The averaging reduces the variance, compared to the original  $N$ -point data segment. For more details on the averaging, see "Averaging Method" on page 2-1343.

$$\text{PSD}(f) = \frac{1}{P} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 4 The Spectrum Analyzer computes the power spectral density using:

$$\text{PSD}(f) = \frac{1}{P * F_s} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 5 The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by this equation.

$$P_{\text{spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times \text{NENBW}}{N_{\text{window}}}$$

- 6 The Spectrum Analyzer plots the power as a spectrogram in the **Spectrogram** mode. Each line of the spectrogram is one periodogram. The time resolution of each line is  $1/\text{RBW}$ , which is the minimum attainable resolution. Achieving the resolution you want might require combining several periodograms. You then use interpolation to calculate noninteger values of  $1/\text{RBW}$ . In the spectrogram display, time scrolls from top to bottom, so the most recent data appears at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

The Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth (RBW).

$$N_{\text{samples}} = \frac{\left(1 - \frac{O_p}{100}\right) \times \text{NENBW} \times F_s}{\text{RBW}}$$

where  $O_p$  on page 2-1338 is the overlap percentage, NENBW on page 2-1339 is the normalized effective noise bandwidth,  $F_s$  on page 2-1339 is the input sample rate, and RBW on page 2-1339 is the resolution bandwidth.

The Spectrum Analyzer shows the number of samples per update in the Spectrum Analyzer status bar.

You can enable **Samples/Update** in the status bar only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Overlap Percentage ( $O_p$ )

The overlap percentage  $O_p$  is the value you specify in the **Overlap %** property. To view the **Overlap %** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Window Options** section.

When you increase the overlap percentage, the Spectrum Analyzer needs fewer new input samples to compute a new spectral update.

| $O_p$ | $N_{samples}$ |
|-------|---------------|
| 0%    | 100           |
| 50%   | 50            |
| 80%   | 20            |

### Normalized Effective Noise Bandwidth (NENBW)

The normalized effective noise bandwidth  $NENBW$  is a window parameter that measures the noise performance of the window.  $NENBW$  is determined using the window length and the window coefficients, and is given by the following equation:

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[ \sum_{n=1}^{N_{window}} w(n) \right]^2}$$

$w(n)$  denotes the vector of window coefficients (calculated internally).  $N_{window}$  is the window length the Spectrum Analyzer needs to compute one spectral update, and is directly related to the resolution bandwidth and normalized effective noise bandwidth.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

The rectangular window has the smallest  $NENBW$ , with a value of 1. All other windows have a larger  $NENBW$  value. For example, the Hann window has an  $NENBW$  value of approximately 1.5.

The Spectrum Analyzer shows the value of  $NENBW$  in the Spectrum Analyzer status bar.

You can enable  $NENBW$  only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Input Sample Rate ( $F_s$ )

$F_s$  is the sample rate of the input signal. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section. You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **Sample Rate**.

### Resolution Bandwidth (RBW)

Resolution bandwidth controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that the scope can resolve. A smaller value gives a higher spectral resolution and lowers the noise floor, that is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

You can set the resolution bandwidth through the **RBW (Hz)** property. To view **RBW (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to **Auto**, the Spectrum Analyzer calculates using this equation.

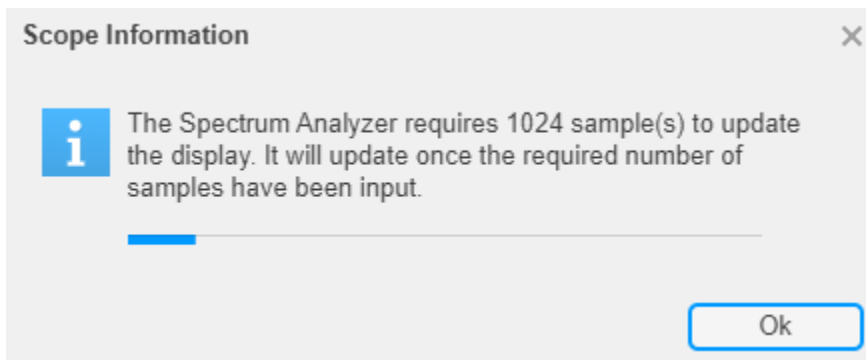

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- Specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

*span* is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. Spectrum Analyzer shows the span through the **Span (Hz)** property. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip, navigate to the **Frequency Options** section, and set **Frequency Span** to **Span** and **Center Frequency**.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **RBW**.

### Nyquist Frequency Interval

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the Nyquist frequency interval is

$$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

When you clear the **Two-Sided Spectrum**, the Nyquist frequency interval is

$$\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

## Frequency Vector

When you set **Frequency (Hz)** to Auto, the software calculates the frequency vector for the frequency-domain input.

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the frequency vector is:

$$\left[ -\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right]$$

When you clear the **Two-Sided Spectrum**, the frequency vector is:

$$\left[ 0, \frac{\text{SampleRate}}{2} \right]$$

## Occupied BW

The Spectrum Analyzer calculates *Occupied BW* using these steps.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, sum the power distributed in each frequency until the result is

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, sum the power distributed in each frequency until the result reaches

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

## Distortion Measurements

The Spectrum Analyzer calculates Distortion Measurements using these steps.

- 1 Estimate spectral content by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values by treating all these values as if they belong to the peak. Using this method, the algorithm removes all spectral content centered at DC (0 Hz) from the spectrum and records the amount of bandwidth cleared ( $W_0$ ).
- 2 Determine the fundamental power ( $P_1$ ) from the remaining maximum value of the displayed spectrum. Create a local estimate ( $Fe_1$ ) of the fundamental frequency by computing the central moment of the power near the peak. Record the bandwidth of the fundamental power content ( $W_1$ ). Then remove the power from the fundamental as in step 1.
- 3 Determine the power and width of the higher-order harmonics ( $P_2, W_2, P_3, W_3$ , etc.) in succession by examining the frequencies closest to the appropriate multiple of the local estimate ( $Fe_1$ ).

Remove any spectral content that decreases monotonically about the harmonic frequency from the spectrum before proceeding to the next harmonic.

- 4 After removing the DC, fundamental, and harmonic content from the spectrum, examine the power of the remaining spectrum for its sum ( $P_{remaining}$ ), peak value ( $P_{maxspur}$ ), and median value ( $P_{estnoise}$ ).
- 5 Compute the sum of all the removed bandwidth as  $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$ .

Compute the sum of powers of the second and higher-order harmonics as  $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$ .

- 6 Estimate the sum of the noise power as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum})/RBW$$

Where  $dF$  is the absolute difference between frequency bins, and  $RBW$  is the resolution bandwidth of the window.

- 7 Then compute the metrics for SNR, THD, SINAD, and SFDR from the estimates.

$$THD = 10 \cdot \log_{10} \left( \frac{P_{harmonic}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left( \frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left( \frac{P_1}{P_{noise}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left( \frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

## Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer might exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 Ignore the DC component.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, the Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4  $N^{\text{th}}$  order intermodulation products occur at  $A \cdot F1 + B \cdot F2$ ,

where  $F1$  and  $F2$  are the sinusoid input frequencies and  $|A| + |B| = N$ .  $A$  and  $B$  are integer values.

- 5 For intermodulation measurements, compute the third-order intercept (TOI) point as follows.

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = (TOI_{lower} + TOI_{upper})/2$

Where  $P$  is power in decibels of the measured power referenced to 1 milliwatt (dBm).

### Averaging Method

The Spectrum Analyzer can calculate the moving average using two methods:

- Video bandwidth — The Spectrum Analyzer uses a time-domain lowpass filter to smooth the noise in the signal. The video bandwidth (VBW) filter smooths the trace and decreases noise, and the Spectrum Analyzer applies the filter to the data before displaying it.

Video bandwidth is the bandwidth of the lowpass filter that Spectrum Analyzer uses to average or smooth the noise in the signal before displaying it in the scope. The Spectrum Analyzer computes the video bandwidth using this equation:

$$VBW = \frac{(1 - \lambda)RBW}{2\pi\lambda NENBW}$$

where,

- $\lambda$  is the forgetting factor.
- RBW on page 2-1339 is the resolution bandwidth.
- NENBW on page 2-1339 is the normalized effective noise bandwidth.

Video bandwidth does not affect the level of the noise (noise floor), but only increases the signal-to-noise ratio and smooths the trace of the noise. When you decrease the value of VBW, the signal-to-noise ratio improves.

The cutoff frequency of the video bandwidth filter is given by:

$$\omega_c = \frac{2\pi VBW}{F_s/NFFT}$$

where  $F_s$  is the input sample rate and NFFT is the number of FFT points.

The Spectrum Analyzer shows the values of sample rate, VBW, and NFFT in the status bar at the bottom of the display. To enable, right-click the status bar and select **Sample Rate**, **VBW**, and **NFFT**.

- Exponential — The moving average algorithm uses the exponential weighting method to update the weights and compute the moving average recursively for each  $Z$  vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- $\lambda$  — Forgetting factor
- $w_N$  — Weighting factor applied to the current  $Z$  vector
- $z_N$  — Current  $Z$  vector

- $\bar{z}_{N-1}$  — Moving average until the previous  $Z$  vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$  — Effect of the previous  $Z$  vectors on the average
- $\bar{z}_N$  — Moving average including the current  $Z$  vector

## Version History

Introduced in R2014b

### R2023a: Spectrum Analyzer with improved responsiveness and toolstrip interface in Simulink

In R2023a, the Spectrum Analyzer block is more responsive and its toolstrip interface is improved to provide you easy access to spectral analysis, estimation, and measurements. You can configure and display Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

### PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate PLC code, but is not included in the generated code.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

# Spectrum Estimator

Estimate power spectrum or power-density spectrum

## Library

Estimation / Power Spectrum Estimation

dspspect3

## Description

The Spectrum Estimator block outputs the power spectrum or power-density spectrum of a real or complex input signal, using the Welch method of averaged modified periodograms and the filter bank approach.

When you choose the filter bank approach, the block uses an analysis filter bank to estimate the power spectrum. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

When you choose the Welch method, the block computes the averaged modified periodograms to compute the spectral estimate. The block buffers the input data into overlapping segments. Use the block parameters to set the length of the data segments, the amount of data overlap between consecutive segments, and other features of the power spectrum.

For more information on the Welch method and the filter bank method, see “Algorithms” on page 2-1351.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

## Parameters

### Main Tab

#### Method

Specify the spectral estimation method.

- **Filter bank** (default) — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The block computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.

- **Welch** — The block uses the Welch averaged modified periodograms method to compute the power spectrum over the narrow subbands.

### Number of taps per band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to **Number of taps per band** times the FFT length.

This parameter applies when you set **Method** to `Filter bank`. The default is 12.

### Spectrum type

Type of spectrum to compute. You can set this parameter to:

- **Power** (default) — Compute the power spectrum.
- **Power density** — Compute the power spectral density.

This parameter is nontunable.

### Frequency resolution method

Frequency resolution method. You can set this parameter to:

- **Auto** (default) — The Spectrum Estimator block computes the resolution bandwidth (RBW) so that the frequency span fits 1024 RBW intervals.
  - **Welch method** — The window length, *winLen*, is calculated using  $winLen = NENBW \times Fs/RBW$ . *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate.
  - **Filter bank method** — The FFT length is the ceiling of the ratio of **Sample rate (Hz)** to the computed resolution bandwidth.
- **RBW** — Specify the resolution bandwidth, which is used to determine the window length (Welch method) or the FFT length (filter bank method). When the block uses the Welch method, the behavior is equivalent to that of the Spectrum Analyzer block. The window length is calculated using  $winLen = NENBW \times Fs/RBW$ . *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate. The FFT length is equal to the ceiling of the ratio of **Sample rate (Hz)** to **RBW (Hz)**.
- **Window length** — Specify the window or segment length to use in the Welch algorithm. This option appears when you set **Method** to `Welch`.
- **Number of frequency bands** — Specify the number of polyphase branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. This option appears when you set **Method** to `Filter bank`.

This parameter is nontunable.

### RBW (Hz)

Resolution bandwidth, specified as a positive scalar in Hz. The default is 5. This parameter applies when you set **Frequency resolution method** to `RBW`. The ceiling of the ratio of the frequency span to RBW must be greater than 2.

This parameter is nontunable.

### Number of bands source

Source of the number of frequency bands. This parameter applies when you set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`. You can set this parameter to:

- Same as input frame length (default) — The FFT length is set to the frame size of the input.
- Specify on dialog — The FFT length is the value you specify in **Number of bands**.

This parameter is nontunable.

### Number of bands

Number of frequency bands, or the FFT length the filter bank uses to compute the power spectral estimate, specified as a positive scalar. The default is 1024. This parameter applies when you set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and **Number of bands source** to Specify on dialog. This parameter is nontunable.

### Window length source

Source of the window length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input. Specify this option to obtain behavior equivalent to that of the Periodogram block.
- Specify on dialog — Window length is the value you specify in the **Window length** parameter.

This parameter is nontunable.

### Window length

Length of the window used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. The default is 1024. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **Window length source** to Specify on dialog. This parameter is nontunable.

### FFT length source

Source of the FFT length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Auto (default) — The block sets the FFT length to the frame size of the input.
- Property — The block sets the FFT length to the value you specify in **FFT length**.

This parameter is nontunable.

### FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **FFT length source** to Property. The default is 1024. This parameter is nontunable.

### Inherit sample rate from input

When you select this check box, the block sample rate is computed as  $N/T_s$ , where  $N$  is the frame size of the input signal and  $T_s$  is the sample time of the input signal.

This check box applies when you do one of the following:

- Set **Method** to Welch and **Frequency resolution method** to Window length.
- Set **Method** to Filter bank and **Frequency resolution method** to Number of frequency bands.

When you clear this check box, the block sample rate is the value you specify in **Sample rate (Hz)**. By default, this check box is selected. This parameter is nontunable.

### Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you do one of the following:

- Set **Frequency resolution method** to Auto or RBW.
- Set **Method** to Welch, **Frequency resolution method** to Window length, and clear the **Inherit sample rate from input** check box.
- Set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and clear the **Inherit sample rate from input** check box.

This parameter is nontunable.

### Window function

Window function the Welch algorithm uses, specified as one of Chebyshev | Flat Top | Hamming | Hann | Kaiser | Rectangular. This parameter appears when you set **Method** to Welch. The default is Hann. This parameter is nontunable.

### Sidelobe attenuation of window (dB)

Sidelobe attenuation of the window, specified as a real positive scalar greater than or equal to 45, in dB. The default is 60. This parameter appears when you set **Method** to Welch and **Window function** to Chebyshev or Kaiser. This parameter is nontunable.

### Averaging method

Specify the averaging method as Exponential (default) or Running. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter.

### Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is 1. The spectrum estimator computes the current power spectrum estimate by averaging the last  $N$  power spectrum estimates, where  $N$  is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to Running.

### Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to Exponential.

### Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to Exponential and clear the **Specify forgetting factor from input port** parameter.

**Advanced Tab****Window overlap (%)**

Percentage of overlap between successive data windows, specified as a scalar from 0 and 100. The default value is 0. To enable this parameter, on the **Main Tab**, set **Method** to **Welch**. This parameter is nontunable.

**Reference load (ohms)**

Load used as a reference to compute the power values, specified as a real positive scalar expressed in ohms. The default value is 1. This parameter is nontunable.

**Frequency range**

Frequency range of the spectrum estimator. You can set this parameter to:

- **One-sided** — The spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length  $(NFFT/2) + 1$  and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ . `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length  $(NFFT + 1)/2$  and is computed over the frequency range  $[0 \text{ SampleRate}/2]$ .
- **Two-sided** — The spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $[0 \text{ SampleRate})$ , where `SampleRate` is the sample rate of the input signal.
- **Centered (default)** — The spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $(-\text{SampleRate}/2 \text{ SampleRate}/2]$  when the FFT length is even and  $(-\text{SampleRate}/2 \text{ SampleRate}/2)$  when the FFT length is odd.

This parameter is nontunable.

**Power units**

Units used to measure power. You can set this parameter to:

- **'Watts'** (default) — The spectrum estimator measures power in watts.
- **'dBw'** — The spectrum estimator measures power in decibel-watts.
- **'dBm'** — The spectrum estimator measures power in decibel-milliwatts.

This parameter is nontunable.

**Output max-hold spectrum**

When you select this check box, the block computes the max-hold spectrum of the input signal by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

**Output min-hold spectrum**

When you select this check box, the block computes the min-hold spectrum of the input signal by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

**Output frequency vector**

When you select this check box, the block outputs the frequency vector. By default, this check box is not selected. This parameter is nontunable.

**Output effective RBW**

When you select this check box, the block computes the effective resolution bandwidth. By default, this check box is not selected. This parameter is nontunable.

**Simulate using**

Type of simulation to run. You can set this parameter to:

- **Code generation** (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

**Supported Data Types**

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> </ul> |

**Algorithms****Welch's Method of Averaged Modified Periodograms**

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input,  $x$ :

- 1 Multiply  $x$  by the window and scale the result by the window power.
- 2 Compute the FFT of the signal,  $Y$ , and take the square magnitude using  $Z = Y \cdot \text{conj}(Y)$ .
- 3 Compute the current power spectrum estimate by taking the moving average of the last  $N$  number of  $Z$ 's, and scaling the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 2-1352.

**Filter Bank**

The filter-bank-based spectrum estimator uses an analysis filter bank to estimate the power spectrum. The filter bank splits a broadband input signal,  $x(n)$ , of sample rate  $fs$  into multiple narrow band signals,  $y_0(m), y_1(m), \dots, y_{M-1}(m)$ , of sample rate  $fs/M$ .

The variable  $M$  represents the number of frequency bands in the filter bank. When you specify FFT length,  $M$  equals the FFT length. When you do not specify FFT length,  $M$  is equal to the number of rows in the input signal. The number of taps per frequency band sets the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands  $M$ . For more information on the analysis filter bank and how it is implemented, see the "More About" on page 4-198 and the "Algorithm" on page 4-200 sections in `dsp.Channelizer`.

After the broadband input signal is split into multiple narrow bands, the spectrum estimator computes the power in each narrow band using the following equation. Each  $Z_i$  value becomes the estimate of the power over that narrow frequency band.

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

$L$  is length of the narrow band signal  $y_i(m)$ , where  $i = 1, 2, \dots, M-1$ .

The power values in all the narrow bands (denoted by  $Z_i$ ) form the  $Z$  vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The filter bank estimator algorithm averages the current  $Z$  vector with the previous  $Z$  vectors using one of the two moving average methods: running or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see "Averaging Method" on page 2-1352.

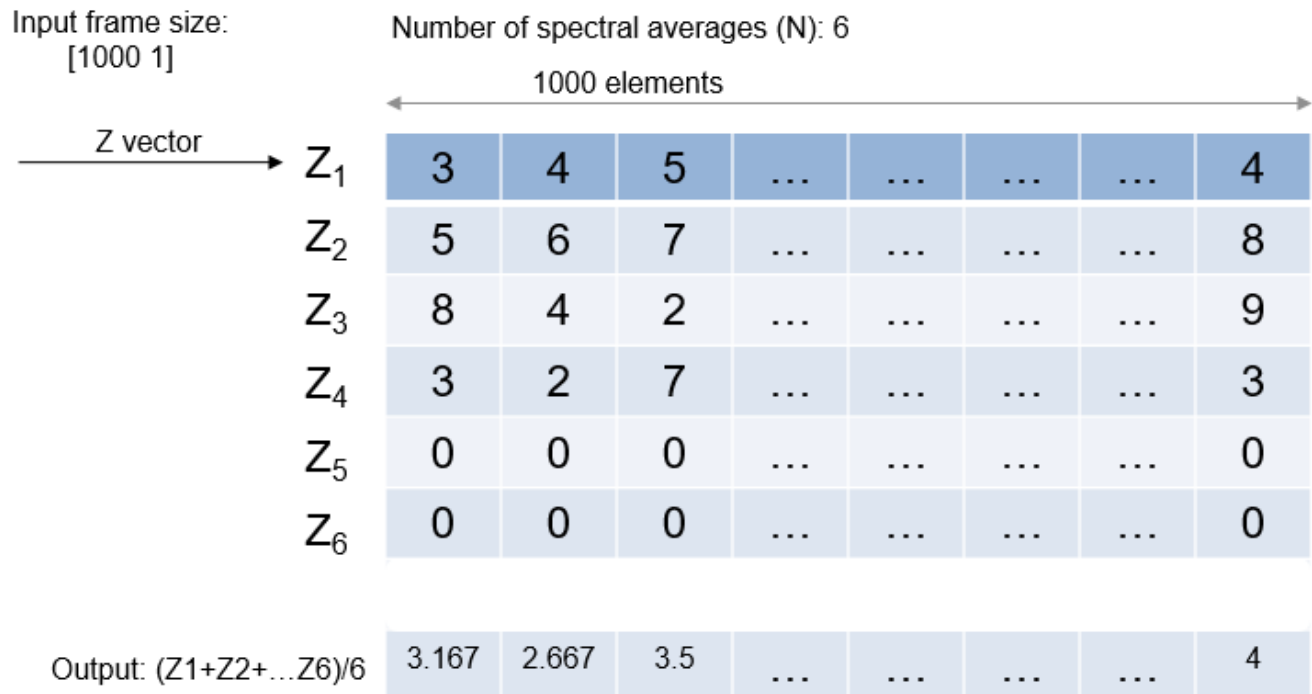

### Averaging Method

The moving average is calculated using one of the two methods:

- **Running** — For each frame of input, average the last  $N$ -scaled  $Z$  vectors, which are computed by the algorithm. The variable  $N$  is the value you specify for the number of spectral averages. If the algorithm does not have enough  $Z$  vectors, the algorithm uses zeros to fill the empty elements.

- **Exponential** — The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- $\lambda$  — Forgetting factor
- $w_N$  — Weighting factor applied to the current Z vector
- $z_N$  — Current Z vector
- $\bar{z}_{N-1}$  — Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$  — Effect of the previous Z vectors on the average
- $\bar{z}_N$  — Moving average including the current Z vector

# Stack

Store inputs into LIFO register

## Library

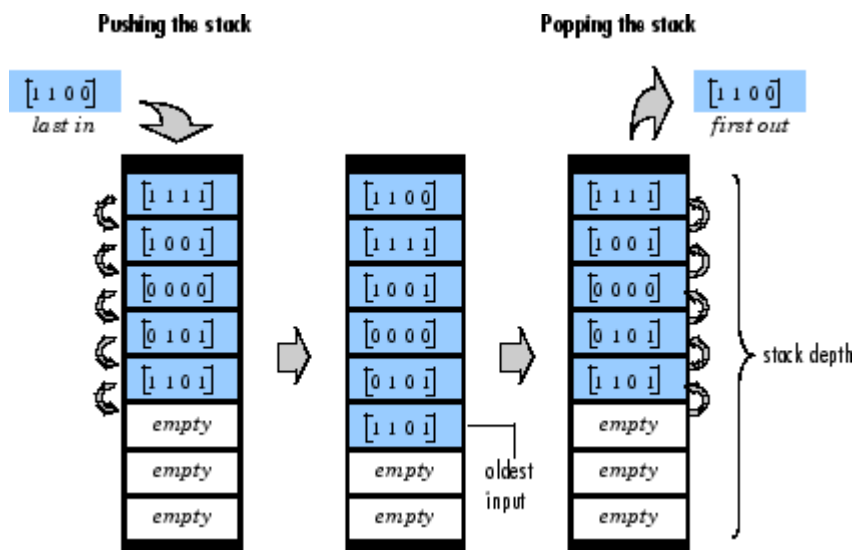

Signal Management / Buffers

dspbuff3

## Description

The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the In port onto the top of the stack when a trigger event is received at the Push port. When a trigger event is received at the Pop port, the block *pops* the top element off the stack and holds the Out port at that value. The last input to be pushed onto the stack is always the first to be popped off.

A trigger event at the optional Rst port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the Rst port empties the stack *and* sets the value at the Out port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the Out port value is only reset to zero in this case when you select **Clear output port on reset**.

When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

- 1 Rst
- 2 Push
- 3 Pop

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the Push, Pop, and Rst ports in the **Trigger type** pop-up menu:

- **Rising edge** — Triggers execution of the block when the trigger input does one of the following:
  - Rises from a negative value to a positive value or zero
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers execution of the block when the trigger input does one of the following:
  - Falls from a positive value to a negative value or zero
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers execution of the block when the trigger input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers execution of the block at each sample time that the trigger input is not zero.

---

**Note** If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

---

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the Push port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the Pop port but the register is empty. The following options are available for both cases:

- **Ignore** — Ignore the trigger event, and continue the simulation.
- **Warning** — Ignore the trigger event, but display a warning message in the MATLAB command window.
- **Error** — Display an error dialog box and terminate the simulation.

---

**Note** The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

---

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the Num output port by selecting the **Show number of stack entries port** parameter.

---

**Note** When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

---

## Examples

### Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from 1 to 0 or 0 to 1 in the Push, Pop, and Rst columns below represents a distinct trigger event. A 1 in the Empty column indicates an empty buffer, while a 1 in the Full column indicates a full buffer.

| In | Push | Pop | Rst | Stack                                      | Out | Empty | Full | Num |
|----|------|-----|-----|--|-----|-------|------|-----|
| 1  | 0    | 0   | 0   | <i>top</i> █         █ <i>bottom</i>       | 0   | 1     | 0    | 0   |
| 2  | 1    | 0   | 0   | <i>top</i> █ 2         █ <i>bottom</i>     | 0   | 0     | 0    | 1   |
| 3  | 0    | 0   | 0   | <i>top</i> █ 3   2       █ <i>bottom</i>   | 0   | 0     | 0    | 2   |
| 4  | 1    | 0   | 0   | <i>top</i> █ 4   3   2     █ <i>bottom</i> | 0   | 0     | 0    | 3   |
| 5  | 0    | 0   | 0   | <i>top</i> █ 5   4   3   2 █ <i>bottom</i> | 0   | 0     | 1    | 4   |

| In | Push | Pop | Rst | Stack  | Out | Empty | Full | Num |
|----|------|-----|-----|--|-----|-------|------|-----|
| 6  | 0    | 1   | 0   | top  bottom | 5   | 0     | 0    | 3   |
| 7  | 0    | 0   | 0   | top  bottom | 4   | 0     | 0    | 2   |
| 8  | 0    | 1   | 0   | top  bottom | 3   | 0     | 0    | 1   |
| 9  | 0    | 0   | 0   | top  bottom | 2   | 1     | 0    | 0   |
| 10 | 1    | 0   | 0   | top  bottom | 2   | 0     | 0    | 1   |
| 11 | 0    | 0   | 0   | top  bottom | 2   | 0     | 0    | 2   |
| 12 | 1    | 0   | 1   | top  bottom | 0   | 0     | 0    | 1   |

Note that at the last step shown, the Push and Rst ports are triggered simultaneously. The Rst trigger takes precedence, and the stack is first cleared and then pushed.

## Parameters

### Stack depth

The number of entries that the LIFO register can hold.

### Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

### Push full stack

Response to a trigger received at the Push port when the register is full. Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports.

When Dynamic reallocation is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

### Pop empty stack

Response to a trigger received at the Pop port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

### Show empty stack indicator port

Enable the Empty output port, which is high (1) when the stack is empty, and low (0) otherwise.

### Show full stack indicator port

Enable the Full output port, which is high (1) when the stack is full, and low (0) otherwise. The Full port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

### Show number of stack entries port

Enable the Num output port, which tracks the number of entries currently on the stack. When inputs to the In port are double-precision values, the outputs from the Num port are double-precision values. Otherwise, the outputs from the Num port are 32-bit unsigned integer values.

**Show reset port to clear internal stack buffer**

Enable the Rst input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

**Clear output port on reset**

Reset the Out port to zero (in addition to clearing the stack) when a trigger is received at the Rst input port.

**Supported Data Types**

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following limitations apply:

- Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.
- When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box must be set to `grt_malloc.tlc` - Generic Real-Time Target with dynamic memory allocation.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

# Standard Deviation

Standard deviation of input or sequence of inputs

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Standard Deviation block computes the standard deviation of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input. You can specify the dimension using the **Find the standard deviation value over** parameter. The Standard Deviation block can also track the standard deviation in a sequence of inputs over a period of time. To track the standard deviation in a sequence of inputs, select the **Running standard deviation** parameter.

---

**Note** The **Running** mode in the Standard Deviation block will be removed in a future release. To compute the running standard deviation in Simulink, use the Moving Standard Deviation block instead.

---

## Ports

### Input

**In** — Data input  
vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double

**Rst** — Reset port  
scalar

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

### Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

## Output

**Port 1** — Standard deviation along the specified dimension

scalar | vector | matrix |  $N$ -D array

The data type of the output matches the data type of the input.

When you do not select the **Running standard deviation** parameter, the block computes the standard deviation in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input at each individual sample time. Each element in the output array  $y$  is the standard deviation of the corresponding column, row, or entire input. The output array  $y$  depends on the setting of the **Find the standard deviation value over** parameter. Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ . When you set **Find the standard deviation value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the standard deviation of the  $M$ -by- $N$ -by- $P$  input matrix.
- **Each row** — The output at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the standard deviation of each vector over the second dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is an  $M$ -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the standard deviation of each vector over the first dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the standard deviation of each vector over the third dimension of the input.

When you select **Running standard deviation**, the block tracks the standard deviation of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the standard deviation of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running standard deviation  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the standard deviation of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Data Types: single | double

## Parameters

### Main Tab

**Running standard deviation** — Option to select running standard deviation  
off (default) | on

When you select the **Running standard deviation** parameter, the block tracks the standard deviation value of each channel in a time sequence of inputs.

**Find the standard deviation value over** — Dimension over which the block computes the standard deviation  
Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the standard deviation over each column.
- **Each row** — The block outputs the standard deviation over each row.
- **Entire input** — The block outputs the standard deviation over the entire input.
- **Specified dimension** — The block outputs the standard deviation over the dimension, specified in the **Dimension** parameter.

### Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

**Dimension** — Custom dimension  
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the standard deviation is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

### Dependencies

To enable this parameter, set **Find the standard deviation value over** to **Specified dimension**.

**Input processing** — Method to process the input in running mode  
Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the standard deviation of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an

$M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the standard deviation of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running standard deviation  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

### Variable-Size Inputs

When your inputs are of variable size, and you select the **Running standard deviation** parameter, then:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
  - When the input size difference is in the number of channels (number of columns), the state is reset.
  - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

### Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

#### Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running standard deviation whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running standard deviation for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

---

**Note** When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

### Block Characteristics

|                           |                 |
|---------------------------|-----------------|
| <b>Data Types</b>         | double   single |

|                                 |     |
|---------------------------------|-----|
| <b>Multidimensional Signals</b> | no  |
| <b>Variable-Size Signals</b>    | yes |
| <b>Zero-Crossing Detection</b>  | no  |

## More About

### Standard Deviation

The standard deviation of a discrete-time signal is the square root of the variance of the signal.

Standard deviation gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input,  $u$ , of size  $M$ -by- $N$ , the standard deviation is given by the following equation:

$$y = \sigma = \sqrt{\frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}}$$

- $u_{ij}$  is the input data element at indices  $i, j$ .
- $M$  is the length of the  $j$ th column.
- $N$  is the number of columns.

For complex inputs, the standard deviation is given by the following equation:

$$\sigma = \sqrt{\sigma_{Re}^2 + \sigma_{Im}^2}$$

- $\sigma_{Re}^2$  is the variance of the real part of the complex input.
- $\sigma_{Im}^2$  is the variance of the imaginary part of the complex input.

## Algorithms

### Standard Deviation

When you clear the **Running standard deviation** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `std` function, when it is called as `y = std(u, D)`.

- $u$  is the data input.
- $D$  is the dimension.
- $y$  is the standard deviation along the specified dimension.

The standard deviation along the entire input is identical to calling the `std` function as `y = std(u(:))`.

For a complex input signal, the standard deviation is the square root of the sum of the variances of the real and imaginary parts.

$$\sigma = \sqrt{\sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2}$$

## Version History

Moving Standard Deviation

## SVD Solver

Solve  $AX = B$  using singular value decomposition

### Libraries:

DSP System Toolbox / Math Functions / Matrices and Linear Algebra / Linear System Solvers

## Description

The SVD Solver block solves the linear system  $AX = B$ . The linear system can be overdetermined, underdetermined, or exactly determined. The block solves the system by applying singular value decomposition (SVD) factorization to the input matrix at the **A** port.

## Ports

### Input

**A** — Input *A* matrix  
*M*-by-*N* matrix

Specify the input matrix *A* as an *M*-by-*N* matrix through this port. Inputs *A* and *B* must have the same number of rows.

Data Types: `single` | `double`

**B** — *B* matrix  
*M*-by-*L* matrix | *M*-by-1 vector

Specify the matrix *B* in the  $AX = B$  equation as an *M*-by-*L* matrix or an *M*-by-1 vector.

When you specify an *M*-by-1 vector, the block treats the length-*M* unoriented vector input at port **B** as an *M*-by-1 matrix. Inputs *A* and *B* must have the same number of rows.

Data Types: `single` | `double`

### Output

**X** — Solution to system of equations  
*N*-by-*L* matrix

The output at the **X** port is the *N*-by-*L* matrix *X*. The block computes *X* to minimize the sum of the squares of the elements of  $B - AX$  (the residual).

When *B* is a vector, this solution minimizes the vector 2-norm of the residual. When *B* is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of *X* are the solutions to the *L* corresponding systems  $AX_k = B_k$ , where  $B_k$  is the *k*th column of *B*, and  $X_k$  is the *k*th column of *X*.

*X* is known as the minimum-norm-residual solution to  $AX = B$ . The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but the solution is not unique for

underdetermined linear systems. Thus when you apply the SVD Solver block to an underdetermined system, the block computes  $X$  to minimize the number of nonzero entries in  $X$ .

Data Types: `single` | `double`

**E** — Show error status report  
logical scalar

The block returns a logical scalar value of 0 if the singular value decomposition calculation converges, and a logical scalar value of 1 if the singular value decomposition calculation does not converge.

Data Types: `Boolean`

## Parameters

**Show error status port (E)** — Select to report failure to converge

`off` (default) | `on`

Select to enable the **E** output port, which reports the failure to converge as one of the following:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port **X** is an undefined matrix of the expected size.

## Block Characteristics

# Time Scope

Display and analyze signals generated during simulation and log signal data to MATLAB

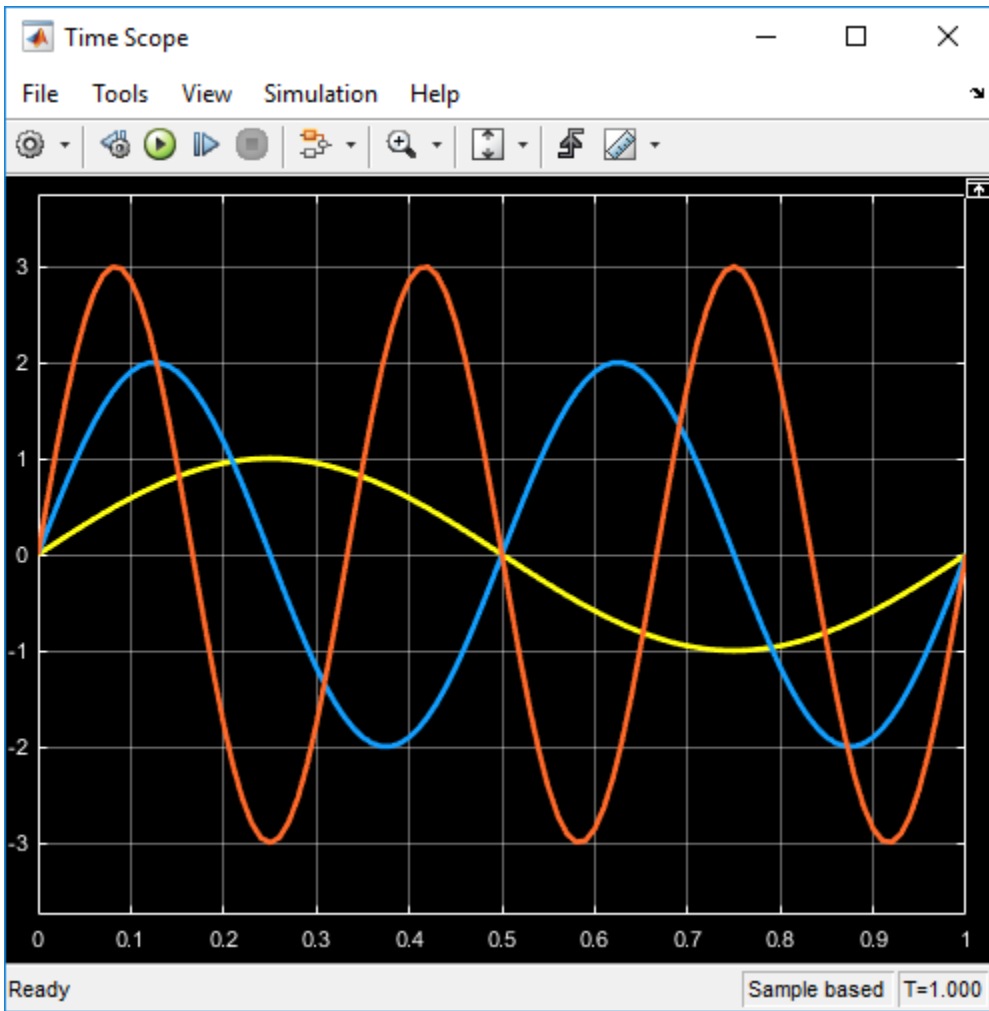

**Libraries:**

DSP System Toolbox / Sinks

DSP System Toolbox HDL Support / Sinks

## Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope” (Simulink).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same y-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple y-axes. All the y-axes have a common time range on the x-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — Scope data is saved during a simulation. If a scope is closed at the start of a simulation, when you open the scope after a simulation, the scope displays simulation results for attached input signals.

---

**Note** If you have a high sample rate or long simulation time, you may run into issues with memory or system performance because the scope saves data internally. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

---

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically” (Simulink).

## Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- If you step through a model, the scope only updates when the scope block runs. This means that the time shown in the status bar may not match the model time.
- When connected to a constant signal, a scope block may plot a single point.
- The scope shows gaps in the display when the signal value is NaN.

- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.
- Scope displays have limitations in Rapid Accelerator mode. See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” (Simulink)
- When the Scope is in a ForEach subsystem, the scope only displays the last index.

## Ports

### Input

**Port\_1** — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

### Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

### Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to **Dataset**. You can use any **Save format** to log virtual bus signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

## Properties

### Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

**Main**

**Open at simulation start** — Specify when scope window opens

off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

**Programmatic Use**

See `OpenAtSimulationStart`.

**Display the full path** — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

**Number of input ports** — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

**Programmatic Use**

See `NumInputPorts`.

**Layout** — Number and arrangement of displays

1-by-1 display (default) | an arrangement of m-by-n axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

**Programmatic Use**

See `LayoutDimensions`.

**Sample time** — Simulation interval between scope updates

-1 (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers. For a more detailed explanation of sample time with the scope, see “Sample Time with Scope Blocks” (Simulink)

**Programmatic Use**

See `SampleTime`.

**Input processing** — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

**Programmatic Use**

See `FrameBasedProcessing`.

**Maximize axes** — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 2-0 and “Y-label” on page 2-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

**Programmatic Use**

See `MaximizeAxes`.

**Time****Time span** — Length of x-axis to display

`Auto` (default) | `User defined` | `One frame period`

- `Auto` — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 2-0 and “Time span” on page 2-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- **User defined** — Enter any value less than the total simulation time.
- **One frame period** — Use the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to **Columns as channels (frame based)**.

#### **Programmatic Use**

See `TimeSpan`.

**Time span overrun action** — Display data beyond visible x-axis

Wrap (default) | Scroll

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- **Wrap** — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- **Scroll** — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

#### **Programmatic Use**

See `TimeSpanOverrunAction`.

**Time units** — x-axis units

None (default for Scope) | Metric (default for Time Scope) | Seconds

- **Metric** — Display time units based on the length of “Time span” on page 2-0 .
- **Seconds** — Display time in seconds.
- **None** — Do not display time units.

#### **Programmatic Use**

See `TimeUnits`.

**Time display offset** — x-axis offset

0 (default) | scalar | vector

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- **Scalar** — Offset all channels of an input signal by the same time value.
- **Vector** — Independently offset the channels.

#### **Programmatic Use**

See `TimeDisplayOffset`.

**Time-axis labels** — Display of x-axis labels

Bottom Displays Only (default for Scope) | All (default for Time Scope) | None

Specify how x-axis (time) labels display:

- All — Display x-axis labels on all y-axes.
- None — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- Bottom displays only — Display x-axis label on the bottom y-axis.

#### **Dependencies**

To enable this property, set:

- “Show time-axis label” on page 2-0 to on.
- “Maximize axes” on page 2-0 to off.

The “Active display” on page 2-0 property determines which display is affected.

#### **Programmatic Use**

See `TimeAxisLabels`.

**Show time-axis label** — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

#### **Dependencies**

To enable this property, set “Time-axis labels” on page 2-0 to All or Bottom Displays Only.

The “Active display” on page 2-0 property determines which display is affected.

#### **Programmatic Use**

See `ShowTimeAxisLabel`.

#### **Display**

**Active display** — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

#### **Programmatic Use**

See `ActiveDisplay`.

**Title** — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

**Dependency**

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See Title.

**Show legend** — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

---

**Note** The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

---

**Dependency**

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See ShowLegend.

**Show grid** — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

**Dependency**

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See ShowGrid.

**Plot signals as magnitude and phase** — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.

- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

**Dependency**

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See `PlotAsMagnitudePhase`.

**Y-limits (Minimum)** — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

**Tunable:** Yes

**Dependency**

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See `YLimits`.

**Y-limits (Maximum)** — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

**Tunable:** Yes

**Dependency**

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See `YLimits`.

**Y-label** — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (`%<SignalUnits>`) to the label. At the beginning of a simulation, Simulink replaces (`%SignalUnits`) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter `Velocity (%<SignalUnits>)`.

**Dependency**

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 2-0 property determines which display is affected.

**Programmatic Use**

See YLabel.

**Logging****Limit data points to last** — Limit buffered data values

off and 5000 (default) | on | positive integer

Limit data saved by the scope internally. By default all data points are saved so that you can view the scope visualization after the simulation finishes. For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

---

**Note** If you do not select **Limit data points to last** and you have a high sample rate or long simulation time, you may run into issues with memory or system performance.

---

When you select this property, the scope saves the latest  $n$  data points, where  $n$  the specified number of data points.

- Off — Save and plot all data values.
- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

In some cases, selecting this property can have the effect of plotting signals for less than the entire time range of a simulation (for example if your sample time is small). If the scope plots a portion of your signals, consider increasing the number of data points to save.

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

**Programmatic Use**

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

**Decimation** — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every  $N$ th data point, where  $N$  is the decimation factor entered in the text box. A value of 1 buffers all data values.
- Off — Save all scope data values.

**Dependency**

To enable this property, select “Log data to workspace” (Simulink).

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

**Programmatic Use**

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

**Log data to workspace** — Save data to MATLAB workspace

off (default) | on

Select this check box to enable logging and enable the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Scope Block” (Simulink).

**Programmatic Use**

See `DataLogging`.

**Variable name** — Name of saved data variable

`ScopeData` (default) | string

Specify a variable name for saving scope data in the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

**Dependency**

To enable this property, select “Log data to workspace” (Simulink).

**Programmatic Use**

See `DataLoggingVariableName`.

**Save format** — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a `Dataset` object, by default a `timeseries` object.
- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

**Dependency**

To enable this property, select “Log data to workspace” (Simulink).

**Programmatic Use**

See `DataLoggingSaveFormat`.

## Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

**Axes scaling** — Y-axis scaling mode

Manual (default) | Auto | After N Updates

- **Manual** — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- **Auto** — Scale the y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to Auto and clear the **Do not allow Y-axis limits to shrink** check box.
- **After N Updates** — Scale y-axis after the number of time steps specified in the **Number of updates** text box (10 by default). Scaling occurs only once during each run.

### Programmatic Use

See AxesScaling.

**Do not allow Y-axis limits to shrink** — When y-axis limits can change

on (default) | off

Allow y-axis range limits to increase but not decrease during a simulation.

### Dependency

To use this property, set **Axes scaling** to Auto.

**Number of updates** — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

### Dependency

To use this property, set **Axes scaling** to After N Updates.

### Programmatic Use

See AxesScalingNumUpdates.

**Scale axes limits at stop** — When y-axis limits can change

on (default) | off

- **On** — Scale axes when simulation stops.
- **Off** — Scale axes continually.

### Dependency

To use this property, set **Axes scaling** to Auto.

**Y-axis Data range (%)** — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

**Y-axis Align** — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the y-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the y-axis range.

**Autoscale X-axis limits** — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

**X-axis Data range (%)** — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

**X-axis Align** — Alignment along x-axis

Center (default) | Left | Right

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- Right — Align signals with the maximum values of the x-axis range.
- Center — Center signals between the minimum and maximum values.
- Left — Align signals with the minimum values of the x-axis range.

**Style Properties**

To open the Style dialog box, from the scope menu, select **View > Style**.

**Figure color** — Background color for window

black (default) | color

Background color for the scope.

**Plot type** — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select **Auto**, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

**Axes colors** — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

**Preserve colors for copy to clipboard** — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

**Properties for line** — Line to change

Channel 1 (default)

Select active line for setting line style properties.

**Visible** — Line visibility

on (default) | off

Show or hide a signal on the plot.

#### Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

**Line** — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

#### Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

**Marker** — Data point marker style

None (default) | marker shape

Select marker shape.

#### Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

## Block Characteristics

|                                 |  |
|---------------------------------|--|
| <b>Data Types</b>               | Boolean   bus <sup>a</sup>   double   enumerated   fixed point   half   integer   single |
| <b>Direct Feedthrough</b>       | no   |
| <b>Multidimensional Signals</b> | yes  |
| <b>Variable-Size Signals</b>    | yes  |
| <b>Zero-Crossing Detection</b>  | no   |

<sup>a</sup> Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format.

## Tips

If you run your simulation for a long time, you may run into out-of-memory issues because the scope saves data. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

## Version History

Introduced in R2015b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

### PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

## Toeplitz

Generate matrix with Toeplitz symmetry

## Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

## Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (*Col*) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (*Row*) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row) % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

$$y(i,j) = y(i-1,j-1)$$

and the output has dimension  $[\text{length}(\text{Col}) \ \text{length}(\text{Row})]$ . The  $y(1,1)$  element is inherited from the *Col* input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, *u*, defining both the first row and first column of the matrix.

```
y = toeplitz(u) % Equivalent MATLAB code
```

The output has dimension  $[\text{length}(u) \ \text{length}(u)]$ . For example, the Toeplitz matrix generated from the input vector  $[1 \ 2 \ 3 \ 4]$  is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

## Parameters

### Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

### Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$$y(i, j) = \text{conj}(y(j, i))$$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

## Supported Data Types

| Port     | Supported Data Types   |
|----------|--|
| Input    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers (real signals only)</li> </ul> |

## To Audio Device

Write audio data to computer's audio device

## Compatibility

---

**Note** The To Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Writer block instead.

---

## Library

Sinks

dspsnks4

## Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- 8-bit integer
- 16-bit integer
- 24-bit integer
- 32-bit float
- Determine from input data type

If you choose Determine from input data type, the following table summarizes the block's behavior.

| Input Data Type  | Device Data Type      |
|--|-----------------------|
| Double-precision floating point or single-precision floating point | 32-bit floating point |
| 32-bit integer   | 24-bit integer        |
| 16-bit integer   | 16-bit integer        |
| 8-bit integer  | 8-bit integer         |

If you choose **Determine** from **input data type** and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

### Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.

- 1 At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.
- 2 At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the From Audio Device block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.
- 3 The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional **Under run** output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

### Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions  $N \times 3$  (3-channel data). You want the output to be redirected as follows:

- First data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1
- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

### Troubleshooting

#### Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration.*

The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.

- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

### Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

| Platform | Command   |
|----------|---|
| Mac      | <pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh)  export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre> |
| Linux    | <pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh)  export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>   |
| Windows  | <pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>  |

### Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

On systems with two speakers, the front center channel is split between the right and left speakers.

- Multichannel input — Channels are assigned to speakers as follows:
  - One channel — Front center
  - Two channels — Front left, front right
  - Four channels — Front left, front right, rear left, rear right
  - Six channels — Front left, front right, front center, low frequency, rear left, rear right
  - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
  - For all other channel combinations, the channel assignment is dictated by the audio card.

## Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO
- Linux: ALSA, OSS
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where  $N$  is a scalar. Choose  $N$  based on the API choice above.

## Parameters

### Device

Specify which device to send the audio data to.

### Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

### Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

### Device data type

Specify the data type of the audio data sent to the device.

### Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

**Buffer size (samples)**

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

**Queue duration (seconds)**

Specify the size of the queue in seconds.

**Use default mapping between Data and Device Output Channels**

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

**Device Output Channels**

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

**Output number of samples by which the queue was underrun**

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-1393.

**Supported Data Types**

| Port     | Supported Data Types  |
|----------|---|
| Input    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• 32-bit signed integers</li> <li>• 16-bit signed integers</li> <li>• 8-bit unsigned integers</li> </ul> |
| Underrun | 32-bit unsigned integer   |

**See Also**

**Version History**

**Introduced in R2007b**

## To Multimedia File

Stream video frames and audio samples to multimedia file

## Library

Sinks

dspsnks4

## Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

---

**Note** This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode WMV and WMA files.

---

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation in DSP System Toolbox” for details.

### Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC

- OGG
- OPUS
- MPEG4 (only on Windows 7 and macOS)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and macOS. You can use both M4A and MP4 extensions.

The following platform specific restrictions apply when writing these files:

### Windows 7

- Only sample rates of 44100 and 48000 Hz are supported.
- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- The output data is padded on both the front and back of the signal, with extra samples of silence.

Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.

- A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.

### macOS

- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.

### Linux

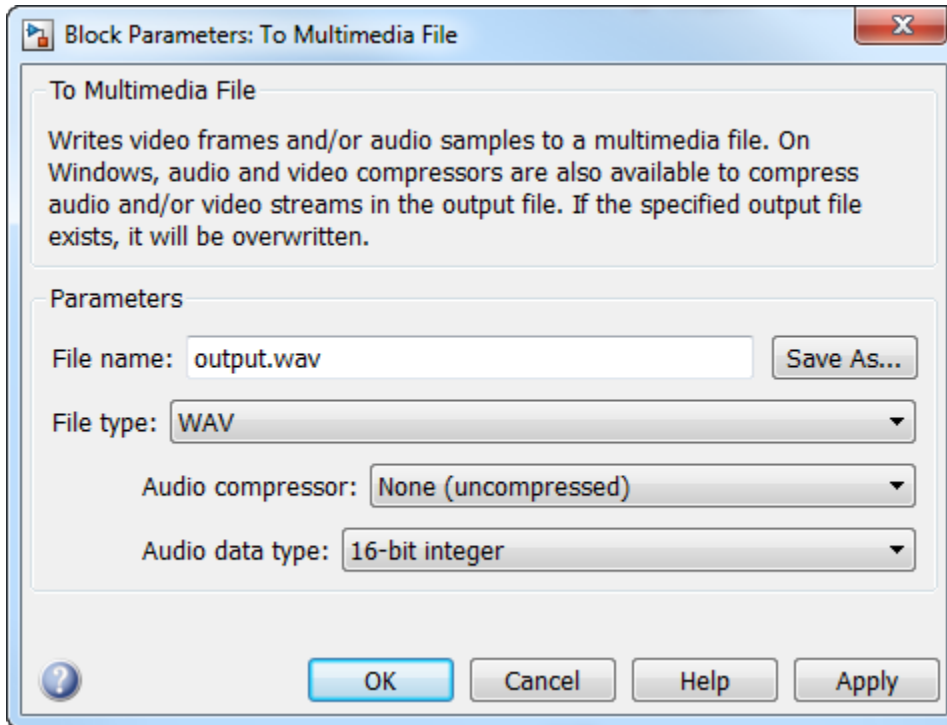

- To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

### Ports

| Port             | Description  |
|------------------|--|
| <b>Image</b>     | $M$ -by- $N$ -by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.   |
| <b>R, G, B</b>   | Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.   |
| <b>Audio</b>     | $M$ -by- $N$ matrix. $M$ is the number of samples in each channel, and $N$ is the number of channels.  |
| <b>Y, Cb, Cr</b> | Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions:<br>$Y: M \times N$<br>$Cb: M \times \frac{N}{2}$<br>$Cr: M \times \frac{N}{2}$ |

## Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.

### File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

### File type

Specify the file type of the multimedia file. You can select AVI, WAV, MJ2000, WMA, WMV, MPEG4, FLAC, OGG, or OPUS. By default, the **File type** is set to WAV.

### Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select **Video and audio**, **Video only**, or **Audio only**. This parameter is visible only when you set **File type** to AVI, MPEG4, OGG or OPUS.

### Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed audio data to the multimedia file.

---

**Note** The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

---

**Audio data type**

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

**Video compressor**

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed video data to the multimedia file.

---

**Note** The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

---

**Compression Factor (>1)**

Specify the compression factor as an integer scalar greater than 1. This parameter is applicable only when the **File type** is set to MJ2000 and **Video compressor** is set to Lossy. By default, this parameter is set to 10.

**File color format**

Select the color format of the data stored in the file. You can select either RGB or YCbCr 4:2:2.

**Image signal**

Specify how the block accepts a color video signal. If you select **One multidimensional signal**, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select **Separate color signals**, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

**Video Quality (0-100)**

Quality of the video specified as an integer scalar in the range [0 100]. This parameter is applicable only when **File name** is set to MPEG4 and **Write** is set to **Video only**. By default, this parameter is set to 75.

**Troubleshooting****Running an Executable Outside MATLAB**

To run your generated standalone executable application in Shell, you need to set your environment to the following:

| Platform | Command   |
|----------|---|
| Mac      | <pre>setenv DYLD_LIBRARY_PATH "\$ {DYLD_LIBRARY_PATH}:\$MATLABROOT/bin/ maci64" (csh/tcsh)  export DYLD_LIBRARY_PATH= \$DYLD_LIBRARY_PATH:\$MATLABROOT/bin/ maci64 (Bash)</pre> <p>For more information, see <a href="#">Append library path to "DYLD_LIBRARY_PATH" in MAC</a>.</p> |

| Platform | Command   |
|----------|---|
| Linux    | <pre>setenv LD_LIBRARY_PATH \$ {LD_LIBRARY_PATH}:%MATLABROOT/bin/ glnxa64 (csh/tcsh)  export LD_LIBRARY_PATH= \$LD_LIBRARY_PATH:%MATLABROOT/bin/ glnxa64 (Bash)</pre> |
| Windows  | <pre>set PATH=%PATH%;%MATLABROOT%\bin\win64</pre>   |

## Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

| Port      | Supported Data Types  | Supports Complex Values? |
|-----------|---|--------------------------|

## Version History

Introduced before R2006a

### R2022b: Support for OPUS audio file format

The To Multimedia File block supports OPUS file format (.opus).

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

## To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time

### Library

dspwin32

### Description

---

**Note** The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Audio Device block.

---

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

---

**Note** Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

---

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length- $M$  vector, where  $M$  is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based  $M$ -by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

| Input Data Type  | Valid Input Amplitude Range                   |
|--|---|
| double   | $-1 \leq \textit{amplitude} < 1$              |
| single   | $-1 \leq \textit{amplitude} < 1$              |
| int16  | $-32768 \leq \textit{amplitude} \leq 32767$   |
| uint8  | $0 \leq \textit{amplitude} \leq 255$          |
| Fixed point with a word length of 16 and a fraction length of 15 | $-1 \leq \textit{amplitude} \leq 1 - 2^{-15}$ |

### Buffering

Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

**Note** This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**

The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = \textit{samplingfrequency} = \frac{1}{\textit{samptime}}$$

| $F_s$ (Hz)                 | Internal Buffer Size (samples) |
|----------------------------|--------------------------------|
| $F_s < 8000$               | $\min(64, 2 * F_s)$            |
| $8000 \leq F_s < 22,050$   | 128                            |
| $22,050 \leq F_s < 44,100$ | 256                            |
| $44,100 \leq F_s < 96,000$ | 512                            |
| $F_s \geq 96,000$          | 1024                           |

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

### Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,
  - 1 Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
  - 2 Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.

- If your model is not running in real time, try to make it run in real time by
  - 1 Optimizing the model (using a more efficient implementation), or
  - 2 Using a Simulink "Acceleration" (Simulink) mode, or
  - 3 Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

### Parameters

#### Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

**Automatically determine internal buffer size**

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1404.

**User-defined internal buffer size (samples)**

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

**Initial output delay (seconds)**

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

**Use default audio device**

Select to direct audio output to the system's default audio device.

**Audio device**

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

**Enable 24-bit output for double and single precision input signals**

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

**Supported Data Types**

| Port  | Supported Data Types   |
|-------|--|
| Input | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed point with a word length of 16 and a fraction length of 15</li> <li>• 16-bit signed integers</li> <li>• 8-bit unsigned integers</li> </ul> |

## To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (.wav) format

## Library

dspwin32

## Description

---

**Note** The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

---

The To Wave File block streams audio data to a Microsoft Wave (.wav) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block,  $u$ , can contain audio data with one or more channels. A signal with  $C$  channels is represented as a sample-based length- $C$  vector or a frame-based  $M$ -by- $C$  matrix. The amplitude of the input should be in the range  $\pm 1$ . Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

---

**Note** AVI files are the only supported file type for non-Windows platforms.

---

## Parameters

### File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the .wav extension.

### Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- 8 — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels

- 32 — Allocates 32 bits to each sample, allowing a resolution of  $2^{32}$  levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

#### Minimum number of samples for each write to file

Specify the number of consecutive samples,  $L$ , to write with each file access. To reduce the required number of file accesses, the block writes  $L$  consecutive samples to the file during each access for  $L \geq M$ . For  $L < M$ , the block instead writes  $M$  consecutive samples during each access. Larger values of  $L$  result in fewer file accesses, which reduces run-time overhead.

## Supported Data Types

| Port  | Supported Data Types   |
|-------|--|
| Input | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Signed fixed point with a word length of 16 and a fraction length of 15</li> <li>• 16-bit signed integers</li> <li>• 8-bit unsigned integers</li> </ul> |

## Version History

Introduced in R2010a

## Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output

### Library

dspobslib

### Description

---

**Note** The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

---

The Triggered Delay Line block acquires a collection of  $M_o$  input samples into a frame, where you specify  $M_o$  in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⚡). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by  $M_o-1$  samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period,  $T_{fo}=T_{si}$ .

#### Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length- $N$  vector inputs (1-D, row, or column) into a sequence of overlapping sample-based  $M_o$ -by- $N$  matrix outputs, where you specify  $M_o$  in the **Delay line size** parameter ( $M_o>1$ ). That is, each input vector becomes a *row* in the sample-based output matrix. When  $M_o=1$ , the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

#### Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based  $M_f$ -by- $N$  matrix inputs into an sequence of overlapping frame-based  $M_o$ -by- $N$  matrix outputs, where  $M_o$  is

the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame).  $M_o$  can be greater or less than the input frame size,  $M_i$ . Each of the  $N$  input channels is rebuffered independently.

### Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step ( $t=0$ ). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

### Parameters

#### Trigger type

The type of event that triggers the block's execution.

#### Delay line size

The length of the output frame (number of rows in output matrix),  $M_o$ .

#### Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

### Supported Data Types

## Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

**Libraries:**  
DSP System Toolbox / Signal Operations

### Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (⚡). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

### Ports

#### Input

**trigger** — Trigger signal  
scalar | vector | matrix

Triggering input signal, specified as a scalar, vector, or matrix. This port is labelled with ⚡.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

#### Output

**Port\_1** — Signal imported from workspace  
scalar | vector | matrix | 3-D array

The block outputs the signal imported from the workspace when triggered by the control signal at the input port.

When the **Signal** parameter specifies an  $M$ -by- $N$  matrix ( $M \neq 1$ ), each of the  $N$  columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter,  $M_0$ . When triggered, the block outputs an  $M_0$ -by- $N$  matrix containing  $M_0$  consecutive samples from each signal channel. For convenience, an imported row vector ( $M=1$ ) is treated as a single channel, so the output dimension is  $M_0$ -by-1.

When the **Signal** parameter specifies an  $M$ -by- $N$ -by- $P$  array, the block generates a single page of the array (an  $M$ -by- $N$  matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

### Parameters

**Signal** — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

When the **Signal** parameter specifies an  $M$ -by- $N$  matrix ( $M \neq 1$ ), each of the  $N$  columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter,  $M_o$ . When triggered, the block outputs an  $M_o$ -by- $N$  matrix containing  $M_o$  consecutive samples from each signal channel. For convenience, an imported row vector ( $M=1$ ) is treated as a single channel, so the output dimension is  $M_o$ -by-1.

When the **Signal** parameter specifies an  $M$ -by- $N$ -by- $P$  array, the block generates a single page of the array (an  $M$ -by- $N$  matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

**Trigger type** — Type of triggering event

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the block to execute.

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge occurs.

**Initial output** — Initial output value

0 (default) | scalar | vector | matrix

The value to output until the first trigger event is received. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** can be a vector of length  $M_o$  or a scalar to repeat across the  $M_o$  elements of the initial output frames. For matrix outputs ( $M_o$ -by- $N$  or  $M$ -by- $N$ ), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

**Samples per frame** — Samples per frame

1 (default) | positive integer

The number of samples,  $M_o$ , to buffer into each output frame specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

**Form output after final data value by** — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.

- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical. For example, the *i*th frame of one cycle contains the same samples as the *i*th frame of any other cycle.

The block does not extrapolate the imported signal beyond the last sample.

## Block Characteristics

# Triggered To Workspace

Write input sample to MATLAB workspace when triggered

**Libraries:**  
DSP System Toolbox / Sinks

## Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. To open the Configuration Parameters, in the **Modeling** tab of the Simulink model toolstrip, click **Model Settings**. In the left pane of the window that opens, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

## Ports

### Input

**Input** — Data to log to workspace

scalar | vector | matrix | bus

Specify the data to log to the workspace when the block receives a trigger at the **Trigger** port. The Triggered To Workspace block supports logging real and complex data of any built-in data type or user-defined data types such as buses, enumerations, and fixed-point data.

### Tips

Logging fixed-point data requires a Fixed-Point Designer license.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | string | fixed point | enumerated | bus | image

**Trigger** — Trigger signal

scalar | vector | matrix

Specify the trigger signal that controls the execution of the block as a scalar, vector, or a matrix.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

## Parameters

**Trigger type** — Trigger type

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the execution of the block.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (✚). At all other times, the block ignores input 1. You specify the triggering event at input 2 using the **Trigger type** parameter:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block for a **Rising edge** or a **Falling edge**.

**Variable name** — Workspace variable name

yout (default) | character vector | string

The name of the workspace variable in which to store the data. By default, the Triggered To Workspace block saves logged data in a variable called `yout`. When a model contains multiple Triggered To Workspace blocks, you must specify a unique value in the **Variable name** parameter of each block.

**Decimation** — Decimation factor

1 (default) | scalar

Specify a decimation factor to reduce the effective sample rate for the logged data. For a decimation factor  $D$  the Triggered To Workspace block logs the value of every  $D^{\text{th}}$  sample. For example, when you specify the **Decimation** value as 2, the Triggered To Workspace block logs every other data point.

For more information about controlling which samples the block logs during simulation, see “Specify Signal Values to Log” (Simulink).

**Maximum number of rows** — Maximum number of rows to be saved

1000 (default) | positive integer

Specify the maximum number of rows (one row per time step) that the block saves ( $P$ ) as a positive integer.

**Save 2-D signals as** — Arrangement of 2-D samples values in logged data

2-D array (concatenate along first dimension) (default) | 3-D array (concatenate along third dimension)

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace.

When you select:

- **2-D array (concatenate along first dimension)** — The block vertically concatenates each  $M$ -by- $N$  matrix input with the previous input to produce a 2-D output array. The block saves the data as a  $P$ -by- $N$  matrix, where  $P$  is the value of the **Maximum number of rows** parameter.

When the simulation progresses long enough for the block to acquire more than  $P$  samples, the block stores only the most recent  $P$  samples. The **Decimation factor**  $D$  allows you to store only every  $D^{\text{th}}$  input matrix.

- **3-D array (concatenate along third dimension)** — The block saves an  $M$ -by- $N$  input as a 3-D array in which each  $M$ -by- $N$  page represents a single sample from each of the  $M*N$  channels (the most recent input matrix occupies the last page). The maximum size of this 3-D array is limited to  $M$ -by- $N$ -by- $P$ , where  $P$  is the value of the value of the **Maximum number of rows** parameter.

When the simulation progresses long enough for the block to acquire more than  $P$  inputs, the block stores only the last  $P$  inputs. The **Decimation factor**  $D$  allows you to store only every  $D^{\text{th}}$  input matrix.

**Log fixed-point data as a fi object** — Log fixed-point data as a fi object

off (default) | on

Specify how to log fixed-point input data. By default, the Triggered To Workspace block logs fixed-point input data as double. When you select this parameter, the Triggered To Workspace block logs fixed-point input as a Fixed-Point Designer fi object.

Using the Triggered To Workspace block to log fixed-point data requires a license for Fixed-Point Designer.

## Block Characteristics

|                                 |  |
|---------------------------------|--|
| <b>Data Types</b>               | Boolean   double   enumerated   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no   |
| <b>Multidimensional Signals</b> | no   |
| <b>Variable-Size Signals</b>    | no   |
| <b>Zero-Crossing Detection</b>  | no   |

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

**Fixed-Point Conversion**

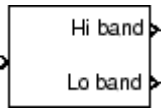

Design and simulate fixed-point systems using Fixed-Point Designer™.

# Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as shown in this figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1428 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

## Ports

### Input

#### Input 1 — Data input

column vector | matrix

Specify the data input as a column vector or a matrix of size  $M$ -by- $N$ . The columns in the input signal represent  $N$  independent channels.

The block supports variable-size input signals (frame length changes during simulation) when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing. When you specify variable-size input signals, they can be of arbitrary frame length, that is, the input frame length does not have to be even. When you specify fixed-size signals, the frame length can be arbitrary under certain conditions. For more details, see “Frame-Based Processing” on page 2-1425 and “Sample-Based Processing” on page 2-1427.

When the input is fixed point, it must be signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Output

**Hi band** — High-frequency subband  
column vector | matrix

The block outputs the high-frequency subband as a column vector or a matrix.

When you set **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of 2.

The output has an upper bound size of  $\text{ceil}(M/2)$ -by- $N$  for an input of size  $M$ -by- $N$ .

- **Allow multirate processing** -- The block decimates the signal such that the output sample rate is half the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-1425 and “Sample-Based Processing” on page 2-1427.

Data Types: single | double | int8 | int16 | int32 | fixed point

**Lo band** — Low-frequency subband  
column vector | matrix

The block outputs the low-frequency subband as a column vector or a matrix.

When you set **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate and decimates the signal by decreasing the output frame size by a factor of 2.

The output has an upper bound size of  $\text{ceil}(M/2)$ -by- $N$  for an input of size  $M$ -by- $N$ .

- **Allow multirate processing** -- The block decimates the signal such that the output sample rate is half the input sample rate.

The output frame size is the same as the input frame size.

For more details, see “Frame-Based Processing” on page 2-1425 and “Sample-Based Processing” on page 2-1427.

Data Types: single | double | int8 | int16 | int32 | fixed point

## Parameters

### Main Tab

**Lowpass FIR filter coefficients** — Lowpass FIR filter coefficients

[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327] (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter

based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specify FIR Filters” on page 2-1425.

#### **Highpass FIR filter coefficients** — Highpass FIR filter coefficients

`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specify FIR Filters” on page 2-1425.

#### **Input processing** — Input processing

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information, see “Frame-Based Processing” on page 2-1425 and “Sample-Based Processing” on page 2-1427.

#### **Rate options** — Rate options

`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1427 for more information.

#### **Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

`off` (default) | `on`

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be even. The block uses this parameter only for fixed-size input signals and ignores it if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have an arbitrary frame length, that is, the frame length does not have to be an even number.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be even. The output is a variable-size signal.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be even.

### Dependency

To enable this parameter, set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

### Data Types Tab

**Rounding mode** — Rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to Nearest.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block effectively operates in full-precision mode.

---

**Saturate on integer overflow** — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

---

**Coefficients** — Data type of the coefficients

Inherit: Same word length as input (default) | `fixd(1,16)` | `fixd(1,16,0)`

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1429 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Coefficients Minimum** — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Coefficients Maximum** — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Product output** — Product output data type

Inherit: `Inherit via internal rule` (default) | `Inherit: Same as input` | `fixd(1,16,0)`

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1429 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

---

**Note** The actual product output word length can be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

---

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Accumulator** — Data type of accumulator

Inherit: `Inherit via internal rule (default)` | `Inherit: Same as input` | `Inherit: Same as product output` | `fixd(1,16,0)`

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1429 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Output** — Data type of output

Inherit: `Same as accumulator (default)` | `Inherit: Same as input` | `Inherit: Same as product output` | `fixd(1,16,0)`

Specify the output data type. See “Fixed-Point Data Types” on page 2-1429 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Output Minimum** — Output minimum

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Output Maximum** — Output maximum

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))

- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Specify FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

### Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an  $M$ -by- $N$  matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and the two outputs of the block have the same sample rate. The block treats each column of the

input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The frame length of each output has an upper bound size of  $\text{ceil}(M/2)$ .

In this mode, if you input a fixed-size signal (frame length does not change during simulation) and select the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length can be arbitrary and does not have to be an even number. If you clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be an even number.

In this mode, if you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** parameter appears on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length   | Input Size   | Output Size                                     |
|----------------------------|-------------------------------|--|--------------|---|
| Fixed-size input signal    | Yes                           | When you select <b>Allow arbitrary frame length for fixed-size input signals</b> | $M$ -by- $N$ | Upper bound size of $\text{ceil}(M/2)$ -by- $N$ |
| Variable-size input signal | Yes                           | Always   | $M$ -by- $N$ | Upper bound size of $\text{ceil}(M/2)$ -by- $N$ |

- When you set the **Rate options** parameter to Allow multirate processing, the input and the two outputs of the Two-Channel Analysis Subband Filter block are of the same size, but the sample rate of the output is half that of the input. In this mode, the block treats a  $M$ -by- $N$  matrix input as  $N$  independent channels and decomposes each channel over time. The block outputs two  $M$ -by- $N$  matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column.

In this mode, the block accepts only fixed-size signals and these signals can have arbitrary frame length. That is, the frame length does not have to be even.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to Columns as channels (frame based) and **Rate options** to Allow multirate processing.

| Input Signal            | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size   | Output Size  |
|-------------------------|-------------------------------|--|--------------|--------------|
| Fixed-size input signal | Yes                           | Always                                   | $M$ -by- $N$ | $M$ -by- $N$ |

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1427 section.

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an  $M$ -by- $N$  matrix input as  $M \cdot N$  independent channels. The block decomposes each channel over time and outputs two  $M$ -by- $N$  matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

In this mode, the block accepts only fixed-size signals and these signals can have an arbitrary frame length.

This table summarizes the support for arbitrary input frame length when you set **Input processing** to `Elements as channels (sample based)`. **Rate options** is automatically set to `Allow multirate processing`.

| Input Signal               | Block Support for this Signal | Support for Arbitrary Input Frame Length | Input Size     | Output Size    |
|----------------------------|-------------------------------|--|----------------|----------------|
| Fixed-size input signal    | Yes                           | Always                                   | $M$ -by- $N$   | $M$ -by- $N$   |
| Variable-size input signal | No                            | Not applicable                           | Not applicable | Not applicable |

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1427 section.

### Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time  $t=0$ ) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

| Input processing                    | Treat each discrete rate as a separate task | Latency  |
|-------------------------------------|---|--|
| Elements as channels (sample based) | Off   | None.  |
|                                     | On  | One sample. The first output sample in each channel always has a value of 0. |
| Columns as channels (frame based)   | On or Off                                   | One frame. All samples in the first output frame have a value of 0.          |

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an  $n$ -level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1427 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires lesser memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of  $2^n$ .
- You are decomposing the signal into  $n+1$  or  $2^n$  subbands.

In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

### 3-Level Dyadic Analysis Filter Banks

#### Conceptual illustration

#### Two-Channel Analysis Subband Filter block implementation

Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of  $2^n$  into  $n+1$  subbands, where  $n = 3$ .

In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.

Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of  $2^n$ .

#### Dyadic Analysis Filter Bank block implementation

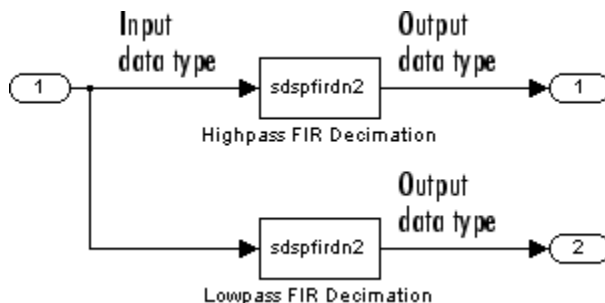

The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

### Fixed-Point Data Types

Fixed-point data types in the Two-Channel Analysis Subband Filter Bank block.

The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in "Parameters" on page 2-1420. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

## Version History

Introduced before R2006a

**R2023a: Support for arbitrary input frame length**

This block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and the block allows for multirate processing.
- Input signal is a fixed-size signal, the block enforces single-rate processing, and you select the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an input signal with an arbitrary frame length, the input frame length does not have to be even.

For more details, see “Frame-Based Processing” on page 2-1425 and “Sample-Based Processing” on page 2-1427.

# Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as shown in this figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1438.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

## Ports

### Input

**Hi band** — High-frequency subband  
vector | matrix

Specify the high-frequency subband as a vector or a matrix. Both the high-frequency subband and the low-frequency subbands must have the same size and data type.

When the input is fixed-point, it must be signed only.

Data Types: single | double | int8 | int16 | int32 | fixed point

**Lo band** — Low-frequency subband  
vector | matrix

Specify the low-frequency subband as a vector or a matrix. Both the high-frequency subband and the low-frequency subbands must have the same size and data type.

When the input is fixed-point, it must be signed only.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Output

**Output 1** — Synthesized output

`vector` | `matrix`

The block returns the synthesized output as a vector or a matrix. The number of rows in the output is the sum of the number of rows of the input signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Parameters

### Main Tab

**Lowpass FIR filter coefficients** — Lowpass FIR filter coefficients

[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352] (default)

A vector of lowpass FIR filter coefficients, in descending powers of  $z$ . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specify FIR Filters” on page 2-1436.

**Highpass FIR filter coefficients** — Highpass FIR filter coefficients

[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327] (default)

A vector of highpass FIR filter coefficients, in descending powers of  $z$ . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specify FIR Filters” on page 2-1436.

**Input processing** — Input processing

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

For more information, see “Frame-Based Processing” on page 2-1436 and “Sample-Based Processing” on page 2-1437.

**Rate options** — Rate options

Enforce single-rate processing (default) | Allow multirate processing

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- **Allow multirate processing** — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1437 for more information.

**Data Types Tab****Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to **Nearest**.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is `Inherit`: `Inherit via internal rule`
- **Accumulator** is `Inherit`: `Inherit via internal rule`
- **Output** is `Inherit`: `Same as accumulator`

With these data type settings, the block effectively operates in full-precision mode.

---

**Saturate on integer overflow** — Saturate on integer overflow

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

---

**Note** The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit`: `Inherit via internal rule`.
- **Accumulator** data type is `Inherit`: `Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

---

**Coefficients** — Data type of the coefficients

Inherit: Same word length as input (default) | `fixd(1,16)` | `fixd(1,16,0)`

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1438 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Coefficients Minimum** — Minimum value of filter coefficients

`[]` (default) | scalar

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Coefficients Maximum** — Maximum value of filter coefficients

`[]` (default) | scalar

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform automatic scaling of fixed-point data types.

**Product output** — Product output data type

Inherit: `Inherit via internal rule` (default) | `Inherit: Same as input` | `fixd(1,16,0)`

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1438 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

---

**Note** The actual product output word length can be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

---

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Accumulator** — Data type of accumulator

Inherit: `Inherit via internal rule (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixd(1,16,0)`

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1438 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Output** — Data type of output

Inherit: `Same as accumulator (default)` | Inherit: `Same as input` | Inherit: `Same as product output` | `fixd(1,16,0)`

Specify the output data type. See “Fixed-Point Data Types” on page 2-1438 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

**Output Minimum** — Output Minimum

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

**Output Maximum** — Output Maximum

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))

- Automatic scaling of fixed-point data types

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

## Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

## More About

### Specify FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector [b(1) b(2) ... b(m)].

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

### Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based), the block accepts any two  $M$ -by- $N$  matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to Enforce single-rate processing, the input to the block can be any two  $M$ -by- $N$  matrices with the same frame rate. The block treats each input

column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1437 section.

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two  $M$ -by- $N$  matrices with the same sample rates. The block treats each  $M$ -by- $N$  matrix as  $M \cdot N$  independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1437 section.

### Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time  $t=0$ ) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

| Input processing                    | Treat each discrete rate as a separate task | Latency  |
|-------------------------------------|---|--|
| Elements as channels (sample based) | Off   | None.  |
|                                     | On  | One sample. The first output sample in each channel always has a value of 0. |
| Columns as channels (frame based)   | Off or On                                   | One frame. All samples in the first output frame have a value of 0.          |

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

## Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an  $n$ -level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1437 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires lesser memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from  $2^n$  or  $n+1$  subbands.
- The frame size of the signal you are reconstructing is a multiple of  $2^n$ .
- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

### 3-Level Dyadic Synthesis Filter Banks

#### Conceptual illustration

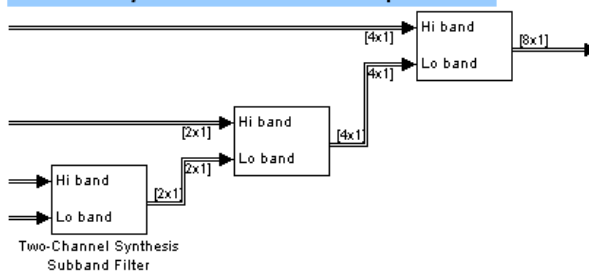

Both implementations of the dyadic analysis filter bank reconstruct a frame-based signal from  $n+1$  subbands, where  $n = 3$ .

In this case, the Dyadic Synthesis Filter Bank block's implementation is more efficient, since the input subbands have the properties of the outputs of a Dyadic Analysis Filter Bank block.

Use the Two-Channel Synthesis Subband Filter block implementation for other cases, such as to handle separate sample-based vectors or matrices of subbands (rather than a single sample-based vector or matrix of concatenated subbands), or to output sample-based signals.

#### Two-Channel Synthesis Subband Filter block implementation

#### Dyadic Synthesis Filter Bank block implementation

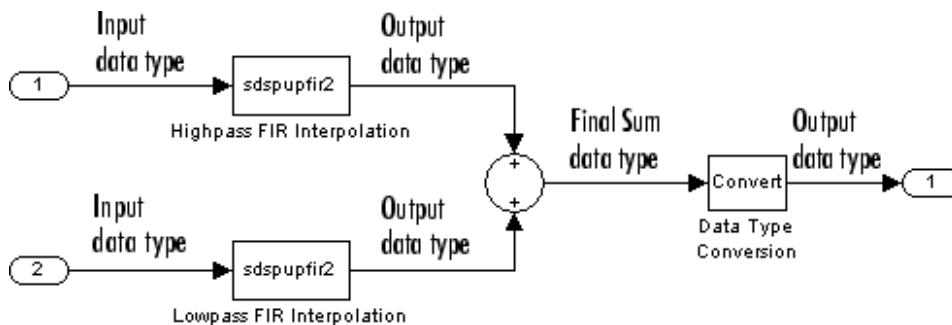

The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

### Fixed-Point Data Types

Fixed-point data types in the Two-Channel Synthesis Subband Filter block.

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in “Parameters” on page 2-1432. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in the output data type. You also set these data types in the block dialog box as discussed in the “Parameters” on page 2-1432 section.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# UDP Receive

Receive UDP packets on a given IP port

**Libraries:**  
DSP System Toolbox / Sources

## Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. Due to the nature of the UDP transmission protocol, the receiver is not guaranteed to receive all the data packets that you send using the UDP Send block. With each sample, the block outputs the contents of a single UDP packet as a data vector.

The local IP port number on which the block receives the UDP packets is tunable in the generated code. The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment or redeploy it, but you must account for the extra `.dll` files. The `packNGo` function creates a ZIP file that contains the pieces required to run or rebuild this code. For more details, see “How To Run a Generated Executable Outside MATLAB”.

## Ports

### Output

**Message** — Data received  
vector

Data received by the UDP Receive block, returned as a one-dimensional vector of the data type specified in **Data type for Message**. If you select **Message is complex**, the block treats the received message as complex data.

If the packet gets dropped during transmission and the receiver does not receive the packet, the data received output is empty.

This port is unnamed until you clear the **Output variable-size signal** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

**Length** — Length of data packet  
scalar

Length of the data packet received, returned as a scalar. This value is determined by the value of the **Maximum length for Message** parameter.

### Dependencies

This port appears only when you clear the **Output variable-size signal** parameter.

Data Types: `uint16`

## Parameters

**Local IP port** — Number of IP port

25000 (default) | scalar in the range [1, 65535]

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter `sudo matlab`.

**Remote IP address ('0.0.0.0' to accept all)** — IP address from which to accept packets

'0.0.0.0' (default) | IP address

Specify the IP address from which to accept UDP packets. Specify a specific IP address to block UDP packets from other addresses. To accept packets from any IP address, specify '0.0.0.0'.

**Receive buffer size (bytes)** — Size of buffer that receives UDP packets

8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that receives the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

**Maximum length for Message** — Maximum length of output data

255 (default) | scalar

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal to or greater than the data size of a UDP packet. The system truncates data that exceeds this length.

If you disable **Output variable-size signal**, the block output is the length specified by this parameter.

**Data type for Message** — Data type of message

uint8 (default) | single | double | int8 | int16 | int32 | uint16 | uint32 | boolean

Specify the data type of the vector elements in the message output. Match the data type to the data input used to create the UDP packets.

**Message is complex** — Message data complexity

off (default) | on

Specify whether the block receives a message as complex data. Select this parameter to receive a message as complex data. Clear this parameter if a received message is real data.

**Output variable-size signal** — Message output that varies in length

on (default) | off

Specify whether your model supports signals of varying length. If your model supports signals of varying length, select this parameter. In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, clear this parameter. In that case:

- The block emits a fixed-length output that is the same length as specified by **Maximum length for Message**.
- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.

If you disable this parameter, the block emits output that is the length specified by **Maximum length for Message**.

**Sample time (seconds)** — Frequency of calls to block

1 (default) | scalar

Specify the frequency at which the scheduler calls the UDP Receive block, in seconds. Enter a value greater than zero. In real-time operation, setting this parameter to a smaller value reduces the likelihood of dropped UDP messages.

## Block Characteristics

|                                 |                                     |
|---------------------------------|-------------------------------------|
| <b>Data Types</b>               | Boolean   double   integer   single |
| <b>Direct Feedthrough</b>       | no                                  |
| <b>Multidimensional Signals</b> | no                                  |
| <b>Variable-Size Signals</b>    | yes                                 |
| <b>Zero-Crossing Detection</b>  | no                                  |

## Version History

Introduced in R2010a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code in several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

# UDP Send

Send UDP message

## Libraries:

DSP System Toolbox / Sinks

## Description

The UDP Send block sends data packets over the network using the User Datagram Protocol (UDP). UDP is a simple message-based connectionless protocol and does not have an end-to-end connection. The protocol sends data packets in one direction from source to destination without verifying the readiness of the receiver. The protocol has no handshaking mechanism. The data packets can get dropped for several reasons. There is no acknowledgement, retransmission, or timeout in UDP. However, UDP is a very simple transmission protocol and is suitable for time-sensitive applications where dropping packets is preferable to waiting for packets delayed due to retransmission.

The UDP Send block transmits an input data vector as a UDP packet to a remote IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the generated code.

Some Simulink blocks and .exe files built from models that contain those blocks require shared libraries, such as .dll files on Windows. The UDP Send block requires the `networkdevice.dll` library file. To meet this requirement, follow the example on the `packNGo` function page to package the code files for your model. The resulting compressed folder contains the .dll files that the model requires, including `networkdevice.dll`. To run this type of .exe file outside of a MATLAB environment, place the required .dll files in the same folder as the .exe file or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

## Ports

### Input

**Input** — Input data vector  
vector

Specify the input data vector that the block transmits as a UDP packet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

## Parameters

**Remote IP address ('255.255.255.255' for broadcast)** — IP address from which to accept UDP packets

'127.0.0.1' (default) | IP address | string

Specify the IP address or host name to which to send UDP packets. If you specify a host name, specify it as a string. To broadcast a UDP packet, specify '255.255.255.255'.

**Remote IP port** — Number of remote IP port  
25000 (default) | scalar in the range [1, 65535]

Specify the IP port number to which to send UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter `sudo matlab`.

**Local IP port source** — Source of local IP port  
Automatically determine (default) | Specify via dialog

Specify whether the block uses a local port number that the system assigns or that you specify by using the **Local IP port** parameter. For the system to assign the port number, select **Automatically determine**. If the receiving address expects UDP packets from a specific port number, select **Specify via dialog** and specify the port number by using the **Local IP port** parameter.

**Local IP port** — Number of local IP port  
-1 (default) | scalar in the range [1, 65535]

Specify the IP port number from which the block sends UDP packets. Use this parameter when the receiving address expects messages from a specific port number.

#### Parameter Dependencies

To enable this parameter, set **Local IP port source** to **Specify via dialog**.

**Send buffer size (bytes)** — Size of buffer that sends UDP packets  
8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that sends the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

## Block Characteristics

## Version History

Introduced in R2010a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed ZIP file. Using this ZIP file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Remote IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

## Unbuffer

Unbuffer input frame into sequence of scalar outputs

## Library

Signal Management / Buffers

dspbuff3

## Description

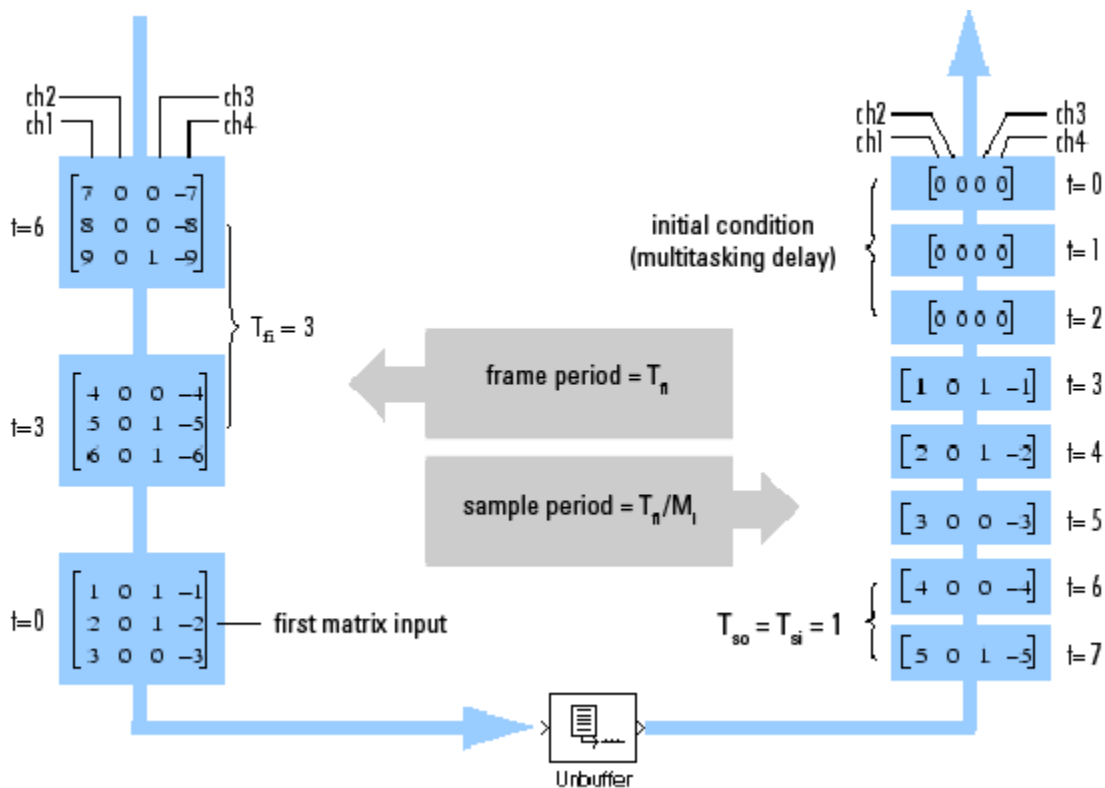

The Unbuffer block unbuffers an  $M_i$ -by- $N$  input into a 1-by- $N$  output. That is, inputs are unbuffered row-wise so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.

The block adjusts the output rate so that the *sample period* is the same at both the input and output,  $T_{so}=T_{si}$ . Therefore, the output sample period for an input of frame size  $M_i$  and frame period  $T_{fi}$  is  $T_{fi}/M_i$ , which represents a *rate*  $M_i$  times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the `ex_unbuffer_ref1` on page 5-1369 example model, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.

## Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at  $t=0$ ) appears as the first output sample.

## Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or  $M_i$  samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first  $M_i$  output samples of every channel
- A length- $M_i$  vector containing the values of the first  $M_i$  output samples for every channel
- An  $M_i$ -by- $N$  matrix containing the values of the first  $M_i$  output samples in each of  $N$  channels

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Parameters

### Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

## Supported Data Types

| Port   | Supported Data Types   |
|--------|--|
| Input  | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |
| Output | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |

## Uniform Decoder

Decode integer input into floating-point output

## Library

Quantizers

dspquant2

## Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of  $2^B$  uniformly spaced floating-point values in the range  $[-V, (1-2^{1-B})V]$ , where you specify  $B$  in the **Bits** parameter (as an integer between 2 and 32) and  $V$  is a floating-point value specified by the **Peak** parameter. The smallest input value representable by  $B$  bits (0 for an unsigned input data type;  $-2^{B-1}$  for a signed input data type) is mapped to the value  $-V$ . The largest input value representable by  $B$  bits ( $2^B-1$  for an unsigned input data type;  $2^{B-1}-1$  for a signed input data type) is mapped to the value  $(1-2^{1-B})V$ . Intermediate input values are linearly mapped to the intermediate values in the range  $[-V, (1-2^{1-B})V]$ .

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by  $B$  bits. When you select **Saturate**, *unsigned* input values greater than  $2^B-1$  saturate at  $2^B-1$ ; *signed* input values greater than  $2^{B-1}-1$  or less than  $-2^{B-1}$  saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values,  $u$ , greater than  $2^B-1$  are wrapped back into the range  $[0, 2^B-1]$  using  $\text{mod-}2^B$  arithmetic.

$$u = \text{mod}(u, 2^B)$$

*Signed* input values,  $u$ , greater than  $2^{B-1}-1$  or less than  $-2^{B-1}$  are wrapped back into that range using  $\text{mod-}2^B$  arithmetic.

$$u = (\text{mod}(u+2^B/2, 2^B) - (2^B/2))$$

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

## Parameters

### Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

### Bits

Specify the number of input bits, B, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

### Overflow mode

Specify the block's behavior when the integer input is outside the range representable by B bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

### Output type

Specify the precision of the floating-point output, `single` or `double`.

# Uniform Encoder

Quantize and encode floating-point input into integer output

## Library

Quantizers

dspquant2

## Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

- 1 Quantizes the value using the same precision
- 2 Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of  $2^B$  uniformly spaced levels in the range  $[-V, (1-2^{1-B})V]$ , where you specify  $B$  in the **Bits** parameter and you specify  $V$  in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits,  $B$ , can be any integer value between 2 and 32, inclusive. Inputs greater than  $(1-2^{1-B})V$  or less than  $-V$  saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of  $2^B$  integer values. When the **Output type** is set to **Unsigned integer**, the smallest quantized floating-point value,  $-V$ , is mapped to the integer 0, and the largest quantized floating-point value,  $(1-2^{1-B})V$ , is mapped to the integer  $2^B-1$ . Intermediate quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range  $[0, 2^B-1]$ . For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than  $B$ .

When the **Output type** is set to **Signed integer**, the smallest quantized floating-point value,  $-V$ , is mapped to the integer  $-2^{B-1}$ , and the largest quantized floating-point value,  $(1-2^{1-B})V$ , is mapped to the integer  $2^{B-1}-1$ . Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range  $[-2^{B-1}, 2^{B-1}-1]$ . The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than  $B$ .

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “About Data Types in Simulink” (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

| Bits     | Unsigned Integer | Signed Integer |
|----------|------------------|----------------|
| 2 to 8   | uint8            | int8           |
| 9 to 16  | uint16           | int16          |
| 17 to 32 | uint32           | int32          |

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

## Parameters

### Peak

The largest input amplitude to be encoded,  $V$ . Real or imaginary input values greater than  $(1-2^{1-B})V$  or less than  $-V$  saturate (independently for complex inputs) at those limits.

### Bits

Specify the number of bits,  $B$ , needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is  $2^B$ .

### Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

# Unwrap

Unwrap signal phase

**Libraries:**  
DSP System Toolbox / Signal Operations

## Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of  $2\pi$  to each channel element. The block recognizes phase discontinuities larger than the value of the **Tolerance** parameter. For more information on phase unwrapping, see “Definition of Phase Unwrap” on page 2-1460.

## Ports

### Input

**Port\_1** — Signal input  
scalar | vector | matrix

Signal input to unwrap, specified as a scalar, vector, or matrix. The input must have radian phase entries.

Data Types: single | double

### Output

**Port\_1** — Signal output  
scalar | vector | matrix

Unwrapped signal output, returned as a scalar, vector, or matrix.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Data Types: single | double

## Parameters

**Tolerance (radians)** — Jump size  
pi (default) | scalar value

The jump size that the block recognizes as a true phase discontinuity. The default is set to  $\pi$  (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than  $\pi$ .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Input processing** — Method to process the input  
Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of these options:

- **Columns as channels (frame based) (default)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

**Reset initial phase to zero for each input frame** — Checking successive frames  
off (default) | on

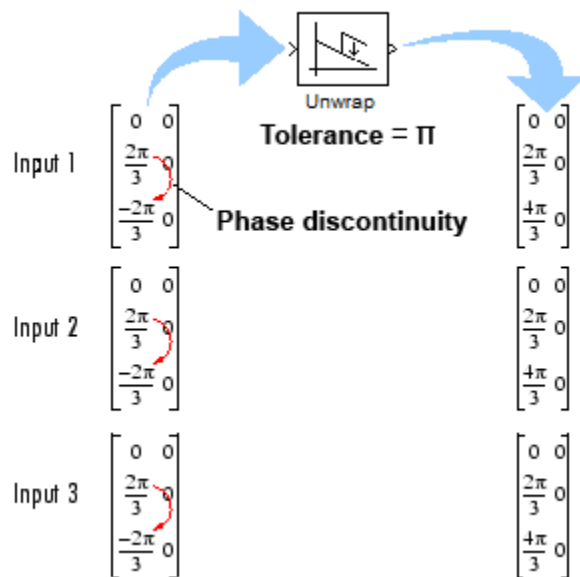

When you clear this parameter, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input.

This figure illustrates how the block unwraps data when you clear this parameter.

When you select this parameter, the block treats each frame of input data independently and resets the initial phase value for each new input frame.

This figure illustrates how the block unwraps data when you select this parameter.

For more information, see “Frame-Based Processing” on page 2-1462.

### Dependencies

To enable this parameter, set the **Input processing** parameter to Columns as channels (frame based). In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See “Sample-Based Processing” on page 2-1463 for more information.

### Block Characteristics

| <b>Zero-Crossing Detection</b>  | no              |

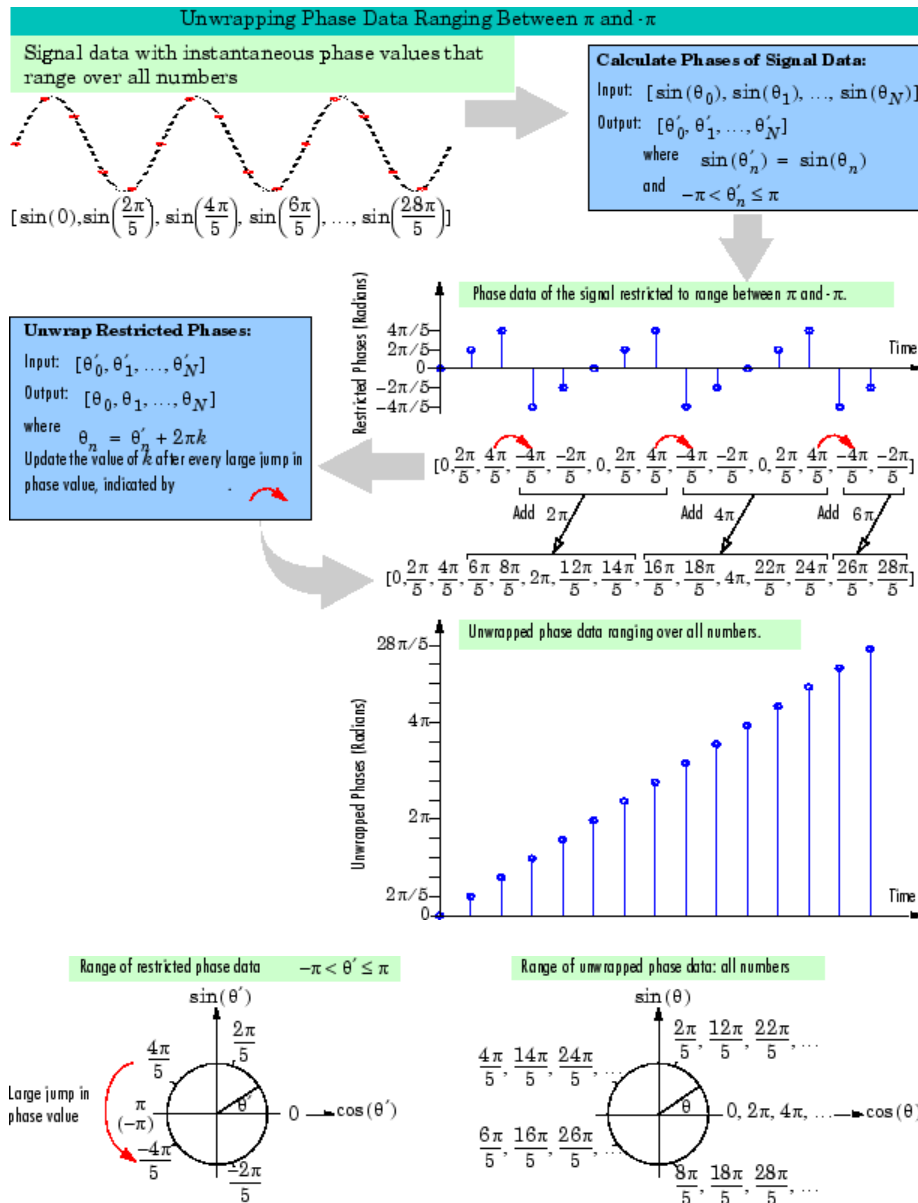

### More About

#### Definition of Phase Unwrap

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of  $2\pi$  to each phase input to restore original phase values, as illustrated in the diagram. For more information on the unwrap algorithm used by this block, see “Unwrap Method” on page 2-1461.

Algorithms that compute the phase of a signal often only output phases between  $-\pi$  and  $\pi$ . For instance, such algorithms compute the phase of  $\sin(2\pi + 3)$  to be 3, since  $\sin(3) = \sin(2\pi + 3)$ , and

since the actual phase,  $2\pi + 3$ , is not between  $-\pi$  and  $\pi$ . Such algorithms compute the phases of  $\sin(-4\pi + 3)$  and  $\sin(16\pi + 3)$  to be 3 as well.

## Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding  $2\pi k$  to each successive channel element, and updating  $k$  at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

This code shows how the block unwraps the data in a given input channel  $u$ .

```
k=0; % initialize k to 0
i=1; % initialize the counter to 1
alpha=pi; % set alpha to the desired Tolerance. In this case, pi

for i = 1:(size(u)-1)
    yout(i,:) = u(i) + (2*pi*k); % add 2*pi*k to ui
```

```

if((abs(u(i+1)-u(i))>(abs(alpha))) %if diff is greater than alpha, increment or decrement k
    if u(i+1)<u(i) % if the phase jump is negative, increment k
        k=k+1;
    else % if the phase jump is positive, decrement k
        k=k-1;
    end
end
end
end
yout((i+1,:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input

```

## Frame-Based Processing

When you configure the block to perform frame-based processing, by setting the **Input processing** parameter to **Columns as channels (frame based)**, the block supports two different unwrap modes. In both modes, the block adds  $2\pi k$  to each input channel's elements, and updates  $k$  at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value ( $k$ ) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

### Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Reset initial phase to zero for each input frame** parameter. This figure illustrates how the block unwraps data in this mode.

### Unwrapping Within Frames

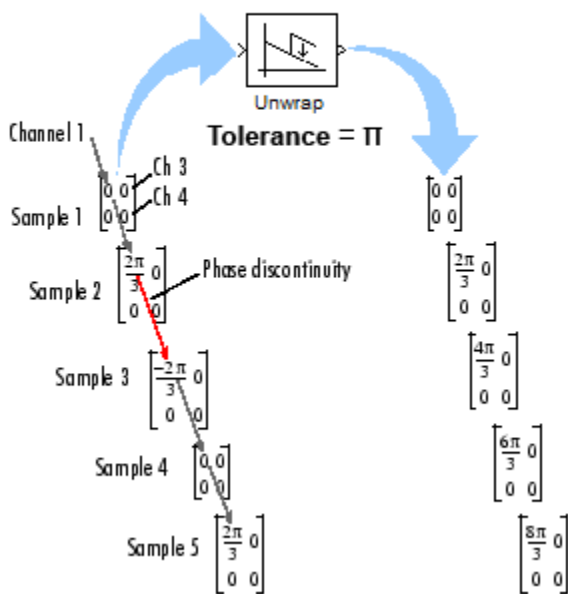

When you select the **Reset initial phase to zero for each input frame** parameter, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. This figure illustrates how the block unwraps data in this mode.

### Sample-Based Processing

When you configure the block to perform sample-based processing, by setting the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. This figure illustrates how the block unwraps data when performing sample-based processing.

# Upsample

Resample input at higher rate by inserting zeros

## Libraries:

DSP System Toolbox / Signal Operations

DSP System Toolbox HDL Support / Signal Operations

## Description

The Upsample block resamples each channel of the  $M_1$ -by- $N$  input at a rate  $L$  times higher than the input sample rate by inserting  $L-1$  zeros between consecutive samples. Specify the integer  $L$  in the **Upsample factor**, **L** parameter or through the input port **L**.

You can use this block inside triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

## Ports

### Input

**in** — Input signal

scalar | vector | matrix

Specify the input signal as a real or a complex-valued scalar, vector, or a matrix signal.

When you set **Input processing** to Columns as channels (frame based) and **Rate options** to Enforce single-rate processing, the input can be a variable-size signal. When the input is a variable-size signal, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

This port is unnamed until you set **Upsample factor source** to Input port.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

**L** — Upsample factor

positive integer  $\leq L_{max}$

Specify the upsample factor  $L$  as a positive integer less than or equal to the value you specify in the **Maximum upsample factor**, **Lmax** parameter.

### Dependency

To enable this port, set the **Upsample factor source** parameter to Input port.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

### Output

**Port\_1** — Upsampled signal

scalar | vector | matrix

The Upsample block outputs a signal that has the same data type and complexity as the input signal. The size of the output depends on the value of the upsample factor and the option you select in the **Rate options** parameter.

If you set **Upsample factor, L** to  $L$  and **Rate options** to:

- **Enforce single-rate processing** -- The block maintains the input sample rate by increasing the output frame size by a factor of  $L$ .
- **Allow multirate processing** -- The block resamples the signal such that the output sample rate is  $L$  times faster than the input sample rate. The output signal has the same frame size as the input signal.

When you input the upsample factor through the input port **L**, the **Rate options** parameter is automatically set to **Enforce single-rate processing**. In this case, the block maintains the input sample rate at the output by increasing the output frame size by a factor of  $L$ .

The output is a variable-size signal when one or both of these conditions are met:

- Input is a variable-size signal.
- Upsample factor is input through the port **L**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

## Parameters

**Upsample factor source** — Mode of specifying upsample factor

`Dialog parameter (default)` | `Input port`

Specify the upsample factor through one of these options:

- `Dialog parameter` -- The block enables the **Upsample factor, L** parameter on the block dialog box.
- `Input port` -- The block enables the input port **L** through which you can specify the upsample factor.

**Upsample factor, L** — Upsample factor

`3 (default)` | `positive integer`

Specify the upsample factor  $L$  by which to increase the input sample rate as a positive integer.

### Dependency

To enable this parameter, set **Upsample factor source** to `Dialog parameter`.

**Sample offset (0 to L-1)** — Sample offset

`0 (default)` | `integer in the range [0, L-1]`

Specify the sample offset  $D$  as an integer in the range  $[0, L-1]$ .

Use the **Sample offset (0 to L-1)** parameter to delay the output samples by a specific number of sample periods. Doing so enables you to select any of the  $L$  possible output phases. The value you specify in the **Sample offset (0 to L-1)** parameter must be an integer in the range  $0 \leq D < (L - 1)$ .

When you input the upsample factor through the input port **L**, the **Sample offset (0 to L-1)** parameter is not enabled in the block dialog box. In this case, the sample offset  $D$  is automatically set to 0.

#### Dependency

To enable this parameter, set **Upsample factor source** to `Dialog` parameter.

#### Maximum upsample factor, $L_{max}$ — Maximum upsample factor

16 (default) | positive integer  $\geq 1$

Specify the maximum upsample factor  $L_{max}$  as a positive integer greater than or equal to 1. The upsample factor you specify through the input port **L** must be less than or equal to  $L_{max}$ .

#### Dependency

To enable this parameter, set **Upsample factor source** to `Input` port.

#### Input processing — Method to process input signals

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of these options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

#### Dependency

To enable this parameter, set **Upsample factor source** to `Dialog` parameter.

When you set **Upsample factor source** to `Input` port, the **Input processing** parameter is automatically set to `Columns as channels (frame based)`.

#### Rate options — Method to upsample input

`Enforce single-rate processing` (default) | `Allow multirate processing`

Specify the method that the block uses to upsample the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of  $L$ . To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is  $L$  times faster than the input sample rate.

**Dependency**

To enable this parameter, set **Upsample factor source** to `Dialog` parameter.

When you set **Upsample factor source** to `Input port`, the **Rate options** parameter is automatically set to `Enforce single-rate processing`.

**Initial conditions** — Initial conditions

0 (default) | scalar | vector | matrix

Specify the value with which the block is initialized for cases of nonzero latency as a scalar, vector, or a matrix. The scalar value appears in the output as the sample  $D+1$ . If this parameter is set to a vector or a matrix, the size of this parameter should be the same as that of the input. This parameter appears only when you configure the block to perform multirate processing.

**Dependencies**

To enable this parameter, set **Rate options** to `Allow multirate processing`.

**Block Characteristics**

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | Boolean   double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no  |
| <b>Multidimensional Signals</b> | no  |
| <b>Variable-Size Signals</b>    | yes   |
| <b>Zero-Crossing Detection</b>  | no  |

**More About****Frame-Based Processing**

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input.

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame size than the input. For upsampling by a factor of  $L$ , the output frame size is  $L$  times larger than the input frame size ( $M_o = M_i * L$ ), but the input and output frame rates are equal.

For an example of single-rate upsampling, see “Upsample Signal In Single-Rate Frame-Based Processing Mode”.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an  $M_i$ -by- $N$  matrix input as  $N$  independent channels. The block upsamples each column of the input over time by keeping the frame size constant ( $M_i = M_o$ ), and making the output frame period ( $T_{fo}$ )  $L$  times shorter than the input frame period ( $T_{fi} = T_{fo} / L$ ).

See the “Upsample Signal In Multirate Frame-Based Processing Mode” example to see the Upsample block in this mode.

### Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an  $M$ -by- $N$  matrix input as  $M*N$  independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is  $L$  times higher than the input sample rate ( $T_{so} = T_{si}/L$ ), and the input and output sizes are identical.

### Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you specify an upsample factor of 1 or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at  $t = 0$ ) immediately after the consecutive zeros  $D$ , which you specify in the **Sample offset (0 to L-1)** parameter. When you input the upsample factor through the input port **L**,  $D = 0$ . This output ( $D+1$ ) is followed in turn by the  $L-1$  inserted zeros and the next input sample.

### Nonzero Latency

The Upsample block has tasking latency for a multirate multitasking operation:

- In multirate sample-based processing mode, the initial condition for each channel appears as output sample  $D+1$ , and is followed by  $L-1$  inserted zeros. The channel first input appears as output sample  $D+L+1$ . The **Initial conditions** parameter can be an  $M_i$ -by- $N$  matrix containing one value for each channel, or a scalar value that the block applies to all signal channels.
- In multirate frame-based processing mode, the first row of the initial condition matrix appears as output sample  $D+1$ , and is followed by  $L-1$  inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample  $M_iL+D+1$ . The **Initial conditions** parameter can be an  $M_i$ -by- $N$  matrix, or a scalar value that the block repeats across all elements of the input matrix.

---

**Note** For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

## Version History

Introduced before R2006a

### R2022b: Support for variable-size input signal

Starting in R2022b, when you set **Input processing** to `Columns as channels (frame based)` and **Rate options** to `Enforce single-rate processing`, the input can be a variable-size signal. That is, the frame size (number of rows) and the number of channels (columns) of the signal can change during simulation.

When the input is a variable-size signal, the output is also a variable-size signal.

### R2023a: Tune upsample factor through input port

You can now specify the upsample factor through an input port when the Upsample block operates in the single-rate frame-based processing mode. When you specify the upsample factor through the input port, you can change the factor during simulation.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (`string.h`) under certain conditions.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

### Best Practices

Consider whether your model can use the Repeat block instead of the Upsample block. The Repeat block uses fewer hardware resources, so as a best practice use the Upsample block only when your algorithm requires zero-padding upsampling.

See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).

### HDL Architecture

This block has one default HDL architecture.

### HDL Block Properties

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

### Restrictions

- **Input processing** set to `Columns as channels (frame based)` is not supported.

- **Upsample factor source** set to `Input` port is not supported.

**Complex Data Support**

This block supports code generation for complex signals.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

# Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

## Libraries:

DSP System Toolbox / Filtering / Filter Designs

## Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using the specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters specified in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

This block also supports SIMD code generation. For details, see “Code Generation” on page 2-1480.

## Ports

### Input

**x** — Data input  
vector | matrix

Specify the data input as a vector or a matrix. The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as having a single channel.

The block accepts variable-size input signals, that is, you can change the size of each input channel during simulation but you cannot change the number of channels.

This port is unnamed until you select one of these parameters:

- **Specify cutoff frequency from input port**
- **Specify center frequency from input port**
- **Specify bandwidth from input port**

Data Types: `single` | `double`

**Fcut** — Filter cutoff frequency  
positive scalar

Specify the cutoff frequency of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

**Dependencies**

To enable this port, select the **Specify cutoff frequency from input port** parameter.

Data Types: `single` | `double`

**Fc** — Filter center frequency

positive scalar

Specify the center frequency of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

**Dependencies**

To enable this port, select the **Specify center frequency from input port** parameter.

Data Types: `single` | `double`

**BW** — Filter bandwidth

positive scalar

Specify the bandwidth of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

**Dependencies**

To enable this port, select the **Specify bandwidth from input port** parameter.

Data Types: `single` | `double`

**Output****Port\_1** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double`

**Parameters****FIR filter order** — FIR filter order

30 (default) | positive integer

Specify the order of the FIR filter as a positive integer scalar.

**Filter type** — Filter type

Lowpass (default) | Highpass | Bandpass | Bandstop

Specify the type of FIR filter. You can set this parameter to:

- Lowpass
- Highpass

- Bandpass
- Bandstop

**Specify cutoff frequency from input port** — Specify cutoff frequency from input port

off (default) | on

When you select this check box, specify the cutoff frequency through the **Fcut** port. When you clear this check box, specify the cutoff frequency in the block dialog box through the **Filter cutoff frequency** parameter.

#### Dependency

To enable this parameter, set **Filter type** to Lowpass or Highpass.

**Filter cutoff frequency** — Filter cutoff frequency

512 (default) | positive scalar

Specify the cutoff frequency of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the filter cutoff frequency is in Hz and must be less than half the value of the input sample rate.
- **Use normalized frequency (0 to 1)** -- The value of the filter cutoff frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

#### Dependencies

To enable this parameter:

- Set **Filter type** to Lowpass or Highpass.
- Clear the **Specify cutoff frequency from input port** parameter.

**Specify center frequency from input port** — Specify center frequency from input port

off (default) | on

When you select this check box, specify the center frequency through the **Fc** port. When you clear this check box, specify the center frequency in the block dialog box through the **Filter center frequency** parameter.

#### Dependencies

To enable this parameter, set **Filter type** to Bandpass or Bandstop.

**Filter center frequency** — Filter center frequency

44100/4 (default) | positive scalar

Specify the center frequency of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- Specify on dialog or Inherit from input port -- The value of the filter center frequency is in Hz and must be less than half the value of the input sample rate.
- Use normalized frequency (0 to 1) -- The value of the filter center frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

**Dependencies**

To enable this parameter:

- Set **Filter type** to Bandpass or Bandstop.
- Clear the **Specify center frequency from input port** parameter.

**Specify bandwidth from input port** — Specify bandwidth from input port

off (default) | on

When you select this check box, specify the filter bandwidth through the **BW** port. When you clear this check box, specify the filter bandwidth in the block dialog box through the **Filter bandwidth** parameter.

**Dependency**

To enable this parameter, set **Filter type** to Bandpass or Bandstop.

**Filter bandwidth** — Filter bandwidth

7680 (default) | positive scalar

Specify the bandwidth of the FIR filter as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- Specify on dialog or Inherit from input port -- The value of the filter bandwidth is in Hz and must be less than half the value of the input sample rate.
- Use normalized frequency (0 to 1) -- The value of the filter bandwidth is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

**Dependencies**

To enable this parameter:

- Set **Filter type** to Bandpass or Bandstop.
- Clear the **Specify bandwidth from input port** parameter.

**Window function** — Window function

Hann (default) | Hamming | Chebyshev | Kaiser

Specify the window function used to design the FIR filter. You can set this parameter to:

- Hann
- Hamming
- Chebyshev
- Kaiser

**Chebyshev window sidelobe attenuation (dB)** — Chebyshev window sidelobe attenuation

60 (default) | positive scalar

Specify the sidelobe attenuation of the Chebyshev window as a real positive scalar.

**Dependencies**

To enable this parameter, set **Window function** to Chebyshev.

**Kaiser window parameter** — Kaiser window parameter

0.5 (default) | real scalar

Specify the Kaiser window parameter as a real scalar.

**Dependencies**

To enable this parameter, set **Window function** to Kaiser.

**Sample rate mode** — Mode to specify the input sample rate

Specify on dialog (default) | Inherit from input port | Use normalized frequency (0 to 1)

Specify the input sample rate using one of these options:

- **Specify on dialog** -- Specify the input sample rate in the block dialog box using the **Input sample rate (Hz)** parameter.
- **Inherit from input port** -- The block inherits the sample rate from the input signal as  $N / T_s$ , where  $N$  is the frame size of the input signal and  $T_s$  is the sample time of the input signal.
- **Use normalized frequency (0 to 1)** -- Specify the filter cutoff frequency, center frequency, and the filter bandwidth in normalized frequency units (0 to 1).

**Input sample rate (Hz)** — Input sample rate

44100 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar in Hz.

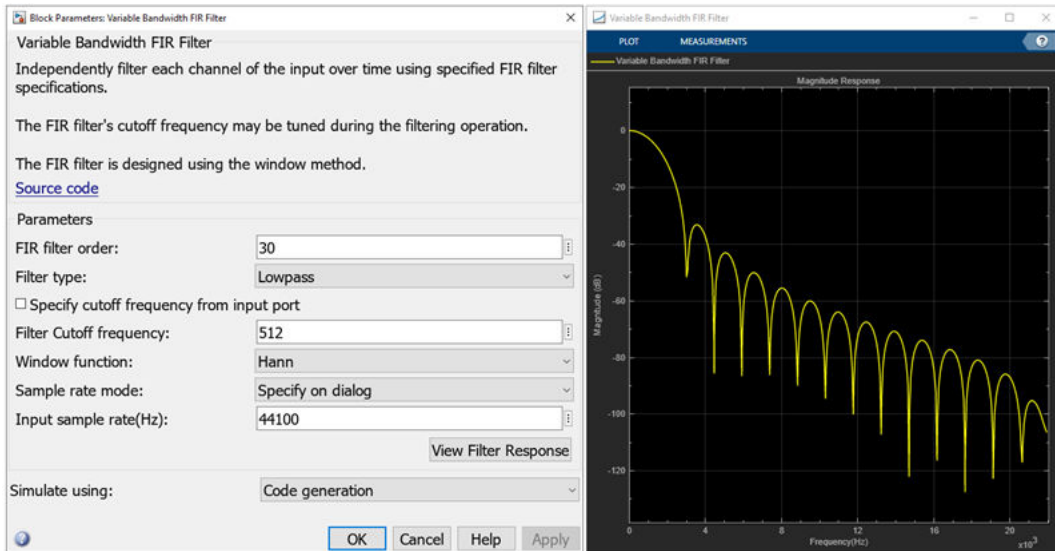

**Dependencies**

To enable this parameter, set the **Sample rate mode** parameter to **Specify on dialog**.

**View Filter Response** — View Filter Response  
button

Open the dynamic filter visualizer and display the magnitude response of the variable bandwidth FIR filter. The response is based on the parameters you select in the block dialog box. To update the

magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

### FIR Transformations

All transformations assume a lowpass filter of length  $2N+1$ .

#### Lowpass to Lowpass

Consider an ideal lowpass brickwall filter with normalized cutoff frequency  $\omega_{c1}$ . By taking the inverse discrete Fourier transform of the ideal frequency response, and clipping the resulting sequence to length  $2N+1$ , the impulse response is:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{LP}(n) = \frac{\omega_c}{\pi} \cdot w(0) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{LP}(n) = \frac{\sin(\omega_c n)}{\pi n} \cdot w(n) \end{aligned}$$

where  $w(n)$  is the window vector. Tune the lowpass filter coefficients to a new cutoff frequency  $\omega_{c2}$  as follows:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{LP}(n) = \frac{\omega_{c2}}{\pi} \cdot \omega(0) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{LP}(n) = \frac{\sin(\omega_{c2} n)}{\pi n} \cdot \omega(n) \end{aligned}$$

You do not need to recompute the window every time you tune the cutoff frequency.

### Lowpass to Highpass

Assuming a lowpass filter with normalized 6-dB cutoff frequency  $\omega_c$ , you can obtain a highpass filter with the same cutoff frequency by taking the complementary of the lowpass frequency response:

$$H_{HP}(e^{j\omega}) = 1 - H_{LP}(e^{j\omega})$$

Taking the inverse discrete Fourier transform of the above response, you have the following highpass filter coefficients:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{hp}(n) = 1 - h_{LP}(n) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{hp}(n) = -h_{LP}(n) \end{aligned}$$

### Lowpass to Bandpass

Obtain a bandpass filter centered at frequency  $\omega_0$  by shifting the lowpass response:

$$H_{BP}(e^{j\omega}) = H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)})$$

The bandwidth of the resulting bandpass filter is  $2\omega_c$ , as measured between the two cutoff frequencies of the bandpass filter. The equivalent bandpass filter coefficients are then:

$$\begin{aligned} h_{BP}(n) &= (e^{j\omega_0 n} + e^{-j\omega_0 n})h_{LP}(n) \\ & \text{which can be written as:} \\ h_{BP}(n) &= 2\cos(\omega_0 n)h_{LP}(n) \end{aligned}$$

### Lowpass to Bandstop

You can transform a lowpass filter to a bandstop filter by combining the highpass and bandpass transformations. First make the filter bandpass by shifting the lowpass response, and then invert it to get a bandstop response centered at  $\omega_0$ .

$$H_{BS}(e^{j\omega}) = 1 - (H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)}))$$

This yields the following coefficients:

$$\begin{aligned} & \text{for } n = 0 \\ & h_{BS}(n) = 1 - 2\cos(\omega_0 n)h_{LP}(n) \\ & \text{for } 1 \leq |n| \leq N \\ & h_{BS}(n) = -2\cos(\omega_0 n)h_{LP}(n) \end{aligned}$$

### Generalized Transformation

You can combine these transformations to transform a lowpass filter to a lowpass, highpass, bandpass, or bandstop filter with arbitrary cutoffs.

For example, to transform a lowpass filter with cutoff  $\omega_{c1}$  to a highpass with cutoff  $\omega_{c2}$ , you first apply the lowpass-to-lowpass transformation to get a lowpass filter with cutoff  $\omega_{c2}$ , and then apply the lowpass-to-highpass transformation to get the highpass with cutoff  $\omega_{c2}$ .

To get a bandpass filter with center frequency  $\omega_0$  and bandwidth  $\beta$ , we first apply the lowpass-to-lowpass transformation to go from a lowpass with cutoff  $\omega_c$  to a lowpass with cutoff  $\beta/2$ , and then

apply the lowpass-to-bandpass transformation to get the desired bandpass filter. You can use the same approach for a bandstop filter.

## Version History

Introduced in R2015a

### R2023a: Support for normalized frequencies

When you set the **Sample rate mode** parameter to Use normalized frequency (0 to 1), you can specify the filter cutoff frequency, center frequency, and filter bandwidth in normalized frequency units (0 to 1).

## Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using the IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

## Ports

### Input

**x** — Data input  
vector | matrix

Specify the data input as a vector or a matrix. The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as having a single channel.

The block accepts variable-size input signals, that is, you can change the size of each input channel during simulation but you cannot change the number of channels.

This port is unnamed until you select one of these parameters:

- **Specify passband frequency from input port**
- **Specify center frequency from input port**
- **Specify bandwidth from input port**

Data Types: single | double

**Fp** — Filter passband frequency  
positive scalar

Specify the passband frequency of the IIR filter as a real positive scalar in Hz or in normalized frequency units.

### Dependencies

To enable this port, select the **Specify passband frequency from input port** parameter.

Data Types: `single` | `double`

**Fc** — Filter center frequency  
positive scalar

Specify the center frequency of the IIR filter as a real positive scalar in Hz or in normalized frequency units.

#### **Dependencies**

To enable this port, select the **Specify center frequency from input port** parameter.

Data Types: `single` | `double`

**BW** — Filter bandwidth  
positive scalar

Specify the bandwidth of the IIR filter as a real positive scalar in Hz or in normalized frequency units.

#### **Dependencies**

To enable this port, select the **Specify bandwidth from input port** parameter.

Data Types: `single` | `double`

#### **Output**

**Port\_1** — Filtered output  
vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double`

### **Parameters**

**Filter type** — Filter type

Lowpass (default) | Highpass | Bandpass | Bandstop

Specify the type of IIR filter. You can set this parameter to:

- Lowpass
- Highpass
- Bandpass
- Bandstop

**IIR filter order** — IIR filter order

8 (default) | positive integer

Specify the order of the IIR filter as a positive integer.

**Specify passband frequency from input port** — Specify passband frequency from input port

off (default) | on

When you select this check box, specify the filter passband frequency through the **Fp** port. When you clear this check box, specify the passband frequency in the block dialog box through the **Filter passband frequency** parameter.

**Dependency**

To enable this parameter, set **Filter type** to Lowpass or Highpass.

**Filter passband frequency** — Filter passband frequency

512 (default) | positive scalar

Specify the filter passband frequency as a real, positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- Specify on dialog or Inherit from input port -- The value of the filter passband frequency is in Hz and must be less than half the value of the input sample rate.
- Use normalized frequency (0 to 1) -- The value of the filter passband frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

**Dependencies**

To enable this parameter:

- Set **Filter type** to Lowpass or Highpass.
- Clear the **Specify passband frequency from input port** parameter.

**Specify center frequency from input port** — Specify center frequency from input port

off (default) | on

When you select this check box, specify the center frequency of the IIR filter through the **Fc** port. When you clear this check box, specify the center frequency in the block dialog box through the **Filter center frequency** parameter.

**Dependencies**

To enable this parameter, set **Filter type** to Bandpass or Bandstop.

**Filter center frequency** — Filter center frequency

44100/4 (default) | positive scalar

Specify the filter center frequency as a real positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- Specify on dialog or Inherit from input port -- The value of the filter center frequency is in Hz and must be less than half the value of the input sample rate.
- Use normalized frequency (0 to 1) -- The value of the filter center frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

**Dependencies**

To enable this parameter:

- Set **Filter type** to Bandpass or Bandstop.
- Clear the **Specify center frequency from input port** parameter.

**Specify bandwidth from input port** — Specify bandwidth from input port

off (default) | on

When you select this check box, specify the bandwidth of the IIR filter through the **BW** port. When you clear this check box, specify the filter bandwidth in the block dialog box through the **Filter bandwidth** parameter.

**Dependencies**

To enable this parameter, set **Filter type** to Bandpass or Bandstop.

**Filter bandwidth** — Filter bandwidth

7680 (default) | positive scalar

Specify the filter bandwidth as a positive scalar in Hz or in normalized frequency units.

If you set the **Sample rate mode** parameter to:

- **Specify on dialog or Inherit from input port** -- The value of the filter bandwidth is in Hz and must be less than half the value of the input sample rate.
- **Use normalized frequency (0 to 1)** -- The value of the filter bandwidth is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

**Dependencies**

To enable this parameter:

- Set **Filter type** to Bandpass or Bandstop.
- Clear the **Specify bandwidth from input port** parameter.

**Filter passband ripple (dB)** — Filter passband ripple

1 (default) | positive scalar

Specify the filter passband ripple as a real, positive scalar.

**Filter Stopband attenuation (dB)** — Filter Stopband attenuation

60 (default) | positive scalar

Specify the filter stopband attenuation as a real, positive scalar.

**Sample rate mode** — Mode to specify the input sample rate

Specify on dialog (default) | Inherit from input port | Use normalized frequency (0 to 1)

Specify the input sample rate using one of these options:

- **Specify on dialog** -- Specify the input sample rate in the block dialog box using the **Input sample rate (Hz)** parameter.
- **Inherit from input port** -- The block inherits the sample rate from the input signal as  $N / T_s$ , where  $N$  is the frame size of the input signal and  $T_s$  is the sample time of the input signal.
- **Use normalized frequency (0 to 1)** -- Specify the filter passband frequency, center frequency, and the filter bandwidth in normalized frequency units (0 to 1).

**Input sample rate (Hz)** — Input sample rate

44100 (default) | positive scalar

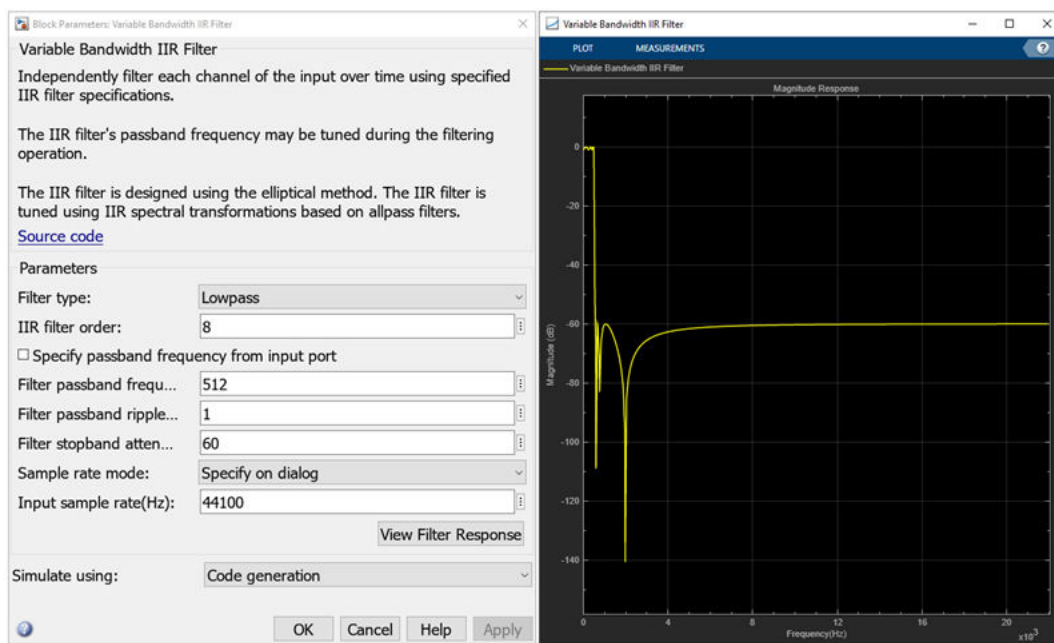

Specify the sample rate of the input signal as a positive scalar in Hz.

#### Dependencies

To enable this parameter, set the **Sample rate mode** parameter to **Specify on dialog**.

**View Filter Response** — View Filter Response button

Opens the dynamic filter visualizer and displays the magnitude response of the variable bandwidth IIR filter. The response is based on the parameters you select in the Block Parameters dialog box. To update the magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

This filter covers frequency transformations. The algorithm designs a lowpass IIR prototype using the elliptical method by specifying its order, passband frequency, passband ripple, and stopband

attenuation. The passband ripple and stopband attenuation are equal to the values of the `PassbandRipple` and `StopbandAttenuation` properties. The algorithm sets the prototype passband frequency to 0.5. If the `FilterType` property is 'Lowpass' or 'Highpass', the order of the prototype filter is equal to the value of `FilterOrder`. If the `FilterType` property is 'Bandpass' or 'Bandstop', the order of the prototype filter is equal to `FilterOrder/2`. The prototype is a Direct Form II Transposed cascade of second-order sections (Biquad filter). The prototype is transformed into the desired filter using the algorithms used in "Digital Frequency Transformations". Each prototype SOS section is transformed separately. When `FilterType` is 'Lowpass' or 'Highpass', the resulting filter remains a Direct Form II Transposed cascade of second order sections. If the `FilterType` is 'Bandpass' or 'Bandstop', the resulting filter is a cascade of Direct Form II Transposed cascade of fourth order sections.

## Version History

Introduced in R2015a

### R2023a: Support for normalized frequencies

When you set the **Sample rate mode** parameter to Use normalized frequency (0 to 1), you can specify the filter passband frequency, center frequency, and filter bandwidth in normalized frequency units (0 to 1).

## Variable FIR Decimation

Polyphase FIR decimation with tunable decimation factor

### Libraries:

DSP System Toolbox / Filtering / Multirate Filters

### Description

The Variable FIR Decimation block performs an efficient polyphase FIR decimation with a tunable decimation factor. You can update the decimation factor and the filter coefficients in the block dialog box or through an input port while the simulation is running.

Conceptually, the FIR decimator (as shown in the schematic) consists of an anti-aliasing FIR filter followed by a downsampler. To design an FIR anti-aliasing filter, use the `designMultirateFIR` function.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The downsampler that follows downsamples each channel of filtered data by taking every  $M$ -th sample and discarding the  $M - 1$  samples that follow.  $M$  is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is  $1/M$  times the original sample rate.

Note that the actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-1500.

The block supports C and C++ code generation.

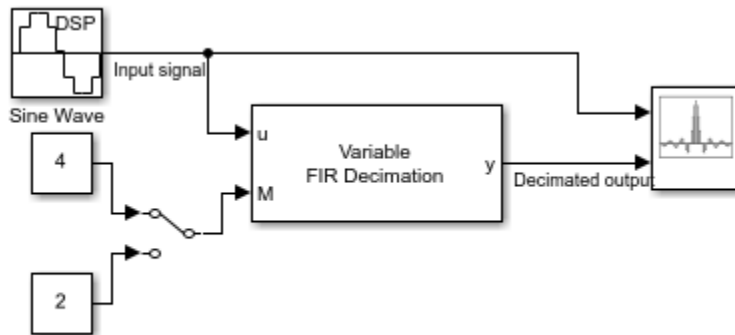

### Examples

## Decimate Sinusoidal Signal with Tunable Decimation Factor

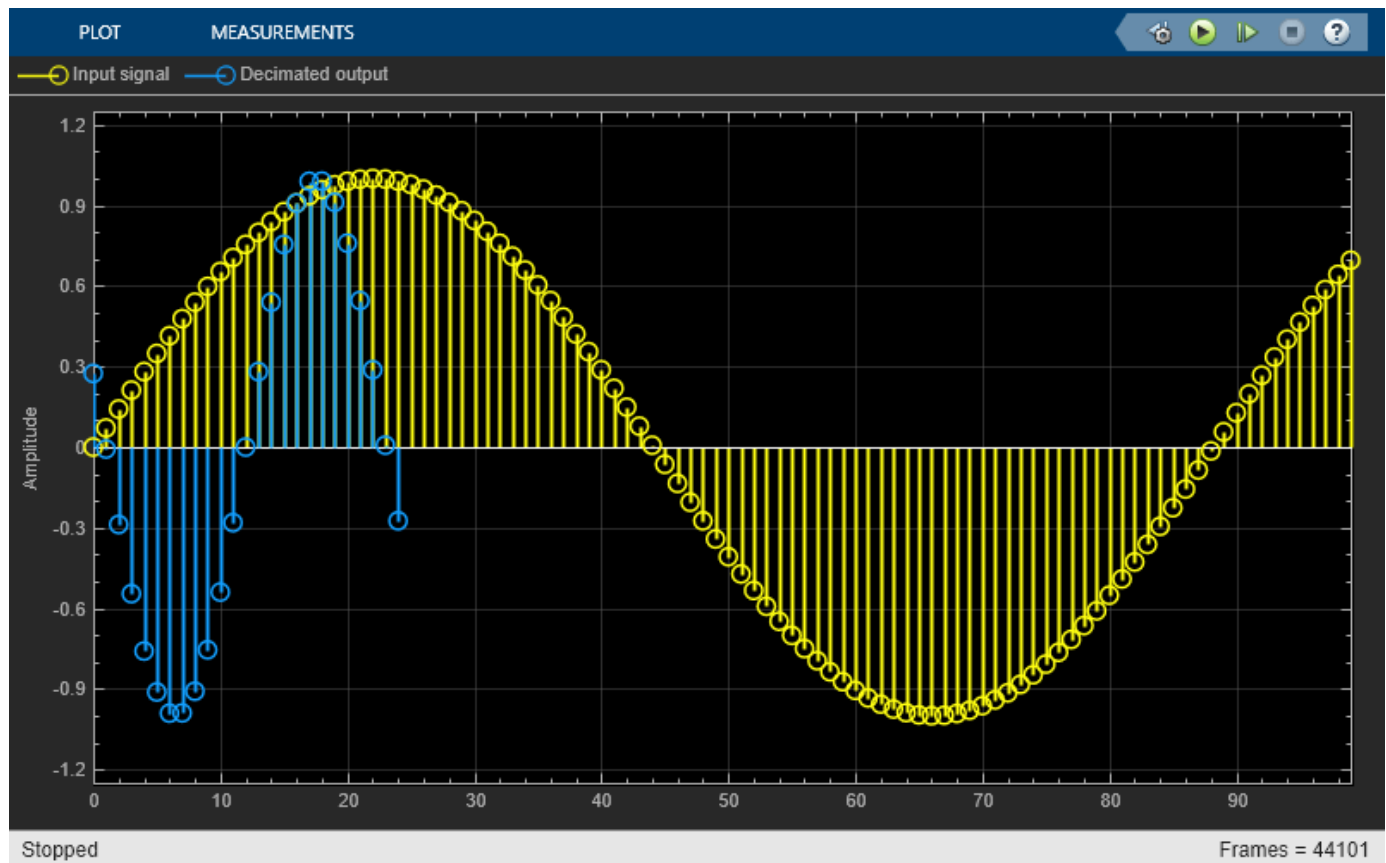

Decimate a sinusoidal signal by varying the decimation factor using the Variable FIR Decimation block. You can vary the decimation factor in the block dialog box or through an input port while the simulation is running.

Open the model. The input is a sinusoidal signal with a frequency of 500 Hz, sample time of  $1/44100$  s, and contains 100 samples per frame. Pass this signal through the Variable FIR Decimation block. The **Maximum decimation factor** parameter in the block is 24. The decimation factor that you input through the port is 4.

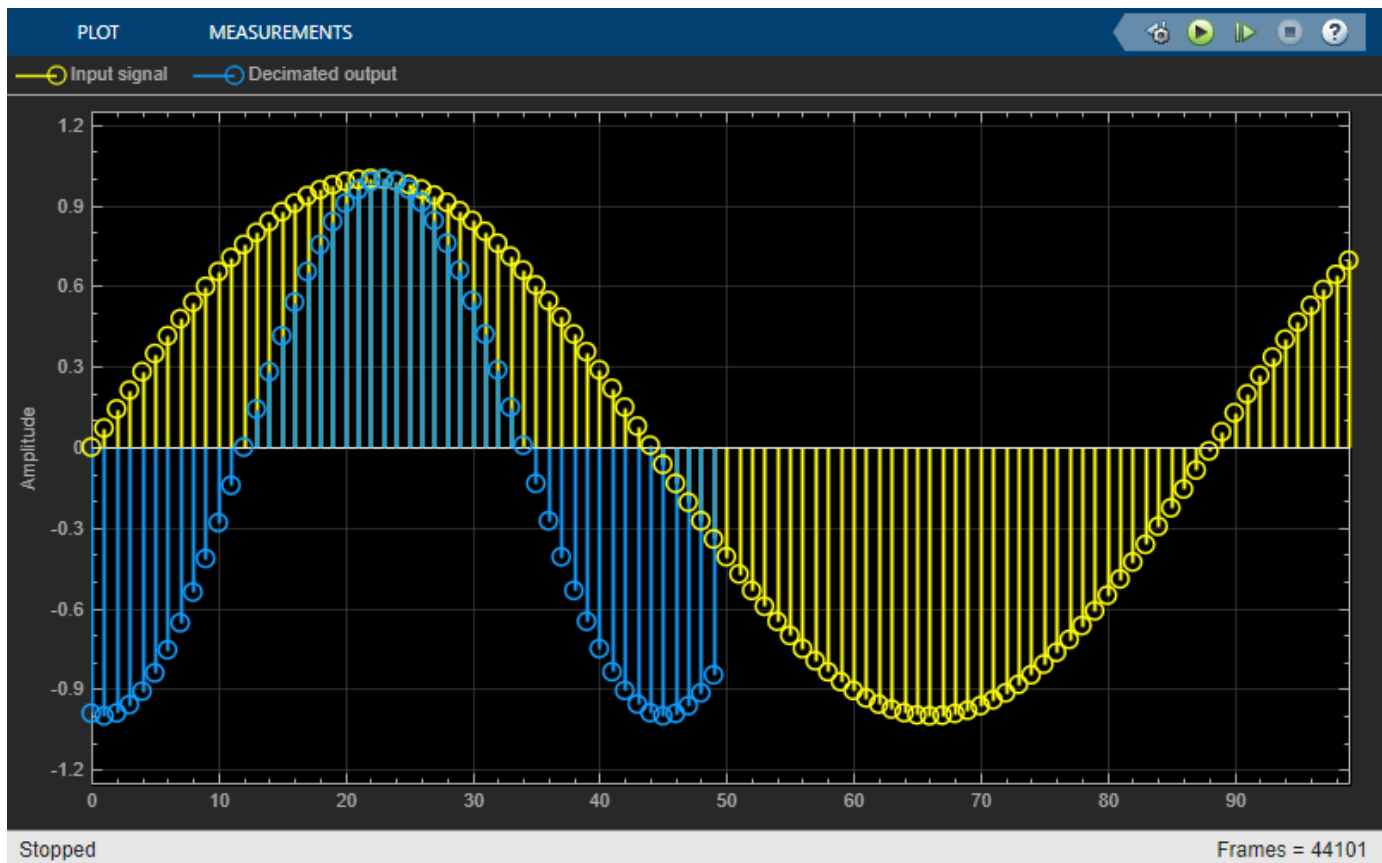

Copyright 2023 The MathWorks, Inc.

Run the model. The Array Plot block shows the input signal and the decimated output on the display.

While the simulation is running, change the decimation factor to 2 by clicking the Manual Switch. The span of the decimated output updates in the Array Plot display. You can change the decimation factor to any value that is an integer factor of the maximum decimation factor of 24.

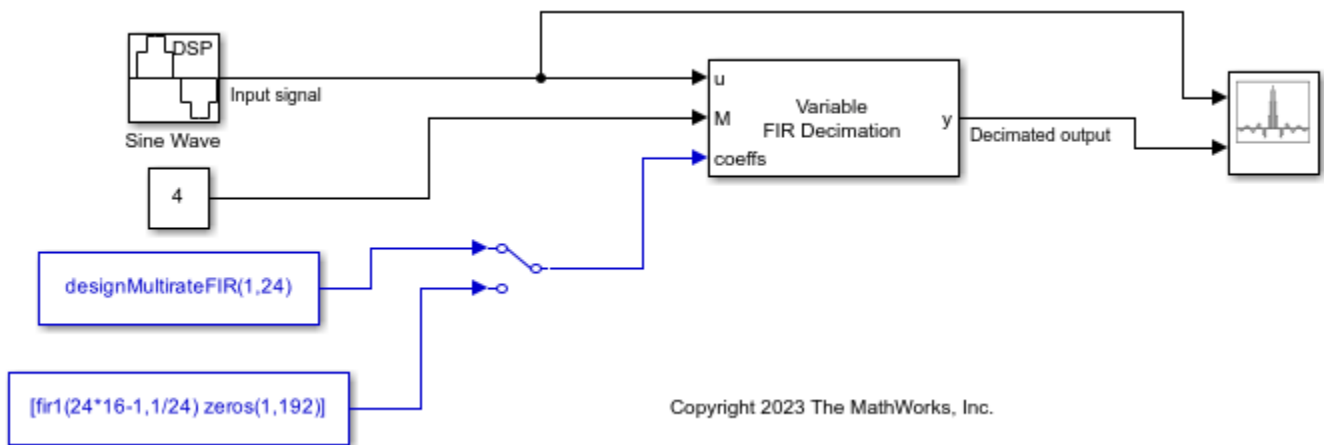

If you specify the decimation factor in the block dialog box, you can tune the **Decimation factor** parameter in the block dialog box while the simulation is running and the block updates the decimated output accordingly.

### Specify Filter Coefficients Through Input Port

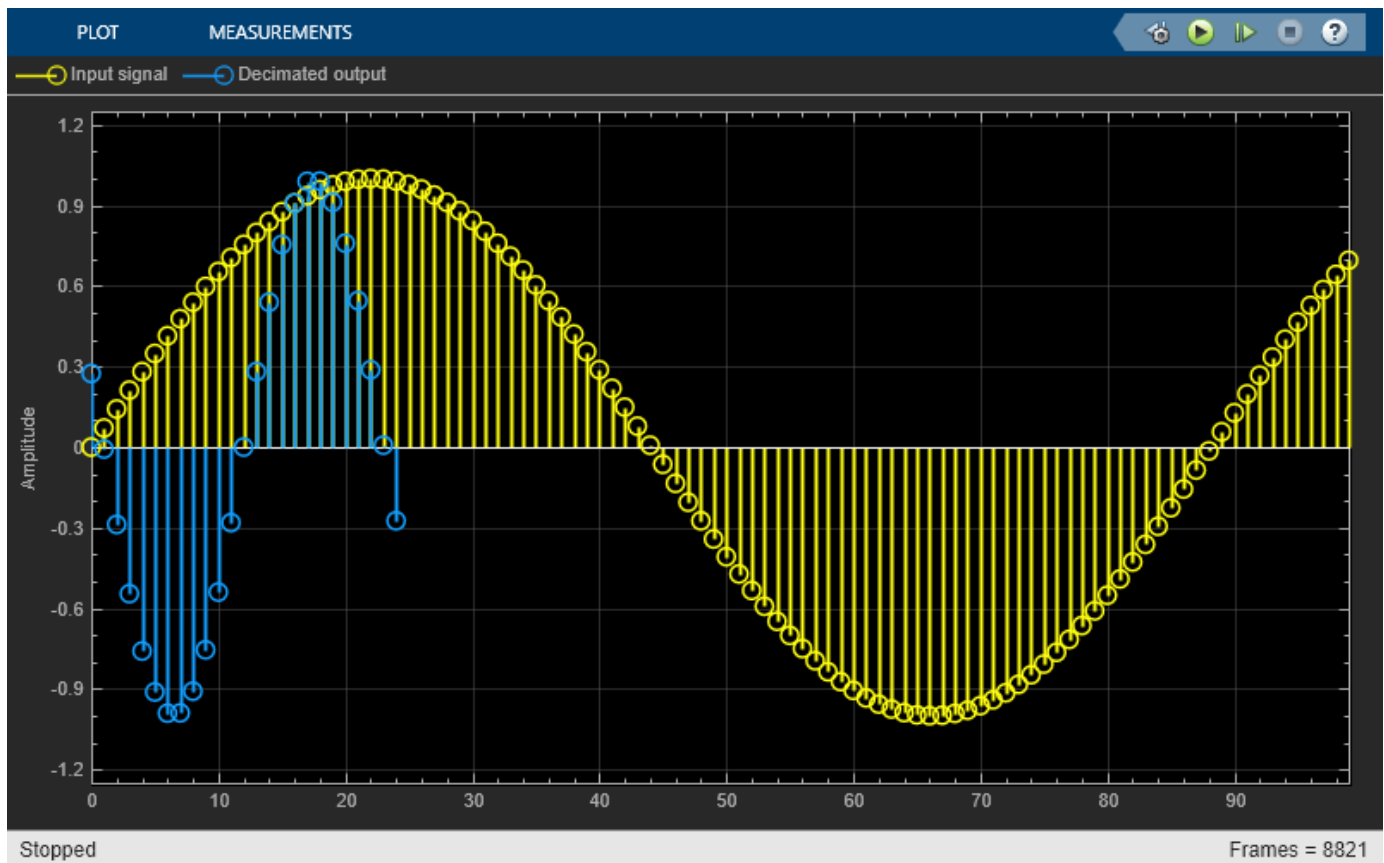

Decimate a sinusoidal signal using the Variable FIR Decimation block. You can vary the filter coefficients in the block dialog or through an input port while the simulation is running.

Open the model. The input is a sinusoidal signal with a frequency of 500 Hz, sample time of 1/44100 s, and contains 100 samples per frame. Pass this signal through the Variable FIR Decimation block. The **Maximum decimation factor** parameter in the Variable FIR Decimation block is set to 24. Specify the decimation factor and the filter coefficients through the **M** and the **coeffs** ports, respectively. The decimation factor is 4 and the filter coefficients are generated using the `designMultirateFIR(1,24)` function. This function generates an effective anti-aliasing lowpass filter with a normalized cutoff frequency no greater than 1/24.

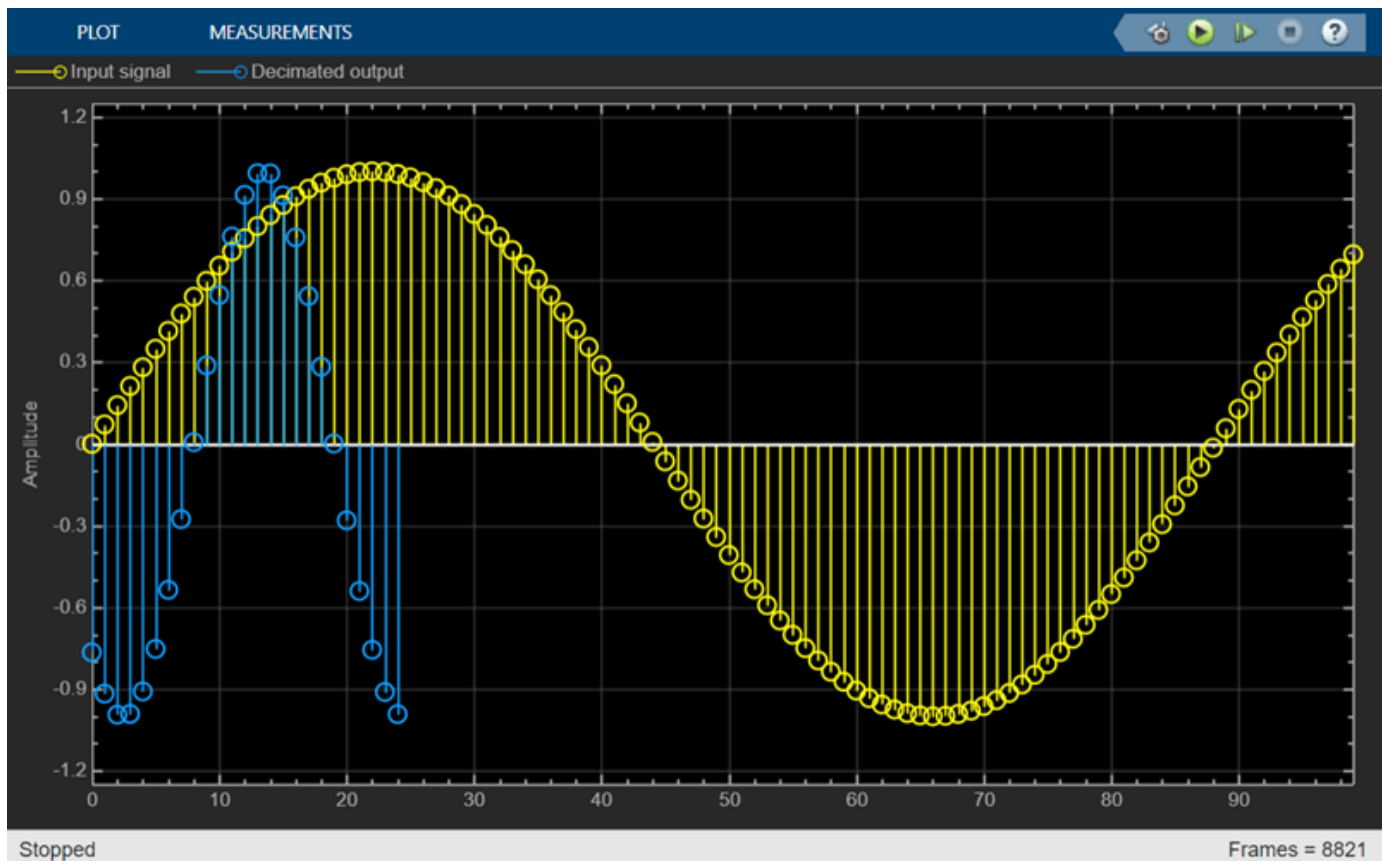

You can vary the filter coefficients using the Manual Switch.

Run the model. The Array Plot block shows the input signal and the decimated output in the display.

While the simulation is running, change the filter coefficients by clicking the Manual Switch. On the second branch, the `fir1` function generates the coefficients of a lowpass filter that has a similar passband frequency response and the same number of coefficients as the first filter. Note that you cannot change the number of filter coefficients while the simulation is running.

## Ports

### Input

**u** — Data input  
vector | matrix

Specify the data input as a vector or a matrix of size  $P$ -by- $Q$ . The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single channel.

The block accepts variable-size input signals, that is, you can change the size of each input channel during simulation, but you cannot change the number of channels.

Data Types: `single` | `double`

**M** — Decimation factor input port  
positive integer

Specify the decimation factor  $M$  as a positive integer that is an integer factor of the maximum decimation factor. For example, if you set **Maximum decimation factor** to 24, then the possible values for decimation factor are 1, 2, 3, 4, 6, 8, 12, and 24.

You can tune the decimation factor while the simulation is running. For an example, see “Decimate Sinusoidal Signal with Tunable Decimation Factor” on page 2-1488.

**Dependencies**

To enable this port, select the **Specify decimation factor from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**coeffs** — Prototype filter coefficients  
vector

Specify the lowpass FIR filter coefficients in descending powers of  $z$  as a vector.

The transfer function  $H(z)$  of the FIR filter is given by:

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

Compute the filter coefficients based on the maximum decimation factor  $M_{max}$  instead of the decimation factor  $M$  that you specify during simulation. For example, if  $M_{max}$  is 24 and  $M$  is 8, and you used `designMultirateFIR` as the design function, compute the filter coefficients using `designMultirateFIR(1,24)` instead of `designMultirateFIR(1,8)`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than  $1/M_{max}$ . To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

You can change the filter coefficients during simulation but the number of filter coefficients must remain constant. For an example, see “Specify Filter Coefficients Through Input Port” on page 2-1491.

**Dependencies**

To enable this port, set the **Coefficient source** parameter to `Input port`.

Data Types: `single` | `double`

**Output**

**y** — Decimated output  
vector | matrix

Decimated output, returned as a vector or a matrix. The size of the output signal is same as the size of the input signal. However, the block computes a maximum of  $\text{ceil}(P/M)$ -by- $Q$  output samples, where  $P$  is the input frame size,  $Q$  is the number of input channels, and  $M$  is the decimation factor that you specify during simulation.

The complexity of the output signal depends on the complexity of the input signal and the complexity of the filter coefficients. See this table for more details.

| Input Signal | Filter Coefficients | Output Signal |
|--------------|---------------------|---------------|
| Real         | Complex             | Complex       |
| Real         | Real                | Real          |

| Input Signal | Filter Coefficients | Output Signal |
|--------------|---------------------|---------------|
| Complex      | Complex             | Complex       |
| Complex      | Real                | Complex       |

Data Types: single | double

## Parameters

**Maximum decimation factor** — Maximum decimation factor

24 (default) | positive integer

Specify the maximum decimation factor  $M_{max}$  as a positive integer. The decimation factor you specify through the input port **M** must be a factor of the value you specify in this parameter.

**Specify decimation factor from input port** — Specify decimation factor from input port

on (default) | off

When you select this parameter, you can specify the decimation factor through the input port **M**. When you clear this parameter, you can specify the decimation factor in the block dialog box through the **Decimation factor** parameter.

**Decimation factor** — Decimation factor

24 (default) | positive integer

Specify the decimation factor  $M$  as a positive integer that is an integer factor of the maximum decimation factor  $M_{max}$ . For example, if you set **Maximum decimation factor** to 24, then the possible values for **Decimation factor** are 1, 2, 3, 4, 6, 8, 12, and 24.

You can tune the decimation factor while the simulation is running.

**Tunable:** Yes

### Dependencies

To enable this parameter, clear the **Specify decimation factor from input port** parameter.

**Coefficient source** — FIR filter coefficient source

Auto (default) | Dialog parameter | Input port

Specify the FIR filter coefficient source as one of the following:

- **Auto** -- The block designs an FIR decimator using the decimation factor in the **Decimation factor** parameter. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [1].

- **Dialog parameter** -- Specify the filter coefficients through the **Prototype filter coefficients** parameter in the block dialog box.

- Input port -- Specify the filter coefficients through the **coeffs** input port.

### Prototype filter coefficients — Prototype filter coefficients

`designMultirateFIR(1,24)` (default) | vector

Specify the lowpass FIR filter coefficients in descending powers of  $z$  as a vector. By default, `designMultirateFIR(1,24)` computes the filter coefficients with the maximum decimation factor  $M_{max}$  of 24.

The transfer function  $H(z)$  of the FIR filter is given by:

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr`, or `firceqrip`.

Compute the filter coefficients based on the maximum decimation factor  $M_{max}$  instead of the decimation factor  $M$  that you specify during simulation. For example, if  $M_{max}$  is 24 and  $M$  is 8, and you used `designMultirateFIR` as the design function, compute the filter coefficients using `designMultirateFIR(1,24)` instead of `designMultirateFIR(1,8)`.

To act as an effective anti-aliasing filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than  $1/M_{max}$ . To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

**Tunable:** Yes

### Dependencies

To enable this parameter, set the **Coefficient source** parameter to Dialog parameter.

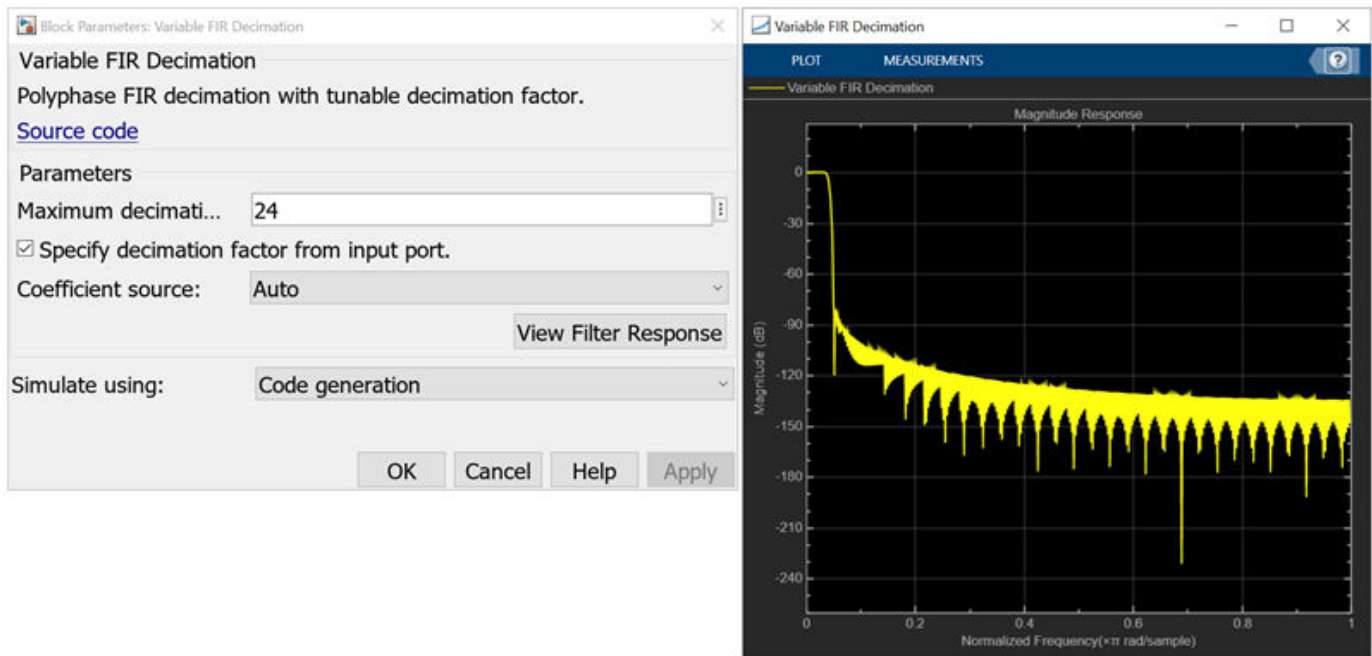

### View Filter Response — View Filter Response

button

Click this button to open the dynamic filter visualizer and display the magnitude response of the variable FIR decimation filter. The response is based on the parameters you select in the block dialog box. To update the magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You cannot view the filter response when you set the **Coefficient source** parameter to Input port. To view the filter response, set the **Coefficient source** parameter to Auto or Dialog parameter.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings. Click **Magnitude Phase** to display the magnitude and phase response of the filter.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## More About

### Phase Continuity

Under certain conditions, the Variable FIR Decimation block maintains the phase across consecutive frames of data.

| Input Conditions                         | Downsample Factor Source   | Output Signal        | Phase Continuity |
|--|--|----------------------|------------------|
| Variable-size input signal               | Specify in block dialog box<br><br>Downsample factor does not change during simulation | Variable-size signal | Yes              |
| Fixed-size or variable-size input signal | Specify through input port<br><br>Downsample factor does not change during simulation  | Variable-size signal | Yes              |

Under certain conditions, the phase resets to 0 and is not maintained across consecutive frames of data.

| Input Conditions                         | Downsample Factor Source   | Output Signal        | Phase Continuity  |
|--|--|----------------------|-------------------|
| Fixed-size input signal                  | Specify in block dialog box<br><br>Downsample factor changes during simulation | Fixed-size signal    | Phase resets to 0 |
| Fixed-size or variable-size input signal | Specify through input port<br><br>Downsample factor changes during simulation  | Variable-size signal | Phase resets to 0 |

### Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into  $M$  different subfilters, where  $M$  is the decimation factor that you specify during simulation. For more details on the polyphase implementation, see “Algorithms” on page 2-1500.

Let  $h(n)$  denote the FIR filter impulse response of length  $N+1$  and  $x(n)$  the input signal. Decimating the filter output by a factor of  $M$  is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting  $M = 2$ , the input values  $x(0), x(2), x(4), \dots$  are combined only with the filter coefficients  $h(0), h(2), h(4), \dots$ , and the input values  $x(1), x(3), x(5), \dots$  are combined only with the filter coefficients  $h(1), h(3), h(5), \dots$ . By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of  $M$ , there are  $M$  phases and therefore  $M$  subfilters.

## Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see “Polyphase Subfilters” on page 2-1499.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_{M_{\max}}z^{-M_{\max}} + b_{2M_{\max}}z^{-2M_{\max}} + \dots + b_{N-M_{\max}+1}z^{-(N-M_{\max}+1)}) + \\ & z^{-1}(b_1 + b_{M_{\max}+1}z^{-M_{\max}} + b_{2M_{\max}+1}z^{-2M_{\max}} + \dots + b_{N-M_{\max}+2}z^{-(N-M_{\max}+1)}) + \\ & \quad \vdots \\ & z^{-(M_{\max}-1)}(b_{M_{\max}-1} + b_{2M_{\max}-1}z^{-M_{\max}} + b_{3M_{\max}-1}z^{-2M_{\max}} + \dots + b_Nz^{-(N-M_{\max}+1)}) \end{aligned}$$

$M_{\max}$  is the number of polyphase components, and its value equals the maximum decimation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^{M_{\max}}) + z^{-1}E_1(z^{M_{\max}}) + \dots + z^{-(M_{\max}-1)}E_{M_{\max}-1}(z^{M_{\max}})$$

$E_0(z^{M_{\max}}), E_1(z^{M_{\max}}), \dots, E_{M_{\max}-1}(z^{M_{\max}})$  are the polyphase components of the FIR filter  $H(z)$ .

During simulation, the algorithm reconstructs the filter  $H(z)$  based on the decimation factor  $M$  that you specify during simulation. Rewriting  $H(z)$  in terms of the decimation factor  $M$ .

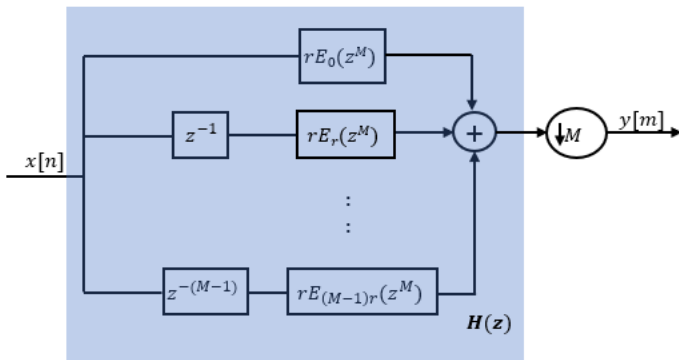

$$H(z) = rE_0(z^M) + z^{-1}rE_1(z^M) + \dots + z^{-(M-1)}rE_{(M-1)r}(z^M)$$

where,  $r = M_{\max}/M$ .

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

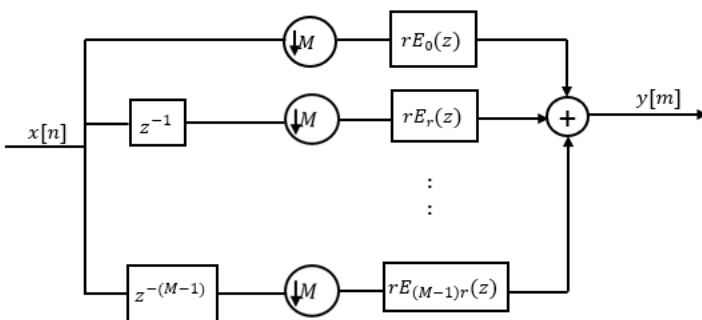

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches  $(M-1)r$ ,  $(M-2)r$ , and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch comes to the branch 0, the decimator outputs  $y[m]$ . The decimator effectively outputs one sample for every  $M$  samples it receives. Hence the sample rate at the output of the FIR decimation filter is  $fs/M$ .

# Variable FIR Interpolation

Polyphase FIR interpolation with tunable interpolation factor

## Libraries:

DSP System Toolbox / Filtering / Multirate Filters

## Description

The Variable FIR Interpolation block performs an efficient polyphase FIR interpolation with a tunable interpolation factor. You can update the interpolation factor and the filter coefficients in the block dialog box or through an input port while the simulation is running.

Conceptually, the FIR interpolator (as shown in the schematic) consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. To design an FIR anti-imaging filter, use the `designMultirateFIR` function. The upsampler upsamples each channel of the input to a higher rate by inserting  $L-1$  zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is  $L$  times the original sample rate.

However, the actual block algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 2-1512.

The block supports C and C++ code generation.

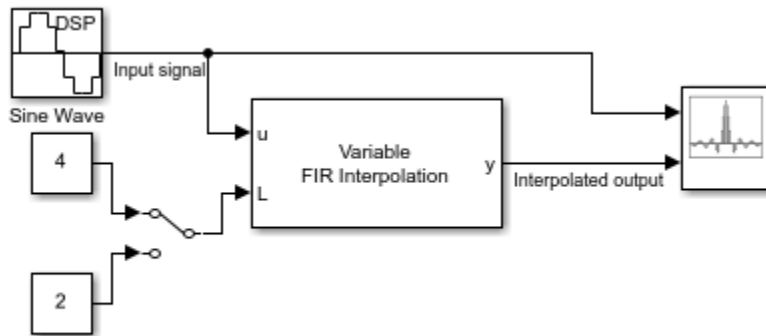

## Examples

### Interpolate Sinusoidal Signal with Tunable Interpolation Factor

Interpolate a sinusoidal signal by varying the interpolation factor using the Variable FIR Interpolation block. You can vary the interpolation factor in the block dialog box or through an input port while the simulation is running.

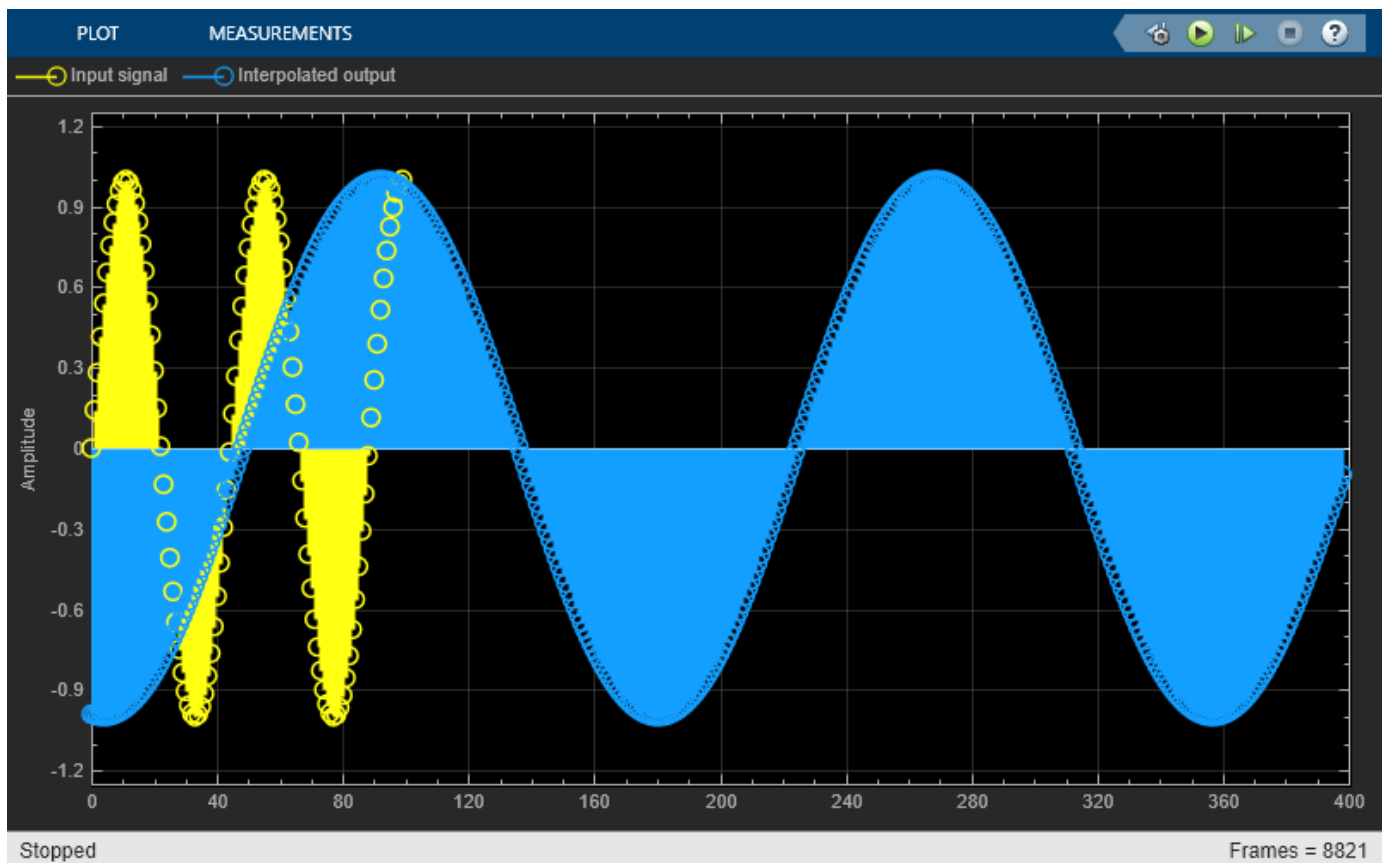

Open the model. The input is a sinusoidal signal with a frequency of 500 Hz, sample time of 1/44100 s, and contains 100 samples per frame. Pass this signal through the Variable FIR Interpolation block.

The **Maximum interpolation factor** parameter in the block is 24. The interpolation factor that you input through the port is 4.

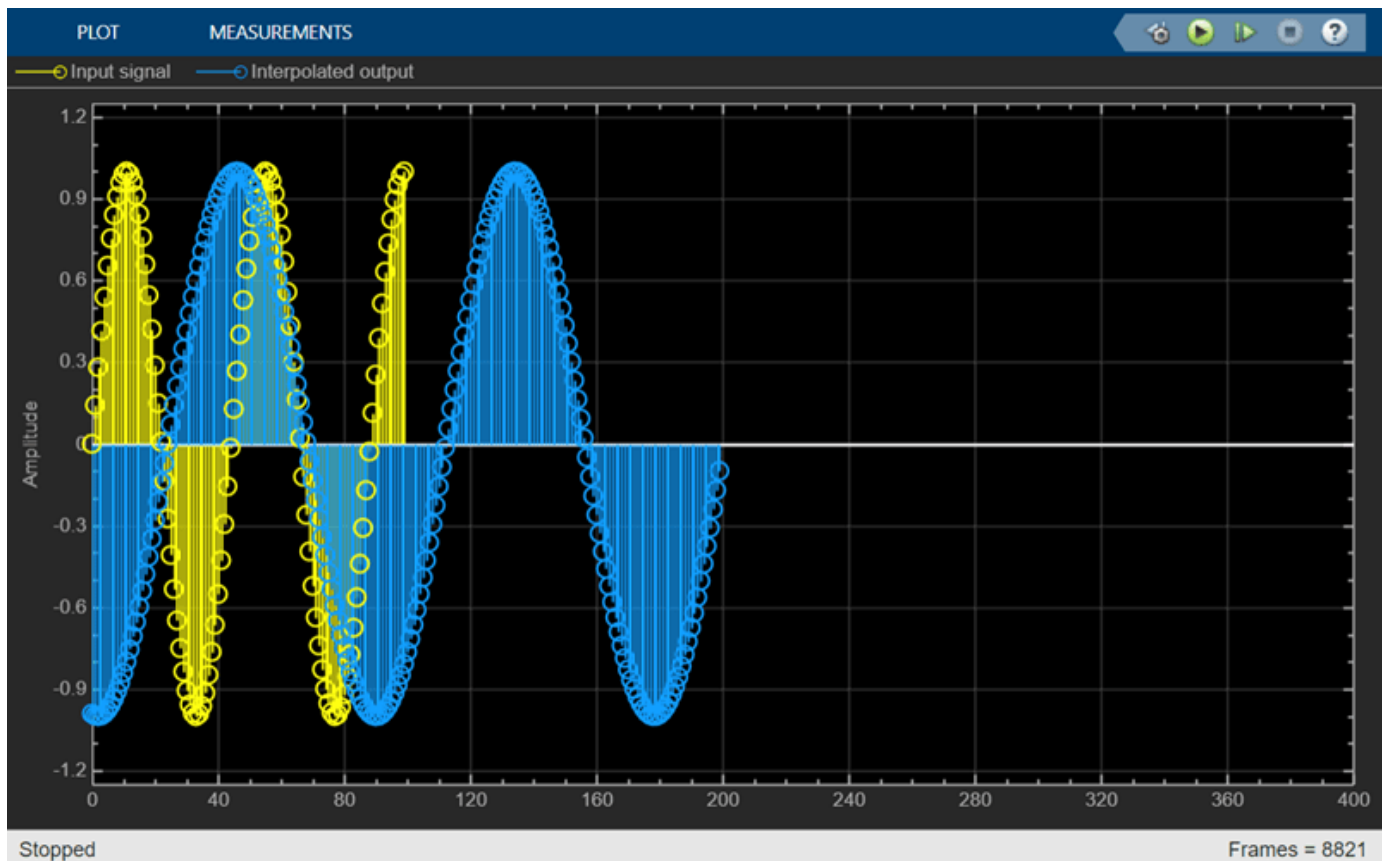

Copyright 2023 The MathWorks, Inc.

Run the model. The Array Plot block shows the input signal and the interpolated output on the display.

While the simulation is running, change the interpolation factor to 2 by clicking the Manual Switch. The span of the interpolated output updates in the Array Plot display. You can change the interpolation factor to any value that is an integer factor of the maximum interpolation factor of 24.

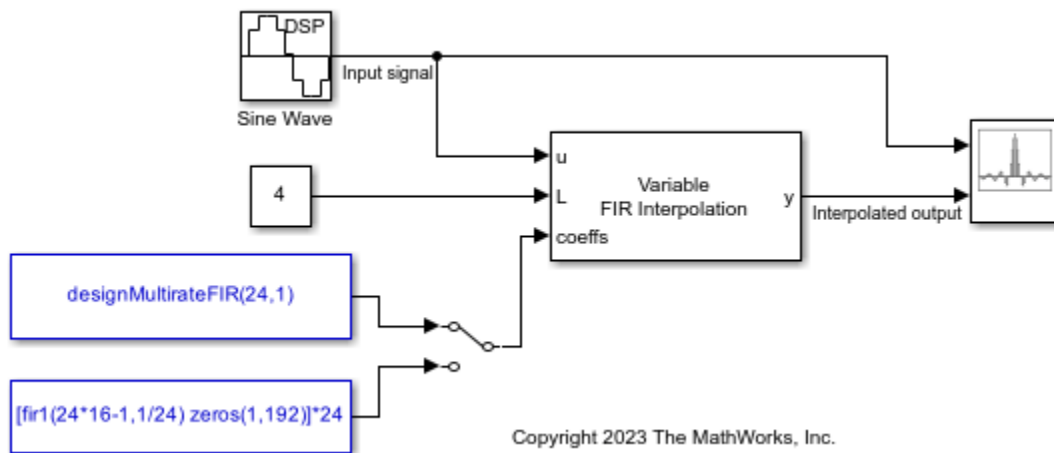

If you specify the interpolation factor in the block dialog box, you can tune the **Interpolation factor** parameter in the block dialog box while the simulation is running and the block updates the interpolated output accordingly.

### Specify Filter Coefficients Through Input Port

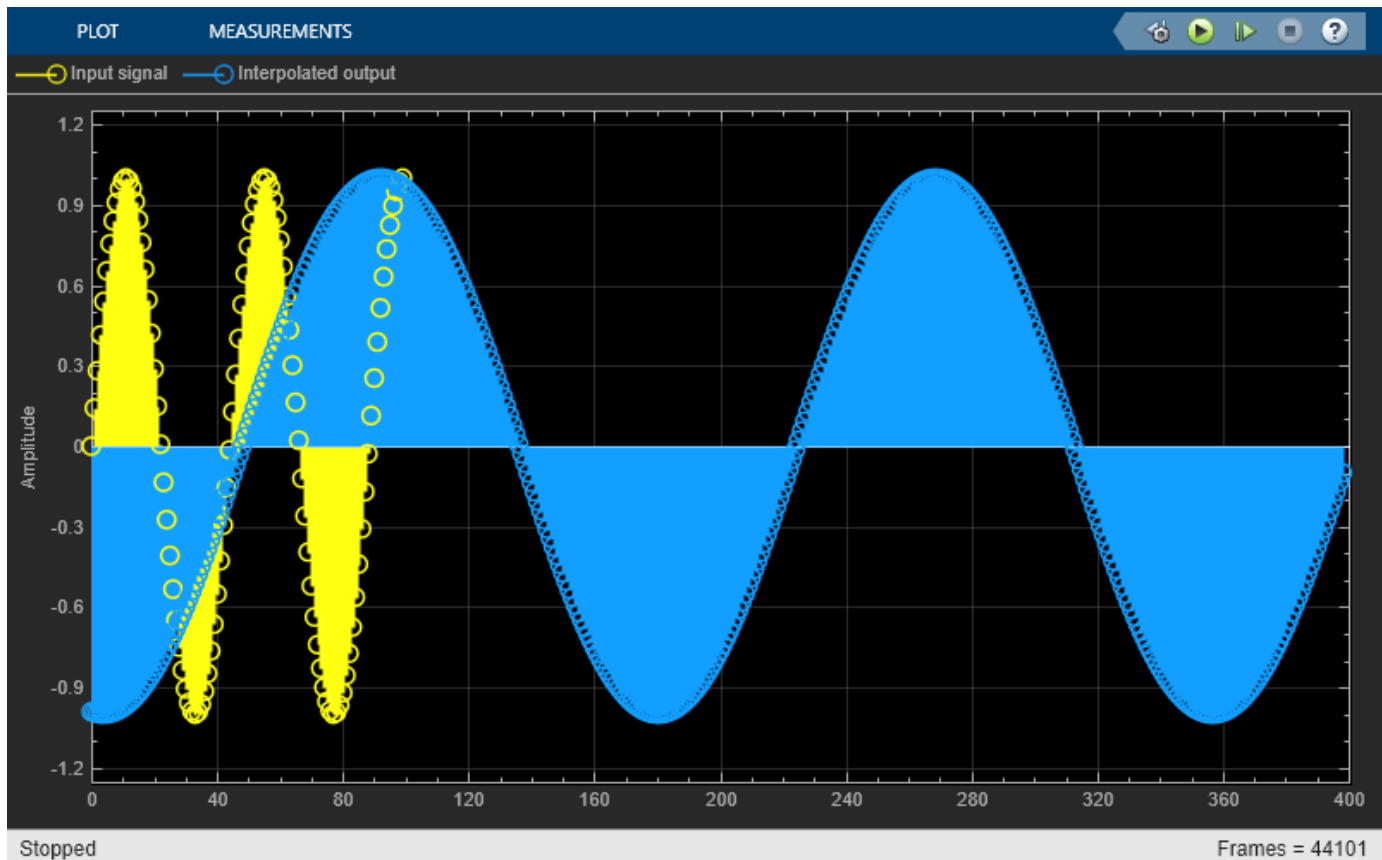

Interpolate a sinusoidal signal using the Variable FIR Interpolation block. You can vary the filter coefficients in the block dialog box or through an input port while the simulation is running.

Open the model. The input is a sinusoidal signal with a frequency of 500 Hz, sample time of 1/44100 s, and contains 100 samples per frame. Pass this signal through the Variable FIR Interpolation block. The **Maximum interpolation factor** parameter in the Variable FIR Interpolation block is set to 24. Specify the interpolation factor and the filter coefficients through the **L** and the **coeffs** ports, respectively. The interpolation factor is 4 and the filter coefficients are generated using the `designMultirateFIR(24,1)` function. This function generates an effective anti-imaging lowpass filter with a normalized cutoff frequency no greater than 1/24.

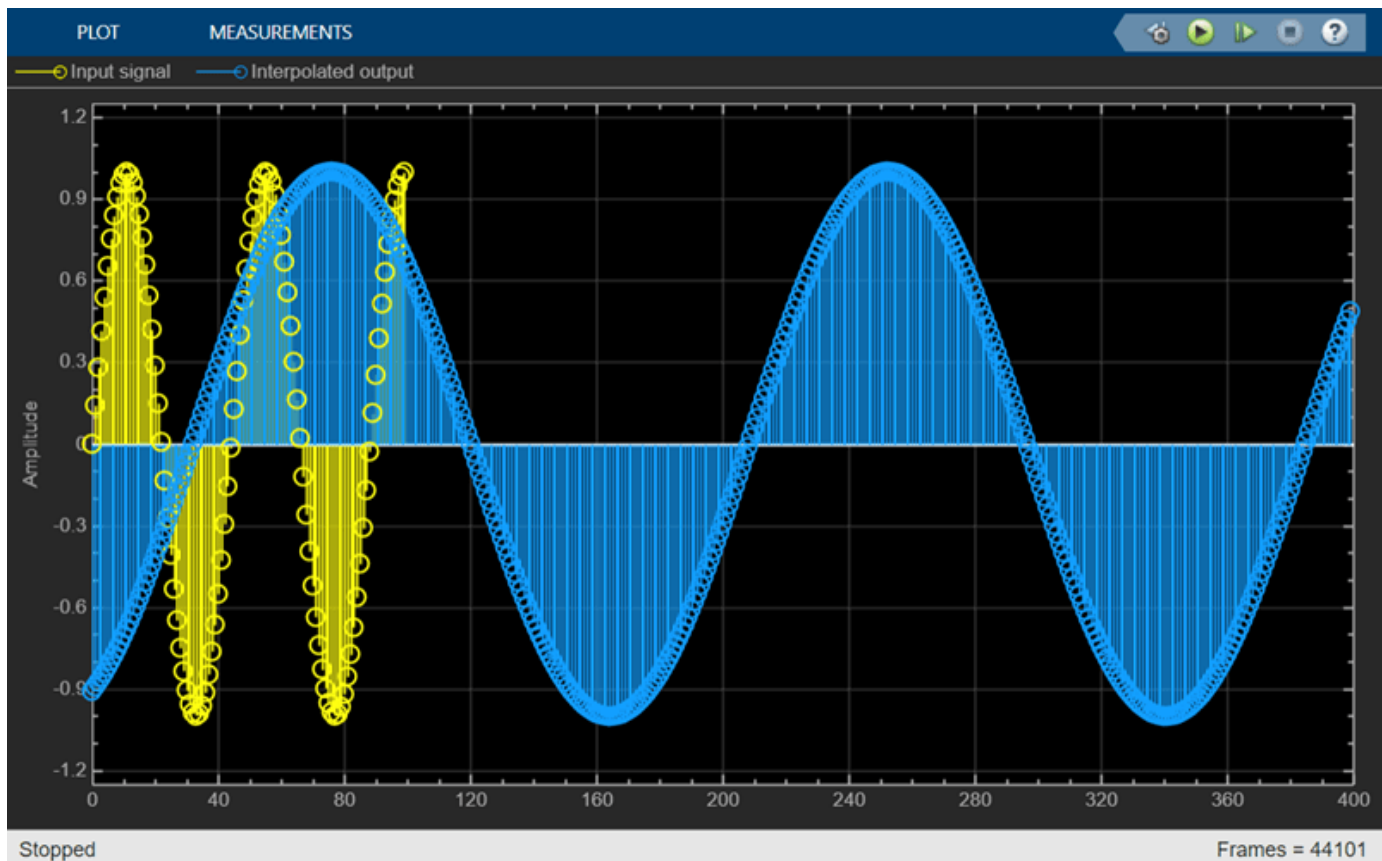

You can vary the filter coefficients using the Manual Switch.

Run the model. The Array Plot block shows the input signal and the interpolated output in the display.

While the simulation is running, change the filter coefficients by clicking the Manual Switch. On the second branch, the `fir1` function generates the coefficients of a lowpass filter that has a similar passband frequency response and the same number of coefficients as the first filter. Note that you cannot change the number of filter coefficients while the simulation is running.

## Ports

### Input

**u** — Data input  
vector | matrix

Specify the data input as a vector or a matrix. The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single channel.

The block accepts variable-size input signals, that is, you can change the size of each input channel during simulation, but you cannot change the number of channels.

Data Types: `single` | `double`

**L** — Interpolation factor input port  
positive integer

Specify the interpolation factor  $L$  as a positive integer that is an integer factor of the maximum interpolation factor. For example, if you set **Maximum interpolation factor** to 24, then the possible values for interpolation factor are 1, 2, 3, 4, 6, 8, 12, and 24.

You can tune the interpolation factor while the simulation is running. For an example, see “Interpolate Sinusoidal Signal with Tunable Interpolation Factor” on page 2-1503.

**Dependencies**

To enable this port, select the **Specify interpolation factor from input port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**coeffs** — Prototype filter coefficients  
vector

Specify the numerator coefficients of the FIR filter transfer function  $H(z)$ .

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

Compute the filter coefficients based on the maximum interpolation factor  $L_{max}$  instead of the interpolation factor  $L$  that you specify during simulation. For example, if  $L_{max}$  is 24 and  $L$  is 8, and you used `designMultirateFIR` as the design function, compute the filter coefficients using `designMultirateFIR(24,1)` instead of `designMultirateFIR(8,1)`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the maximum interpolation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

You can change the filter coefficients during simulation but the number of filter coefficients must remain constant. For an example, see “Specify Filter Coefficients Through Input Port” on page 2-1505.

**Dependencies**

To enable this port, set the **Coefficient source** parameter to `Input port`.

Data Types: `single` | `double`

**Output**

**y** — Interpolated output  
vector | matrix

Interpolated output, returned as a vector or a matrix. The size of the output signal is  $L_{max} \times$  input frame size-by- $N$ , where  $N$  is the number of input channels and  $L_{max}$  is the maximum interpolation factor. However, the block computes only  $L \times$  input frame size-by- $N$  samples. The remaining samples in the output signal are zero.

The complexity of the output signal depends on the complexity of the input signal and the complexity of the filter coefficients. See this table for more details.

| Input Signal | Filter Coefficients | Output Signal |
|--------------|---------------------|---------------|
| Real         | Complex             | Complex       |
| Real         | Real                | Real          |

| Input Signal | Filter Coefficients | Output Signal |
|--------------|---------------------|---------------|
| Complex      | Complex             | Complex       |
| Complex      | Real                | Complex       |

Data Types: single | double

## Parameters

**Maximum interpolation factor** — Maximum interpolation factor

24 (default) | positive integer

Specify the maximum interpolation factor  $L_{max}$  as a positive integer. The interpolation factor you specify through the input port **L** must be a factor of the value you specify in this parameter.

**Specify interpolation factor from input port** — Specify interpolation factor from input port

on (default) | off

When you select this parameter, you can specify the interpolation factor through the input port **L**. When you clear this parameter, you can specify the interpolation factor in the block dialog box through the **Interpolation factor** parameter.

**Interpolation factor** — Decimation factor

24 (default) | positive integer

Specify the interpolation factor  $L$  as a positive integer that is an integer factor of the maximum interpolation factor. For example, if you set **Maximum interpolation factor** to 24, then the possible values for **Interpolation factor** are 1, 2, 3, 4, 6, 8, 12, and 24.

You can tune the interpolation factor while the simulation is running.

**Tunable:** Yes

### Dependencies

To enable this parameter, clear the **Specify interpolation factor from input port** parameter.

**Coefficient source** — FIR filter coefficient source

Auto (default) | Dialog parameter | Input port

Specify the FIR filter coefficient source as one of the following:

- **Auto** -- The block designs an FIR interpolator using the interpolation factor in the **Interpolation factor** parameter. The `designMultirateFIR` function designs the filter and returns the coefficients used by the block.

For more information on the filter design, see Orfanidis [1].

- **Dialog parameter** -- Specify the filter coefficients through the **Prototype filter coefficients** parameter in the block dialog box.

- **Input port** -- Specify the filter coefficients through the **coeffs** input port.

**Prototype filter coefficients** — Prototype filter coefficients

`designMultirateFIR(24,1)` (default) | vector

Specify the numerator coefficients of the FIR filter transfer function  $H(z)$ .

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

You can generate the FIR filter coefficient vector,  $\mathbf{b} = [b_0, b_1, \dots, b_N]$ , using one of the DSP System Toolbox filter design functions such as `designMultirateFIR`, `firnyquist`, `firhalfband`, `firgr` or `firceqrip`.

Compute the filter coefficients based on the maximum interpolation factor  $L_{max}$  instead of the interpolation factor  $L$  that you specify during simulation. For example, if  $L_{max}$  is 24 and  $L$  is 8, and you used `designMultirateFIR` as the design function, compute the filter coefficients using `designMultirateFIR(24,1)` instead of `designMultirateFIR(8,1)`.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the maximum interpolation factor. To design such a filter, use the `designMultirateFIR` function.

The block internally initializes all filter states to zero.

You can change the filter coefficients during simulation but the number of filter coefficients must remain constant.

**Tunable:** Yes

**Dependencies**

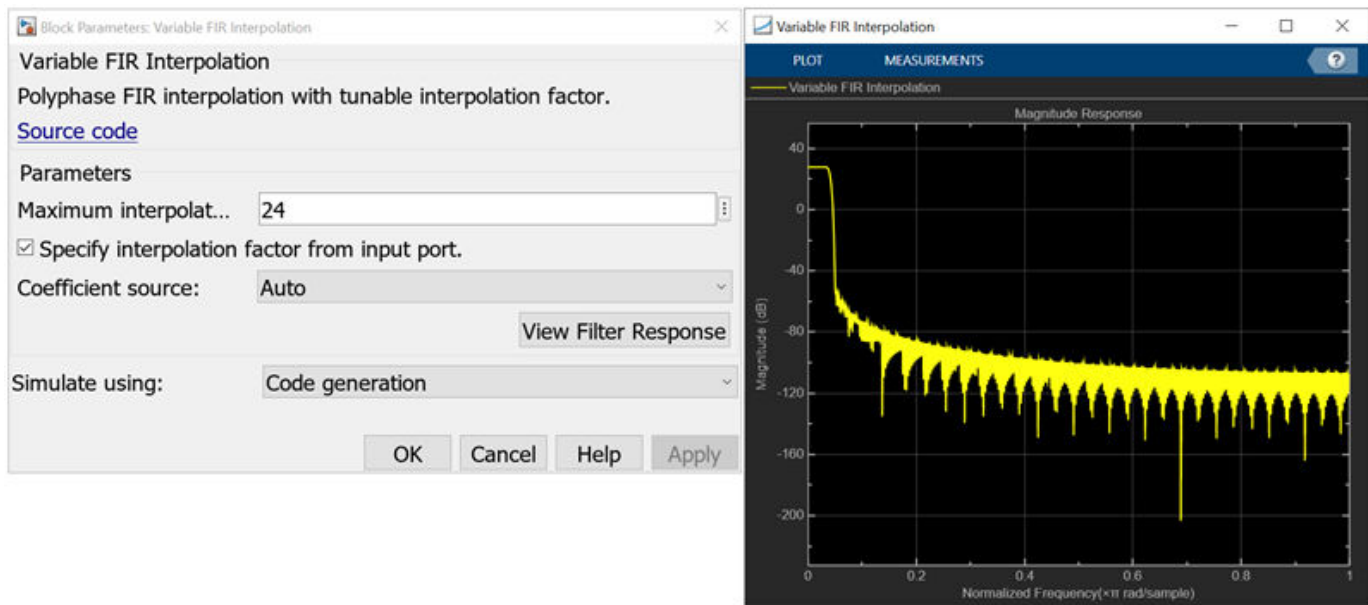

To enable this parameter, set the **Coefficient source** parameter to `Dialog` parameter.

**View Filter Response** — View Filter Response

button

Click this button to open the dynamic filter visualizer and display the magnitude response of the variable FIR interpolation filter. The response is based on the parameters you select in the block dialog box. To update the magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You cannot view the filter response when you set the **Coefficient source** parameter to `Input port`. To view the filter response, set the **Coefficient source** parameter to `Auto` or `Dialog` parameter.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings. Click **Magnitude Phase** to display the magnitude and phase response of the filter.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

**Simulate using** — Simulate using

Code generation (default) | Interpreted execution

Specify the type of simulation to run. You can set this parameter to:

- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.
- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | yes             |
| <b>Zero-Crossing Detection</b>  | no              |

## Algorithms

The FIR interpolation filter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H(z) = & \left( b_0 + b_{L_{\max}}z^{-L_{\max}} + b_{2L_{\max}}z^{-2L_{\max}} + \dots + b_{N-L_{\max}+1}z^{-(N-L_{\max}+1)} \right) + \\
 & z^{-1} \left( b_1 + b_{L_{\max}+1}z^{-L_{\max}} + b_{2L_{\max}+1}z^{-2L_{\max}} + \dots + b_{N-L_{\max}+2}z^{-(N-L_{\max}+1)} \right) + \\
 & \vdots \\
 & z^{-(L_{\max}-1)} \left( b_{L_{\max}-1} + b_{2L_{\max}-1}z^{-L_{\max}} + b_{3L_{\max}-1}z^{-2L_{\max}} + \dots + b_Nz^{-(N-L_{\max}+1)} \right)
 \end{aligned}$$

$L_{\max}$  is the number of polyphase components, and its value equals the maximum interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^{L_{\max}}) + z^{-1}E_1(z^{L_{\max}}) + \dots + z^{-(L_{\max}-1)}E_{(L_{\max}-1)}(z^{L_{\max}})$$

$E_0(z^{L_{\max}}), E_1(z^{L_{\max}}), \dots, E_{L_{\max}-1}(z^{L_{\max}})$  are polyphase components of the FIR filter  $H(z)$ .

During simulation, the algorithm reconstructs the filter  $H(z)$  based on the interpolation factor  $L$  that you specify during simulation. Rewriting  $H(z)$  in terms of the interpolation factor  $L$ .

$$H(z) = E_0(z^L) + z^{-1}E_r(z^L) + \dots + z^{-(L-1)}E_{(L-1)r}(z^L)$$

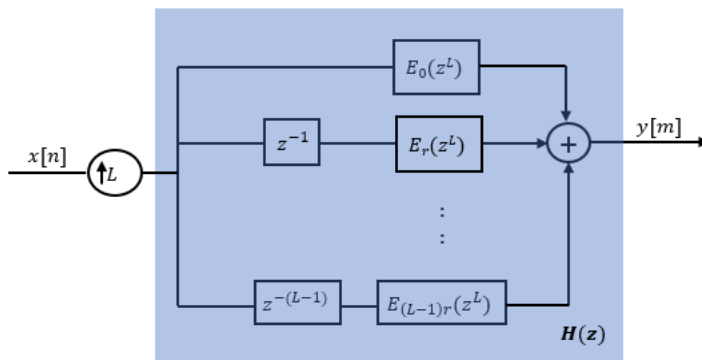

where,  $r = L_{max}/L$ .

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter  $H(z)$ .

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving

one sample from each branch. The interpolator effectively outputs  $L$  samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is  $Lfs$ .

# Variable Fractional Delay

Delay input by time-varying fractional number of sample periods

## Libraries:

DSP System Toolbox / Signal Operations

## Description

The Variable Fractional Delay block delays the input signal by a specified number of fractional samples along each channel of the input. The block can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Delay Signal Using Multitap Fractional Delay”.

When the delay has a fractional value, the block interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set **Interpolation mode** parameter to one of **Linear**, **FIR**, or **Farrow**. The block supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample.

The block assumes that the input values at the **Delay** port are between  $D_{min}$  and  $D_{max}$ , where  $D_{min}$  appears in the **Valid delay range** section on the **Main** tab of the block dialog, and  $D_{max}$  is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than  $D_{min}$  to  $D_{min}$  and delay values greater than  $D_{max}$  to  $D_{max}$ .

You must consider additional factors when selecting valid Delay values for the **FIR** and **Farrow** interpolation modes. For details, see “Algorithms” on page 2-1528.

## Ports

### Input

**In** — Data input  
vector | matrix

Specify the data input as a vector or matrix. The data input must have the same data type as the delay input.

This block supports variable-size input signal. That is, you can change the number of input rows during the simulation. However, the number of channels must remain constant.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Delay** — Delay input  
scalar | vector | matrix | *N*-D array

Specify the delay input as a scalar, vector, matrix, or *N*-D array. The delay can be an integer or a fractional value. The block interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This block supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal during simulation. However, the block must make sure that the resulting number of output channels remains constant throughout the simulation.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input. For an example, see “Delay Signal Using Multitap Fractional Delay”.

| Data Input   | Delay Input        | Output             | Effect of Delay Input on Data Input   |
|--|--------------------|--------------------|---|
| $N$ (unoriented, one channel)                              | scalar             | Unoriented ( $N$ ) | One delay value applied to the input channel  |
| $N$ (unoriented, one channel)                              | Unoriented ( $N$ ) | Unoriented ( $N$ ) | Delay value varies within the frame from sample to sample   |
| $N$ (unoriented, one channel)                              | 1-by- $P$          | $N$ -by- $P$       | $P$ taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ (unoriented, one channel)                              | $N$ -by- $P$       | $N$ -by- $P$       | $P$ taps. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | scalar             | $N$ -by-1          | One delay value applied to the input channel  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | Unoriented ( $N$ ) | $N$ -by-1          | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by-1          | $N$ -by-1          | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | 1-by- $P$          | $N$ -by- $P$       | $P$ taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by- $P$       | $N$ -by- $P$       | $P$ taps. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | scalar             | $N$ -by- $L$       | One delay value applied to all input channels   |

| <b>Data Input</b>  | <b>Delay Input</b>    | <b>Output</b>         | <b>Effect of Delay Input on Data Input</b>   |
|--|-----------------------|-----------------------|--|
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$             | $N$ -by- $L$          | Unique delay value for each input channel  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1             | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.                                    |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$          | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Different delay values for each input channel.                                |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by-1-by- $P$        | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Same delay for all channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$ -by- $P$    | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Taps vary across channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1-by- $P$     | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.      |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$ -by- $P$ | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel. |

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

| <b>Data Input</b>                                     | <b>Delay Input</b> | <b>Output</b>      | <b>Effect of Delay Input on Data Input</b>                |
|---|--------------------|--------------------|---|
| $N$ (unoriented, one channel)                         | scalar             | Unoriented ( $N$ ) | One delay value applied to the input channel              |
| $N$ (unoriented, one channel)                         | Unoriented ( $N$ ) | Unoriented ( $N$ ) | Delay value varies within the frame from sample to sample |
| $N$ -by-1 (one channel with frame size equal to $N$ ) | scalar             | $N$ -by-1          | One delay value applied to the input channel              |

| Data Input  | Delay Input        | Output       | Effect of Delay Input on Data Input   |
|---|--------------------|--------------|---|
| $N$ -by-1 (one channel with frame size equal to $N$ )         | Unoriented ( $N$ ) | $N$ -by-1    | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )         | $N$ -by-1          | $N$ -by-1    | Delay value varies within the frame from sample to sample   |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | scalar             | $N$ -by- $L$ | One delay value applied to all input channels   |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | 1-by- $L$          | $N$ -by- $L$ | Unique delay value for each input channel   |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | $N$ -by-1          | $N$ -by- $L$ | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.     |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | $N$ -by- $L$       | $N$ -by- $L$ | Delay value varies within the frame from sample to sample. Different delay values for each input channel. |

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Output

**Port\_1** — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The data type and complexity of the output match the data type and complexity of the data input.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input.

| Data Input                    | Delay Input | Output             | Effect of Delay Input on Data Input          |
|-------------------------------|-------------|--------------------|--|
| $N$ (unoriented, one channel) | scalar      | Unoriented ( $N$ ) | One delay value applied to the input channel |

| <b>Data Input</b>  | <b>Delay Input</b> | <b>Output</b>      | <b>Effect of Delay Input on Data Input</b>  |
|--|--------------------|--------------------|---|
| $N$ (unoriented, one channel)                              | Unoriented ( $N$ ) | Unoriented ( $N$ ) | Delay value varies within the frame from sample to sample   |
| $N$ (unoriented, one channel)                              | 1-by- $P$          | $N$ -by- $P$       | $P$ taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ (unoriented, one channel)                              | $N$ -by- $P$       | $N$ -by- $P$       | $P$ taps. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | scalar             | $N$ -by-1          | One delay value applied to the input channel  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | Unoriented ( $N$ ) | $N$ -by-1          | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by-1          | $N$ -by-1          | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | 1-by- $P$          | $N$ -by- $P$       | $P$ taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by- $P$       | $N$ -by- $P$       | $P$ taps. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | scalar             | $N$ -by- $L$       | One delay value applied to all input channels   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$          | $N$ -by- $L$       | Unique delay value for each input channel   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1          | $N$ -by- $L$       | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.   |

| Data Input   | Delay Input           | Output                | Effect of Delay Input on Data Input  |
|--|-----------------------|-----------------------|--|
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$          | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Different delay values for each input channel.                                |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by-1-by- $P$        | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Same delay for all channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$ -by- $P$    | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Taps vary across channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1-by- $P$     | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.      |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$ -by- $P$ | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel. |

When the **Input processing** parameter is set to **Elements as channels (sample based)**, the table below shows the effect of the dimension of the delay input on the data input.

| Data Input  | Delay Input        | Output             | Effect of Delay Input on Data Input                       |
|---|--------------------|--------------------|---|
| $N$ (unoriented, one channel)                         | scalar             | Unoriented ( $N$ ) | One delay value applied to the input channel              |
| $N$ (unoriented, one channel)                         | Unoriented ( $N$ ) | Unoriented ( $N$ ) | Delay value varies within the frame from sample to sample |
| $N$ -by-1 (one channel with frame size equal to $N$ ) | scalar             | $N$ -by-1          | One delay value applied to the input channel              |
| $N$ -by-1 (one channel with frame size equal to $N$ ) | Unoriented ( $N$ ) | $N$ -by-1          | Delay value varies within the frame from sample to sample |
| $N$ -by-1 (one channel with frame size equal to $N$ ) | $N$ -by-1          | $N$ -by-1          | Delay value varies within the frame from sample to sample |

| Data Input  | Delay Input  | Output       | Effect of Delay Input on Data Input   |
|---|--------------|--------------|---|
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | scalar       | $N$ -by- $L$ | One delay value applied to all input channels   |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | 1-by- $L$    | $N$ -by- $L$ | Unique delay value for each input channel   |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | $N$ -by-1    | $N$ -by- $L$ | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.     |
| $N$ -by- $L$ ( $L$ channels with $N$ samples in each channel) | $N$ -by- $L$ | $N$ -by- $L$ | Delay value varies within the frame from sample to sample. Different delay values for each input channel. |

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

**Interpolation mode** — Method of interpolation

Linear (default) | FIR | Farrow

Specify the method of interpolation. Using this method, the block interpolates the signal to obtain new samples at noninteger sampling intervals.

- **Linear** -- Linear interpolation. In this mode, the block stores the  $\mathbf{D}_{\max}+1$  most recent samples the **In** port receives for each channel.  $\mathbf{D}_{\max}$  is the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** -- Polyphase FIR interpolation. In this mode, the block stores the  $\mathbf{D}_{\max}+\mathbf{P}+1$  most recent samples the **In** port receives for each channel.  $\mathbf{P}$  is the value you specify in the **Interpolation filter half-length (P)** parameter.
- **Farrow** -- LaGrange method. In this mode, the block stores the  $\mathbf{D}_{\max}+\frac{\mathbf{N}}{2}+1$  most recent samples the **In** port receives for each channel.  $\mathbf{N}$  is the value you specify in the **Farrow filter length (N)** parameter.

For more details on these methods, see “Algorithms” on page 2-1528.

**Interpolation filter half-length (P)** — Half length of interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of the FIR interpolation filter. For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

Example: 6

Example: 10

#### Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Interpolation points per input sample** — Number of interpolation points per input sample  
10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed.

Example: 20

Example: 5

#### Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Normalized input bandwidth (0 to 1)** — Normalized input bandwidth  
1 (default) | real scalar in the range (0, 1]

Normalized input bandwidth at which to constrain the interpolated output samples. A value of 1 equals the Nyquist frequency, or half the sampling frequency,  $F_s$ . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above  $F_s/4$ , you can specify a value of 0.5.

Example: 0.5

Example: 0.8

#### Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

**Farrow filter length (N)** — Length of Farrow filter  
4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure. If the length equals 2, the filter performs linear interpolation.

Example: 4

Example: 10

### Dependencies

This parameter applies only when you set **Interpolation mode** to Farrow.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

**Maximum delay (Dmax) in samples** — Maximum delay  
100 (default) | integer in the range [0 65535]

Maximum delay the block can produce,  $D_{max}$ . Input delay values exceeding this maximum are clipped to  $D_{max}$ .

Example: 200

Example: 500

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### Input processing — Method to process the input

`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel. The block treats each of the  $R$  input columns as independent channels containing  $M_i$  sequential time samples.

The input to the **Delay** port,  $v$ , contains floating-point values that specify the number of sample intervals to delay the current input.

The input to the **Delay** port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- $M$  column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The **Delay** port entry can also be a length- $R$  row vector, containing one delay for each channel. Finally, the **Delay** port entry can be an  $M$ -by- $R$  matrix, containing a different delay for each corresponding element of the input.

For example, if  $v$  is the  $M_i$ -by-1 matrix  $[v(1) \ v(2) \ \dots \ v(M_i)]'$ , the earliest sample in the current frame is delayed by  $v(1)$  fractional sample intervals, the following sample in the frame is delayed by  $v(2)$  fractional sample intervals, and so on. The block applies the set of fractional delays contained in  $v$  identically to every channel of a multichannel input.

- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. The block treats each element of the  $N$ -D input array,  $u$ , as an independent channel. The input to the **Delay** port,  $v$ , must either be an  $N$ -D array of the same size and dimension as the input  $u$ , or be a scalar value, such that  $D_{min} \leq v \leq D_{max}$ .

For example, consider an  $M$ -by- $R$  input matrix. The block treats each of the  $M \times R$  matrix elements as independent channels. The input to the **Delay** port can be an  $M$ -by- $R$  matrix of floating-point values in the range  $D_{min} \leq v \leq D_{max}$  that specifies the number of sample intervals to delay each

channel of the input, or it can be a scalar floating-point value,  $D_{min} \leq v \leq D_{max}$ , by which to equally delay all channels.

In sample-based processing mode, the block treats an unoriented vector input as an  $M$ -by-1 matrix. In this mode, the output is also an unoriented vector.

**InitialConditions** — Initial values in the memory

0 (default) | scalar | 1-by- $R$ -by- $D$  array | 1-by- $R$ -by- $(D+L)$  array

Specify the values within the block's memory at the start of the simulation. The dimensions of this parameter can vary depending on whether you want fixed or time-varying initial conditions. The block treats each of the  $R$  input columns as a frame containing  $M$  sequential time samples from an independent channel.

For an  $M$ -by- $R$  input matrix,  $u$ , you can set this parameter as follows:

- To specify fixed initial conditions, set this parameter to a scalar value. The block initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the interpolation method. To specify different time-varying initial conditions for each channel, set this parameter as follows:
  - If you set the **Interpolation mode** to Linear, set the **Initial conditions** to an array of size 1-by- $R$ -by- $D$ , where  $D$  is the value in **Maximum delay (Dmax) in samples** parameter.
  - If you set the **Interpolation mode** to FIR or Farrow, set the **Initial conditions** to an array of size 1-by- $R$ -by- $(D+L)$ , where  $D$  is the value of the maximum delay. For FIR interpolation,  $L$  is the value of the interpolation filter half length. For Farrow interpolation,  $L$  equals floor of half the value of the farrow filter length (floor( farrow filter length/2)).

Example: 1

Example: randn(1,3,104)

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

**Disable direct feedthrough by increasing minimum possible delay by one** — Disable direct feedthrough

off (default) | on

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by *frame size* - 1. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

**For small input delay values** — Action to take for small input delay values

Clip to the minimum value necessary for centered kernel (default) | Use off-centered kernel | Switch to linear interpolation if kernel cannot be centered

Specify the block's behavior when the input delay values are too small to center the kernel.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

- In both FIR and Farrow interpolation modes, you can select **Clip to the minimum value necessary for centered kernel**. This option forces the block to increase  $D_{min}$  to the smallest value necessary to keep the kernel centered.
- In FIR interpolation mode, you can select **Switch to linear interpolation if kernel cannot be centered**. This option forces the block to preserve the value of  $D_{min}$  and compute all interpolated values using **Linear** interpolation.
- In Farrow interpolation mode, you can select **Use off-centered kernel**. This option forces the block to preserve the value of  $D_{min}$  and compute the interpolated values using a farrow filter with an off-centered kernel.

### Dependencies

This parameter applies only when **Interpolation mode** is set to FIR or Farrow.

**Valid delay range (in samples)** — Range of valid delay values

[0 100] (default) | [ $D_{min}$   $D_{max}$ ]

This parameter is read-only.

The delay range values [ $D_{min}$   $D_{max}$ ] are calculated (in samples) by the block based on the current parameter settings.  $D_{min}$  is the smallest possible valid delay value (in samples). The block clips all input delay values less than  $D_{min}$  to  $D_{min}$ .  $D_{max}$  is the maximum valid delay value (in samples). The block clips all input delay values greater than  $D_{max}$  to  $D_{max}$ .

When the **Interpolation mode** is set to one of the following:

- **Linear** --  $D_{min}$  equal 0.  $D_{max}$  equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** --  $D_{min}$  equals  $P - 1$ , where  $P$  is the value you specify in **Interpolation filter half-length (P)**.  $D_{max}$  equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **Farrow** --  $D_{min}$  equals  $N/2 - 1$ , where  $N$  is the value you specify in **Farrow filter length (N)**.  $D_{max}$  equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.

Example: [1 100]

Example: [2 100]

Example: [3 100]

### Fixed-Point Properties

#### Fixed-Point Properties

**Rounding mode** — Rounding method for fixed-point operations

Zero (default) | Ceiling | Convergent | Floor | Nearest | Round | Simplest

Specify the rounding mode for fixed-point operations as one of the following:

- Zero
- Ceiling

- Convergent
- Floor
- Nearest
- Round
- Simplest

For more details, see rounding mode.

**Saturate on integer overflow** — Method of overflow action  
off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Coefficients** — Data type of the coefficients  
Same word length as input (default) | Specify word length

Specify the data type of the filter coefficients as one of the following:

- `Same word length as input` -- The word length of the filter coefficients matches that of the input to the block. The fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- `Specify word length` -- Specify the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

For more information on the coefficients data type this block uses, see the “Fixed Point” on page 2-1531 section.

**Product output** — Data type of the product output  
Same as first input (default) | Binary point scaling

Specify the data type of the product output as one of the following:

- `Same as first input` -- The block specifies the product output data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the product output, in bits.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 2-1531 section.

**Accumulator** — Data type of accumulation operation  
Same as product output (default) | Same as first input | Binary point scaling

Specify the data type of an accumulation operation as one of the following:

- `Same as product output` -- The block specifies the accumulator data type to be the same as that of the product output data type.

- `Same as first input` -- The block specifies the accumulator data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator output, in bits.

For more information on the accumulator data type this block uses, see the “Fixed Point” on page 2-1531.

**Product output polyval** — Data type of the product polynomial value

`Same as first input (default) | Binary point scaling`

Specify the data type of the product polynomial value as one of the following:

- `Same as first input` -- The block specifies the product polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the product output polynomial, in bits.

For more information on the product polynomial value data type this block uses, see the “Fixed Point” on page 2-1531 section.

#### Dependencies

This property applies when you set **Interpolation mode** to Farrow.

**Accumulator polyval** — Data type of the accumulator polynomial value

`Same as first input (default) | Binary point scaling`

Specify the data type of the accumulator polynomial value as one of the following:

- `Same as first input` -- The block specifies the accumulator polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator polynomial value, in bits.

For more information on the accumulator polynomial value data type that this block uses, see the “Fixed Point” on page 2-1531 section.

#### Dependencies

This property applies when you set **Interpolation mode** to Farrow.

**Multiplicand polyval** — Data type of multiplicand polynomial value

`Same as first input (default) | Binary point scaling`

Specify the data type of the multiplicand polynomial value as one of the following:

- `Same as first input` -- The block specifies the multiplicand polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the multiplicand polynomial value, in bits.

For more information on the multiplicand polynomial value data type this block uses, see the “Fixed Point” on page 2-1531 section.

### Dependencies

This property applies when you set **Interpolation mode** to Farrow.

**Output** — Data type of block output

Same as accumulator (default) | Same as first input | Binary point scaling

Specify the data type of the block output as one of the following:

- `Same as accumulator` -- The block specifies the output data type to be the same as that of the accumulator output data type.
- `Same as first input` -- The block specifies the output data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the block output, in bits.

For more information on the output data type this block uses, see the “Fixed Point” on page 2-1531 section.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

### Block Characteristics

|                                 |   |
|---------------------------------|---|
| <b>Data Types</b>               | double   fixed point   integer   single |
| <b>Direct Feedthrough</b>       | no                                      |
| <b>Multidimensional Signals</b> | no                                      |
| <b>Variable-Size Signals</b>    | yes                                     |
| <b>Zero-Crossing Detection</b>  | no                                      |

### Algorithms

The delay value specified at the **Delay** port serves as an index into the block's memory,  $U$ , which stores, at a minimum, the  $D_{\max}+1$  most recent samples received at the **In** port for each channel. For example, an integer delay of 5 on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory,  $U(6)$ . The block computes fractional delays by interpolating between stored samples. The block uses a linear, FIR, or farrow interpolation method to interpolate signal values at noninteger sample intervals.

#### Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector,  $y$ , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- $i$  -- Index of the current sample
- $v$  -- Fractional delay
- $v_i$  -- Integer part of the delay
- $v_f$  -- Fractional part of the delay
- $U$  -- Input data vector
- $y$  -- Output data vector
- $U(i - v_i)$ ,  $U(i - v_i - 1)$  -- Two samples in memory nearest to the specified delay
- $i - v_i$  -- Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the  $D_{max} + 1$  most recent samples received at the input for each channel, where  $D_{max}$  is the maximum delay specified.  $U$  represents the stored samples.

### FIR Interpolation Mode

In the FIR interpolation mode, the block stores the  $D_{max} + P + 1$  most recent samples received at the input for each channel, where  $P$  is the specified interpolation filter half-length.

In this mode, the block provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P - 1, \quad i = 0, 1, \dots, L - 1$$

If  $v$  is less than  $P - 1$ , the behavior depends on the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than  $P - 1$ ), by setting the **For small input delay values** parameter:

- **Clip to the minimum value necessary for centered kernel** -- The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- **Switch to linear interpolation if kernel cannot be centered** -- Fractional delays are computed using linear interpolation when the input delay value is less than  $P - 1$ .

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the  $L$  filter arms of the polyphase structure is  $2P$ . In most cases, using values of  $P$  between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length ( $P$ ) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length ( $P$ ) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample ( $L$ ) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above  $F_s/4$ , you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

---

**Note** You can consider each of the  $L$  interpolation filters to correspond to one output phase of an upsample-by- $L$  FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

---

### Farrow Interpolation Mode

In the farrow interpolation mode, the block stores the  $D_{max}+N/2+1$  most recent samples received at the input for each channel, where  $N$  is the specified farrow filter length.

The algorithm uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the behavior when the input delay value is too small to center the kernel (less than  $\frac{N}{2} - 1$ ), use the Farrow small delay action setting.

- **Clip to the minimum value necessary for centered kernel** -- The block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases  $D_{min}$  but yields more accurate interpolation values.
- **Use off-centered kernel** -- The fractional delays are computed using a Farrow filter with an off-centered kernel. This mode does not increase  $D_{min}$ , but the results for input delay values less than  $\frac{N}{2} - 1$  are less accurate than the results achieved by keeping the kernel centered.

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the Variable Fractional Delay for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the block and cannot be directly specified on the block dialog box.

| Data Type             | Word Length                               | Fraction Length         |
|-----------------------|---|-------------------------|
| vf data type          | Same word length as the coefficients      | Same as the word length |
| HoldInteger data type | Same word length as the input delay value | 0 bits                  |
| Integer data type     | 32 bits                                   | 0 bits                  |

**Note** When the input is fixed point, all internal data types are signed fixed point.

To compute the integer ( $v_i$ ) and fractional ( $v_f$ ) parts of the input delay value ( $v$ ), the Variable Fractional Delay block uses the following equations:

$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - v_i \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

### Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the Variable Fractional Delay block.

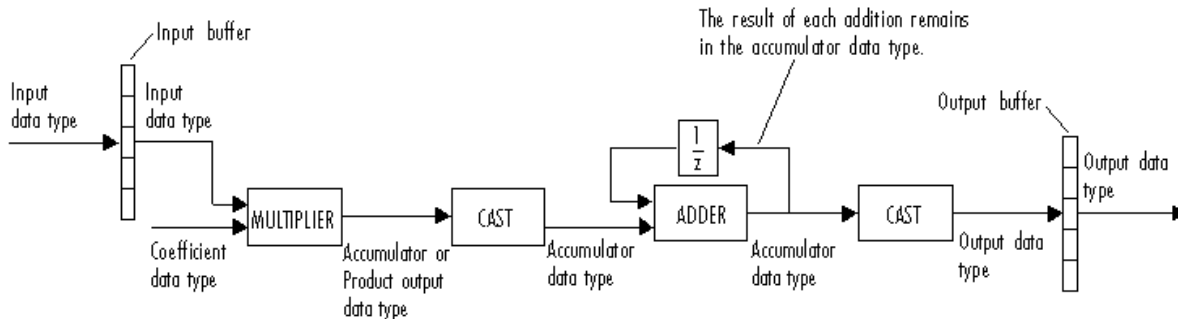

### FIR Interpolation Mode

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value ( $v_f$ ).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

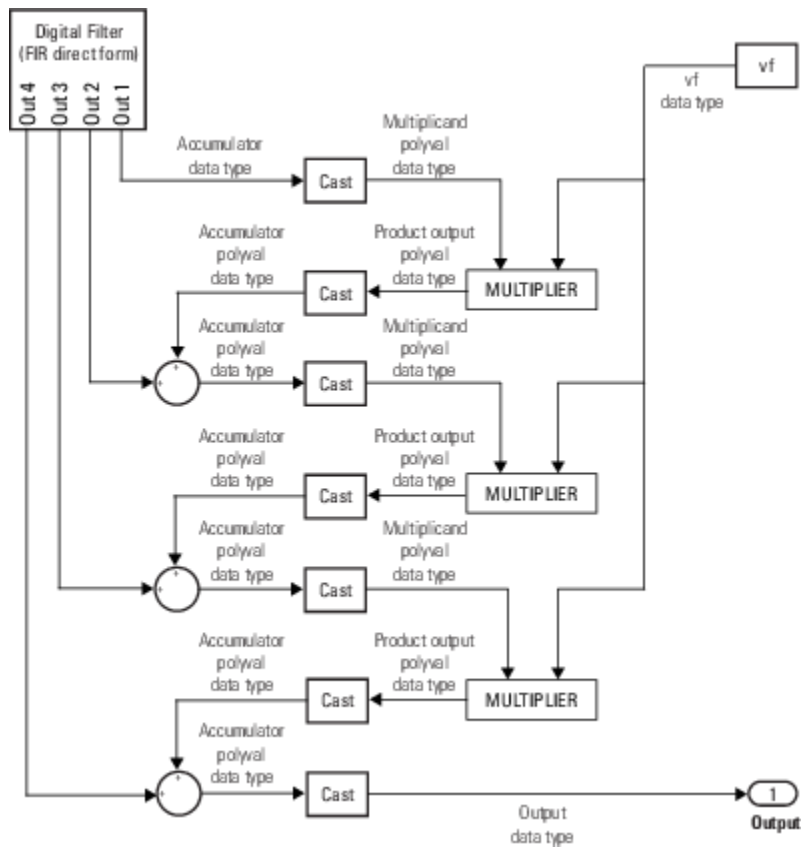

You can set the coefficient, product output, accumulator, and output data types in the block. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

### Farrow Interpolation Mode

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to Clip to the minimum value necessary for centered kernel

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4.
- Farrow small delay action is set to Use off-centered kernel.

Diff is computed from the integer part of the delay value ( $v_i$ ) and the farrow filter length ( $N$ ) according to the following equation:

$$Diff = v_i - \left(\frac{N - 1}{2}\right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = - Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter's FIR direct form filter.

## Variable Integer Delay (Obsolete)

Delay input by time-varying integer number of sample periods

### Library

dspobslib

### Description

---

**Note** The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See “Functionality being removed or replaced for blocks and System objects”.

---

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to **Elements as channels (sample based)**, the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to **Columns as channels (frame based)**, the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to  $D$ , where  $D$  is the **Maximum delay**. Delay values greater than  $D$  or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

| Variable Integer Delay Block   | Delay Block   |
|--|---|
| The delay is provided as an input to the Delay port.   | You specify the delay as a parameter setting in the dialog box.   |
| Delay can vary with time; for example, when the block performs frame-based processing, the $n$ th element's delay in the first input frame can differ from the $n$ th element's delay in the second input frame. | Delay cannot vary with time; for example, when the block performs frame-based processing, the $n$ th element's delay is the same for every input frame. |

| Variable Integer Delay Block  | Delay Block   |
|---|---|
| When you use the Variable Integer Delay block in a feedback loop, you must check the <b>Disable direct feedthrough by increasing minimum possible delay by one</b> check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero. | You can use the Delay block to break an algebraic loop. |

### Sample-Based Processing

When you set the **Input processing** parameter to **Elements as channels (sample based)**, the Variable Integer Delay block supports N-D input arrays. When the input is an  $M$ -by- $N$ -by- $P$  array, the block treats each of the  $M*N*P$  elements as independent channels, and applies the delay at the Delay port to each channel.

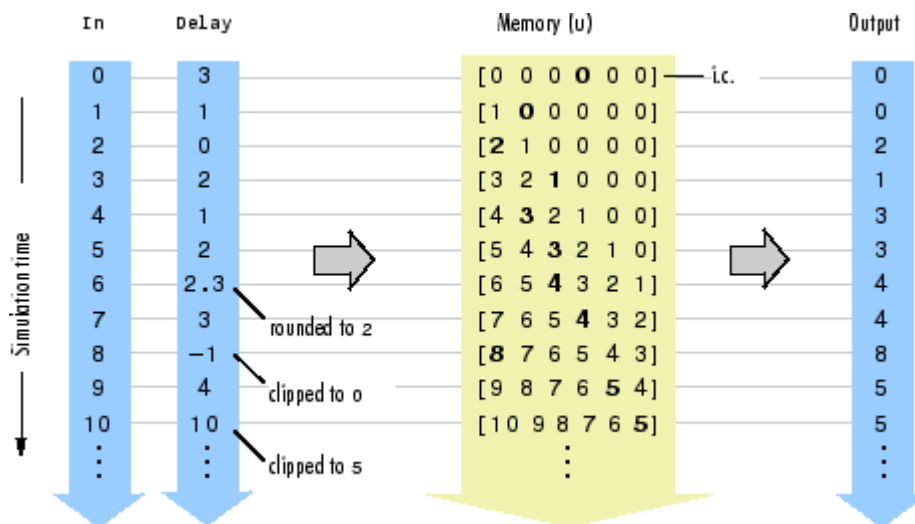

The Variable Integer Delay block stores the  $D+1$  most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

For example, when the input to the In port,  $u$ , is a scalar signal, the block stores a vector,  $U$ , of the  $D+1$  most recent signal samples. When the current input sample is  $U(1)$ , the previous input sample is  $U(2)$ , and so on, then the block's output is

```
y = U(v+1); % Equivalent MATLAB code
```

where  $v$  is the input to the Delay port. A delay value of 0 ( $v=0$ ) causes the block to pass through the sample at the In port in the same simulation step that it is received. The block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.

The current input at each time step is immediately stored in memory as  $U(1)$ . This allows the current input to be available at the output for a delay of 0 ( $v=0$ ).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

### Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of  $D$  samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general  $M$ -by- $N$  input and the parameter settings in this figure,

the block initializes 100  $M$ -by- $N$  matrices in memory with zeros.

- Array of size  $M$ -by- $N$ -by- $D$ . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1538 below for details.

### Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of  $D$  samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing  $D$  elements with which to initialize memory samples  $U(2:D+1)$ , where  $D$  is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes  $U(2:6)$  with values  $[-1, -1, -1, 0, 1]$ .

- Array of dimension  $M$ -by- $N$ -by- $D$  with which to initialize memory samples  $U(2:D+1)$ , where  $D$  is the **Maximum delay** and  $M$  and  $N$  are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations  $U(2:5)$  with values

$$\mathbf{U}(2) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad \mathbf{U}(3) = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix}, \quad \mathbf{U}(4) = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix}, \quad \mathbf{U}(5) = \begin{bmatrix} 4 & 4 & 4 \\ 4 & 4 & 4 \end{bmatrix}$$

An  $M$ -by- $N$ -by- $P$ -by- $D$  array can be entered for the **Initial Conditions** parameter when the input is an  $M$ -by- $N$ -by- $P$  array. The  $(M,N,P,T)$ th sample of the **Initial Conditions** matrix provides the initial condition value for the  $(M,N,P)$ th channel of the input matrix at delay =  $D-t+1$  samples.

### Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the input can be an  $M$ -by- $N$  matrix. The block treats each of the  $N$  input columns as independent channels containing  $M$  sequential time samples.

In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- $M$  column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length- $N$  row vector, containing one delay for each channel. Finally, the Delay port entry can be an  $M$ -by- $N$  matrix, containing a different delay for each corresponding element of the input.

Vector  $v$  does not specify when the samples in the current input frame will appear in the output. Rather,  $v$  indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample  $v(1)$  intervals earlier in the sequence, the second sample in the current output frame is the input sample  $v(2)$  intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** ( $D_{max}$ ) is 5, and the **Initial conditions** parameter is set to -1. The delay input changes from  $[1 \ 3 \ 0 \ 5]$  to  $[2 \ 0 \ 0 \ 2]$  after the second input frame. The samples in each output frame are the values in memory indexed by the elements of  $v$ :

$$\begin{aligned} y(1) &= U(v(1)+1) \\ y(2) &= U(v(2)+1) \\ y(3) &= U(v(3)+1) \\ y(4) &= U(v(4)+1) \end{aligned}$$

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

### Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of  $D$  samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general  $M$ -by- $N$  input with the parameter settings below, the block initializes five samples in memory with zeros.

|                          |   |
|--------------------------|---|
| Maximum delay (samples): | 5 |
| Initial conditions:      | 0 |

- Array of size 1-by- $N$ -by- $D$ . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1540 below for details.

### Time-Varying Initial Conditions

The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of  $D$  samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing  $D$  elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input  $[1:100; 1:100]'$  with a

frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

- Array of size 1-by- $N$ -by- $D$ . In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

By specifying a 1-by- $N$ -by- $D$  initial condition array such that each 1-by- $N$  vector entry is identical, you can implement different fixed initial conditions for each channel.

## Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

## Parameters

### Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

### Initial conditions

The values with which the block's memory is initialized.

### Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

---

**Note** The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

---

### Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by *frame size* - 1. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

## Supported Data Types

| Port  | Supported Data Types   |
|-------|--|
| In    | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |
| Delay | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul>   |
| Out   | <ul style="list-style-type: none"> <li>• Double-precision floating point</li> <li>• Single-precision floating point</li> <li>• Fixed point (signed and unsigned)</li> <li>• Boolean</li> <li>• 8-, 16-, and 32-bit signed integers</li> <li>• 8-, 16-, and 32-bit unsigned integers</li> </ul> |

# Variable Selector

Select subset of rows or columns from input

## Libraries:

DSP System Toolbox / Signal Management / Indexing

DSP System Toolbox HDL Support / Signal Management

## Description

The Variable Selector block extracts a subset of rows or columns from the  $M$ -by- $N$  input matrix  $u$  at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When an element of the indexing vector references a nonexistent row or column of the input, the block implements the action that you specify by using the **Invalid index** parameter.

When the indexing vector elements are of the Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

---

**Note** The Variable Selector block always copies the selected input rows or columns to a contiguous block of memory (unlike the Simulink Selector block).

---

## Ports

### Input

**In $N$**  —  $N$ th input signal

scalar | vector | matrix

$N$ th input signal, where  $N$  is the number of inputs specified in the “Number of input signals” on page 2-0 parameter.

When the input is an unoriented vector, the “Select” on page 2-0 parameter is ignored and the output is an unoriented vector of length  $L$  containing those elements specified by the length- $L$  indexing vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

**Idx** — Index vector

scalar | vector

Specify a scalar value or vector containing the indices of the input rows or columns that appear in the output matrix.

**Dependencies**

This port appears only when you set the “Selector mode” on page 2-0 to **Variable**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

**Output**

**OutN** — *N*th Output signal

`scalar` | `vector` | `matrix`

*N*th output signal, corresponding to the *N*th input signal, where *N* is the number of inputs specified in the “Number of input signals” on page 2-0 parameter. The output is returned as a scalar, vector, or matrix as the same type, size, and complexity as the corresponding input.

For variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:) % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx) % Equivalent MATLAB code
```

where `idx` is the length-*L* indexing vector. The row selection output size is *L*-by-*N* and the column selection output size is *M*-by-*L*. Input rows or columns can appear any number of times in the output, or not at all.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

**Parameters**

**Number of input signals** — Number of inputs

1 (default) | positive integer

Specify the number of input signals as a positive integer. An input port is created on the block for each input signal.

**Select** — Select dimension

`Rows` (default) | `Columns`

Specify the dimension of the input to select, `Rows` or `Columns`.

When **Select** is set to:

- `Rows` -- The block extracts rows from each input matrix.
- `Columns` -- The block extracts columns from each input matrix.

When the input is an unoriented vector, the **Select** parameter is ignored. The output is an unoriented vector of length *L* containing those elements specified by the length-*L* indexing vector.

**Selector mode** — Indexing mode

`Variable` (default) | `Fixed`

Specify the type of indexing operation to perform, **Variable** or **Fixed**.

When **Selector mode** is set to:

- **Variable** -- The length- $L$  vector input to the “Idx” on page 2-0 port selects  $L$  rows or columns of each input to pass through to the output. You can update the elements of the indexing vector at each sample time, but the vector length must remain the same throughout the simulation.
- **Fixed** -- The **Idx** port is disabled. The length- $L$  vector that you specified in the “Elements” on page 2-0 parameter selects  $L$  rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation but the vector length must remain the same.

**Elements** — Selected elements

[1 3] (default) | scalar | vector

Specify a vector containing the indices of the input rows or columns that appear in the output matrix.

**Tunable:** Yes

**Dependencies**

This parameter appears only when you set the “Selector mode” on page 2-0 to **Fixed**.

**Index mode** — Index mode

Zero-based (default) | One-based

When set to **One-based**, an index value of 1 refers to the first row or column of the input. When set to **Zero-based**, an index value of 0 refers to the first row or column of the input.

**Invalid index** — Error handling

Clip Index (default) | Clip and Warn | Generate Error

Specify how the block handles an invalid index value. You can select one of these options:

- **Clip index** — Clip the index to the nearest valid value and do not issue an alert.

For example, if the block receives a 64-by-4 input and the “Select” on page 2-0 parameter is set to:

- **Rows** -- The block clips an index of 72 to 64.
- **Columns** -- The block clips an index of 72 to 4.

In both cases, the block clips an index of -2 to 1.

- **Clip and warn** — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- **Generate error** — Display an error dialog box and terminate the simulation.

**Tunable:** Yes

**Fill empty spaces in outputs (for logical indexing)** — Fill in empty spaces in outputs  
on (default) | off

When the indexing vector elements are of a Boolean data type, the block performs logical indexing. Logical indexing can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the “Fill values” on page 2-0 parameter.

**Fill values** — Fill values  
0 (default) | scalar value | integer

Specify the fill values when the block performs logical indexing.

#### Dependencies

This parameter appears only when you select the “Fill empty spaces in outputs (for logical indexing)” on page 2-0 parameter.

### Block Characteristics

### Version History

Introduced before R2006a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the memcpy or memset function (string.h) under certain conditions.

#### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

#### HDL Architecture

This block has one default HDL architecture.

**HDL Block Properties**

|                                  |  |
|----------------------------------|--|
| <b>ConstrainedOutputPipeline</b> | Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder). |
| <b>InputPipeline</b>             | Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).                 |
| <b>OutputPipeline</b>            | Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).               |

**Complex Data Support**

This block supports code generation for complex signals.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

# Variance

Variance of input or sequence of inputs

**Libraries:**  
DSP System Toolbox / Statistics

## Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

---

**Note** The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the Moving Variance block instead.

---

## Ports

### Input

**In** — Data input  
vector | matrix |  $N$ -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

**Rst** — Reset port  
scalar

Specify the event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

### Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than **None**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

### Output

**Port\_1** — Variance along the specified dimension  
scalar | vector | matrix |  $N$ -D array

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array  $y$  is the variance of the corresponding column, row, or entire input. The output array  $y$  depends on the setting of the **Find the variance value over** parameter.

Consider a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ . When you set **Find the variance value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the variance of the  $M$ -by- $N$ -by- $P$  input matrix.
- **Each row** — The output at each sample time consists of an  $M$ -by-1-by- $P$  array, where each element contains the variance of each vector over the second dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is an  $M$ -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- $N$ -by- $P$  array, where each element contains the variance of each vector over the first dimension of the input. For an  $M$ -by- $N$  matrix input, the output at each sample time is a 1-by- $N$  row vector.

In this mode, the block treats length- $M$  unoriented vector inputs as  $M$ -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an  $M$ -by- $N$  matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set **Input processing** to:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the variance of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running variance  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the variance of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

The data type of the output matches the data type of the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

## Parameters

### Main Tab

**Running variance** — Option to select running variance  
off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

**Find the variance value over** — Dimension over which variance is computed  
Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the variance over each column.
- **Each row** — The block outputs the variance over each row.
- **Entire input** — The block outputs the variance over the entire input.
- **Specified dimension** — The block outputs the variance over the dimension specified in the **Dimension** parameter.

### Dependencies

To enable this parameter, clear the **Running variance** parameter.

**Dimension** — Custom dimension  
1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

### Dependencies

To enable this parameter, set **Find the variance value over** to **Specified dimension**.

**Input processing** — Method to process the input in running mode  
Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size  $M$ -by- $N$ , the block outputs an  $M$ -by- $N$  matrix. Each element  $y_{ij}$  of the output contains the variance of the elements in the  $j$ th column of all inputs since the last reset, up to and including the element  $u_{ij}$  of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size  $M$ -by- $N$ -by- $P$ , the block outputs an  $M$ -by- $N$ -by- $P$  array. Each element  $y_{ijk}$  of the output contains the variance of the element  $u_{ijk}$  for all inputs since the last reset.

When a reset event occurs, the running variance  $y_{ijk}$  in the current frame is reset to the element  $u_{ijk}$ .

### Variable-Size Inputs

When your inputs are of variable size, and you select the **Running variance** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
  - When the input size difference is in the number of channels (number of columns), the state is reset.
  - When the input size difference is in the length of channels (number of rows), the state is not reset, and the running operation is carried out as usual.

### Dependencies

To enable this parameter, select the **Running variance** parameter.

### Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to **Elements as channels (sample based)**, the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to **Columns as channels (frame based)**, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

---

**Note** When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

---

### Dependencies

To enable this parameter, select the **Running variance** parameter.

### Data Types Tab

---

**Note** To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

---

### Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

### Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Input-squared product output** — Data type of the input-squared termSame as `input` (default) | Binary point scaling

The squares of the input elements are stored in the **Input-squared product output** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see “Fixed Point” on page 2-1555.

You can set this parameter to:

- `Inherit`: Same as `input` — The data type is same as the input data type.
- `Binary point scaling` — The **Input-squared product output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

**Input-sum-squared product** — Data type of the input-sum-squared termSame as `input-squared product` (default) | Binary point scaling

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2-1555.

You can set this parameter to:

- `Same as input-squared product` — The data type is the same as the input squared-product data type.
- `Binary point scaling` — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

**Accumulator** — Accumulator data typeSame as `input-squared product` (default) | Same as `input` | Binary point scaling

**Accumulator** specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2-1555 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- `Same as input-squared product` — The accumulator data type is the same as the input-squared product data type.
- `Same as input` — The accumulator data type is the same as the input data type.
- `Binary point scaling` — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

**Output** — Output data typeSame as `input-squared product` (default) | Same as `accumulator` | Same as `input` | Binary point scaling

**Output** specifies the data type of the output of the Variance block. See “Fixed Point” on page 2-1555 for information about the use of the output data type in this block. You can set it to:

- Same as `input-squared product` — The output data type is the same as the input-squared product data type.
- Same as `accumulator` — The output data type is the same as the accumulator data type.
- Same as `input` — The output data type is the same as the input data type.
- `Binary point scaling` — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

## Block Characteristics

|                                 |   |

## More About

### Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal. Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input,  $u$ , of size  $M$ -by- $N$ , the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

where,

- $u_{ij}$  is the input data element at indices  $i, j$ .
- $M$  is the length of the  $j$ th column.
- $N$  is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

where,

- $\sigma_{\text{Re}}^2$  is the variance of the real part of the complex input.
- $\sigma_{\text{Im}}^2$  is the variance of the imaginary part of the complex input.

## Algorithms

### Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function when it is called as `y = var(u,theta,D)`, where,

- `u` is the data input.
- `D` is the dimension.
- `y` is the variance along the specified dimension.

When this block calculates the variance along the entire input, the result is identical to calling the `var` function as `y = var(u(:))`.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For purely real or imaginary input  $u$  of size  $M$ -by- $N$ , the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

# Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value

## Library

Quantizers

dspquant2

## Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a  $k$ -by- $N$  matrix of values, where  $k \geq 1$  and  $N \geq 1$ . Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where  $0 \leq \text{index} < N$  and  $N$  is the number of columns of the codebook matrix. Use the **Action for out of range index value** parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to  $N$  to be set to  $N-1$ , select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to  $N$  are set to  $N-1$ , select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

## Data Type Support

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port,

the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be Same as input, double, single, Fixed-point, User-defined, or Inherit via back propagation.

## Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.

### Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where  $0 \leq \text{index} < N$  and  $N$  is the length of the codebook vector. Select **Clip** when you want any index values less than 0 to be set to 0 and any index values greater than or equal to  $N$  to be set to  $N-1$ . Select **Clip and warn** when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to  $N$  are set to  $N-1$ . Select **Error** when you want the simulation to stop and display an error when the index values are out of range.

### Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook values using the block's input port, C.

### Codebook values

Enter a  $k$ -by- $N$  matrix of quantized output values, where  $1 \leq k$  and  $1 \leq N$ . Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select **Specify via dialog**.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.

### Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

### Codebook and Output Data Type Assistant Parameters

#### Mode

Select how you would like to specify the data type properties of the **Codebook and output data type**. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Same as input`
- **Built in**— Lets you specify a built in data type, for example, `double`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

**Signedness**

Specify the **Signedness** for the **Codebook and output data type**.

**Scaling**

Specify the **Scaling** for the **Codebook and output data type**.

For more information see “Scaling” in the DSP System Toolbox User's Guide.

**Word length**

Specify the **Word length** for the **Codebook and output data type**.

**Fraction length**

Specify the **Fraction length** for the **Codebook and output data type**.

**Data type override**

Specify the data type override mode. You can select one of the following options:

- **Inherit** — Inherits the data type override setting specified for the model.
- **Off** — Ignores the data type override setting specified for the model and uses the fixed-point data type you specify

This parameter appears only when you set the **Mode** parameter to **Built in** or **Fixed Point**. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

## Vector Quantizer Design

(Removed) Design vector quantizer using Vector Quantizer Design Tool (VQDTool)

---

**Note** The Vector Quantizer Design block has been removed.

---

### Library

Quantizers

dspquant2

### Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdtool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a  $k$ -by- $M$  matrix of values you want to use to train the quantizer codebook. The variable  $k$ , where  $k \geq 1$ , is the length of each training vector. It also represents the dimension of your quantizer. The variable  $M$ , where  $M \geq 2$ , is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook. In this case, the block picks  $N$  random training vectors as the initial codebook, where  $N$  is the **Number of levels** parameter and  $N \geq 2$ . When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select **Squared error** for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook  $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$ . This codebook has  $N$  codewords; each codeword has  $k$  elements. The  $i$ -th codeword is defined as  $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$ . The training set has  $M$  columns and is defined as  $U = [U_1 \ U_2 \ \dots \ U_M]$ , where the  $p$ -th training vector is  $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]'$ . The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

When you select **Weighted squared error** for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the  $p$ -th column of the training vector,  $U_p$ , is defined as  $W_p = [w_{1p} \ w_{2p} \ \dots \ w_{kp}]'$ , then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^k w_{jp}(a_{ji} - u_{jp})^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are **Relative threshold** and **Maximum iteration**. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select **Relative threshold**. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose **Maximum iteration**. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose **Whichever comes first** and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select **Lower indexed codeword**. To associate the training vector with the higher indexed codeword, select **Higher indexed codeword**.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

---

**Note** If, for the **Distortion measure** parameter, you choose **Squared error**, the **Codebook update method** parameter is set to **Mean**.

---

If, for the **Distortion measure** parameter, you choose **Weighted squared error** and you choose **Mean** for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}, TS_3 = \begin{bmatrix} 10 \\ 12 \end{bmatrix}, \text{ and } TS_7 = \begin{bmatrix} 11 \\ 12 \end{bmatrix}.$$

The new codeword vector is calculated as  $CW_{new} = \begin{bmatrix} \frac{1 + 10 + 11}{3} \\ \frac{2 + 12 + 12}{3} \end{bmatrix}$

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose **Centroid** and you specify the weighting factors

$$W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}, W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}, \text{ and } W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}, \text{ the new codeword vector is calculated as}$$

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1) + (1)(10) + (0.3)(11)}{0.1 + 1 + 0.3} \\ \frac{(0.2)(2) + (0.6)(12) + (0.4)(12)}{0.2 + 0.6 + 0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

---

**Note** You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

---

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the  $i$ -th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is associated with the first codeword is  $\frac{40}{200}$ . The probabilities that training vectors are associated with the second, third, and fourth codewords are  $\frac{60}{200}$ ,  $\frac{20}{200}$ , and  $\frac{80}{200}$ , respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^N -p_i \log_2 p_i$$

where  $N$  is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the  $i$ -th iteration as

$$H = - \left( \frac{40}{200} \log_2 \frac{40}{200} + \frac{60}{200} \log_2 \frac{60}{200} + \frac{20}{200} \log_2 \frac{20}{200} + \frac{80}{200} \log_2 \frac{80}{200} \right)$$

$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select **Current model** to create a block with your parameters in

the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

## Parameters

### Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is  $1e5$ .

### Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Choose `User defined` to enter your own initial codebook values.

### Number of levels

Enter the number of codeword vectors,  $N$ , in your codebook matrix, where  $N \geq 2$ .

### Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

### Distortion measure

When you select `Squared error`, the block finds the nearest codeword by calculating the squared error (unweighted). When you select `Weighted squared error`, the block finds the nearest codeword by calculating the weighted squared error.

### Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

### Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

**Relative threshold**

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

**Maximum iteration**

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

**Tie-breaking rules**

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the higher indexed codeword.

**Codebook update method**

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector. Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

**Destination**

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

**Block type**

Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

**Encoder block name**

Enter a name for the Vector Quantizer Encoder block.

**Decoder block name**

Enter a name for the Vector Quantizer Decoder block.

**Overwrite target block**

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

**Generate Model**

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

**Design and Plot**

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

### Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

### Supported Data Types

- Double-precision floating point

## Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure

## Library

Quantizers

dspquant2

## Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook,  $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$ . This codebook has  $N$  codewords; each codeword has  $k$  elements. The  $i$ -th codeword is defined as a column vector,  $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$ . The multichannel input has  $M$  columns and is defined as  $U = [U_1 \ U_2 \ \dots \ U_M]$ , where the  $p$ -th input column vector is  $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]$ . The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

where the weighting factor is defined as  $W = [w_1 \ w_2 \ \dots \ w_k]$ . The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an  $k$ -by- $N$  matrix of values, where  $k \geq 1$  and  $N \geq 1$ . Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each

codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select **Squared error** when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select **Weighted squared error** when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select **Specify via dialog** to enter a weighting factor vector in the dialog box. Choose **Input port** to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the  $p$ -th input column vector,  $U_p$ , as previously defined. When you want to neglect the effect of the first element of this vector, enter  $[0 \ 1 \ 1 \ \dots \ 1]$  as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select **Choose the lower index**. To represent the input column vector by the higher index valued codeword, select **Choose the higher index**.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1569 or “Supported Data Types” on page 2-1572.

### Data Type Support

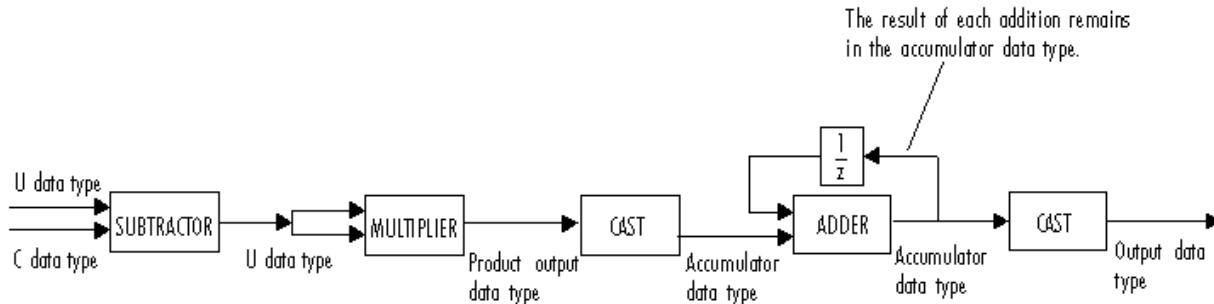

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or `Fixed-point`. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at

port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or `Fixed-point`. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

### Fixed-Point Data Types

The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.

You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

## Dialog Box

### Main Tab

#### Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, `C`.

#### Codebook

Enter a  $k$ -by- $N$  matrix of values, where  $1 \leq k$  and  $1 \leq N$ , to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

#### Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

#### Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port `W` on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

#### Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, `U`. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

**Tie-breaking rule**

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

**Output codeword**

Select this check box to output the codeword vectors nearest to the input column vectors.

**Output quantization error**

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

**Index output data type**

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I. To inherit the index output data type, select `Inherit via back propagation`.

**Data Types Tab****Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

**Overflow mode**

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

**Product output**

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.

## Accumulator

As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

# Waterfall

(To be removed) View vectors of data over time

---

**Note** The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

---

**Libraries:**

DSP System Toolbox / Obsolete Blocks

## Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times.

The data is displayed in 3D in the Waterfall window. By default, the  $x$ -axis represents amplitude, the  $y$ -axis represents samples, and the  $z$ -axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on the displayed data, suspend the data capture, freeze the scope display, save the scope position, and export data to the workspace.

The toolbar buttons are labeled on the Waterfall window as it appears when you double-click a Waterfall block.

## Ports

### Input

**Port\_1** — Signal or signals to visualize  
 scalar | vector | matrix | array

The Waterfall block accepts most numeric data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

### Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box. To open the Parameters dialog box, click the Scope parameters button.

You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box for the block to accept your changes.

## Display

These parameters control the Waterfall display.

**Display traces** — Number of data vectors to display  
6 (default) | positive integer

Number of data vectors to display in the Waterfall window, specified as a positive integer.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** NumTraces

**Type:** positive scalar specified as a character vector

**Update interval** — Number of vectors to store  
1 (default) | positive integer

Number of vectors the block should store before it displays them to the window, specified as a positive integer.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** UpdateInterval

**Type:** positive scalar specified as a character vector

**Colormap** — Colors of display  
autumn (default) | gray | hot | pink | jet | copper | red | white

Colors for the displayed data, specified as a valid colormap.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** CMapStr

**Type:** character vector

**Type:** valid colormap name, see `map`

**Transparency** — Transparency of oldest and newest data vectors  
newest: opaque, oldest: transparent (default)

Transparency of the oldest and newest data vectors, specified with the sliders. The leftmost position makes the data vector transparent. The rightmost position makes the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** TNewest and TOldest

**Type:** number between [0,1] specified as a character vector

## Axes

These parameters control the axes in the Waterfall window.

**Y Min** — Minimum value of y-axis

-1 (default) | integer

Minimum value of the y-axis specified as an integer.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** YMin

**Type:** character vector

**Y Max** — Maximum value of y-axis

1 (default) | integer

Maximum value of the y-axis specified as an integer

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** YMax

**Type:** character vector

**Axis color** — Color of axes

'w' (default) | RGB triplet | specified color name | hexadecimal color code

Color of the axes, specified as a RGB triplet, specified color name, or hexadecimal color code.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ ; for example,  $[0.4 \ 0.6 \ 0.7]$ .
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

| Color Name | Short Name | RGB Triplet | Hexadecimal Color Code | Appearance  |
|------------|------------|-------------|------------------------|---|
| "red"      | "r"        | [1 0 0]     | "#FF0000"              |  |
| "green"    | "g"        | [0 1 0]     | "#00FF00"              |  |
| "blue"     | "b"        | [0 0 1]     | "#0000FF"              |  |
| "cyan"     | "c"        | [0 1 1]     | "#00FFFF"              |  |
| "magenta"  | "m"        | [1 0 1]     | "#FF00FF"              |  |
| "yellow"   | "y"        | [1 1 0]     | "#FFFF00"              |  |
| "black"    | "k"        | [0 0 0]     | "#000000"              |  |
| "white"    | "w"        | [1 1 1]     | "#FFFFFF"              |  |

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

| RGB Triplet            | Hexadecimal Color Code | Appearance  |
|------------------------|------------------------|---|
| [0 0.4470 0.7410]      | "#0072BD"              |  |
| [0.8500 0.3250 0.0980] | "#D95319"              |  |
| [0.9290 0.6940 0.1250] | "#EDB120"              |  |
| [0.4940 0.1840 0.5560] | "#7E2F8E"              |  |
| [0.4660 0.6740 0.1880] | "#77AC30"              |  |
| [0.3010 0.7450 0.9330] | "#4DBEEE"              |  |
| [0.6350 0.0780 0.1840] | "#A2142F"              |  |

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `AxisColor`

**Type:** character vector within a character vector

**Example:** `set_param(block, 'AxisColor', char('b'))`

**X Axis** — x-axis label

`Samples (default) | string`

Enter the x-axis label.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `XLabel`

**Type:** character vector

**Y Axis** — y-axis label

`Amplitude (default) | string`

Enter the y-axis label.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `YLabel`

**Type:** character vector

**Z Axis** — z-axis label

`Time (default) | string`

Enter the z-axis label.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `ZLabel`

**Type:** character vector

### Data History

These parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace.

**History traces** — Number of vectors to store  
10 (default) | positive integer

Number of vectors (traces) that you want the block to store, specified as a positive integer.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `HistoryLength`

**Type:** positive integer specified as a character vector

**When the buffer is full** — Behavior of full buffer  
`Overwrite` (default) | `Suspend` | `Extend`

Use this parameter to control the behavior of the block when the buffer is full:

- `Overwrite` — The old data is replaced with the new data.
- `Suspend` — The block stops storing data in the buffer; but the simulation continues to run.
- `Extend` — The block extends the buffer so that it can continue to store all the input data.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `HistoryFull`

**Type:** character vector

**Data logging** — Export data from block  
`Selected` (default) | `All visible` | `All history`

Use this parameter to control which data is exported from the block:

- `Selected` — The selected data vector is exported.
- `All visible` — All of the data vectors displayed in the Waterfall window are exported.
- `All history` — All of the data vectors stored in the history buffer of the block are exported.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `ExportMode`

**Type:** character vector

**Export variable** — Variable name of exported data  
`ExportData` (default) | valid MATLAB variable name

Name of the variable that represents your data in the MATLAB workspace.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `MLExportName`

**Type:** character vector

**Export at end of simulation** — Automatically export data  
`off` (default) | `on`

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `AutoExport`

**Values:** 'off' | 'on'

### Triggering

These parameters control when the Waterfall block starts and stops capturing data.

#### Begin recording — When to start capturing data

Immediately (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block starts capturing data:

- **Immediately** — The Waterfall window captures the input data as soon as the simulation starts.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function”.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `TrigStartMode` | `TrigStartT` | `TrigStartN` | `TrigStartFcn`

**Type:** character vector

#### Stop recording — When to stop capturing data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block stops capturing data:

- **Never** — The block captures the input data as long as the simulation is running.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function”.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** `TrigStopMode` | `TrigStopT` | `TrigStopN` | `TrigStopFcn`

**Type:** character vector

**Re-arm trigger** — When to capture data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block begins waiting to capture data.

- **Never** — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function”.

**Dependency**

To enable this parameter, set **Stop recording** to After T seconds, After N inputs, or User-defined.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** TrigRearmMode | TrigRearmT | TrigRearmN | TrigRearmFcn

**Type:** character vector

**Transform**

These parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.

The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose **Complex-> Angle**, the block assumes that the input is complex. But the block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

**Transform** — Transformation to apply to input

None (default) | Amplitude-&gt; dB | Complex-&gt; Mag Lin | Complex-&gt; Mag dB | ...

Choose a transform that you would like to apply to the input of the Waterfall block:

- **None** — The input is displayed as it is received by the block.
- **Amplitude-> dB** — The block converts the input amplitude into decibels.
- **Complex-> Mag Lin** — The block converts the complex input into linear magnitude.
- **Complex-> Mag dB** — The block converts the complex input into magnitude in decibels.
- **Complex-> Angle** — The block converts the complex input into phase.
- **FFT-> Mag Lin Fs/2** — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.
- **FFT-> Mag dB Fs/2** — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- **FFT-> Angle Fs/2** — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.

- Power -> dB — The block converts the input power into decibels.
- User-defined fcn — see “Function” on page 2-0 .
- User-defined expr — see “Expression” on page 2-0 .

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** XFormMode

**Type:** character vector

**Function** — Custom transformation function

abs (default)

Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function”.

### Dependency

To enable this parameter, set **Transform** to User-defined fcn.

### Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

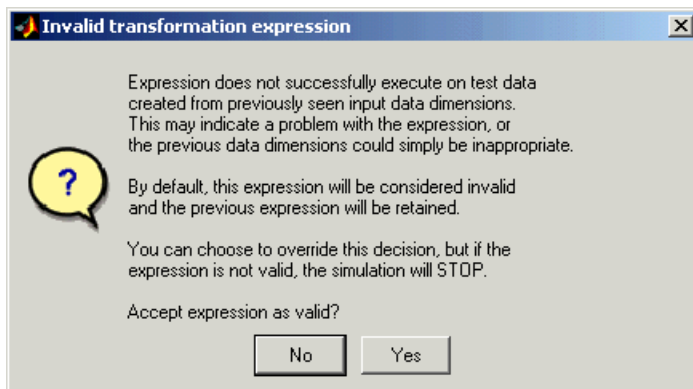

**Block Parameter:** XFormFcn

**Type:** character vector

**Expression** — Custom transformation expression

(u+1)/2 (default) | expression with real-valued output

Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, this window appears.

When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

### Dependency

To enable this parameter, set **Transform** to User-defined expr.

**Programmatic Use**

Control this parameter from the command-line using `set_param` and `get_param`.

**Block Parameter:** XFormExpr

**Type:** character vector

**Block Characteristics**

**Version History**

**Introduced before R2006a**

**R2020b: Waterfall block will be removed**

*Not recommended starting in R2020b*

The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

**Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

**HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

**PLC Code Generation**

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

**Fixed-Point Conversion**

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

# Wavelet Scattering

Model wavelet scattering network in Simulink

## Libraries:

DSP System Toolbox / Feature Extractors

## Description

The Wavelet Scattering block creates a framework for wavelet time scattering in the Simulink environment. Use this block to derive low-variance features from real-valued data and then use those features in machine learning and deep learning applications. The block uses predefined wavelet filters to compute the scalogram and applies an averaging filter to the scalogram for feature extraction. For more information, see “Wavelet Scattering” (Wavelet Toolbox). To perform wavelet scattering in MATLAB, use the `waveletScattering` function.

The Wavelet Scattering block requires Wavelet Toolbox.

## Ports

### Input

**Input** — Input signal

vector | matrix

Specify the input signal as a vector or a matrix. The block treats each column in the matrix as a separate channel. For example, the block treats a 1-by- $N_{chann}$  row vector as  $N_{chann}$  separate channels.

When the input data type is `single`, the block performs internal operations in single-precision. The input data type determines the precision of the scattering decomposition in the filter banks.

The input frame length does not have to match the signal length specified in the block dialog box. The block uses a buffer to feed the wavelet scattering algorithm with frames of length **Signal length (samples)**. If the input frame size does not match the signal length, the block runs in multirate mode.

Data Types: `single` | `double`

### Output

**Output** — Output signal

matrix | 3-D array

Output signal, returned as a matrix or a 3-D array.

For a column vector input, the output dimensions are  $N_{path}$ -by- $N_{scat}$ , where  $N_{path}$  is the number of scattering paths and  $N_{scat}$  is the number of scattering coefficients in each path, or the resolution of the scattering coefficients.

For matrix inputs, the output dimensions are  $N_{path}$ -by- $N_{scat}$ -by- $N_{chann}$ , where  $N_{chann}$  is the number of columns in the input.

Data Types: `single` | `double`

## Parameters

**Signal length (samples)** — Signal length in samples  
1024 (default) | positive integer  $\geq 16$

Specify the signal length in samples as a positive integer  $\geq 16$ .

The input frame length does not have to match the signal length. The block uses a buffer to feed the wavelet scattering algorithm with frames of length **Signal length**. If the input frame size does not match the signal length, the block runs in multirate mode.

Data Types: `double`

**Overlap length (Samples)** — Overlap length in samples  
0 (default) | positive integer

Specify the overlap (in samples) between consecutive frames of a signal as a nonnegative integer.

Data Types: `double`

**Specify sample rate** — Specify sample rate  
off (default) | on

Specify the sample rate on the block dialog using the **Sample rate (Hz)** parameter. If you do not select this check box, the frequencies are in cycles/sample and the Nyquist frequency is  $\frac{1}{2}$ .

Data Types: `Boolean`

**Sample rate (Hz)** — Sample rate  
16e3 (default) | positive scalar

Specify the sample rate in Hz as a positive scalar.

## Dependencies

To enable this parameter, select the **Specify sample rate** parameter.

Data Types: `double`

**Invariance scale (samples)** — Scattering transform invariance scale in samples  
512 (default) | positive integer

Specify the scattering transform invariance scale in samples as a positive integer. Invariance scale specifies the translation invariance of the scattering transform.

If you do not specify the sample rate, invariance scale is measured in samples. If you specify the sample rate, invariance scale is measured in seconds.

Invariance scale cannot exceed the signal length. If signal length is 1000 samples and you do not specify a sample rate, the maximum value of the invariance scale is 1000 samples.

**Dependencies**

To enable this parameter, clear the **Specify sample rate** parameter.

Data Types: double

**Invariance scale (s)** — Scattering transform invariance scale in seconds  
0.032 (default) | positive scalar

Specify the scattering transform invariance scale in samples as a positive scalar. Invariance scale specifies the translation invariance of the scattering transform.

If you do not specify the sample rate, invariance scale is measured in samples. If you specify the sample rate, invariance scale is measured in seconds. By default, invariance scale is one-half the signal length.

Invariance scale cannot exceed the signal length. If signal length is 1000 samples and you specify a sample rate of 200 Hz, then the maximum value of the invariance scale is 5.

**Dependencies**

This parameter appears only when you select the **Specify sample rate** parameter.

Data Types: double

**Quality factors** — Quality factors for scattering filter banks  
[8,1] (default) | positive integer | vector of monotonically decreasing positive integers

Specify the quality factors for the scattering filter banks as a positive integer or a vector of monotonically decreasing positive integers. A filter bank quality factor is the number of wavelet filters per octave. Quality factors cannot exceed 32 and must be greater than or equal to 1.

By default, the wavelet scattering network the block creates has two filter banks. The first filter bank has a quality factor of eight wavelets per octave and the second filter bank has a quality factor of 1 wavelet per octave.

Data Types: double

**Reduce the number of scattering paths** — Optimize scattering transform  
off (default) | on

Specify whether to optimize the scattering transform and reduce the number of scattering paths.

When you select this parameter, the algorithm reduces the number of scattering paths to compute based on a bandwidth consideration. The scattering transform excludes scattering paths of order 2 and greater that do not satisfy this criterion:

The center frequency minus  $\frac{1}{2}$  the 3-dB bandwidth of the wavelet filter in the  $(i+1)^{\text{th}}$  filter bank must overlap 0 (DC) plus  $\frac{1}{2}$  the 3-dB bandwidth of the wavelet filter in the  $i^{\text{th}}$  filter bank.

If this criterion is not satisfied, the higher-order path is excluded. Selecting the **Reduce the number of scattering paths** parameter can significantly reduce the number of scattering paths and computational complexity of the scattering transform for most networks.

Data Types: Boolean

**Oversampling factor** — Oversampling factor  
0 (default) | nonnegative integer | Inf

Specify the oversampling factor as a nonnegative integer or Inf.

The oversampling factor specifies the factor by which the number of scattering coefficients per signal increase on a  $\log_2$  scale. By default, the **Oversampling factor** is set to 0, which corresponds to critically downsampling the coefficients. To obtain a fully undecimated scattering transform, set **Oversampling factor** to Inf.

Setting **Oversampling factor** to a value that results in more coefficients than samples is equivalent to setting **Oversampling factor** to Inf. Increasing the **Oversampling factor** significantly increases the computational complexity and memory requirements of the scattering transform.

If you set **Oversampling factor** to 2, the scattering transform returns  $2^2$  times as many coefficients for each scattering path with respect to the critically sampled number.

Data Types: double

**Boundary signal extension** — Signal extension method  
periodic (default) | reflection

Specify the signal extension method to apply at the boundary as:

- **periodic** — Extend signal periodically to length  $2^{\text{ceil}(\log_2(N))}$ , where  $N$  is the signal length.
- **reflection** — Extend signal by reflection to length  $2^{\text{ceil}(\log_2(2N))}$ , where  $N$  is the signal length.

The signal is extended to match the length of the wavelet filters. The length of the filters are powers of two.

The signal extension method is for internal operations. Results are downsampled back onto the scale of the original signal before being returned.

### Scattering coefficients

**Include zeroth-order coefficients** — Include zeroth-order coefficients  
off (default) | on

Specify whether to include the zeroth-order coefficients.

Data Types: Boolean

**Normalization** — Coefficient normalization  
none (default) | parent

Specify the type of normalization to apply to the scattering coefficients as **none** or **parent**. If specified as **parent**, scattering coefficients of order greater than 0 are normalized by their parents along the scattering path.

**Transform** — Transformation on coefficients  
none (default) | log

Specify the type of transformation to apply to the scattering coefficients as none or log.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Direct Feedthrough</b>       | no              |
| <b>Multidimensional Signals</b> | no              |
| <b>Variable-Size Signals</b>    | no              |
| <b>Zero-Crossing Detection</b>  | no              |

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block does not support code generation if the dynamic memory allocation is off. To turn on the dynamic memory allocation, run this command in the MATLAB command prompt.

```
set_param(gcs, 'MATLABDynamicMemAlloc', 'on')
```

## Window Function

Compute and apply window to input signal

### Libraries:

DSP System Toolbox / Signal Operations

## Description

The Window Function block has three modes of operation that enable you to apply a window, or compute a window, or compute and apply a window to an input signal. You can select the mode via the **Operation** parameter. In each mode, the block first creates a window vector  $w$  by sampling the window specified in the **Window type** parameter.

## Ports

### Input

**In** — Input signal

vector | matrix |  $N$ -D array

Input signal, specified as a vector, matrix, or an  $N$ -D array. When the input is fixed point, it can be signed only.

This port is enabled only when you set **Operation** to either `Apply window to input` or `Generate and apply window`.

This port is unnamed when you set **Operation** to `Apply window to input`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

### Output

**Out** — Output

vector | matrix |  $N$ -D array

Output signal, returned as a vector, matrix, or an  $N$ -D array.

The **Out** port is enabled only when **Operation** is set to:

- **Apply window to input** -- The block computes an  $M$ -by-1 window vector  $w$  and applies it to the  $M$ -by- $N$  input, where  $M$  is the number of rows in the input signal.
- **Generate and apply window** -- The block generates an  $M$ -by-1 window vector  $w$  and applies it to the input.

The output signal has the same dimensions as the input signal. For more details, see “Operation” on page 2-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

**Win** — Window output vector

Window output, returned as a vector. When **Operation** is set to **Apply window to input** or **Generate and apply window**, the window vector is of the same length as the number of rows in the input signal. When **Operation** is set to **Generate window**, the length of window vector is determined by the **Window length** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

## Parameters

### Main

**Operation** — Modes of operation

`Apply window to input (default)` | `Generate window` | `Generate and apply window`

The Window Function block has three modes of operation that you can select through the **Operation** parameter. In each mode, the block first creates a window vector  $w$  by sampling the window specified in the **Window type** parameter at  $M$  discrete points. The operation modes are:

- **Apply window to input**

In this mode, the block computes an  $M$ -by-1 window vector  $w$  and applies it to the input. The output  $y$  always has the same dimension as the input.

When the input is an  $M$ -by- $N$  matrix  $u$ , the window is multiplied element-wise with each of the  $N$  channels in the input matrix  $u$ . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- $M$  unoriented vector input is treated as an  $M$ -by-1 vector.

- **Generate window**

In this mode, the block generates an unoriented window vector  $w$  with length  $M$  specified by the **Window length** parameter. The **In** port is disabled for this mode.

- **Generate and apply window**

In this mode, the block generates an  $M$ -by-1 window vector  $w$  and applies it to the input. The block produces two outputs:

- At the **Out** port, the block produces the result of the multiplication  $y$ , which has the same dimension as the input.
- At the **Win** port, the block produces the  $M$ -by-1 window vector  $w$ .

When the input is an  $M$ -by- $N$  matrix  $u$ , the window is multiplied element-wise with each of the  $N$  channels in the input matrix  $u$ . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- $M$  1-D vector input is treated as an  $M$ -by-1 vector.

#### Window type — Type of window

Hamming (default) | Bartlett | Blackman | ...

This table lists the available window types.

| Window Type | Description  |
|-------------|--|
| Bartlett    | Computes a Bartlett window.<br>$w = \text{bartlett}(M)$  |
| Blackman    | Computes a Blackman window.<br>$w = \text{blackman}(M)$  |
| Boxcar      | Computes a rectangular window.<br>$w = \text{rectwin}(M)$  |
| Chebyshev   | Computes a Chebyshev window with stopband ripple $R$ .<br>$w = \text{chebwin}(M, R)$   |
| Hamming     | Computes a Hamming window.<br>$w = \text{hamming}(M)$  |
| Hann        | Computes a Hann window (also known as a Hanning window).<br>$w = \text{hann}(M)$   |
| Hanning     | Obsolete. This window type is included only for compatibility with older models. Use the Hann <b>Window type</b> instead of Hanning whenever possible. |
| Kaiser      | Computes a Kaiser window with the Kaiser parameter $\beta$ .<br>$w = \text{kaiser}(M, \beta)$  |
| Taylor      | Computes a Taylor window.<br>$w = \text{taylorwin}(M)$   |
| Triang      | Computes a triangular window.<br>$w = \text{triang}(M)$  |

| Window Type  | Description  |
|--------------|--|
| User Defined | <p>Computes the user-defined window function specified by the entry in the <b>Window function name</b> parameter, <code>usrwin</code>.</p> <pre>w = usrwin(M) % Window takes no extra parameters w = usrwin(M,x<sub>1</sub>,...,x<sub>n</sub>) % Window takes extra parameters {x<sub>1</sub> ... x<sub>n</sub>}</pre> |

**Sampling** — Type of sampling  
Symmetric (default) | Periodic

Specify the window sampling for generalized-cosine windows.

For the generalized-cosine windows (Blackman, Hamming, Hann, and Hanning), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length  $M$  is computed as:

```
w = hamming(M) % Symmetric (aperiodic) window
```

When **Sampling** is set to `Periodic`, the same window is computed as:

```
w = hamming(M+1) % Periodic (asymmetric) window
w = w(1:M)
```

Tunable (Simulink) in simulation only.

#### Dependencies

This parameter is visible only when you select Blackman, Hamming, Hann, or Hanning for the **Window type** parameter.

**Sample mode** — Sample mode  
Continuous (default) | Discrete

Specify the sample mode for the block, `Continuous` or `Discrete`, when it is in the `Generate window mode`. In the `Apply window to input` and `Generate and apply window modes`, the block inherits the sample mode from its driving block.

#### Dependencies

This parameter is visible only when you select `Generate window` for the **Operation** parameter.

**Sample time** — Sample time  
1 (default) | real scalar

Specify the sample time for the block when **Operation** is set to `Generate window` and **Sample mode** is set to `Discrete`. When **Operation** is set to `Apply window to input` and `Generate and apply window`, the block inherits the sample time from its driving block.

#### Dependencies

This parameter is visible only when you set **Sample mode** to `Discrete`.

**Window length** — Length of window  
64 (default) | positive integer

Specify the length of the window to apply.

**Dependencies**

This parameter is visible only when you select **Generate window** for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

**Stopband attenuation in dB** — Stopband attenuation in dB  
50 (default) | nonnegative scalar

Specify the level of stopband attenuation  $R_s$  in decibels.

Tunable (Simulink) in simulation only.

**Dependencies**

This parameter is visible only when you select **Chebyshev** for the **Window type** parameter.

**Beta** — Kaiser window  $\beta$  parameter  
10 (default) | real scalar

Specify the **Kaiser** window  $\beta$  parameter. Increasing  $\beta$  widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response.

Tunable (Simulink) in simulation only.

**Dependencies**

This parameter is visible only when you select **Kaiser** for the **Window type** parameter.

**Number of sidelobes** — Number of sidelobes  
4 (default) | positive integer

Specify the number of sidelobes as a scalar integer value greater than zero.

**Dependencies**

This parameter is visible only when you select **Taylor** for the **Window type** parameter.

**Maximum sidelobe level relative to mainlobe (dB)** — Maximum sidelobe level relative to mainlobe  
-30 (default) | scalar less than or equal to zero

Specify in decibels the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of -30 produces sidelobes with peaks 30 dB down from the mainlobe peak.

**Dependencies**

This parameter is visible only when you select Taylor for the **Window type** parameter.

**Window function name** — Window function name

hamming (default) | character vector

Specify the name of the user-defined window function to be calculated by the block. The output window vector returned by the custom window function must be of data type **double**.

**Dependencies**

This parameter is visible only when you select User defined for the **Window type** parameter.

**Specify additional arguments to the hamming function** — Specify additional arguments to the window function

off (default) | on

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length.

**Dependencies**

This parameter is visible only when you select User defined for the **Window type** parameter.

**Cell array of additional arguments** — Additional arguments

{'symmetric'} (default) | cell array

Specify the extra parameters required by the user-defined window function, besides the window length.

**Dependencies**

This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

**Data Types**

When the **Operation** parameter on the **Main** tab is set to Generate window, the following parameters appear.

**Window data type** — Window data type

double (default) | single | Fixed-point | User-defined | Inherit via back propagation

Specify the window data type in one of the following ways:

- double
- single
- Fixed-point -- To specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- User-defined -- To specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.

- **Inherit via back propagation** -- To set the window data type and scaling to match the following block.

**Signed** — Window output is signed  
on (default) | off

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

**Dependencies**

This parameter appears only when you set **Window data type** to Fixed-point.

**Word length** — Word length  
16 (default) | positive integer in the range [2 128]

Specify the word length of the fixed-point window data type in bits.

**Dependencies**

This parameter is visible only when you set **Window data type** to Fixed-point.

**User-defined data type (e.g. sfix(16), float('single'))** — user-defined data type  
sfix(16) (default) | built-in data type | fixed-point data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the `fixdt` function.

**Dependencies**

This parameter is only visible when you set **Window data type** to User-defined.

**Set fraction length in output to** — Scaling of fixed-point window data type  
Best precision (default) | User-defined

Specify the scaling of the fixed-point window data type by using either of these methods:

- Choose **Best precision** to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose **User-defined** to specify the window data type scaling in the **Fraction length** parameter.

**Dependencies**

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when the specified window data type is a fixed-point data type.

**Fraction length** — User-defined fraction length  
15 (default) | integer

Specify the fraction length of the fixed-point window data type in bits.

**Dependencies**

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when you set **Set fraction length in output to** to User-defined.

When the **Operation** parameter on the **Main** tab is set to either Apply window to input or Generate and apply window, the following parameters appear.

**Rounding mode** — Rounding mode

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations.

The window vector  $w$  does not obey this parameter. It always rounds to Nearest.

---

**Note** The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of these conditions exist:

- **Product output** is Inherit via internal rule
- **Output** is Same as product output

With these data type settings, the block is effectively operating in a full-precision mode.

---

**Overflow mode** — Overflow mode

Wrap (default) | Saturate

Select the overflow mode for fixed-point operations.

The window vector  $w$  does not obey this parameter. It is always saturated.

**Window** — Window data type

Same word length as input (default) | Specify word length | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the window vector  $w$ .

When you select:

- **Same word length as input** -- The word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.
- **Specify word length** -- You can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.
- **Binary point scaling** -- You can enter the word length and the fraction length of the window vector elements in bits.
- **Slope and bias scaling** -- You can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters. It is always saturated and rounded to Nearest.

**Product output** — Product output data type

Inherit via internal rule (default) | Same as input | Binary point scaling | Slope and bias scaling

Use this parameter to specify how you want to designate the product output word and fraction lengths.

When you select:

- **Inherit via internal rule** -- The product output word length and fraction length are calculated automatically. For information on how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the product output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the product output. This block requires power-of-two slope and a bias of zero.

**Output** — Output data type

Same as product output (default) | Same as input | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the output of the block.

When you select:

- **Same as product output** -- These characteristics match those of the product output.
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the output. This block requires power-of-two slope and a bias of zero.

**Lock data type settings against changes by the fixed-point tools** — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

**Block Characteristics**

## Version History

Introduced before R2006a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on the `memcpy` or `memset` function (`string.h`) under certain conditions.

### Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

**Apply window to input**

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

**Generate window**

In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

**Generate and apply window**

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

You can set the window, product output, and output data types in the block dialog box.

# Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

## Libraries:

DSP System Toolbox / Estimation / Parametric Estimation

## Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This process results in the Yule-Walker equations, which the block solves using the Levinson-Durbin recursion. The block outputs are always nonsingular.

## Ports

### Input

**Input** — Input  
vector | matrix

Specify the input data as a vector or a matrix. The block assumes the input data to be the output of an AR system driven by white noise.

When you specify a matrix, the block treats each column of the matrix as a channel. If the input is a row vector of length  $N$ , then the block treats the input as having  $N$  different channels. If the input is an unoriented vector, the block treats the input as a single channel.

### Dependency

To use an input that is a row vector, set **Output(s)** to A.

Data Types: single | double

### Output

**A** — Normalized estimate of the AR model polynomial coefficients  
vector | matrix

Normalized estimate of the AR model polynomial coefficients  $A(z)$ , returned as a vector or a matrix. If the output is a vector, then it is of length  $p+1$  in descending powers of  $z$ . If the output is a matrix, then each column of the matrix is of length  $p+1$  and contains the normalized estimate of AR model coefficients in descending powers of  $z$ .

The block computes the estimate of these coefficients independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Square of the model gain
- $A(z)$  -- Polynomial coefficients of the AR model

#### Dependency

To enable this port, set the **Output(s)** parameter to A or A and K.

Data Types: single | double

#### **K** — Reflection coefficients

column vector | unoriented vector | matrix

Reflection coefficients (which are a secondary result of the Levinson recursion), returned as a column vector, an unoriented vector of length  $p$ , or a matrix of size  $p$ -by- $N$ , where  $N$  is the number of input channels. For each input channel, port **K** outputs a length- $p$  column whose elements are the AR model reflection coefficients.

#### Dependency

To enable this port, set the **Output(s)** parameter to K or A and K.

To output reflection coefficients  $K$ , specify the input to be a row vector, unoriented vector, or a matrix.

Data Types: single | double

#### **G** — Square of model gain

scalar | vector

Square of the gain of the estimated AR model for each input channel, returned as a scalar or a vector of length  $N$ , where  $N$  is the number of input channels. The port **G** outputs a scalar for each channel.

Here is the equation for the transfer function of the estimated AR model which shows the gain and the polynomial coefficients of the model:

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

where,

- $H(z)$  -- Transfer function of the estimated AR model
- $G$  -- Square of the model gain
- $A(z)$  -- Polynomial coefficients of the AR model

Data Types: single | double

## Parameters

**Output(s)** — Output of AR model coefficients

A (default) | A and K | K

Specify whether the block outputs model coefficients (A), reflection coefficients (K), or both (A and K).

**Inherit estimation order from input dimensions** — Inherit estimation order from input dimensions

on (default) | off

When you select the **Inherit estimation order from input dimensions** parameter, the block sets the order  $p$  of the all-pole model to a value that is one less than the length of each input channel. Otherwise, the order is the value you specify in the **Estimation order** parameter.

**Estimation order** — Order of AR model

4 (default) | nonnegative integer

Specify the order of the AR model  $p$  as a nonnegative integer.

To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length.

### Dependencies

To enable this parameter, clear the **Inherit estimation order from input dimensions** parameter.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | No              |

## More About

### AR( $p$ ) Model

In an AR model of order  $p$ , the current output is a linear combination of the past  $p$  outputs plus a white noise input.

The weights on the  $p$  past outputs minimize the mean squared prediction error of the autoregression. If  $y(n)$  is the current value of the output and  $x(n)$  is a zero-mean white noise input, the AR( $p$ ) model is

$$\sum_{k=0}^p a(k)y(n-k) = x(n).$$

### Reflection Coefficients

The reflection coefficients are the partial autocorrelation coefficients scaled by -1.

The reflection coefficients indicate the time dependence between  $y(n)$  and  $y(n - k)$  after subtracting the prediction based on the intervening  $k - 1$  time steps.

### Compare AR Model Parameter Estimation Methods

This table compares the features of the Burg AR Estimator block to the Covariance AR Estimator, Modified Covariance AR Estimator, and the Yule-Walker AR Estimator blocks.

The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

|                                      | <b>Burg AR Estimator</b>   | <b>Covariance AR Estimator</b>                                    | <b>Modified Covariance AR Estimator</b>   | <b>Yule-Walker AR Estimator</b>  |
|--------------------------------------|--|---|---|--|
| <b>Characteristics</b>               | Does not apply window to data  | Does not apply window to data                                     | Does not apply window to data   | Applies window to data   |
|                                      | Minimizes the forward and backward prediction errors in the least squares sense, with the AR coefficients constrained to satisfy the L-D recursion | Minimizes the forward prediction error in the least squares sense | Minimizes the forward and backward prediction errors in the least squares sense | Minimizes the forward prediction error in the least squares sense (also called "autocorrelation method")         |
| <b>Advantages</b>                    | Always produces a stable model   |   |   | Always produces a stable model   |
| <b>Disadvantages</b>                 |  | Can produce unstable models                                       | Can produce unstable models   | Performs relatively poorly for short data records  |
| <b>Conditions for Nonsingularity</b> |  | Order must be less than or equal to 1/2 the input frame size      | Order must be less than or equal to 2/3 the input frame size                    | Because of the biased estimate, the autocorrelation matrix is guaranteed to positive-definite, hence nonsingular |

### Blocks

Burg AR Estimator | Covariance AR Estimator | Modified Covariance AR Estimator | Yule-Walker Method

## Yule-Walker Method

Power spectral density estimate using Yule-Walker method

### Libraries:

DSP System Toolbox / Estimation / Power Spectrum Estimation

### Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the autocorrelation method, fits an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This process leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves.

The block computes the spectrum from the FFT of the estimated AR model parameters.

### Ports

#### Input

**Input** — Input

column vector | unoriented vector

Specify the input as a column vector or an unoriented vector. This input represents a frame of consecutive time samples from a single-channel signal.

Data Types: `single` | `double`

#### Output

**Output** — Power spectral density estimate

column vector

Power spectral density estimate of the signal at  $N_{fft}$  equally spaced frequency points, returned as a column vector. The frequency points are in the range  $[0, F_s)$ , where  $F_s$  is the sampling rate of the signal.

The block outputs are always nonsingular.

Data Types: `single` | `double`

### Parameters

**Inherit estimation order from input dimensions** — Inherit estimation order from input dimensions

`off` (default) | `on`

When you select **Inherit estimation order from input dimensions** parameter, the block sets the order of the all-pole model (estimation order) to a value that is one less than the length of the input

frame size. Otherwise, the **Estimation order** parameter value specifies the order. The block computes the spectrum from the FFT of the estimated AR model parameters.

#### **Estimation order** — Order of AR model

6 (default) | nonnegative integer

Specify the estimation order of the AR model as a nonnegative integer. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to 1/2 the input vector length.

#### **Dependencies**

To enable this parameter, clear the **Inherit estimation order from input dimensions** parameter.

#### **Inherit FFT length from estimation order** — Inherit FFT length from estimation order

off (default) | on

When you select the **Inherit FFT length from estimation order** parameter, the FFT length  $N_{fft}$  is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** parameter. You can then specify the FFT length as a power of 2 using the **FFT length** parameter. The block zero-pads or wraps the input to  $N_{fft}$  before computing the FFT.

#### **FFT length** — FFT length

256 (default) | positive integer greater than or equal to 2

Enter the number of data points  $N_{fft}$  on which to perform the FFT as a positive integer greater than or equal to 2. When  $N_{fft}$  is larger than the input frame size, the block zero-pads each frame as needed. When  $N_{fft}$  is smaller than the input frame size, the block wraps each frame as needed.

#### **Dependencies**

To enable this parameter, clear the **Inherit FFT length from input dimensions** parameter.

#### **Inherit sample time from input** — Inherit sample time from input

on (default) | off

When you select the **Inherit sample time from input** parameter, the block computes the frequency data from the sample period of the input signal. For the block to produce a valid output, the following conditions must hold:

- The input to the block is the original signal with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

#### **Sample time of original time series** — Sample time of original time-domain signal

1 (default) | positive scalar

Specify the sample time of the original time-domain signal as a positive scalar.

### Dependencies

To enable this parameter, clear the **Inherit sample time from input** parameter.

## Zero Crossing

Count number of times signal crosses zero in single time step

### Libraries:

DSP System Toolbox / Signal Operations

## Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where  $x_i$  is the current value of the signal,  $x_{i-1}$  is the previous value, and so on:

- $x_i < 0$  and  $x_{i-1} > 0$
- $x_i > 0$  and  $x_{i-1} < 0$
- For a positive integer  $L$ ,  $x_i < 0$ ,  $x_{i-1} = 0$ , and  $x_{i-L-1} > 0$ , where  $0 \leq l \leq L$ .
- For a positive integer  $L$ ,  $x_i > 0$ ,  $x_{i-1} = 0$ , and  $x_{i-L-1} < 0$ , where  $0 \leq l \leq L$ .

For the first value of the input signal,  $x_{i-1}$  and  $x_{i-2}$  are zero. The block outputs the number of times the signal crosses zero in a single time step at the **Cnt** port.

## Ports

### Input

**Port\_1** — Data input  
vector | matrix

The input signal specified as a real-valued vector or matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

### Output

**Cnt** — Number of zero crossings  
scalar | row vector

The block outputs the number of zero crossings in the data input as one of these:

- Scalar -- When the data input is a column vector, the block outputs a scalar value representing the number of zero crossings in the data input.
- Row vector -- When the data input is a matrix, the block outputs a row vector with each element in the row vector representing the number of zero crossings in the corresponding column of the data input.

Data Types: uint32

## Parameters

**Input processing** — Method to process input signals

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input.

- Columns as channels (frame based) — When you select this option, the block treats each column of the input as a separate channel.
- Elements as channels (sample based) — When you select this option, the block treats each element of the input as a separate channel.

Hit Crossing

## Zoom FFT

High-resolution FFT of a portion of a spectrum

**Libraries:**  
DSP System Toolbox / Transforms

### Description

The Zoom FFT block computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor  $D$ , and sampling rate  $F_s$ , you can choose the bandwidth of frequencies to analyze  $BW$ , where  $BW = F_s/D$ . You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of  $F_s$  and the FFT length ( $L$ ). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of  $D$ , the new sampling rate,  $F_{sd}$ , is  $F_s/D$ , and the new frame size (and FFT length) is  $L_d = L/D$ . The resolution of the decimated signal is  $F_{sd}/L_d = F_s/L$ . To achieve a higher resolution of the shorter band, use the original FFT length,  $L$ , instead of the decimated FFT length,  $L_d$ .

### Ports

#### Input

**x** — Input data  
vector | matrix

Input data for which the block computes zoom FFT, specified as a vector or a matrix.

The block treats each column of the input signal as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then the block interprets it as a single-channel signal.

When you input a variable-size signal (frame length changes during simulation), the frame length of the signal can be arbitrary, that is, the input frame length does not have to be a multiple of the decimation factor. When you input a fixed-size signal (frame length does not change during simulation), the frame length can be arbitrary only when you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This port is unnamed until you select the **Specify center frequency from input port** parameter and click **Apply**.

Data Types: single | double

**Fc** — Center frequency input  
real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range  $(- \text{SampleRate}/2, \text{SampleRate}/2)$ . *SampleRate* is either inherited from the input signal or specified through the **Input sample rate (Hz)** parameter.

#### Dependency

To enable this port, select the **Specify center frequency from input port** check box and click **Apply**.

Data Types: single | double

#### Output Arguments

**Port\_1** — Zoom FFT output  
vector | matrix

Zoom FFT output, returned as a vector or matrix.

If you select the **Inherit FFT Length from input dimensions** check box, the dimensions of the output signal depend on the dimensions of the input signal, the decimation factor of the Zoom FFT block, and whether you select the **Allow arbitrary frame length for fixed-size input signals** parameter.

This table provides more details on the dimensions of the output signal when you input a fixed-size input signal.

#### Fixed-Size Input Signal

| Input Signal  | Output Signal Dimensions  |
|---|---|
| $P$ -by-1 column vector, where $P$ is a multiple of the decimation factor $D$     | $(P/D)$ -by-1   |
| $P$ -by-1 column vector, where $P$ is not a multiple of the decimation factor $D$ | $\text{ceil}(P/D)$ -by-1 when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors.    |
| $P$ -by- $Q$ matrix, where $P$ is a multiple of the decimation factor $D$         | $(P/D)$ -by- $Q$  |
| $P$ -by- $Q$ matrix, where $P$ is not a multiple of the decimation factor $D$     | $\text{ceil}(P/D)$ -by- $Q$ when you select <b>Allow arbitrary frame length for fixed-size input signals</b> .<br><br>If you do not select <b>Allow arbitrary frame length for fixed-size input signals</b> , the block errors. |

This table gives more details on the dimensions of the output signal when you input a variable-size input signal. When you input a variable-size signal (frame length changes during simulation), the **Allow arbitrary frame length for fixed-size input signals** is visible on the block dialog box but does not have any impact on the input frame length. You can input a variable-size signal of any frame

length even if you do not select the **Allow arbitrary frame length for fixed-size input signals** parameter.

### Variable-Size Input Signal

| Input Signal | Output Signal Dimensions    |
|--------------|-----------------------------|
| $P$ -by- $Q$ | $\text{ceil}(P/D)$ -by- $Q$ |

If you clear the **Inherit FFT Length from input dimensions** check box, the output frame size equals the value you specify in the **FFT length( $L$ )** parameter.

| Input Signal | Output Signal Dimensions |
|--------------|--------------------------|
| $P$ -by- $Q$ | $L$ -by- $Q$             |

The data type of the output is same as the data type of the input.

Data Types: `single` | `double`

## Parameters

**Decimation factor** — Decimation factor  
2 (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the block reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Specify center frequency from input port** — Flag to specify center frequency from input port  
'off' (default) | 'on'

When you select this option and click **Apply**, the input port **Fc** appears on the block icon. You can pass the center frequency through this input port as a scalar.

**Center frequency (Hz)** — Center frequency  
0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range  $(- \text{SampleRate}/2, \text{SampleRate}/2)$ . *SampleRate* is the input sample rate either inherited from the input or specified through the **Input sample rate (Hz)** parameter.

Example: 0.5

Example: 10

### Dependencies

This parameter applies when you clear the **Specify center frequency from input port** check box.

Data Types: `single` | `double`

**Inherit FFT Length from input dimensions** — Flag to inherit FFT length from input dimensions  
'on' (default) | 'off'

When you select this option, the FFT length is the ratio of the input frame size (number of rows in the input) and the **Decimation factor**.

**FFT length** — FFT length  
64 (default) | positive scalar

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the **Decimation factor**.

Example: 24

Example: 52

#### Dependencies

This parameter applies when you clear the **Inherit FFT Length from input dimensions** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Inherit Sample rate from input** — Flag to inherit sample rate from input  
'off' (default) | 'on'

When you clear this check box, the block inherits the sample rate from the input signal.

**Input sample rate (Hz)** — Input sample rate  
44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

**Allow arbitrary frame length for fixed-size input signals** — Allow arbitrary frame length for fixed-size input signals

off (default) | on

Specify whether fixed-size input signals (whose size does not change during simulation) can have an arbitrary frame length, where the frame length does not have to be a multiple of the decimation factor. The block uses this parameter only for fixed-size input signals and ignores it if the input has a variable-size.

When the input signal is a variable-size signal, the signal can have arbitrary frame length, that is, the frame length does not have to be a multiple of the decimation factor.

For fixed-size input signals, if you:

- Select the **Allow arbitrary frame length for fixed-size input signals** parameter, the frame length of the signal does not have to be a multiple of the decimation factor. If the input is not a multiple of the decimation factor, then the output is generally a variable-size signal. Therefore, to support arbitrary input size, the block must also support variable-size operations, which you can enable by selecting the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Clear the **Allow arbitrary frame length for fixed-size input signals** parameter, the input frame length must be a multiple of the decimation factor.

**Simulate using** — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run. You can set this parameter to:

- **Interpreted execution:** Simulate model using the MATLAB interpreter. This option shortens startup time.
- **Code generation:** Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time but provides faster subsequent simulations.

## Block Characteristics

|                                 |                 |
|---------------------------------|-----------------|
| <b>Data Types</b>               | double   single |
| <b>Multidimensional Signals</b> | No              |
| <b>Variable-Size Signals</b>    | Yes             |

## Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band  $[F1, F2]$  of the original input signal, sampled at the rate  $F_s$  Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at  $F_c = (F1 + F2)/2$ , with the bandwidth  $BW = F2 - F1$ , and then downsample the signal by a factor of  $D = \text{floor}(F_s/BW)$ , the desired band comes down to the baseband.

If  $F_c$  cannot be expressed in the form of  $k \times F_s/D$ , where  $k$  is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to  $F_d$ .

$$F_d = F_c - (F_s/D) \times \text{floor}((D \times F_c + F_s/2)/F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

## Version History

Introduced in R2017b

### R2023a: Support for arbitrary input frame length

This block supports input signals with arbitrary frame lengths when the:

- Input signal is a fixed-size signal (frame length does not change during simulation) and you select the **Allow arbitrary frame length for fixed-size input signals** parameter.
- Input signal is a variable-size signal (frame length changes during simulation).

When this block supports an input signal with an arbitrary frame length, the input frame length does not have to be a multiple of the decimation factor and the output is a variable-size signal.

## powermeter

Measure power and CCDF of the power of voltage signal

### Description

The `powermeter` System object computes the power measurements of a voltage signal. When you set the `ComputeCCDF` property to `true`, the object also calculates the complementary cumulative distribution function (CCDF) of the power of a voltage signal. The CCDF measurements that the object outputs are relative power and probability (in percentage). The power measurements include average power, peak power, and peak-to-average power ratio.

For more details on how the object computes the power measurements and the CCDF measurements, see “Algorithms” on page 4-11.

To measure the power and the CCDF of the power of a voltage signal:

- 1 Create the `powermeter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
meter = powermeter  
meter = powermeter(Len,Overlap,Name=Value)  
meter = powermeter(Name=Value)
```

### Description

`meter = powermeter` returns a `powermeter` system object that computes power, peak-to-average power ratio (PAPR), and the complementary cumulative distribution function (CCDF) of the power of voltage signal. The CCDF helps find the probability that the instantaneous signal power exceeds a specified level above the average signal power.

`meter = powermeter(Len,Overlap,Name=Value)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

To enable this syntax, set the `ComputeCCDF` property to `false`.

`meter = powermeter(Name=Value)` returns a `powermeter` system object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with the previous input argument.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Measurement — Desired power measurement

'Average power' (default) | 'Peak power' | 'Peak-to-average power ratio' | 'All'

Desired power measurement, specified as 'Average power', 'Peak power', 'Peak-to-average power ratio' or 'All'.

For more details on how the object computes these measurements, see “Algorithms” on page 4-11.

### ReferenceLoad — Reference load

1 (default) | positive scalar

Reference load used by the power meter to compute the power values in ohms, specified as a positive scalar.

**Tunable:** Yes

Data Types: `single` | `double`

### ComputeCCDF — Compute CCDF

false (default) | true

Specify whether to calculate CCDF as:

- `false` -- The object does not calculate the CCDF measurements. The object computes the power measurements using the “Sliding Window Method” on page 4-11.
- `true` -- The object computes the CCDF measurements.
  - All input samples since object creation or reset are used to compute statistics. The power measurements are stationary.
  - The `WindowLength` and `OverlapLength` properties become read-only and are set to `Inf` and `0` respectively.

Data Types: `logical`

### PowerRange — Power range

50 (default) | positive scalar

The x-axis range of the computed CCDF curves in dB, specified as a positive scalar. The computed CCDF curves end at the maximum relative power, namely, peak-to-average power ratio (PAPR) of the signal, and start at `PAPR - PowerRange`. For the CCDF capability of the `powermeter` object, relative power is the power in dB by which the instantaneous signal power is above the average signal power.

### Dependencies

To enable this property, set the `ComputeCCDF` property to `true`.

Data Types: `single` | `double`

### **PowerResolution — Power Resolution in dB**

0.1 (default) | positive scalar

The x-axis resolution of the computed CCDF curves in dB, specified as a positive scalar.

#### **Dependencies**

To enable this property, set the `ComputeCCDF` property to `true`.

Data Types: `single` | `double`

### **WindowLength — Window length**

256 (default) | nonnegative integer

Sliding window length over which the measurement is computed, specified as a nonnegative integer.

#### **Dependencies**

If the `ComputeCCDF` property is `true`, then `WindowLength` property is set to `Inf` and is read-only.

Data Types: `single` | `double`

### **OverlapLength — Overlap length between windows**

`WindowLength - 1` (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range  $[0, \text{WindowLength} - 1]$ . If not specified, the overlap length is `WindowLength - 1`.

#### **Dependencies**

If the `ComputeCCDF` property is `true`, then `OverlapLength` property is set to 0 and is read-only.

Data Types: `single` | `double`

### **OutputPowerUnits — Output power units**

'dBm' (default) | 'dBW' | 'Watts'

Units of the measured power values, specified as 'dBm', 'dBW', or 'Watts'.

## **Usage**

### **Syntax**

```
avgpwr = meter(x)
peakpwr = meter(x)
papr = meter(x)
[avgpwr, peakpwr, papr] = meter(x)
```

### **Description**

`avgpwr = meter(x)` computes the average power of the input signal `x` when the `Measurement` property is set to 'Average power'. Each column of `x` is treated as an independent channel. The object computes the average power of each channel of the input signal independently.

`peakpwr = meter(x)` computes the peak power of the input signal `x` when the `Measurement` property is set to `'Peak power'`. Each column of `x` is treated as an independent channel. The object computes the peak power of each channel of the input signal independently.

`papr = meter(x)` computes the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to `'Peak-to-average power ratio'`. Each column of `x` is treated as an independent channel. The object computes the peak-to-average power ratio of each channel of the input signal independently.

`[avgpwr, peakpwr, papr] = meter(x)` computes the average power, peak power, and the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to `'All'`. Each column of `x` is treated as an independent channel. The object computes the power measurements of each channel of the input signal independently.

### Input Arguments

#### **x** — Input voltage signal

vector | matrix

Input voltage signal, specified as a vector or a matrix in volts. If `x` is a matrix, the object treats each column as an independent channel and computes the power measurements along each channel.

The object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

### Output Arguments

#### **avgpwr** — Average power

scalar | vector | matrix

Average power of the voltage signal, returned as a scalar, vector or a matrix, with the units determined by the `PowerUnits` property.

If you set the `ComputeCCDF` property to `false`, the object computes the moving average power using the “Sliding Window Method” on page 4-11.

When you input a signal of size  $m$ -by- $n$  to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of `ceil(m/hop size)`-by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary average power of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels in the input signal.

For details on how the object computes the average power, see “Average Power” on page 4-11.

Data Types: `single` | `double`

#### **peakpwr** — Peak power

scalar | vector | matrix

Peak power of the voltage signal, returned as a scalar, vector or a matrix, with the units determined by the `PowerUnits` property.

If you set the `ComputeCCDF` property to `false`, the object computes the moving peak power using the “Sliding Window Method” on page 4-11.

When you input a signal of size  $m$ -by- $n$  to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary peak power of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels in the input signal.

For details on how the object computes the peak power, see “Peak Power” on page 4-12.

Data Types: `single` | `double`

### **papr** — Peak-to-average power ratio

scalar | vector | matrix

Peak-to-average power ratio of the voltage signal, returned as a scalar, vector or a matrix.

If you set the `ComputeCCDF` property to `false`, the object computes the moving peak-to-average power ratio using the “Sliding Window Method” on page 4-11.

When you input a signal of size  $m$ -by- $n$  to the object when the `ComputeCCDF` property is set to `false`, the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-14.

If you set the `ComputeCCDF` property to `true`, the object computes the stationary peak-to-average power ratio of the entire signal along each channel. In this case, the size of the output is 1-by- $M$ , where  $M$  is the number of channels in the input signal.

For details on how the object computes the peak-to-average power ratio, see “Peak-to-Average Power Ratio” on page 4-12.

Data Types: `single` | `double`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to powermeter

|               |   |
|---------------|---|
| plotCCDF      | Plot CCDF curves  |
| ccdf          | Get coordinates of CCDF curves                            |
| relativePower | Use CCDF to find relative power for specified probability |
| probability   | Use CCDF to find probability for specified relative power |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Compute Power Measurements of Voltage Signal

Compute the power measurements of a noisy sinusoidal signal using a power meter. These measurements include average power, peak power, and peak-to-average power ratio.

Assume the maximum voltage of the signal to be 100 V. The instantaneous values of a sinusoidal waveform are given by the equation  $V_i = V_{max} \times \sin(2\pi ft)$ , where  $V_i$  is the instantaneous value,  $V_{max}$  is the maximum voltage of the signal, and  $f$  is the frequency of the signal in Hz.

### Initialization

The input signal is a sum of two sine waves with frequencies set to 1 kHz and 10 kHz, respectively. The frame length and the sampling frequency of the generated signal is 512 samples and 44.1 kHz, respectively.

To measure the power in this signal, create a `powermeter` object. Set `Measurement` to 'All'. This setting enables the object to measure the average power, peak power, and peak-to-average power ratio. Set the length of the sliding window to 16 samples and the reference load to 50 Ohms. Use this object to measure the power in dBm units. Visualize the power measurements using the `timescope` object.

```

FrameLength = 512;
Fs = 44.1e3;
A = 100;
sine1 = dsp.SinWave(Amplitude=A, ...
    Frequency=1e3, ...
    SampleRate=44.1e3, ...
    SamplesPerFrame=FrameLength);
sine2 = dsp.SinWave(Amplitude=A, ...
    Frequency=10e3, ...
    SampleRate=44.1e3, ...
    SamplesPerFrame=FrameLength);
pm = powermeter(16,Measurement="All", ...
    ReferenceLoad=50, ...
    PowerUnits="dBm");
scope = timescope(NumInputPorts=4,SampleRate=Fs, ...
    TimeSpanSource="property", ...
    TimeSpan=96, ...
    YLabel="dBm", ...

```

```

        YLimits=[-30 90]);
title = 'Power Measurements';
scope.ChannelNames = {'Average power', ...
    'Peak power', 'Peak-to-average power ratio', ...
    'Expected Average Power'};
scope.Title = title;

```

### Compute the Power Measurements

Add zero-mean white Gaussian noise with a standard deviation of 0.001 to the sum of sine waves. Vary the amplitude of the sine waves. Measure the average power, peak power, and the peak-to-average power ratio of this noisy sinusoidal signal that has a varying amplitude. For details on how the object measures these power values, see “Algorithms” on page 4-11. Compare the measured values to the expected value of the average power.

The expected value of the average power  $P$  of the noisy sinusoidal signal is given by the following equation.

$$P = \frac{A_1^2}{2R} + \frac{A_2^2}{2R} + \text{var}(\text{noise}),$$

where,

- $A_1$  is the amplitude of the first sinusoidal signal.
- $A_2$  is the amplitude of the second sinusoidal signal.
- $R$  is the reference load in ohms.

In dBm, the expected power is computed using the following equation:

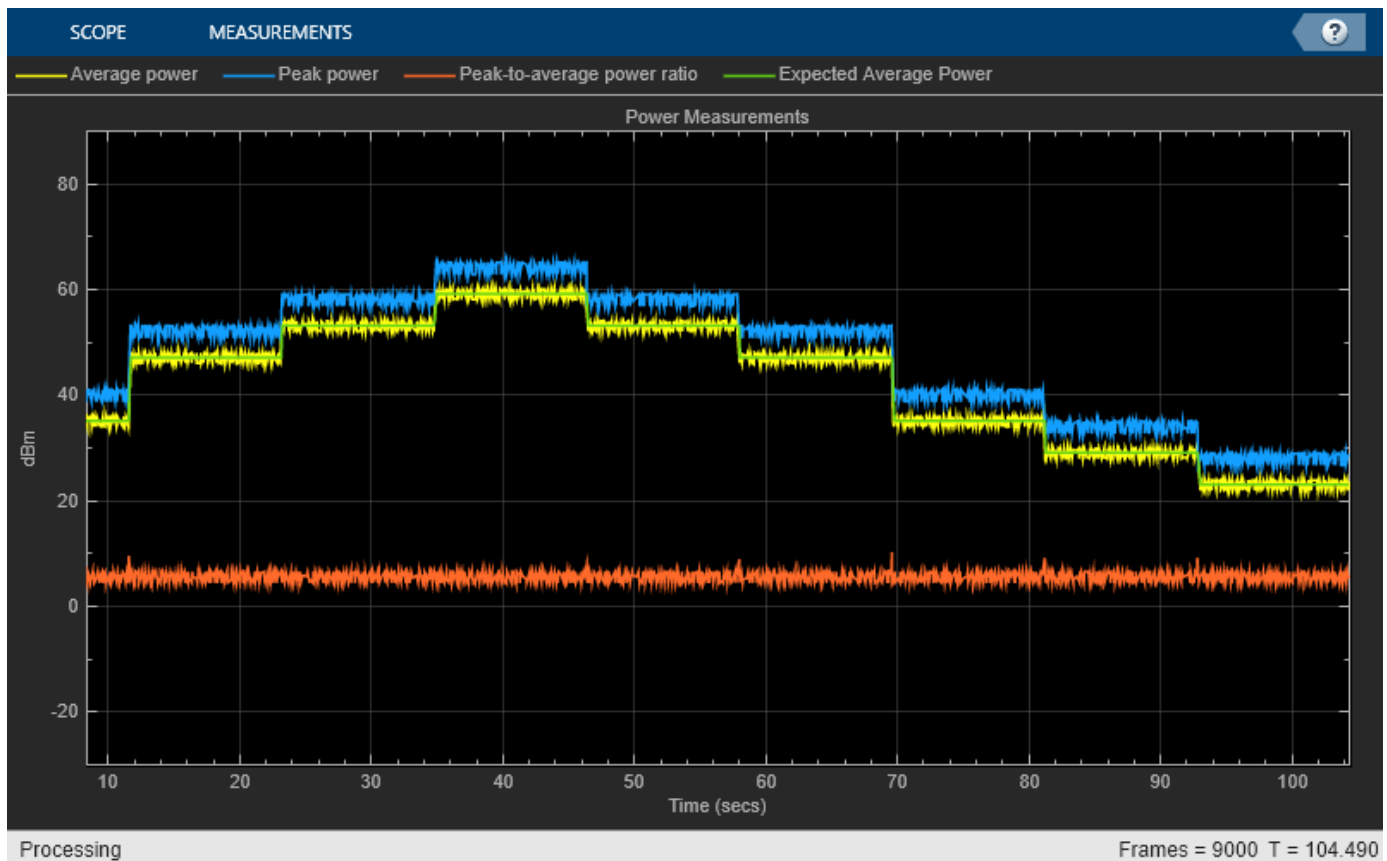

$$\text{expPwr}_{\text{dBm}} = 10\log_{10}(P) + 30.$$

Compare the expected value with the value computed by the object. All values are in dBm. These values match very closely. To verify, view the computed measurements using the `timescope` object.

```

Vect = [1/8 1/2 1 2 1 1/2 1/8 1/16 1/32];
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:1000
        x = V*sine1()+V*sine2()+0.001.*randn(FrameLength,1);
        P = (((V*A)^2)/100)+(((V*A)^2)/100)+(0.001)^2;
        expPwr = (10*log10(P)+30)*ones(FrameLength,1);
        [avgPwr,pkPwr,papr] = pm(x);
        scope(avgPwr,pkPwr,papr,expPwr);
    end
end
end

```

### Compute and Plot CCDF Measurements of Voltage Signal

Compute the CCDF measurements of a voltage signal. The CCDF measurements include the relative power and the probability. Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

Initialize a powermeter object and set the ComputeCCDF property to true. The input to the object is a random voltage signal.

```
x = complex(rand(10000,1)-0.5,rand(10000,1)-0.5);
pm = powermeter(ComputeCCDF=true)
```

```
pm =
  powermeter with properties:
    Measurement: 'Average power'
    ReferenceLoad: 1
    ComputeCCDF: true
    PowerRange: 50
    PowerResolution: 0.1000
    OutputPowerUnits: 'dBm'

  Read-only properties:
    WindowLength: Inf
```

```
OverlapLength: 0
```

By default, the powermeter object computes the average power of the signal in dBm. The reference load is 1 ohm.

```
averagePower = pm(x)
```

```
averagePower = 22.2189
```

Using the probability function, find the probability that the instantaneous power of the signal is 3 dB above the average power. The relative power in this case is 3 dB.

```
prob = probability(pm,3)
```

```
prob = 7.6009
```

Compute the relative power using the relativePower function. Verify that the relative power for the computed probability is indeed 3 dB.

```
relpwr = relativePower(pm,prob)
```

```
relpwr = 3.0000
```

Using the plotCCDF function, plot the CCDF curve. Set the reference curve to Gaussian.

```
plotCCDF(pm,GaussianReference=true)
```

## Algorithms

### Sliding Window Method

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving power measurements using the sliding window method.

In the sliding window method, the block computes the power measurement over a finite duration of the signal. The window length defines the length of the data over which the algorithm computes the power value. The window moves as new data comes in. The output for each input sample is the measurement over the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the sliding window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

For a more detailed example, see “Sliding Window Method”.

If the window is large, the power that the block computes is closer to the stationary power of the data. For data that does not change rapidly, use a long window to get a smoother measurement. For data that changes fast, use a smaller window.

When you configure the power meter to compute the CCDF measurements, the algorithm computes the stationary power of the data. It sets the window length to  $Inf$  and the overlap length to  $0$ , making both the parameters read-only.

### Average Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving average power of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary average power of the voltage signal across each channel.

These equations give the average power in dBm, dBW, and in Watts units.

$$AvgPower_{dBm} = 10\log_{10}(Avg(|x|^2)/R) + 30$$

$$AvgPower_{dBW} = 10\log_{10}(Avg(|x|^2)/R)$$

$$AvgPower_{Watts} = Avg(|x|^2)/R$$

where,

- $x$  is the input voltage signal.
- $R$  is the reference load (in ohms) that the block uses to compute the power value.
- $Avg$  represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, *Avg* represents the stationary average power across each channel.

### Peak Power

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak power of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak power of the voltage signal across each channel.

These equations give the peak power in dBm, dBW, and in Watts units.

$$PeakPower_{dBm} = 10\log_{10}(Max(|x|^2)/R) + 30$$

$$PeakPower_{dBW} = 10\log_{10}(Max(|x|^2)/R)$$

$$PeakPower_{Watts} = Max(|x|^2)/R$$

where,

- *x* is the input voltage signal.
- *R* is the reference load (in ohms) that the block uses to compute the power value.
- *Max* represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, *Max* represents the stationary peak power across each channel.

### Peak-to-Average Power Ratio

When you do not configure the power meter to compute the CCDF measurements, the power meter computes the moving peak-to-average power ratio of the voltage signal across each channel using the Sliding Window Method on page 4-11. When you do configure the power meter to compute the CCDF measurements, the power meter computes the stationary peak-to-average power ratio of the voltage signal across each channel.

These equations give the peak-to-average power ratio in dBm, dBW, and in Watts units.

$$pkAvgPwr_{dBm} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{dBW} = 10\log_{10}(Max(|x|^2)/Avg(|x|^2))$$

$$pkAvgPwr_{Watts} = Max(|x|^2)/Avg(|x|^2)$$

where,

- *x* is the input voltage signal.
- *Avg* represents the moving average power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

When the power meter does compute the CCDF measurements, *Avg* represents the stationary average power across each channel.

- *Max* represents the moving peak power when the power meter does not compute the CCDF measurements. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

When the power meter does compute the CCDF measurements, *Max* represents the stationary peak power across each channel.

## Relative Power

The power meter computes the relative power only when you configure the algorithm to compute the CCDF measurements. The algorithm uses a window of infinite duration to compute the relative power.

Relative power is the amount of power in dB by which the instantaneous signal power is above the average signal power. The block calculates the relative power using these equations:

If output power is in dBm,

$$relPower = 10\log_{10}(|x|^2/R) + 30 - AvgPower_{dBm}$$

If output power is in dBW,

$$relPower = 10\log_{10}(|x|^2/R) - AvgPower_{dBW}$$

If output power is in Watts,

$$relPower = (|x|^2/R) - AvgPower_{Watts}$$

where,

- $x$  is the input voltage signal.
- $R$  is the reference load (in ohms) that the block uses to compute the power value.
- $|x|^2/R$  is the instantaneous signal power in Watts.
- *AvgPower* is the average power of the voltage signal. For more details on how the algorithm computes this measurement, see "Average Power" on page 2-1183.

## Probability

The power meter computes the probability only when you configure the algorithm to compute the CCDF measurements. Probability in percentage refers to the probability that the instantaneous signal power is above the average signal power by the relative power in dB.

## Version History

Introduced in R2021a

### R2022b: Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `ComputeCCDF` property set to `false`, and if you input a signal with a frame length that is a multiple of the hop size (window length

– overlap length), this object generates a fixed-size output signal in the generated code. For more details, see “Code Generation” on page 4-14.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set the `ComputeCCDF` property to `false` and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

| Input Signal  | Input Size   | Output Signal   |
|---------------|--------------|---|
| Fixed-size    | $m$ -by- $n$ | When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- $n$ .<br><br>When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- $n$ . |
| Variable-size | $m$ -by- $n$ | Output is a variable-size signal.<br><br>Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- $n$ .  |

# dsp.AdaptiveLatticeFilter

**Package:** dsp

Adaptive lattice filter

## Description

The `dsp.AdaptiveLatticeFilter` System object computes output, error, and coefficients using a lattice-based FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.AdaptiveLatticeFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
alf = dsp.AdaptiveLatticeFilter
alf = dsp.AdaptiveLatticeFilter(len)
alf = dsp.AdaptiveLatticeFilter(Name,Value)
```

### Description

`alf = dsp.AdaptiveLatticeFilter` returns a lattice-based FIR adaptive filter System object, `alf`. This System object computes the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter(len)` returns an `AdaptiveLatticeFilter` System object with the `Length` property set to `len`.

`alf = dsp.AdaptiveLatticeFilter(Name,Value)` returns an `AdaptiveLatticeFilter` System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Method — Method to calculate filter coefficients**

'Least-squares Lattice' (default) | 'QR-decomposition Least-squares Lattice' | 'Gradient Adaptive Lattice'

Specify the method used to calculate filter coefficients as one of 'Least-squares Lattice', 'QR-decomposition Least-squares Lattice', 'Gradient Adaptive Lattice'. The default value is 'Least-squares Lattice'. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

**Length — Length of filter coefficients vector**

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ForgettingFactor — Least-squares lattice forgetting factor**

1 (default) | positive scalar

Specify the least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation.

**Tunable:** Yes

**Dependencies**

This property applies only if the Method property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**StepSize — Joint process step size of gradient adaptive filter**

0.1 (default) | positive scalar

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1.

**Tunable:** Yes

**Dependencies**

This property applies only if the Method property is set to 'Gradient Adaptive Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Offset — Offset for denominator of StepSize normalization term**

1 (default) | nonnegative scalar

Specify an offset value for the denominator of the StepSize normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small.

**Tunable:** Yes

**Dependencies**

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ReflectionStepSize — Reflection process step size**

`StepSize` property value (default) | positive scalar

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. The default value is the `StepSize` property value.

**Tunable:** Yes

**Dependencies**

Use this property only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**AveragingFactor — Averaging factor of energy estimator**

`1 - StepSize` (default) | positive scalar

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. The default is the value of `1 - StepSize`.

**Tunable:** Yes

**Dependencies**

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double`

**InitialPredictionErrorPower — Initial prediction error power**

`1.0` (default) | positive scalar

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice', the default value is `1.0`. If the `Method` property is set to 'Gradient Adaptive Lattice', the default value is `0.1`.

**Tunable:** Yes

Data Types: `single` | `double`

**InitialCoefficients — Initial coefficients of filter**

`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LockCoefficients — Locked status of coefficient updates**`false (default) | true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

**Tunable:** Yes

**Dependencies**

This property is applicable only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

**Usage****Syntax**`[y,err] = alf(x,d)`**Description**

`[y,err] = alf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `alf` filter, call `alf.Coefficients` after you pass the input and desired signal to the object.

**Input Arguments****x — Data input**`scalar | column vector`

The signal to be filtered by the adaptive lattice filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

**d — Desired signal**`scalar | column vector`

The adaptive lattice filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **y** — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal  $x$  to match the desired signal  $d$ . The filter outputs the converged signal.

Data Types: `single` | `double`

### **err** — Difference between output and desired signal

scalar | column vector

Difference between the output signal  $y$  and the desired signal  $d$ , returned as a scalar or a column vector. The objective of the adaptive lattice filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the adaptive lattice filter coefficients, call `alf.Coefficients` after you pass the input and desired signal to the object algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.AdaptiveLatticeFilter

`mseSim` Estimated mean squared error for adaptive filters

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### QPSK Adaptive Equalization Using Adaptive Lattice Filter

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1000;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
```

```
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

```
lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

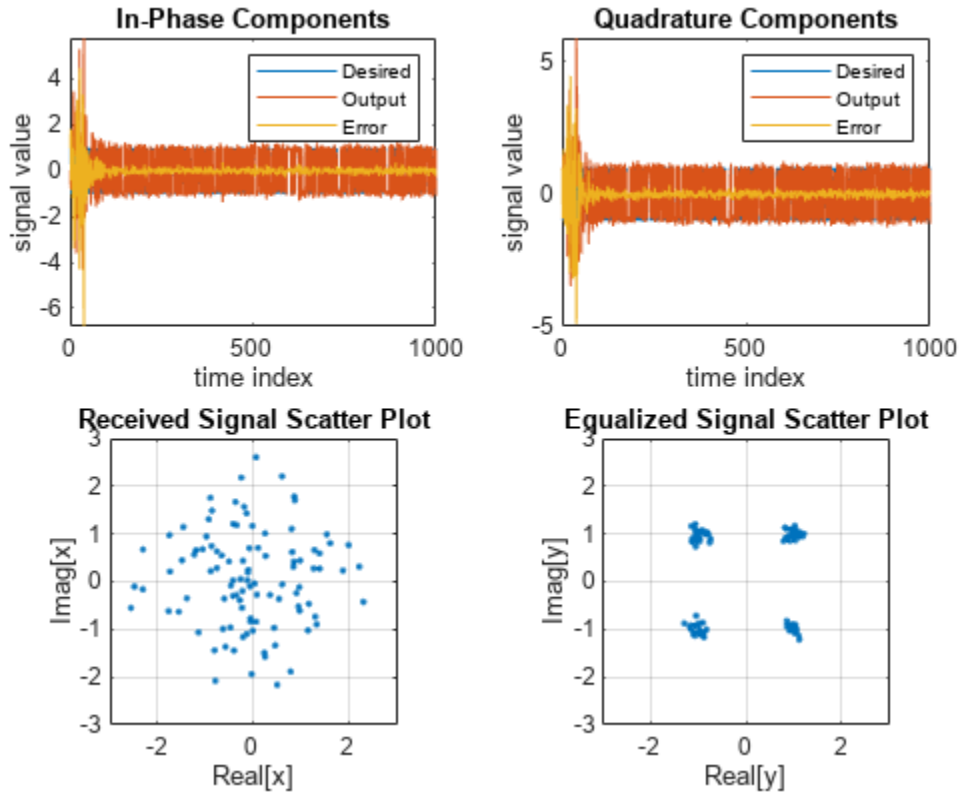

```
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
```

Plot the received and equalized signals' scatter plots.

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
```

```
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

### System Identification of FIR Filter Using Adaptive Lattice Filter

```
ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Decimation factor for analysis
% and simulation results
m = 5;
ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration');
```

```
ylabel('MSE (dB)');  
% Plot the learning curve used for  
% adaptive lattice filter used in system identification  
title('Learning curve')
```

# dsp.AffineProjectionFilter

**Package:** dsp

Compute output, error and coefficients using affine projection (AP) Algorithm

## Description

The `dsp.AffineProjectionFilter` System object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.AffineProjectionFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
apf = dsp.AffineProjectionFilter
apf = dsp.AffineProjectionFilter(len)
apf = dsp.AffineProjectionFilter(Name,Value)
```

### Description

`apf = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `apf`. This System object computes the filtered output and the filter error for a given input and desired signal using the affine projection (AP) algorithm.

`apf = dsp.AffineProjectionFilter(len)` returns an affine projection filter object with the `Length` property set to `len`.

`apf = dsp.AffineProjectionFilter(Name,Value)` returns an affine projection filter object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Method — Method to calculate filter coefficients**

Direct Matrix Inversion (default) | Recursive Matrix Update | Block Direct Matrix Inversion

Specify the method used to calculate filter coefficients as Direct Matrix Inversion, Recursive Matrix Update, Block Direct Matrix Inversion. This property is nontunable.

**Length — Length of filter coefficients vector**

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ProjectionOrder — Projection order of affine projection algorithm**

2 (default) | positive integer

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. This property is nontunable.

Data Types: double

**StepSize — Affine projection step size**

1 (default) | nonnegative scalar

Specify the affine projection step size factor as a scalar nonnegative numeric value between 0 and 1, both inclusive. Setting the step size equal to one provides the fastest convergence during adaptation.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**InitialCoefficients — Initial coefficients of filter**

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InitialOffsetCovariance — Initial values of offset input covariance matrix**

1 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the ProjectionOrder property value. If it is a scalar value, the OffsetCovariance property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the OffsetCovariance property is initialized to the value of that square matrix.

**Tunable:** Yes

**Dependencies**

This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**InitialInverseOffsetCovariance — Initial values of offset input covariance matrix inverse**

20 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix.

**Tunable:** Yes

**Dependencies**

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**InitialCorrelationCoefficients — Initial correlation coefficients**

0 (default) | scalar | vector

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder - 1`.

**Tunable:** Yes

**Dependencies**

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LockCoefficients — Lock coefficient updates**

false (default) | true

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated).

**Tunable:** Yes

**Usage****Syntax**

```
[y,err] = apf(x,d)
```

## Description

`[y,err] = apf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `apf` filter, call `apf.Coefficients` after you pass the input and desired signal to the object.

## Input Arguments

### **x** — Data input

scalar | column vector

The signal to be filtered by the affine projection filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

### **d** — Desired signal

scalar | column vector

The affine projection filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **y** — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

### **err** — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the affine projection filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the affine projection filter coefficients, call `apf.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.AffineProjectionFilter`

`mse` Estimated mean squared error for adaptive filters

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

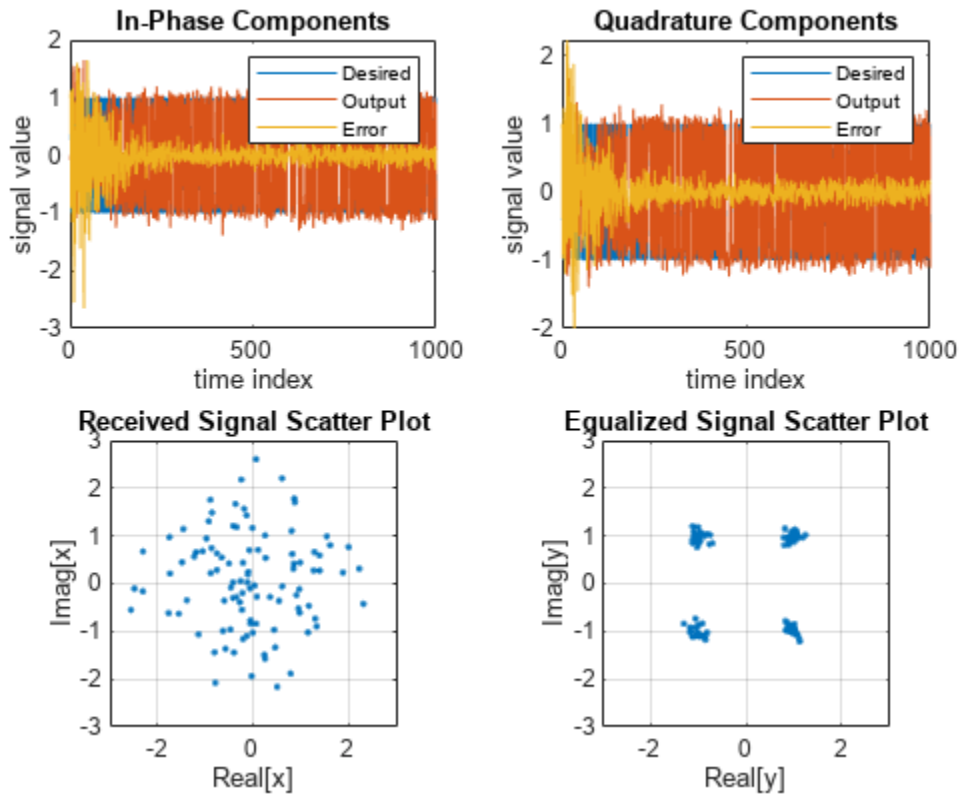

`reset` Reset internal states of System object

## Examples

### QPSK Adaptive Equalization

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16; % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D)) + 1i*randn(1,ntr+D); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance', offset);
[y,e] = apf(x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

### System Identification of FIR Filter Using Affine Projection Filter

```

ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Affine Projection filter Step size.
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 5;

apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
% Plot the learning curve for affine projection filter

```

```
% used in system identification  
title('Learning curve')
```

## Algorithms

The affine projection algorithm (APA) is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}ap(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \dots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n) \ \mathbf{u}(n-1) \ \dots \ \mathbf{u}(n-L))$$

$$\mathbf{y}ap(n) = \mathbf{U}^T ap(n) \mathbf{w}(n) = \begin{pmatrix} y(n) \\ \cdot \\ \cdot \\ \cdot \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}ap(n) = \begin{pmatrix} d(n) \\ \cdot \\ \cdot \\ \cdot \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}ap(n) = \mathbf{d}ap(n) - \mathbf{y}ap(n) = \begin{pmatrix} e(n) \\ \cdot \\ \cdot \\ \cdot \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}ap(n) \mathbf{e}ap$$

where  $\mathbf{C}$  is either  $\varepsilon \mathbf{I}$  if the initial offset covariance is a scalar  $\varepsilon$ , or  $\mathbf{R}$  if the initial offset covariance is a matrix  $\mathbf{R}$ . The variables are as follows:

| Variable             | Description                                       |
|----------------------|---|
| $n$                  | The current time index                            |
| $u(n)$               | The input sample at step $n$                      |
| $\mathbf{U}_{ap}(n)$ | The matrix of the last $L+1$ input signal vectors |
| $\mathbf{w}(n)$      | The adaptive filter coefficients vector           |
| $y(n)$               | The adaptive filter output                        |
| $d(n)$               | The desired signal                                |
| $e(n)$               | The error at step $n$                             |
| $L$                  | The projection order                              |
| $N$                  | The filter order (i.e., filter length = $N+1$ )   |
| $\mu$                | The step size                                     |

# dsp.AllpassFilter

**Package:** dsp

Single section or cascaded allpass filter

## Description

The `dsp.AllpassFilter` object filters each channel of the input using allpass filter implementations. To import this object into Simulink, use the MATLAB System block.

To filter each channel of the input:

- 1 Create the `dsp.AllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
Allpass = dsp.AllpassFilter
Allpass = dsp.AllpassFilter(Name,Value)
```

### Description

`Allpass = dsp.AllpassFilter` returns an allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter(Name,Value)` returns an allpass filter System object, `Allpass`, with each property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Structure — Internal allpass filter structure

Minimum multiplier (default) | Lattice | Wave Digital Filter

You can specify the internal allpass filter implementation structure as one of `Minimum multiplier` | `Lattice` | `Wave Digital Filter`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

**AllpassCoefficients — Allpass polynomial coefficients**`[-2(-1/2) 0.5] (default) | N-by-1 | N-by-2`

Specify the real allpass polynomial filter coefficients. Specify this property as either an *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. The default value defines a stable second-order allpass filter with poles and zeros located at  $\pm\pi/3$  in the Z plane.

**Tunable:** Yes

**Dependencies**

This property is applicable only when the `Structure` property is set to `Minimum multiplier`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**WDFCoefficients — Wave Digital Filter allpass coefficients**`[1/2, -2(1/2)/3] (default) | N-by-1 | N-by-2`

Specify the real allpass coefficients in the Wave Digital Filter form. Specify this property as either a *N*-by-1 or *N*-by-2 matrix of *N* first-order or second-order allpass sections. All elements must have absolute values less than or equal to 1. This value is a transformed version of the default value of `AllpassCoefficients`, computed using `allpass2wdf(AllpassCoefficients)`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Minimum multiplier'`.

**Tunable:** Yes

**Dependencies**

This property is only applicable when the `Structure` property is set to `Wave Digital Filter`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LatticeCoefficients — Lattice allpass coefficients**`[-2(1/2)/3, 1/2] (default) | vector`

Specify the real or complex allpass coefficients as lattice reflection coefficients. Specify this property as either a row vector (single-section configuration) or a column vector. This value is a transformed and transposed version of the default value of `AllpassCoefficients`, computed using `transpose(tf2latc([1 h.AllpassCoefficients]))`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Lattice'`.

**Tunable:** Yes

**Dependencies**

This property is applicable only if the `Structure` property is set to `Lattice`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**TrailingFirstOrderSection — Indicate if last section is first order**`false (default) | true`

Indicate if last section is first order or second order. When you set `TrailingFirstOrderSection` to `true`, the last section is considered to be first-order, and the second element of the last row of the *N*-by-2 matrix is ignored. When you set `TrailingFirstOrderSection` to `false`, the last section is considered to be second-order.

## Usage

### Syntax

```
y = Allpass(x)
```

### Description

`y = Allpass(x)` filters the input signal `x` using an allpass filter to produce the output `y`. Each column of `x` is filtered independently as a separate channel over time.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Examples

### Lowpass Filtering using Two Allpass Filters

Construct the Allpass Filters

```
Fs = 48000;     % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603   0.208818210000029]);
APF2 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957   0.6;...
    -0.324919696232907   0],...
    'TrailingFirstOrderSection',true);
```

Construct the Transfer Function Estimator to estimate the transfer function between the random input and the Allpass filtered output

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange',...
    'onesided','SpectralAverages',2);
```

Construct the ArrayPlot to plot the magnitude response

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits', [-80 5],...
    'YLabel','Magnitude (dB)','SampleIncrement', Fs/FL,...
    'XLabel','Frequency (Hz)','Title','Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Magnitude Response'});
```

Filter the Input and show the magnitude response of the estimated transfer function between the input and the filtered output

```
tic;
while toc < 5
    in = randn(FL,1);
    out = 0.5.*(APF1(in) + APF2(in));
    A = TFE(in, out);
    AP(db(A));
end
```

## Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

$c$  is allpass polynomial coefficients vector. The order,  $n$ , of the transfer function is the length of vector  $c$ .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an  $N$ -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an  $N$ -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as `df1`, `df1t`, `df2`, `df2t`. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

### Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order  $n$ . It also uses  $2n$  delay units and  $2n$  adders. The multipliers use the specified coefficients, which are equal to the polynomial vector  $c$  in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector,  $c$ , is equal to  $[0.1 \ -0.7]$ .

### Wave Digital Filter

This structure uses  $n$  multipliers, but only  $n$  delay units, at the expense of requiring  $3n$  adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector  $w$  is equal to `allpass2wdf([0.1 -0.7])`.

### Lattice

This lattice structure uses  $2n$  multipliers,  $n$  delay units, and  $2n$  adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients `[0.1 -0.7]`.

# dsp.AllpoleFilter

**Package:** dsp

IIR Filter with no zeros

## Description

The `dsp.AllpoleFilter` object filters each channel of the input using allpole filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.AllpoleFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
allpole = dsp.AllpoleFilter
allpole = dsp.AllpoleFilter(Name,Value)
```

### Description

`allpole = dsp.AllpoleFilter` returns an allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the algorithm. This System object uses a specified allpole filter implementation.

`allpole = dsp.AllpoleFilter(Name,Value)` returns an allpole filter System object, `allpole`, with each property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Structure — Filter structure

Direct form (default) | Direct form transposed | Lattice AR

Specify the filter structure as one of | `Direct form` | `Direct form transposed` | `Lattice AR`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

**Denominator — Filter denominator coefficients**

[1 0.1] (default) | row vector

Specify the denominator coefficients as a numeric row vector.

**Tunable:** Yes**Dependencies**

This property is applicable when the Structure property is set to one of `Direct form` | `Direct form transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**ReflectionCoefficients — Lattice filter coefficients**

[0.2 0.4] (default) | row vector

Specify the lattice filter coefficients as a numeric row vector.

**Tunable:** Yes**Dependencies**

This property is applicable when the Structure property is set to `Lattice AR`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**InitialConditions — Initial conditions for the filter states**

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

**Tunable:** YesData Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**CoefficientsDataType — Denominator coefficients word- and fraction-length designations**

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

**ReflectionCoefficientsDataType — Reflection coefficients word- and fraction-length designations**

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom`. This property is nontunable.

## Fixed-Point Properties

### ProductDataType — Product word- and fraction-length designations

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. This property is nontunable.

### AccumulatorDataType — Accumulator word- and fraction-length designations

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. This property is nontunable.

### OutputDataType — Output word- and fraction-length designations

Same as input (default) | Same as accumulator | Custom

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. This property is nontunable.

### StateDataType — State word- and fraction-length designations

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom. This property is nontunable.

### CustomCoefficientsDataType — Custom denominator word- and fraction-lengths

numericType ([,16,15) (default) | numericType

Specify the denominator coefficients fixed-point type as an autosigned numericType (Fixed-Point Designer) object. This property is nontunable.

#### Dependencies

This property is applicable when the CoefficientsDataType property is Custom.

### CustomReflectionCoefficientsDataType — Custom reflection coefficients word- and fraction-lengths

numericType ([,16,15) (default) | numericType

Specify the denominator coefficients fixed-point type as an autosigned numericType (Fixed-Point Designer) object. This property is nontunable.

#### Dependencies

This property is applicable when the ReflectionCoefficientsDataType property is Custom.

### CustomProductDataType — Custom Product word- and fraction-lengths

numericType ([,32,30) (default) | numericType

Specify the product fixed-point type as an autosigned scaled numericType object. This property is nontunable.

#### Dependencies

This property applies when you set the ProductDataType property to Custom.

**CustomAccumulatorDataType — Custom accumulator word- and fraction-lengths**`numericType([],32,30)` (default) | `numericType`

Specify the accumulator fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

**Dependencies**

This property applies when you set the `AccumulatorDataType` property to `Custom`.

**CustomStateDataType — Custom state word- and fraction-lengths**`numericType([],16,15)` (default) | `numericType`

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

**Dependencies**

This property applies when you set the `StateDataType` property to `Custom`.

**CustomOutputDataType — Custom output word- and fraction-lengths**`numericType([],16,15)` (default) | `numericType`

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

**Dependencies**

This property applies when you set the `OutputDataType` property to `Custom`.

**Usage****Syntax**`y = allpole(x)`**Description**

`y = allpole(x)` filters the real or complex input signal `x` using an allpole filter to produce the output `y`.

**Input Arguments****x — Data input**`vector` | `matrix`

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

When the input data is of a fixed-point type, it must be signed. The allpole filter object operates on each channel of the input signal independently over successive calls to the algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Output Arguments

### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.AllpoleFilter`

## Examples

### Lowpass Filter a Waveform with Two Frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

```
t = (0:1000)./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

src = dsp.SignalSource(xin', 4);
sink = dsp.SignalSink;
allpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
allpole.Denominator = asinc;

sa = spectrumAnalyzer('SampleRate',8e3,...
    'Method','welch',...
```

```

        'PlotAsTwoSidedSpectrum',false,...
        'OverlapPercent',80,'SpectrumUnits','dBW',...
        'YLimits',[-150 50]);

while ~isDone(src)
    input = src();
    filteredOutput = allpole(input);
    sink(filteredOutput);
    sa(filteredOutput)
end

```

```

filteredResult = sink.Buffer;
fvtool(allpole,'Fs',8000)

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

## Version History

**Introduced in R2012b**

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the Denominator property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.AnalyticSignal

**Package:** dsp

Analytic signals of discrete-time inputs

## Description

The `dsp.AnalyticSignal` System object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

- 1 Create the `dsp.AnalyticSignal` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
anaSig = dsp.AnalyticSignal
anaSig = dsp.AnalyticSignal(order)
anaSig = dsp.AnalyticSignal(Name,Value)
```

### Description

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real  $M$ -by- $N$  input matrix.

`anaSig = dsp.AnalyticSignal(order)` returns an analytic signal object, `anaSig`, with the "FilterOrder" on page 4-0 property set to `order`.

`anaSig = dsp.AnalyticSignal(Name,Value)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**FilterOrder** — Filter order used to compute Hilbert transform

100 (default) | scalar integer

Order of the equiripple FIR filter used in computing the Hilbert transform, specified as an even integer scalar greater than 3.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Usage****Syntax**

```
y = anaSig(x)
```

**Description**

`y = anaSig(x)` computes the analytic signal,  $y$ , of the  $M$ -by- $N$  input matrix  $x$ , according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where  $j$  is the imaginary unit and  $H\{\mathbf{X}\}$  denotes the Hilbert transform.

Each of the  $N$  columns in  $x$  contains  $M$  sequential time samples from an independent channel. The method computes the analytic signal for each channel.

**Input Arguments****x** — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double

**Output Arguments****y** — Analytic signal output

vector | matrix

Analytic signal output, returned as a vector or a matrix.

Data Types: single | double

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

```
step      Run System object algorithm
```

release Release resources and allow changes to System object property values and input characteristics  
 reset Reset internal states of System object

## Examples

### Compute The Analytic Signal

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';
x = sin(4*pi*t);
anaSig = dsp.AnalyticSignal(200);
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1);
plot(t, x)
title('Original Signal');
subplot(2,1,2), plot(t, [real(y) imag(y)]);
title('Analytic signal of the input')
legend('Real signal','Imaginary signal',...
  'Location','best');
```

## More About

### Analytic Signal

The analytic signal  $x = x_r + jx_i$ , where the real part  $x_r$  is the original data and the imaginary part  $x_i$  contains the Hilbert transform. The imaginary part is a version of the original real sequence with a 90° phase shift. Sines are therefore transformed to cosines, and conversely, cosines are transformed to sines. The Hilbert-transformed series has the same amplitude and frequency content as the original sequence. The transform includes phase information that depends on the phase of the original.

The Hilbert transform is useful in calculating instantaneous attributes of a time series, especially the amplitude and the frequency. The instantaneous amplitude is the amplitude of the complex Hilbert transform. The instantaneous frequency is the time rate of change of the instantaneous phase angle. For a pure sinusoid, the instantaneous amplitude and frequency are constant. The instantaneous phase, however, is a sawtooth, reflecting how the local phase angle varies linearly over a single cycle.

## Algorithms

The algorithm computes the Hilbert transform using an equiripple FIR filter of the specified order  $n$ . The linear phase filter is designed using the Remez exchange algorithm and imposes a delay of  $n/2$  on the input samples.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

## See Also

### Objects

`dsp.FFT` | `dsp.IFFT`

# dsp.ArrayPlot

Display vectors or arrays

## Description

Display vectors or arrays where the data is uniformly spaced along the x-axis.

## Creation

### Syntax

```
scope = dsp.ArrayPlot  
scope = dsp.ArrayPlot(Name=Value)
```

### Description

`scope = dsp.ArrayPlot` creates an Array Plot object, `scope`.

`scope = dsp.ArrayPlot(Name=Value)` sets properties using one or more name-value pairs. For example, `scope = dsp.ArrayPlot(NumInputPorts=3)`

## Properties

Most properties can be changed from the `dsp.ArrayPlot` UI.

### Plot Configuration

#### **NumInputPorts** — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

#### **XDataMode** — Source of the x-data spacing

"Sample increment and X-offset" (default) | "Custom"

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify "Custom", you also must specify the `CustomXData` property values.

You can set this property only when creating the object.

#### **Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **X-Data Mode**.

Data Types: char | string

#### **CustomXData** — X-data values

empty vector (default) | vector

Specify the desired x-data values as a row or column vector of length equal to the frame length of the individual inputs. If you use the default (empty vector) value, the x-data is uniformly spaced and set to  $(0:L-1)$ , where  $L$  is the frame length.

You can set this property only when creating the object.

Example: `scope = dsp.ArrayPlot(XDataMode="Custom", CustomXData=logspace(0, log10(44100/2), 1024))`

#### **Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **X-Data Mode** to **Custom** and specify **Custom X-Data**.

#### **Dependency**

To use this property, set `XDataMode` to "Custom".

#### **SampleIncrement** — Sample increment of input

1 (default) | finite numeric scalar

Specify the spacing between samples along the x-axis as a finite numeric scalar. The input signal is only y-axis data. x-axis data is set automatically based on the `XOffset` and `SampleIncrement` properties.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

#### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Sample Increment**.

#### Dependency

To use this property, set `XDataMode` to 'Sample increment and X-offset'.

#### XOffset — Display offset of x-axis

0 (default) | scalar

Display offset of x-axis, specified as a numeric scalar. x-axis data is set automatically based on both the `SampleIncrement` and `XOffset` values. The x-offset represents the first value on the x-axis.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

#### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Offset**.

#### Dependency

To use this property, set `XDataMode` to "Sample increment and X-offset".

#### XScale — Scale of x-axis

"Linear" (default) | "Log"

Specify whether the scale of the x-axis is "Linear" or "Log". If `XOffset` is a negative value, you cannot set this property to "Log".

#### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XScale**.

Data Types: char | string

#### YScale — Scale of y-axis

"Linear" (default) | "Log"

Specify whether the scale of the y-axis is "Linear" or "Log".

#### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **YScale**.

Data Types: char | string

#### PlotType — Control type of plot

"Stem" (default) | "Line" | "Stairs"

Specify the type of plot to use for all the input signals displayed in the scope window:

- "Stem" - The scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values.
- "Line" - The scope displays the input signal as lines connecting each of the sampled values.
- "Stairs" - The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

### Scope Window Use

Open the **Settings** and set **Plot Type**.

### AxesScaling — Axes scaling mode

"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"

Specify when the scope scales the axes. Valid values are:

- "Auto" — The scope scales the axes as needed to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes once after a set number of visual updates. The number of updates is determined by the value of the `AxesScalingNumUpdates` property.

You can set this property only when creating the object.

### Scope Window Use

Hover over the array plot to see the zoom , pan , and autoscale  buttons. You can also zoom and pan using your mouse.

Data Types: `char` | `string`

### AxesScalingNumUpdates — Number of updates before scaling

100 (default) | real positive integer

Specify the number of updates before scaling as a real, positive scalar integer.

### Dependency

To enable this property, set `AxesScaling` to "Updates".

Data Types: `double`

### Measurements

#### MeasurementChannel — Channel for which to obtain measurements

1 (default) | positive integer

Channel for which to obtain measurements, specified as a positive integer in the range [1 *N*], where *N* is the number of input channels.

**Scope Window Use**

Click the **Measurements** tab on the Array Plot toolstrip. In the **Channel** section, select a **Channel**.

Data Types: double

**CursorMeasurements — Cursor measurements**

CursorMeasurementsConfiguration object

Cursor measurements to display screen or waveform cursors, specified as a CursorMeasurementsConfiguration object.

All CursorMeasurementsConfiguration properties are tunable.

**Scope Window Use**

Click the **Measurements** tab on the Array Plot toolstrip and modify the cursor measurements in the **Cursors** section.

**PeakFinder — Peak finder measurements**

PeakFinderConfiguration object

Peak finder measurements to compute and display the largest calculated peak values, specified as a PeakFinderConfiguration object.

All PeakFinderConfiguration properties are tunable.

**Scope Window Use**

Click the **Measurements** tab on the Array Plot toolstrip and modify the peak finder measurements in the **Peaks** section.

**SignalStatistics — Signal statistics measurements**

SignalStatisticsConfiguration object

Signal statistics measurements to compute and display signal statistics, specified as a SignalStatisticsConfiguration object.

All SignalStatisticsConfiguration properties are tunable.

**Scope Window Use**

Click the **Measurements** tab on the Array Plot toolstrip and modify the signal statistics measurements in the **Statistics** section.

**Visualization****Name — Window name**

'Array Plot' (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the **Title** property.

Data Types: char | string

**Position — Scope window position and size in pixels**

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form `[left bottom width height]`. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

### MaximizeAxes — Maximize axes control

"Auto" (default) | "On" | "Off"

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

### Scope Window Use

Hover over the array plot to see the maximize axes button .

Data Types: `char` | `string`

### Title — Display title

' ' (default) | character vector | string scalar

Specify the display title as a character vector or string.

### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Title**.

Data Types: `char` | `string`

### ShowLegend — Show legend

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

---

**Note** The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

---

### Scope Window Use

On the **Plot** tab, click **Legend**.

Data Types: `logical`

### **ChannelNames — Channel names**

empty cell (default) | cell array of character vectors | array of strings

Specify the input channel names as a cell array of character vectors or an array of strings. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

#### **Dependency**

To see channel names, set `ShowLegend` to `true`.

Data Types: `char`

### **ShowGrid — Display grid**

`true` (default) | `false`

Set this property to `true` to show grid lines on the plot.

#### **Scope Window Use**

Open the **Plot** tab, click **Settings**, and select **Grid**.

### **PlotAsMagnitudePhase — Plot signal as magnitude and phase**

`false` (default) | `true`

- `true` - The scope plots the magnitude and phase of the input signal on two separate axes within the same active display.
- `false` - The scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

#### **Scope Window Use**

On the **Plot** tab, select the **Magnitude Phase** button.

### **XLabel — x-axis label**

`""` (default) | character vector | string scalar

Specify the text for the scope to display below the x-axis.

#### **Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **XLabel**.

Data Types: `char` | `string`

### **YLabel — y-axis label**

"Amplitude" (default) | character vector | string scalar

Specify the text for the scope to display to the left of the y-axis.

**Dependencies**

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values "Magnitude" and "Phase", for the magnitude plot and the phase plot, respectively.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **YLabel**.

Data Types: `char` | `string`

**YLimits — y-axis limits**

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

**Dependencies**

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **Y-Axis Limits** as a two-element numeric vector.

**Usage****Syntax**

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

**Description**

`scope(signal)` displays the signal in the Array Plot.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the Array Plot. The signals can have a different number of channels and different frame lengths.

**Input Arguments****signal — Input signal or signals to visualize**

`scalar` | `vector` | `matrix`

Specify one or more input signals to visualize in the `dsp.ArrayPlot`. Signals can have a different number of channels and different frame lengths.

Example: `scope(signal1,signal2)`

**UI Customization**

To customize the style of signals on the array plot, open the **Settings** and use the bottom row of options to select a signal and modify the style, width, color, and marker type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the object as the first input argument.

|                             |  |
|-----------------------------|--|
| <code>generateScript</code> | Generate MATLAB script to create scope with current settings                                   |
| <code>hide</code>           | Hide scope window  |
| <code>show</code>           | Display scope window   |
| <code>isVisible</code>      | Determine visibility of scope  |
| <code>step</code>           | Run System object algorithm  |
| <code>release</code>        | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>          | Reset internal states of System object   |

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

## Examples

### Plot a Gaussian Distribution

Create a new Array Plot object.

```
scope = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
scope.YLimits = [0 1];
scope.XOffset = -2.5;
scope.SampleIncrement = 0.1;
scope.Title = "Gaussian distribution";
scope.XLabel = "X";
scope.YLabel = "f(X)";
```

Call the Array Plot object to plot a Gaussian distribution.

```
scope(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5)))'
```

You can scale the y-axis to show the plot on a log scale.

```
release(scope)
scope.YScale = 'Log';
scope(exp(-(-2.5:.1:2.5).^2))
```

### Plot Changing Filter Weights

View least mean squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object™.

```
lmsFilter = dsp.LMSFilter(40,Method="Normalized LMS",...
    StepSize=0.002);
```

Create and configure a `dsp.AudioFileReader` System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader("dspafx_8000.wav",...
    SamplesPerFrame=40, ...
    PlayCount=Inf,...
    OutputDataType="double");
```

Create and configure a `dsp.FIRFilter` System object to filter random white noise, creating colored noise.

```
firFilter = dsp.FIRFilter(Numerator=fir1(39,0.25));
```

Create and configure a `dsp.ArrayPlot` object to display the adaptive filter weights.

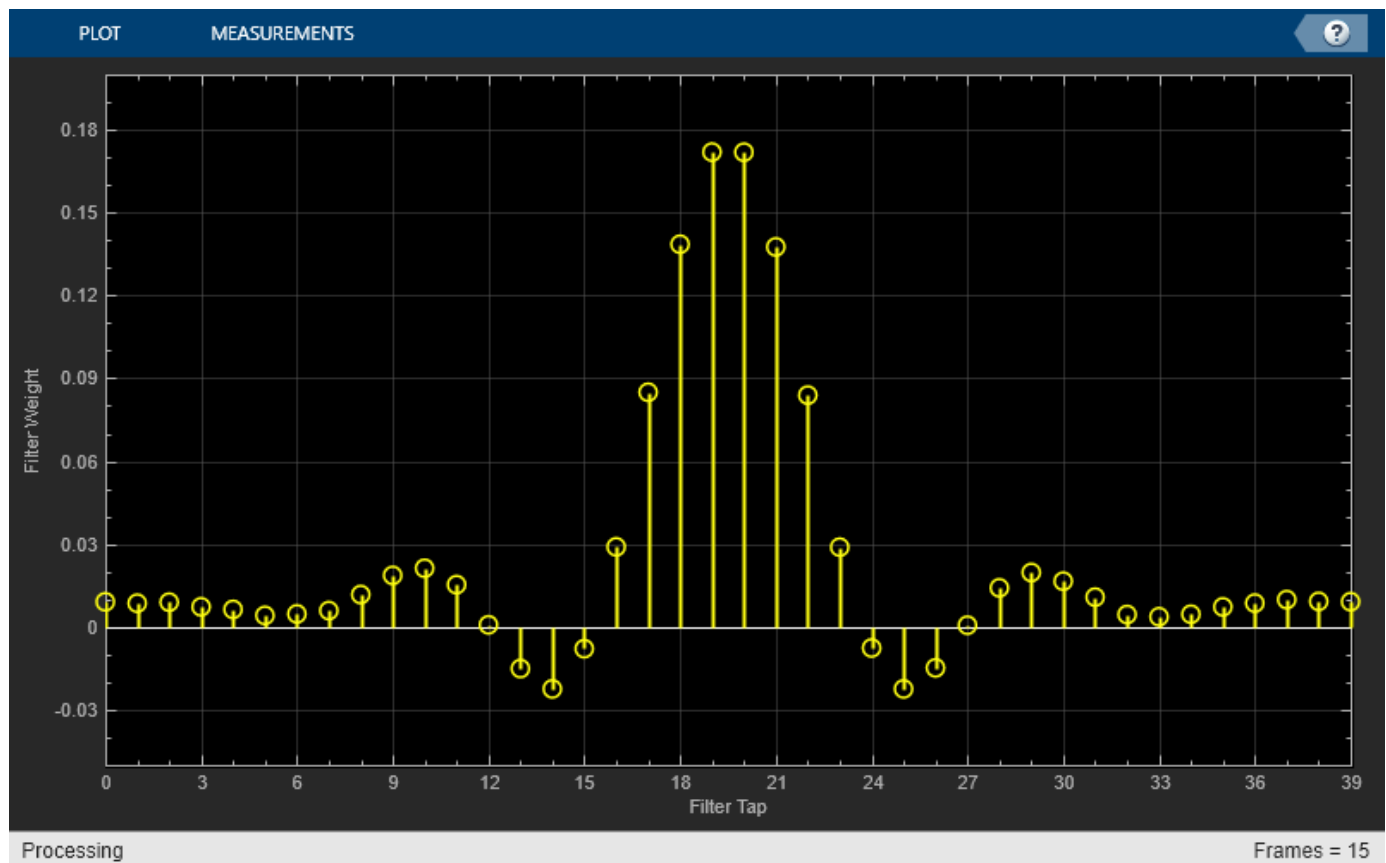

```
scope = dsp.ArrayPlot(XLabel="Filter Tap", ...
    YLabel="Filter Weight", ...
    YLimits=[-0.05 0.2]');

```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;
while numplays < 3
    [y, eof] = signalSource();
    noise = rand(40,1);
    noisefilt = firFilter(noise);
    desired = y + noisefilt;
    [~, ~, wts] = lmsFilter(noise,desired);
    scope(wts);
    numplays = numplays + eof;
end

```

### Power Spectrum of Multichannel Sinusoidal Signal

Compute the power spectrum of a multichannel sinusoidal signal using the `dsp.SpectrumEstimator` System object™. You can get the vector of frequencies at which the spectrum is estimated using the `getFrequencyVector` function. To compute the resolution bandwidth of the estimate (RBW), use the `getRBW` function.

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by  $\pi/2$  and  $\pi/4$ , respectively.

```
sineSignal = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the `dsp.SpectrumEstimator` object for the computation and the `dsp.ArrayPlot` for the plotting.

```
estimator = dsp.SpectrumEstimator('FrequencyRange','onesided');
plotter = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = sineSignal();
pxx = estimator(y);
plotter(pxx)
```

Get the vector of frequencies at which the spectrum is estimated in Hz, using the `getFrequencyVector` function.

```
f = getFrequencyVector(estimator);
```

Compute the resolution bandwidth (RBW) of the estimate using the `getRBW` function.

```
rbw = getRBW(estimator)
```

```
rbw =  
    0.0015
```

The resolution bandwidth of the signal power spectrum is 0.0015 Hz. This frequency is the smallest frequency that can be resolved on the spectrum.

### Power and Max-Hold Spectra of Noisy Sine Wave

Generate a sine wave.

```
sineWave = dsp.SineWave('Frequency',100,...  
    'SampleRate',1000, ...  
    'SamplesPerFrame',1000);
```

Use the spectrum estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

```
SE = dsp.SpectrumEstimator(...  
    'SampleRate',sineWave.SampleRate,...  
    'SpectrumType','Power','PowerUnits','dBm', ...  
    'FrequencyRange','centered',...  
    'OutputMaxHoldSpectrum',true);  
plotter = dsp.ArrayPlot('PlotType','Line',...  
    'XOffset',-500, ...  
    'YLimits',[-60 30],...  
    'Title','Power Spectrum of 100 Hz Sine Wave', ...  
    'YLabel','Power Spectrum (dBm)',...  
    'XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10  
    x = sineWave() + 0.05*randn(1000,1);  
    [Pxx,Pmax] = SE(x);  
    plotter([Pxx Pmax])  
end
```

## Tips

- To close the Array Plot window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the Array Plot window, use the `hide` and `show` functions.

## Version History

Introduced in R2013a

### R2022b: Channel names support array of strings

Starting in R2022b, you can specify the `ChannelNames` property of the `dsp.ArrayPlot` object as an array of strings.

```
ap = dsp.ArrayPlot(ChannelNames=["Input", "Noisy Output"]);
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.ArrayVectorAdder

**Package:** dsp

(Removed) Add array to vector along specified dimension

---

**Note** `dsp.ArrayVectorAdder` has been removed. Use the `+` operator instead. For more information, see “Compatibility Considerations”.

---

## Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

- 1 Define and set up your array-vector addition object. See “Construction” on page 4-69.
- 2 Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('PropertyName', PropertyValue, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is 1.

### VectorSource

Source of vector

Specify the source of the vector values as `|Input port | Property |`. The default is `Input port`.

**Vector**

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

**Fixed-Point Properties****FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

**OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

**VectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point data type as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

**CustomVectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

### AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `| Full precision | Same as first input | Custom |`. The default is `Full precision`.

### CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

### OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as accumulator | Same as first input | Custom |`.

### CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numericType([], 16, 15)`.

## Methods

`step`                    Add vector to N-D array

| Common to All System Objects |  |
|------------------------------|--|
| <code>release</code>         | Allow System object property value changes |

## Examples

### Add a Vector To a Matrix

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;
a = ones(2);
x = [1 2]';
y = ava(a, x);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

## Version History

### Introduced in R2012a

#### **R2021b: dsp.ArrayVectorAdder System object will be removed**

*Warns starting in R2021b*

The dsp.ArrayVectorAdder System object will be removed in a future release. Use the + operator instead.

#### **R2023a: dsp.ArrayVectorAdder System object has been removed**

*Errors starting in R2023a*

The dsp.ArrayVectorAdder System object has been removed. Use the + operator instead.

### Update Code

This table shows how to update existing code to use the + operator.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## step

**System object:** `dsp.ArrayVectorAdder`

**Package:** `dsp`

Add vector to N-D array

### Syntax

`Y = step(ava,A)`

`Y = step(ava,A,V)`

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(ava,A)` returns `Y`, the result of adding the input array `A` to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

`Y = step(ava,A,V)` returns `Y`, the result of adding the input array `A` to the elements of the input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.ArrayVectorDivider

**Package:** dsp

(Removed) Divide array by vector along specified dimension

---

**Note** `dsp.ArrayVectorDivider` has been removed. Use the `./` operator instead. For more information, see “Compatibility Considerations”.

---

## Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

- 1 Define and set up your array-vector division object. See “Construction” on page 4-75.
- 2 Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `avd`, with each property set to the specified value.

## Properties

### Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is 1.

### VectorSource

Source of vector

Specify the source of the vector values as | Input port | Property |. The default is Input port.

### **Vector**

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

### **Fixed-Point Properties**

#### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

#### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`.

#### **VectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point mode as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

#### **CustomVectorDataType**

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

#### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as first input | Custom |`. The default is `Same as first input`.

#### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

## Methods

`step` Divide array by vector

| Common to All System Objects |  |
|------------------------------|--|
| <code>release</code>         | Allow System object property value changes |

## Examples

### Divide a Matrix By a Vector

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
avd = dsp.ArrayVectorDivider;
a = ones(2);
x = [2 3]';
y = avd(a, x)
```

`y = 2×2`

```
    0.5000    0.5000
    0.3333    0.3333
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

## Version History

### Introduced in R2012a

#### **R2021b: dsp.ArrayVectorDivider System object will be removed**

*Warns starting in R2021b*

`dsp.ArrayVectorDivider` System object will be removed in a future release. Use the `./` operator instead.

#### **R2023a: dsp.ArrayVectorDivider System object has been removed**

*Errors starting in R2023a*

The `dsp.ArrayVectorDivider` System object has been removed. Use the `./` operator instead.

### Update Code

This table shows how to update existing code to use the ./ operator.

| Discouraged Usage  | Recommended Replacement   |
|--|---|
| <p><b>Divide along first dimension (column-wise)</b></p> <pre> avd = dsp.ArrayVectorDivider(Dimension=1); a = ones(2); x = [2;3]; y = avd(a,x)  y = 2x2      0.5    0.5     0.333 0.333                     </pre>   | <p><b>Divide along first dimension (column-wise)</b></p> <pre> y = a ./ x  y = 2x2      0.5    0.5     0.333 0.333                     </pre>   |

# **dsp.ArrayVectorMultiplier**

**Package:** dsp

(Removed) Multiply array by vector along specified dimension

---

**Note** `dsp.ArrayVectorMultiplier` has been removed. Use the `.*` operator instead. For more information, see “Compatibility Considerations”.

---

## **Description**

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

- 1 Define and set up your array-vector multiplication object. See “Construction” on page 4-80.
- 2 Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## **Construction**

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('PropertyName', PropertyValue, ...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

## **Properties**

### **Dimension**

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is 2.

### **VectorSource**

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

## Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the VectorSource property to Property. The default is [0.5 0.25]. This property is tunable.

## Fixed-Point Properties

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, Zero. The default is floor.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

### VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as Same word length as input, Custom. This property applies when you set the VectorSource property to Property. The default is Same word length as input.

### CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a numeric type object with a Signedness of Auto. This property applies when you set the VectorSource property to Property and the VectorDataType property to Custom. The default is numeric type ([], 16, 15).

### ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as Full precision, Same as first input, or Custom. The default is Full precision.

### CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

## **Methods**

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## step

**System object:** dsp.ArrayVectorMultiplier

**Package:** dsp

Multiply array by vector

### Syntax

$Y = \text{step}(\text{avm}, A, V)$

$Y = \text{step}(\text{avm}, A)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{avm}, A, V)$  returns  $Y$ , the result of multiplying the input array  $A$  by the elements of input vector  $V$  along the specified dimension when the `VectorSource` property is `Input port`. The length of the input  $V$  must equal the length of the specified dimension of  $A$ .

$Y = \text{step}(\text{avm}, A)$  returns  $Y$ , the result of multiplying the input array  $A$  by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of  $A$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# **dsp.ArrayVectorSubtractor**

**Package:** dsp

(Removed) Subtract vector from array along specified dimension

---

**Note** `dsp.ArrayVectorSubtractor` has been removed. Use the `-` operator instead. For more information, see “Compatibility Considerations”.

---

## **Description**

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

- 1 Define and set up your array-vector subtraction object. See “Construction” on page 4-86.
- 2 Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## **Construction**

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('PropertyName', PropertyValue, ...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

## **Properties**

### **Dimension**

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than 0. The default is 1.

### **VectorSource**

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

## Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

## Fixed-Point Properties

### FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

### OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

### VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

### CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

**AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

**CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

**OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

**CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

**Methods**

`step` Subtract vector from array along specified dimension

| Common to All System Objects |  |
|------------------------------|--|
| <code>release</code>         | Allow System object property value changes |

**Examples**

**Subtract Vector From Matrix**

---

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

---

```

avs = dsp.ArrayVectorSubtractor;
a = ones(2);
x = [1 2]';
y = avs(a, x)

```

y = 2×2

```

    0    0
   -1   -1

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

## Version History

**Introduced in R2012a**

### R2021b: dsp.ArrayVectorSubtractor System object will be removed

*Warns starting in R2021b*

dsp.ArrayVectorSubtractor System object will be removed in a future release. Use the – operator instead.

### R2023a: dsp.ArrayVectorSubtractor System object has been removed

*Errors starting in R2023a*

The dsp.ArrayVectorSubtractor System object has been removed. Use the – operator instead.

## Update Code

This table shows how to update existing code to use the – operator.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| <b>Subtract along first dimension (column-wise)</b><br><pre> avs = dsp.ArrayVectorSubtractor(Dimension=1); a = ones(2); x = [1 2]'; y = avs(a,x) </pre> <p>y = 2×2</p> <pre>     0    0    -1   -1 </pre> | <b>Subtract along first dimension (column-wise)</b><br><pre> y = a - x </pre> <p>y = 2×2</p> <pre>     0    0    -1   -1 </pre> |

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <p><b>Subtract along second dimension (row-wise)</b></p> <pre> avs = dsp.ArrayVectorSubtractor(Dimension=2); a = ones(2); x = [1 2]; y = avs(a,x)  y = 2x2      0    -1     0    -1                     </pre>  | <p><b>Subtract along second dimension (row-wise)</b></p> <pre> y = a - x  y = 2x2      0    -1     0    -1                     </pre>  |
| <p><b>Subtract along <math>N^{\text{th}}</math> dimension</b></p> <pre> d = [3 10 2 3 4]; a = randn(d);  Subtract the array with a vector along the fourth dimension. ## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## step

**System object:** dsp.ArrayVectorSubtractor

**Package:** dsp

Subtract vector from array along specified dimension

### Syntax

$Y = \text{step}(\text{avs}, A, V)$

$Y = \text{step}(\text{avs}, A)$

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

$Y = \text{step}(\text{avs}, A, V)$  returns  $Y$ . The value of  $Y$  results from subtracting the elements of input vector  $V$  from the input array  $A$  along the specified dimension when the `VectorSource` property is `Input port`. The length of the input  $V$  must equal the length of the specified dimension of  $A$ .

$Y = \text{step}(\text{avs}, A)$  returns  $Y$ . The value of  $Y$  results from subtracting the elements of the vector specified in the `Vector` property from the input array  $A$  along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of  $A$ .

---

**Note** `obj` specifies the System object on which to run this `step` method.

---

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.AsyncBuffer

**Package:** dsp

FIFO buffer

## Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer, and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread (`asyncBuff.NumUnreadSamples == asyncBuff.Capacity`), the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-94 and “Write Variable Frame Sizes to Buffer” on page 4-96.

To write and read samples from a FIFO buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

## Creation

### Syntax

```
asyncBuff = dsp.AsyncBuffer  
asyncBuff = dsp.AsyncBuffer(cap)
```

### Description

`asyncBuff = dsp.AsyncBuffer` returns an async buffer System object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Capacity — Number of writable/readable rows in buffer

192000 (default) | positive integer

Number of writable/readable rows in the buffer, specified as a positive integer greater than or equal to 2. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by `info` gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

By default, this property has data type `int32`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### NumUnreadSamples — Number of unread samples in each channel

0 (default) | integer

This property is read-only.

Number of unread samples in each channel (column) of the buffer, specified as an integer greater than or equal to 0. The total number of unread samples in the buffer is `NumUnreadSamples × numChann`. The variable `numChann` is the number of channels in the buffer. The number of channels in the buffer is the number of data columns in the first call to `write`.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Example: `asyncBuff = dsp.AsyncBuffer; input = randn(512,1); numUnreadSamples = write(asyncBuff,input)`

Data Types: `int32`

## Usage

To write and read samples from the async buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

### Specific to `dsp.AsyncBuffer`

`info` Get cumulative overrun and underrun  
`read` Read data from buffer  
`write` Write data to buffer  
`peek` Read data from buffer without changing number of unread samples

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;  
input = randn(512,1);  
write(asyncBuff,input);  
plot(input)  
hold on
```

Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```

outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
end
plot(outTotal,'r')
hold off

```

Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
    CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

### Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

The sine wave is generated using the `sin` function in MATLAB. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;

for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fft0bj(x));
        plotter(log(X));
    end
end
```

### Peek Data from Async Buffer

Read data from the async buffer without changing the number of unread samples using the `peek` function.

Create a `dsp.AsyncBuffer` System object™. The input is a column vector of 100 samples, 1 to 100. Write the data to the buffer.

```
asyncBuff = dsp.AsyncBuffer
asyncBuff =
  AsyncBuffer with properties:
      Capacity: 192000
  NumUnreadSamples: 0
```

```
input = (1:100)';
write(asyncBuff,input);
```

Peek at the first three samples. The output is [1 2 3]′.

```
out1 = peek(asyncBuff,3)
out1 = 3×1
     1
     2
     3
```

The `NumUnreadSamples` is 100, indicating that the peek function has not changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    100
```

After peeking, read 50 samples using the `read` function. The output is [1:50]′.

```
out2 = read(asyncBuff,50)
out2 = 50×1
     1
     2
     3
     4
     5
     6
     7
     8
     9
    10
     :
```

The `NumUnreadSamples` is 50, indicating that the `read` function has changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    50
```

Now peek again at the first three samples. The output is [51 52 53]'. Verify that the `NumUnreadSamples` is still 50.

```
out3 = peek(asyncBuff,3)
```

```
out3 = 3×1
```

```
51
52
53
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
50
```

Read 50 samples again. The output now contains the sequence [51:100]'. Verify that `NumUnreadSamples` is 0.

```
out4 = read(asyncBuff)
```

```
out4 = 50×1
```

```
51
52
53
54
55
56
57
58
59
60
⋮
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
0
```

## Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see “Why Does the `dsp.AsyncBuffer` Object Error When You Call `read` Before `write`?”

## Version History

Introduced in R2017a

# audioDeviceWriter

Play to sound card

## Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.

## Data Flow of Audio Device Writer

- Call the object to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

To stream data to an audio device:

- 1 Create the `audioDeviceWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```

deviceWriter = audioDeviceWriter
deviceWriter = audioDeviceWriter(sampleRateValue)
deviceWriter = audioDeviceWriter( ___,Name,Value)
  
```

### Description

`deviceWriter = audioDeviceWriter` returns a System object, `deviceWriter`, that writes audio samples to an audio output device in real time.

`deviceWriter = audioDeviceWriter(sampleRateValue)` sets the `SampleRate` property to `sampleRateValue`.

`deviceWriter = audioDeviceWriter( ____, Name, Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `deviceWriter = audioDeviceWriter(48000, 'BitDepth', '8-bit integer')` creates a System object, `deviceWriter`, that operates at a 48 kHz sample rate and an 8-bit integer bit depth.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

#### Driver — Driver used to access audio device (Windows only)

'DirectSound' (default) | 'ASIO' | 'WASAPI'

Driver used to access your audio device, specified as 'DirectSound', 'ASIO', or 'WASAPI'.

- ASIO drivers do not come pre-installed on Windows machines. To use the 'ASIO' driver option, install an ASIO driver outside of MATLAB.

---

**Note** If `Driver` is specified as 'ASIO', use `asiosettings` to set the sound card buffer size to the buffer size of your `audioDeviceWriter` System object.

---

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must have an Audio Toolbox license. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

Data Types: `char` | `string`

#### Device — Device used to play audio samples

default audio device (default) | character vector | string scalar

Device used to play audio samples, specified as a character vector or string scalar. Use `getAudioDevices` to list available devices for the selected driver.

Data Types: `char` | `string`

**SampleRate — Sample rate of signal sent to audio device (Hz)**

44100 (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**BitDepth — Data type used by the device**

'16-bit integer' (default) | '8-bit integer' | '24-bit integer' | '32-bit float'

Data type used by the device, specified as a character vector or string scalar. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

Data Types: `char` | `string`**SupportVariableSizeInput — Support variable frame size**`false` (default) | `true`

Option to support variable frame size, specified as `true` or `false`.

- `false` -- If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call. The buffer size of your audio device is the same as the input frame size.
- `true` -- If the `audioDeviceWriter` object is locked, the input frame size can change at each call. The buffer size of your audio device is specified through the `BufferSize` property.

Data Types: `char`**BufferSize — Buffer size of audio device**

4096 (default) | positive integer

Buffer size of audio device, specified as a positive integer.

---

**Note** If `Driver` is specified as 'ASIO', open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

---

**Dependencies**

To enable this property, set `SupportVariableSizeInput` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**ChannelMappingSource — Source of mapping between input matrix and device channels**

'Auto' (default) | 'Property'

Source of mapping between columns of input matrix and channels of audio output device, specified as 'Auto' or 'Property'.

- 'Auto' -- Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.

- 'Property' -- The ChannelMapping property determines the mapping between columns of input matrix and channels of audio output device.

Data Types: char | string

### ChannelMapping — Nondefault mapping between input matrix and device channels

[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

To selectively map between columns of the input matrix and your sound card's output channels, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault ChannelMapping returns an error.

---

**Note** To ensure mono output on only one channel of a stereo device, use the default ChannelMapping setting and provide a stereo signal where one channel is all zeros.

**Example:** outputLeftOnly = [x(:,1) zeros(size(x,1),1)];

**Example:** outputRightOnly = [zeros(size(x,1),1) x(:,1)];

---

### Dependencies

To enable this property, set ChannelMappingSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Usage

### Syntax

```
numUnderrun = deviceWriter(audioToDevice)
```

### Description

numUnderrun = deviceWriter(audioToDevice) writes one frame of audio samples, audioToDevice, to the selected audio device and returns the number of audio samples underrun since the last call to deviceWriter.

**Note:** When you call the audioDeviceWriter System object, the audio device specified by the Device property is locked. An audio device can be locked by only one audioDeviceWriter at a time. To release the audio device, call release on your audioDeviceWriter System object.

### Input Arguments

#### audioToDevice — Audio to device

matrix

Audio signal to write to device, specified as a matrix. The columns of the matrix are treated as independent audio channels.

If `audioToDevice` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range `[-1, 1]`. For other data types, the allowed input range is `[min, max]` of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

## Output Arguments

### **numUnderrun — Number of samples underrun**

scalar

Number of samples by which the audio device writer queue was underrun since the last call to `deviceWriter`.

Data Types: `uint32`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to audioDeviceWriter

|                              |  |
|------------------------------|--|
| <code>getAudioDevices</code> | List available audio devices                         |
| <code>info</code>            | Characteristic information about audio device writer |

## Common to All System Objects

|                       |  |
|-----------------------|--|
| <code>clone</code>    | Create duplicate System object   |
| <code>isLocked</code> | Determine if System object is in use   |
| <code>release</code>  | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>    | Reset internal states of System object   |
| <code>step</code>     | Run System object algorithm  |
| <code>setup</code>    | One-time set up tasks for System objects   |

## Examples

### Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` object with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3')

fileInfo = struct with fields:
    Filename: 'B:\matlab\toolbox\dsp\samples\speech_dft.mp3'
    CompressionMethod: 'MP3'
    NumChannels: 1
```

```
SampleRate: 22050
TotalSamples: 112893
Duration: 5.1199
  Title: []
  Comment: []
  Artist: []
BitRate: 64
```

Create an `audioDeviceWriter` object and specify the sample rate.

```
deviceWriter = audioDeviceWriter('SampleRate', fileInfo.SampleRate);
```

Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
setup(deviceWriter, zeros(fileReader.SamplesPerFrame, ...
    fileInfo.NumChannels))
```

Use the `info` function to obtain the characteristic information about the device writer.

```
info(deviceWriter)
ans = struct with fields:
    Driver: 'DirectSound'
    DeviceName: 'Primary Sound Driver'
    MaximumOutputChannels: 2
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader)
release(deviceWriter)
```

### Reduce Latency due to Output Device Buffer

*Latency* due to the output device buffer is the time delay of writing one frame of data. Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate', fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate %#ok
bufferLatency = 0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
bufferLatency = 0.0116
```

### Determine and Decrease Underrun

*Underrun* refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` object to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,...
    fileInfo.NumChannels))
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

```
Total samples underrun: 0.
```

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

```
Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` objects and set your counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Use `pause` to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 68608.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 3.111474e+00.

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');
```

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 0.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 0.

The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increasing the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.

- Decreasing the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choosing an optimal driver and device for your system.

## Version History

Introduced in R2016a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

## getAudioDevices

List available audio devices

### Syntax

```
devices = getAudioDevices(deviceWriter)
```

### Description

`devices = getAudioDevices(deviceWriter)` returns a list of audio devices that are available and compatible with your I/O audio object, `deviceWriter`.

### Input Arguments

**deviceWriter** — Audio I/O object

`audioDeviceWriter` object

Audio I/O object, specified as an `audioDeviceWriter` object.

Data Types: `object`

### Output Arguments

**devices** — List of available and compatible devices

`array`

List of available and compatible devices. The list of audio devices depends on the specified `Driver` property of your object.

Data Types: `cell`

## Version History

`audioDeviceWriter`

# dsp.AudioFileReader

**Package:** dsp

Stream from audio file

## Description

The `dsp.AudioFileReader` System object reads audio samples from an audio file.

To read audio samples from an audio file:

- 1 Create the `dsp.AudioFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
afr = dsp.AudioFileReader
afr = dsp.AudioFileReader(Filename)
afr = dsp.AudioFileReader(Name,Value)
```

### Description

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader(Filename)` returns an audio file reader object, `afr`, with `Filename` property set to `Filename`.

`afr = dsp.AudioFileReader(Name,Value)` returns an audio file reader System object, `afr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Filename — Name of audio file from which to read

'speech\_dft.mp3' (default) | character vector | string scalar

Specify the name of an audio file as a character vector or a string scalar. If `FilenameIsTunableInCodegen` is set to `false` and the file is on MATLAB path, then you do not need to specify the full name of the file. If `FilenameIsTunableInCodegen` is set to `true`, then the file name must either exist in the current directory, or you must specify the full file path. The file name can be an http web address like `'http://audio.wgbh.org:8004/'`. For an example, see “Read and Play Back Audio File from http Web Address” on page 4-115.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. File attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For an example, see “Tunable Audio File Name in Generated Code” on page 4-116.

The following table lists the supported audio file formats.

| Platforms   | File Name Extensions  |
|-------------|---|
| Windows     | .wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .opus, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov |
| Non-Windows | .avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .opus, .au, .snd, .mov       |

#### **PlayCount — Number of times to play file**

1 (default) | positive integer

Specify a positive integer as the number of times to play the file.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **SamplesPerFrame — Number of samples in audio frame**

1024 (default) | positive integer

Specify the number of samples in an audio frame as a positive, scalar integer value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **OutputDataType — Data type of output**

'double' (default) | 'single' | 'int16' | 'uint8'

Set the data type of the audio data output from the audio file reader object. Specify the data type as 'double', 'single', 'int16', or 'uint8'.

#### **FilenameIsTunableInCodegen — Enable file name tunability in generated code**

false (default) | true

Set this property to true to enable tunability of `Filename` in generated C/C++ code. The file with the specified `Filename` must either exist in the current directory, or you must specify the full file path.

If `FilenameIsTunableInCodegen` is set to `true`, file attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a `.wav` file, then the generated

code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

Data Types: `logical`

### CodegenPrototypeFile — Prototype audio file for code generation

'speech\_dft.mp3' (default) | character vector | string scalar

Specify the name of the prototype audio file used in code generation as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path. The file name can be an http web address, like 'http://audio.wgbh.org:8004/'.

The attributes of the audio file specified in `Filename` (such as the audio format, the number of audio channels, the sample rate, and the bite rate) must match the attributes of the audio file specified in `CodegenPrototypeFile`. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a .wav file, then the generated code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

The following table lists the supported audio file formats:

| Platforms   | File Name Extensions  |
|-------------|---|
| Windows     | .wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .opus, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov |
| Non-Windows | .avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .opus, .au, .snd, .mov       |

### Dependencies

This property applies only when the `FilenameIsTunableInCodegen` property is set to `true`.

### SampleRate — Sampling rate of audio file

positive scalar

This property is read-only.

This property displays the sample rate, in Hz, of the audio file.

Data Types: `double`

### ReadRange — Range of samples to be read

[1 inf] (default) | two-element row vector

Specify the sample range from which to read, as a vector in the form of [`StartSample` `EndSample`], where `StartSample` is the sample at which file reading starts, and `EndSample` is the sample at which file reading stops.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Usage

### Syntax

```
audio = afr()
```

```
[audio,eof] = afr()
```

**Description**

`audio = afr()` outputs one frame of audio samples, `audio`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `audio` contains silence.

`[audio,eof] = afr()` returns an end-of-file indicator, `eof`. `eof` is true each time the output `audio` contains the last audio sample in the file.

**Output Arguments****audio — Audio samples**

column vector

One frame of audio samples, returned as a column vector of length equal to the value you specify in the `SamplesPerFrame` property. The data type of the audio output is specified in the `OutputDataType` property.

Data Types: `single` | `double` | `int16` | `uint8`

**eof — End-of-file indicator**

1 | 0

End-of-file indicator, returned as either a 1 or a 0. A value of 1 is output when `audio` contains the last audio sample in the file.

Data Types: `logical`

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Specific to `dsp.AudioFileReader`**

`info` Information about specific audio file

`isDone` End-of-file status (logical)

**Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

**Examples****Read and Play Back Audio File**

Read and play back an audio file using the standard audio output device.

You can choose to read the entire data or specify a range of data to read from using the `ReadRange` property. By default, `ReadRange` is set to `[1 inf]`, indicating the file reader to read the entire data from the source. In this example, set `ReadRange` to `3Fs`, indicating the file reader to read the first 3 seconds of the data.

```
afr = dsp.AudioFileReader('speech_dft.mp3','ReadRange',[1 3*22050]);
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

### Read and Play Back Audio File from http Web Address

Read audio data from an http web address using the `dsp.AudioFileReader` System object™. Play back the data using the `audioDeviceWriter` System object.

#### Initialization

Create an audio file reader which reads data from `http://audio.wgbh.org:8004/`. Set the sample rate of the audio device writer to be the same as that of the audio file reader.

```
afr = dsp.AudioFileReader('http://audio.wgbh.org:8004/')
```

```
afr =
    dsp.AudioFileReader with properties:

        Filename: 'http://audio.wgbh.org:8004/'
        PlayCount: 1
        SamplesPerFrame: 1024
        OutputDataType: 'double'
        SampleRate: 44100
        ReadRange: [1 Inf]
```

```
adw = audioDeviceWriter(afr.SampleRate)
```

```
adw =
    audioDeviceWriter with properties:

        Driver: 'DirectSound'
        Device: 'Default'
        SampleRate: 44100

    Show all properties
```

### Read and Play Back

Read a specific amount of data from the web address directly and play the data back using the audio device writer.

```
for i = 1:1000
    audio = afr();
    adw(audio);
end
```

Close the input file and the audio output device.

```
release(afr)
release(adw)
```

### **Tunable Audio File Name in Generated Code**

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m

function writeAudio(readfile,writefile)

afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...
    'CodegenPrototypeFile','rock-stereo.wav');
afr.Filename = readfile;
% Filename is funky-stereo.wav and CodegenPrototypeFile is
% rock-stereo.wav.

firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2

afw = dsp.AudioFileWriter('SampleRate',22050);
afw.Filename = writefile;
while ~isDone(afr)
    audio = afr();
    audiod = firdec(audio);
    afw(audiod);
end

release(afr);
release(afw);

end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

## Limitations

- For MP3, MPEG-4 AAC, and AVI audio files on Windows 7 or later and Linux platforms, `dsp.AudioFileReader` object can read fewer samples than expected. On Windows platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- To read OPUS files on a Linux machine, ensure that you have installed `libsndfile 1.0.29` or a later version. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

## Version History

**Introduced in R2012a**

### **R2022b: Support for OPUS audio file format**

The `dsp.AudioFileReader` object supports audio files in the OPUS file format (`.opus`).

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. # dsp.AudioFileWriter

**Package:** dsp

Stream to audio file

## Description

The `dsp.AudioFileWriter` System object writes audio samples to an audio file.

To write audio samples to an audio file:

- 1 Create the `dsp.AudioFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
afw = dsp.AudioFileWriter
afw = dsp.AudioFileWriter(Filename)
afw = dsp.AudioFileWriter(Name,Value)
```

### Description

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

`afw = dsp.AudioFileWriter(Filename)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to `Filename`.

`afw = dsp.AudioFileWriter(Name,Value)` returns an audio file writer object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **Filename — Name of audio file to which to write**

'output.wav' (default) | character vector | string scalar

Specify the name of the audio file as a character vector or a string scalar.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. For an example, see “Tunable Audio File Name in Generated Code” on page 4-116.

**FileFormat — Audio file format**

'WAV' (default) | 'AVI' | 'FLAC' | 'OGG' | 'MPEG4' | 'OPUS' | 'WMA'

Specify which audio file format the object writes. On Microsoft platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', 'MPEG4', 'OPUS', 'WMA'. On Linux platforms, select one of 'AVI', 'WAV', 'FLAC', 'OPUS', or 'OGG'. On macOS platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', 'OPUS', or 'MPEG4'. These abbreviations correspond to the following file formats:

- 'AVI' -- Audio-Video Interleave
- 'WAV' -- Microsoft WAVE Files
- 'WMA' -- Windows Media Audio
- 'FLAC' -- Free lossless audio Codec
- 'OGG' -- Ogg/Vorbis compressed audio file
- 'OPUS' -- Opus compressed audio file
- 'MPEG4' -- MPEG-4 AAC File — You can use both .m4a and .mp4 extensions

The default is 'WAV'.

**SampleRate — Sampling rate of audio data stream**

44100 (default) | positive scalar

Specify the sample rate of the input audio data as a positive, numeric scalar value.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Compressor — Algorithm that compresses audio data**

'None (uncompressed)' (default) | 'CCITT A-Law' | 'CCITT u-Law' | 'GSM 6.10' | 'IMA ADPCM' | 'Microsoft ADPCM' | 'PCM'

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select 'None (uncompressed)' to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid Compressor options for your computer by typing `H.Compressor = '` and then pressing the tab key.

**Dependencies**

This property applies when writing WAV or AVI files on Windows platforms.

**Data Type — Data type of the uncompressed audio**

'int16' (default) | 'double' | 'single' | 'inherit' | 'int24' | 'int32' | 'uint8'

Specify the type of uncompressed audio data written to the file as 'int16', 'double', 'single', 'inherit', 'int24', 'int32', or 'uint8'.

**Dependencies**

This property only applies when writing uncompressed WAV files.

## Usage

## Syntax

```
afw(audio)
```

## Description

`afw(audio)` writes one frame of audio samples, `audio`, to the output file specified by `Filename`. `audio` is either a vector for mono audio input or an  $M$ -by- $N$  matrix for  $N$ -channel audio input respectively.

## Input Arguments

### **audio** — Audio samples

column vector | matrix

One frame of audio samples, returned as a column vector or a matrix. A column vector input indicates a mono audio input. An  $M$ -by- $N$  matrix indicates an  $N$ -channel audio input.

If the input is fixed-point, the input must be a signed fixed-point input with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int16` | `int32` | `uint8` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Write an Audio Signal to WAV File

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'double');
firdec = dsp.FIRDecimator; % decimate by 2
afw = dsp.AudioFileWriter...
    ('speech_dft.wav', ...
    'SampleRate', afr.SampleRate/2);
while ~isDone(afw)
```

```
        audio = afr();
        audiod = firdec(audio);
        afw(audiod);
end

release(afr);
release(afw);
```

### Tunable Audio File Name in Generated Code

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m

function writeAudio(readfile,writefile)

afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...
    'CodegenPrototypeFile','rock-stereo.wav');
afr.Filename = readfile;
% Filename is funky-stereo.wav and CodegenPrototypeFile is
% rock-stereo.wav.

firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2

afw = dsp.AudioFileWriter('SampleRate',22050);
afw.Filename = writefile;
while ~isDone(afr)
    audio = afr();
    audiod = firdec(audio);
    afw(audiod);
end

release(afr);
release(afw);

end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

## Limitations

The following platform-specific restrictions apply when writing these files:

### Windows 7

- Only sample rates of 44100 Hz and 48000 Hz are supported for the MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate.
- Only mono or stereo outputs are allowed for the MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- The output data is padded on both the front and back of the signal, with extra samples of silence.

Windows AAC encoder places sharp fade-in and fade-out on audio signals, causing the signals to be slightly longer in samples when written to disk.

- A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.

### macOS

- Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
- Not all sampling rates are supported, although the Mac Audio Toolbox API does not explicitly specify a restriction.

### Linux

- To support OPUS file format on a Linux machine, you must have `libsndfile 1.0.29` or a later version installed. On Windows and Mac, this file is shipped with MATLAB and is available under `$MATLABROOT/bin/<platform>`.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

## Version History

**Introduced in R2012a**

### **R2022b: Support for OPUS audio file format**

The `dsp.AudioFileWriter` object supports OPUS file format (.opus).

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

# dsp.Autocorrelator

**Package:** dsp

(Removed) Autocorrelation sequence

---

**Note** `dsp.Autocorrelator` has been removed. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

- 1 Create the `dsp.Autocorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ac = dsp.Autocorrelator
ac = dsp.Autocorrelator(Name,Value)
```

### Description

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an  $N$ -D array. By default, the autocorrelator computes the autocorrelation at lags from zero to  $N - 1$ , where  $N$  is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator(Name,Value)` returns an autocorrelator, `ac`, with each property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **MaximumLagSource — Source of maximum lag**

Auto (default) | Property

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval  $[0, N-1]$ , where  $N$  is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range  $[0, \text{MaximumLag}]$ .

### **MaximumLag — Maximum positive lag**

1 (default) | 0 | positive integer

Specify the maximum lag as an integer greater than or equal to 0. The `MaximumLag` must be less than the length of the input data.

### **Dependencies**

This property applies only when the `MaximumLagSource` property is `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Scaling — Autocorrelation function scaling**

None (default) | Biased | Unbiased | Unity at zero-lag

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by  $1/N$ , where  $N$  is the length of the input data. Scaling by  $1/N$  yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by  $1/N$  has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by  $1/N - 1$ . Scaling by  $N - 1$  produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

### **Method — Domain for computing autocorrelations**

Time Domain (default) | Frequency Domain

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals.

### **Fixed-Point Properties**

#### **FullPrecisionOverride — Full precision override for fixed-point arithmetic**

true (default) | false

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

### **RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

#### **Dependencies**

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

### **OverflowAction — Overflow action for fixed-point operations**

Wrap (default) | Saturate

Specify the overflow action as `Wrap` or `Saturate`.

#### **Dependencies**

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

### **ProductDataType — Product word and fraction lengths**

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`.

#### **Dependencies**

This property applies only when you set the `Method` property to `Time Domain`.

### **CustomProductDataType — Product word and fraction lengths**

`numerictype([], 32, 30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

#### **Dependencies**

This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`.

### **AccumulatorDataType — Accumulator word and fraction lengths**

Full precision (default) | Same as product | Same as input | Custom

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`.

#### **Dependencies**

This property applies only when the `Method` property is `Time Domain`.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

**Dependencies**

This property applies only when you set the `Method` property to `Time Domain` and the `AccumulatorDataType` property to `Custom`.

**OutputDataType — Output word and fraction lengths**`Same as accumulator (default) | Same as product | Same as input | Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`.

**Dependencies**

This property applies only when the `Method` property is `Time Domain`.

**CustomOutputDataType — Output word and fraction lengths**`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

**Dependencies**

This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`.

**Usage****Syntax**`y = ac(x)`**Description**

`y = ac(x)` computes the autocorrelation sequence `y` for the columns of the input `x`.

**Input Arguments****x — Data input**`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or an  $N$ -D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When the input signal is complex, the output signal is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **y** — Autocorrelated output

vector | matrix | *N*-D array

Autocorrelated output of the two input signals. The size, data type, and complexity of the output matches that of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Autocorrelation of Noisy Sine Wave

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As the generated figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

## More About

### Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence,  $x(n)$ , the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the input is a length  $N$  realization of a WSS stationary random process,  $r_x(h)$  is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where  $E\{ \}$  is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

## Algorithms

### Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence,  $y$ , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- $y_{0,j}$  is the zero-lag element in the  $j$ th column of the input.
- $i$  is the index of the lag.
- $j$  is the index of the input data column.
- $*$  denotes the complex conjugate.
- $M$  is the number of elements in each column.

- $l$  is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags,  $l=M-1$ . Otherwise,  $l$  is the maximum nonnegative integer lag value specified.
- $u$  is an  $M$ -by- $N$  input matrix.

### Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

## Version History

### Introduced in R2012a

#### **R2021b: dsp.Autocorrelator System object will be removed**

*Warns starting in R2021b*

`dsp.Autocorrelator` System object will be removed in a future release. Use the `xcorr` function instead.

#### **R2023a: dsp.Autocorrelator System object has been removed**

*Errors starting in R2023a*

The `dsp.Autocorrelator` System object has been removed. Use the `xcorr` function instead.

### Update Code

This table shows how to update existing code to use the `xcorr` function.

# dsp.BinaryFileReader

**Package:** dsp

Read data from binary file

## Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `dsp.BinaryFileWriter` System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the “Write and Read Character Data” on page 4-144 and “Write and Read Fixed-Point Data” on page 4-143 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see “Read Complex Data” on page 4-142. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data” on page 4-145.

To read data from a binary file:

- 1 Create the `dsp.BinaryFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
reader = dsp.BinaryFileReader
reader = dsp.BinaryFileReader(fname)
reader = dsp.BinaryFileReader(fname,Name,Value)
```

### Description

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname,Name,Value)` with `Filename` set to `fname`, and each specified property set to the specified value. Unspecified properties have default values.

```
Example: reader =  
dsp.BinaryFileReader('myFilename.bin','SamplesPerFrame',1000,'NumChannels',2)  
;
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Filename — Name of file

'Untitled.bin' (default) | character vector | string scalar

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

### HeaderStructure — Size of header

struct('Field1',[]) (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

### SamplesPerFrame — Number of samples per output frame

1024 (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

### NumChannels — Number of channels

1 (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

### DataType — Type of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Type of data in file, specified as a character vector. This property defines the data type of the matrix returned by the object algorithm.

**IsDataComplex — Specify data complexity**`false` (default) | `true`

Option to specify data complexity, specified as `false` or `true`. When this property is set to `true`, the reader treats the data as complex. The object reads the data as interleaved real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. If this property is set to `false`, the same object reads the data as `[1 5; 2 6]`.

**Usage****Syntax**`data = reader()`**Description**

`data = reader()` reads data from the binary file in a row-major format. The data type, size, and complexity of the data are determined by the properties of the reader object. Once the end of file is reached, the output contains zeros of the specified data type, size, and complexity.

**Output Arguments****data — Data output**`vector` | `matrix`

Data read by the binary file reader, returned as a vector or a matrix. The size of the data is given by `SamplesPerFrame-by-NumChannels`, where `SamplesPerFrame` and `NumChannels` are the properties of the `dsp.BinaryFileReader` object.

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`**Specific to dsp.BinaryFileReader**`isDone`      End-of-data status`readHeader`    Read file header**Common to All System Objects**`step`      Run System object algorithm`release`    Release resources and allow changes to System object property values and input characteristics`reset`      Reset internal states of System object**Examples**

### Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

#### Write the Data

Specify the file header as a structure with the following fields:

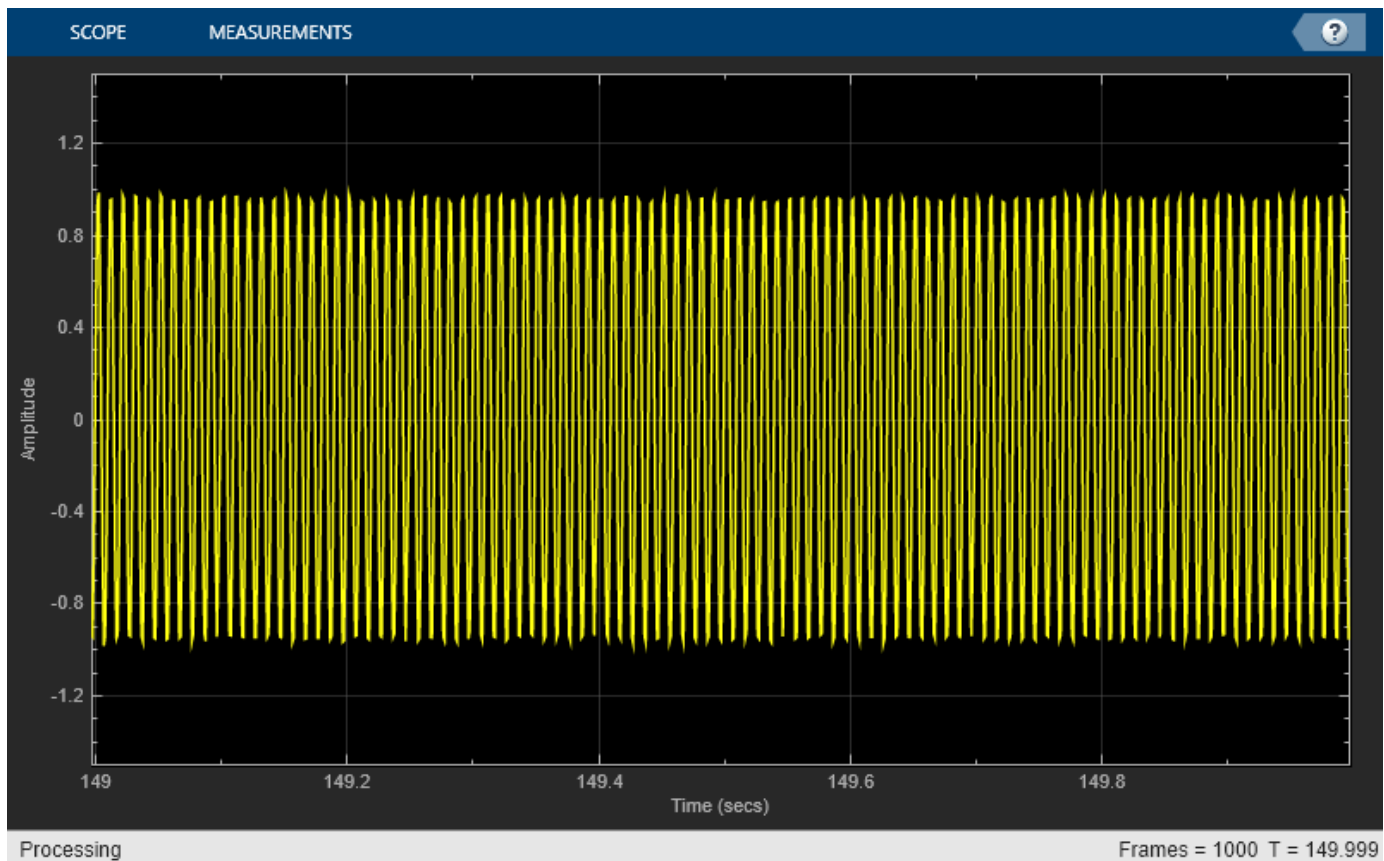

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end
```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

### Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...
    'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
```

```
'HeaderStructure',headerPrototype);  
headerReader = readHeader(reader)
```

```
headerReader =  
  
struct with fields:  
  
    DataType: 'double'  
    Complexity: 0  
    FrameSize: 150  
    NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

```
reader.IsDataComplex = headerReader.Complexity;  
reader.DataType = headerReader.DataType;  
reader.NumChannels = headerReader.NumChannels;  
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = timescope('YLimits',[-1.5 1.5],...  
    'SampleRate',sine.SampleRate,...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1);
```

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

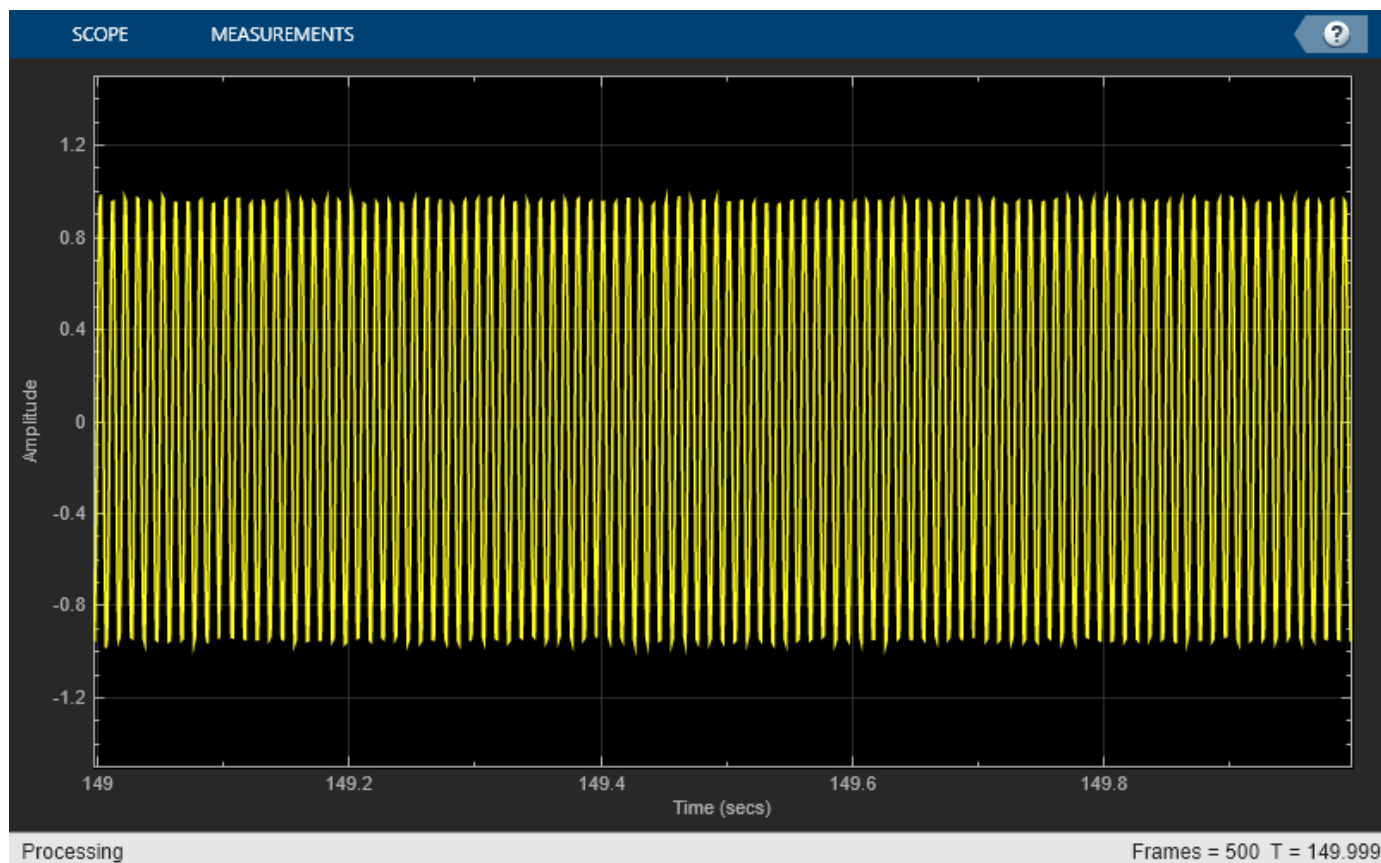

```
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);  
release(scopereader);
```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

### Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

#### Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
               'Complexity',false,...
```

```

        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

### Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```

headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end

```

```
out = 5×4
```

|   |   |   |    |
|---|---|---|----|
| 1 | 2 | 3 | 8  |
| 4 | 5 | 6 | 10 |
| 7 | 8 | 9 | 11 |
| 0 | 0 | 0 | 0  |
| 0 | 0 | 0 | 0  |

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

### Read Header Data

Read the header data from a binary file using the `readHeader` function.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```

fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');

```

```
fwrite(fid, single((1:5).'), 'single');  
fwrite(fid, (1:1000).', 'double');  
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');  
s = struct('A', zeros(1,4), 'B', ones(5,1, 'single'));  
reader.HeaderStructure = s;
```

Read the header using the `readHeader` function.

```
H = readHeader(reader);  
fprintf('H.A: ')  
  
H.A:  
  
fprintf('%d ', H.A);  
  
1 2 3 4  
  
fprintf('\nH.A datatype: %s\n', class(H.A))  
  
H.A datatype: double  
  
fprintf('H.B: ')  
  
H.B:  
  
fprintf('%d ', H.B);  
  
1 2 3 4 5  
  
fprintf('\nH.B datatype: %s\n', class(H.B))  
  
H.B datatype: single
```

### Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat', 'w');  
fwrite(fid, [1 2 3 4; 9 10 11 12], 'double');  
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannels` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat', 'SamplesPerFrame', 2, ...  
    'NumChannels', 2, 'IsDataComplex', true);
```

```

s = struct([]);
reader.HeaderStructure = s;
data = reader();
display(data);

data = 2x2 complex

    1.0000 + 9.0000i    2.0000 +10.0000i
    3.0000 +11.0000i    4.0000 +12.0000i

release(reader);

```

Alternatively, if you do not specify the data as complex, the reader reads the data as a SamplesPerFrame-by- NumChannel matrix of real values.

```

reader.IsDataComplex = false;
data = reader();
display(data);

data = 2x2

     1     9
     2    10

release(reader);

```

### Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

#### Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```

data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

#### Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using

$2^{(-fractionLength)(storedInteger)}$ . If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue, signedness, wordLength, fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat',...
    'SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,...
    wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)

ans = logical
     1
```

### Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

#### Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

#### Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat',...
    'DataType','uint8',...
    'SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

### Change Endianness of Data

By default, the dsp.BinaryFileReader System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the `swapbytes` function.

Write a numeric array into `myfile.dat` in big endian format. Read the data using the dsp.BinaryFileReader object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat','w','b');
fwrite(fid,[1 2 3 4 5 6 7 8],'double');
fclose(fid);
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);
x = reader();
display(x);
```

```
x = 8×1
10-318 ×
```

```
0.3039
0.0003
0.0104
0.0206
0.0256
0.0307
0.0357
0.0408
```

`x` does not match the original data. Change the endianness of `x` using the `swapbytes` function.

```
y = swapbytes(x);
display(y);
```

```
y = 8×1
```

```
1
2
3
4
5
6
7
8
```

`y` matches the original data.

**Package:** dsp

Write data to binary files

## Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see “Write and Read Character Data” on page 4-156 and “Write and Read Fixed-Point Data” on page 4-155. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see “Write and Read Fixed-Point Data” on page 4-155. By default, the writer uses the endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data Before Writing” on page 4-156 .

To write data to a binary file:

- 1 Create the `dsp.BinaryFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
writer = dsp.BinaryFileWriter
writer = dsp.BinaryFileWriter(fname)
writer = dsp.BinaryFileWriter(fname,Name,Value)
```

### Description

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname,Name,Value)` with `Filename` set to `fname` and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example: `writer = dsp.BinaryFileWriter('myFilename.bin','HeaderStructure',struct('field1',1:10,'field2',single(1)));`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Filename — Name of file

'untitled.bin' (default) | character vector | string scalar

Name of the file to which the object writes the data, specified as a character vector or a string scalar. You must specify the full path for the file.

### HeaderStructure — Header to write at beginning of file

struct([]) (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, `(1:10)`, followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

## Usage

### Syntax

```
writer(data)
```

### Description

`writer(data)` writes data to the binary file in a row-major format. Each call to the algorithm writes the elements of `data` at the end of the file. At the first call to the algorithm, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `1 5 2 6 3 7 4 8`.

### Input Arguments

#### data — Data to be written to file

vector | matrix

Data to be written to the binary file in a row-major format, specified as a vector or a matrix. The object writes the data in row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the object writes the data as `[1 2 4 5 8 7 9 2]`.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals  $[1 \ 2; \ 3 \ 4]+1j*[5 \ 6; \ 7 \ 8]$ , then the object writes the elements as  $[1 \ 5 \ 2 \ 6 \ 3 \ 7 \ 4 \ 8]$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

#### Write the Data

Specify the file header as a structure with the following fields:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

sine = dsp.SinWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);
```

```

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end

```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

### Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...
    'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype);
headerReader = readHeader(reader)
```

```
headerReader =
```

```
struct with fields:
```

```
    DataType: 'double'
    Complexity: 0
    FrameSize: 150
    NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

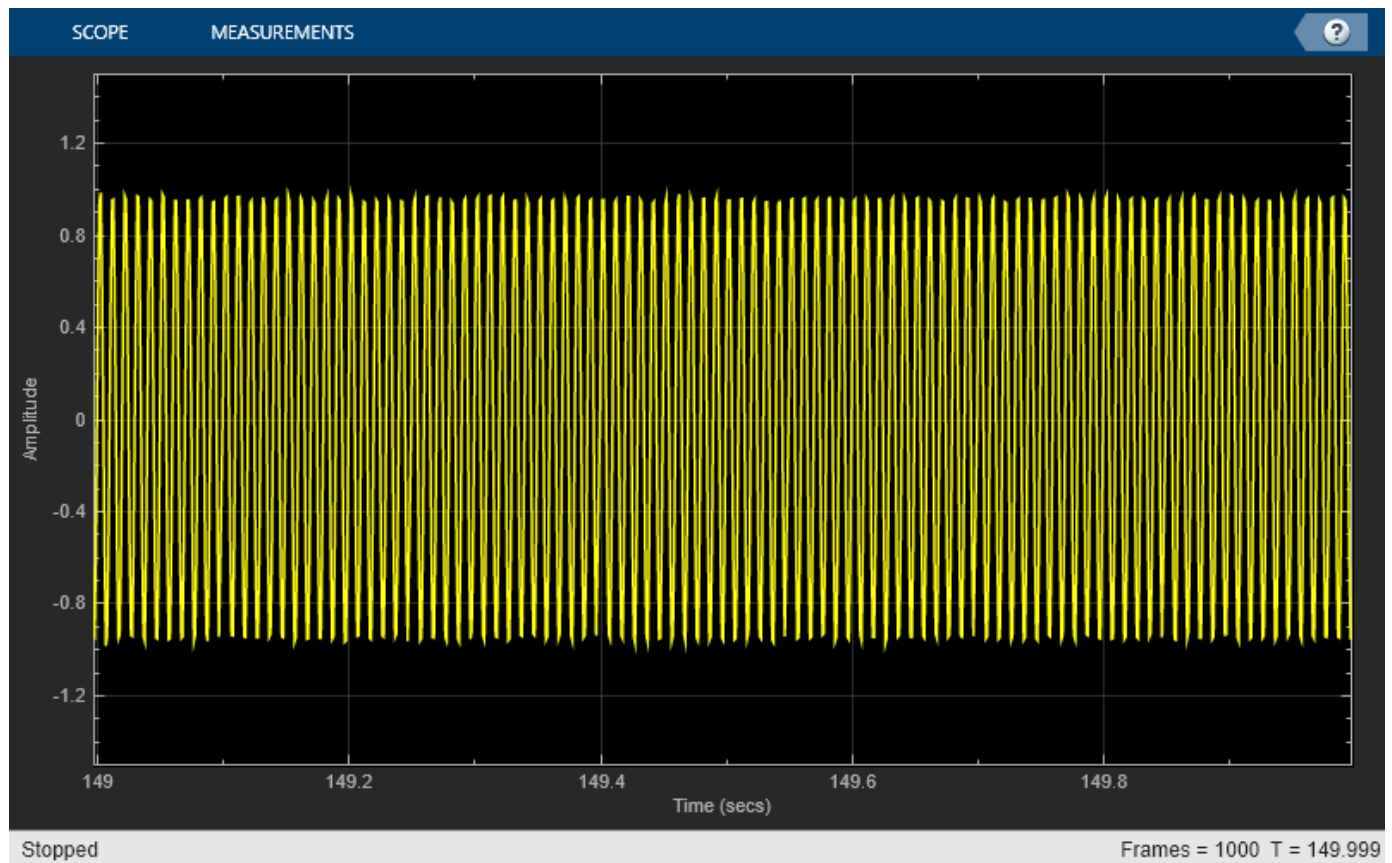

```
reader.IsDataComplex = headerReader.Complexity;
reader.DataType = headerReader.DataType;
reader.NumChannels = headerReader.NumChannels;
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);
```

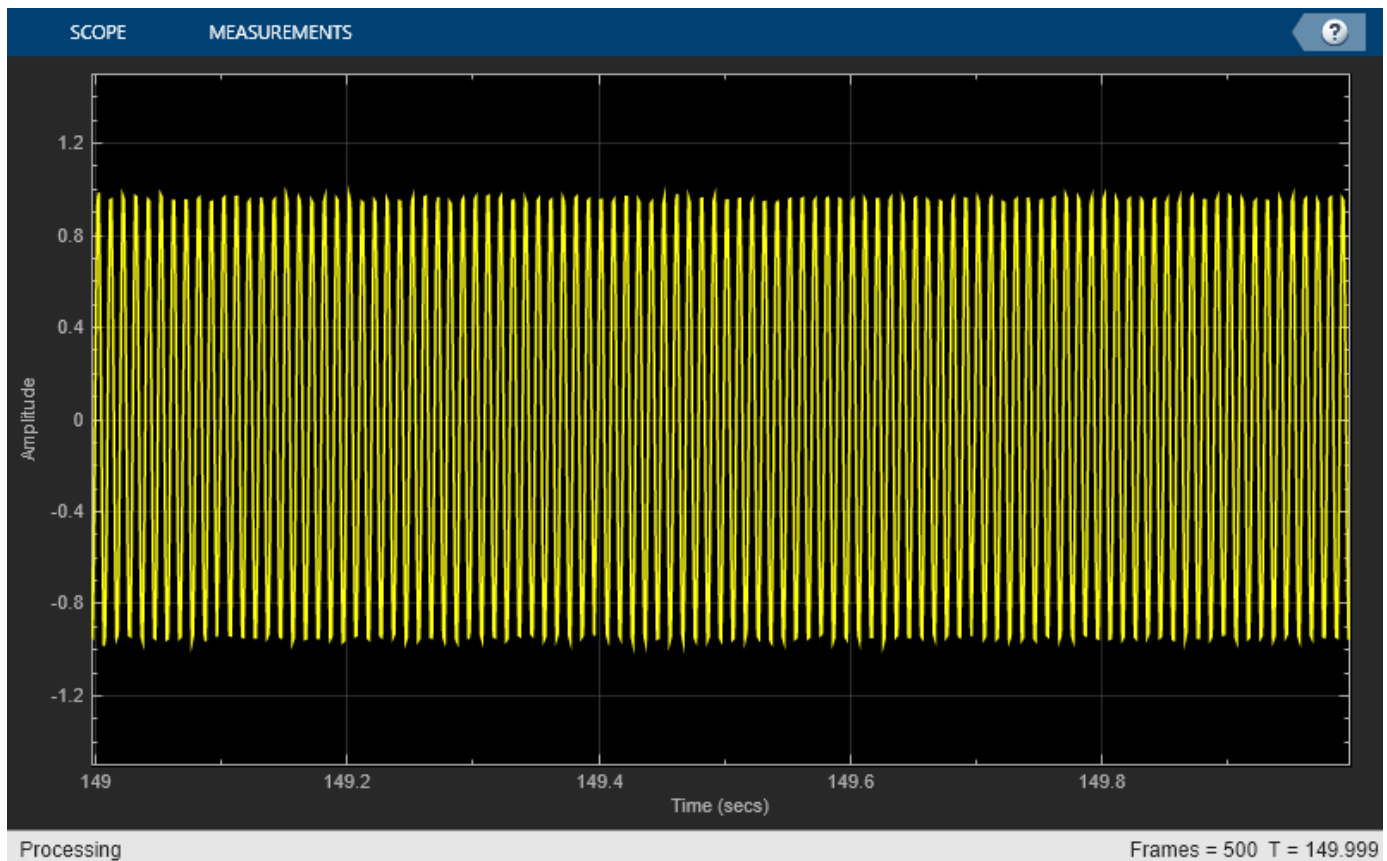

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

```
while ~isDone(reader)
    out = reader();
    scopereader(out)
end
release(reader);
release(scopereader);
```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

### Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

#### Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
    'Complexity',false,...
```

```
        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

### Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out = 5×4
```

```
     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

### Write Complex Data

Create a `dsp.BinaryFileWriter` object which writes to a file named `myfile.dat`. There is no header. The data is complex.

```
writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);
```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);
```

```
dataRead = 1×8
```

```
    1    5    2    6    3    7    4    8
```

### Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

#### Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);
```

```
writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

#### Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using  $2^{(-fractionLength)(storedInteger)}$ . If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue,signedness,wordLength,fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat',...
    'SamplesPerFrame',100,...
    'DataType','int16');
```

```
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);
```

```
fiDataReader = fi(realValue,1,...
    wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans = logical
     1
```

### Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

#### Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

#### Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat',...
    'DataType','uint8',...
    'SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

## Change Endianness of Data Before Writing

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];  
swapData = swapbytes(data);  
writer = dsp.BinaryFileWriter('myfile.dat');  
writer(swapData);
```

## Version History

Introduced in R2016b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

## dsp.BiquadFilter

**Package:** dsp

IIR filter using biquadratic structures

### Description

The `dsp.BiquadFilter` object implements a cascade of biquadratic sections, where the coefficients for each section are supplied by a separate row of an  $N$ -by-6 second-order sections (SOS) matrix. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The resulting filter can be applied to a vector or matrix input, where each column represents a channel of data that is processed independently.

To implement an IIR filter structure using biquadratic or SOS:

- 1 Create the `dsp.BiquadFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
biquad = dsp.BiquadFilter
biquad = dsp.BiquadFilter(sosmatrix,scalevalues)
biquad = dsp.BiquadFilter(Name,Value)
```

#### Description

`biquad = dsp.BiquadFilter` returns a biquadratic IIR (SOS) filter System object, `biquad`, which independently filters each channel (column) of the input over time using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter(sosmatrix,scalevalues)` returns a biquadratic filter object, with the `SOSMatrix` property set to `sosmatrix` and the `ScaleValues` property set to `scalevalues`.

`biquad = dsp.BiquadFilter(Name,Value)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Structure — Filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

Specify the filter structure as 'Direct form I', 'Direct form I transposed', 'Direct form II', 'Direct form II transposed'.

### SOSMatrixSource — SOS matrix source

'Property' (default) | 'Input port'

Specify the source of the SOS matrix as 'Property' or 'Input port'.

### SOSMatrix — SOS matrix

[1 0.3 0.4 1 0.1 0.2] (default) | N-by-6 matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function,  $H(z)$ , of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^2 b_k z^{-k}}{1 - \sum_{l=1}^2 a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as  $(b_0, b_1, b_2, 1, -a_1, -a_2)$ . You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter,  $a_0$ , equals 1 for each filter section, regardless of the specified value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### ScaleValues — Scale values for each biquad section

1 (default) | scalar | vector

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1 values, each value is used for a separate section of the filter.

### Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### InitialConditions — Initial conditions for direct form II structures

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states when the `Structure` property is one of `Direct form II` | `Direct form II transposed`. The number of states or delay elements (zeros and

poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

#### **Dependencies**

This property applies only when you set the `Structure` property to one of `Direct form II` or `Direct form II transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **NumeratorInitialConditions — Initial conditions on zeros side**

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

#### **Dependencies**

This property applies only when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **DenominatorInitialConditions — Initial conditions on poles side**

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the poles. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles

side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

#### Dependencies

This property only applies when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### OptimizeUnityScaleValues — Optimize unity scale values

`true` (default) | `false`

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy.

#### Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

#### ScaleValuesInputPort — How to specify scale values

`true` (default) | `false`

Select how to specify scale values. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

#### Dependencies

This property applies only when the `SOSMatrixSource` property is `Input port`.

#### Fixed-Point Properties

##### RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

##### OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

##### MultiplicandDataType — Multiplicand word and fraction lengths

`Same as output` (default) | `Custom`

Specify the multiplicand fixed-point data type as one of `Same as output` or `Custom`.

#### Dependencies

This property applies only when you set the `Structure` property to `Direct form I transposed`.

**CustomMultiplicandDataType — Custom multiplicand word and fraction lengths**`numerictype([],32,30)` (default) | `numerictype`

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the `MultiplicandDataType` property to Custom.

**SectionInputDataType — Section input word and fraction lengths**`Same as input` (default) | `Custom`

Specify the section input fixed-point data type as either `Same as input` or `Custom`.

**CustomSectionInputDataType — Custom section input word and fraction lengths**`numerictype([],16,15)` (default) | `numerictype`

Specify the section input fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the `SectionInputDataType` property to Custom.

**SectionOutputDataType — Section output word and fraction lengths**`Same as section input` (default) | `Custom`

Specify the section output fixed-point data type as either `Same as section input` or `Custom`.

**CustomSectionOutputDataType — Custom section output word and fraction lengths**`numerictype([],16,15)` (default) | `numerictype`

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the `SectionOutputDataType` property to Custom.

**NumeratorCoefficientsDataType — Numerator coefficients word and fraction lengths**`Same word length as input` (default) | `Custom`

Specify the numerator coefficients fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value.

**Dependencies**

This property applies only when you set the `SOSMatrixSource` property to Property.

**CustomNumeratorCoefficientsDataType — Custom numerator coefficients word and fraction lengths**`numerictype([],16,15)` (default) | `numerictype`

Specify the numerator coefficients fixed-point type as a `numerictype` object with a Signedness of Auto. The word length of the `CustomNumeratorCoefficientsDataType`,

CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must be the same.

#### Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the NumeratorCoefficientsDataType property to Custom.

#### DenominatorCoefficientsDataType — Denominator coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties to the same value.

#### Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

#### CustomDenominatorCoefficientsDataType — Custom denominator coefficients word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the denominator coefficients fixed-point type as a numerictype object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

#### Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the DenominatorCoefficientsDataType property to Custom.

#### ScaleValuesDataType — Scale values word and fraction lengths

Same word length as input (default) | Custom

Specify the scale values fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and DenominatorCoefficientsDataType properties to the same value.

#### Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

#### CustomScaleValuesDataType — Custom scale values word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the scale values fixed-point type as a numerictype object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

#### Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the ScaleValuesDataType property to Custom.

#### NumeratorProductDataType — Numerator product word and fraction lengths

Same as input (default) | Custom | Full precision

Specify the mode to determine the numerator product fixed-point data type as:

- `Same as input` (default) — The numerator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomNumeratorProductDataType` property, which you can use to specify the custom numerator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `DenominatorProductDataType` property to the same value.

#### **CustomNumeratorProductDataType — Custom numerator product word and fraction lengths**

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

#### **Dependencies**

This property applies only when you set the `NumeratorProductDataType` property to `Custom`.

#### **DenominatorProductDataType — Denominator product word and fraction lengths**

`Same as input` (default) | `Custom` | `Full precision`

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `NumeratorProductDataType` property to the same value.

#### **CustomDenominatorProductDataType — Custom denominator product word and fraction lengths**

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

#### **Dependencies**

This property applies only when you set the `DenominatorProductDataType` to `Custom`.

**NumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths**

Same as product (default) | Same as input | Custom

Specify the numerator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the DenominatorAccumulatorDataType property to the same value.

**CustomNumeratorAccumulatorDataType — Custom numerator accumulator word and fraction lengths**

numericitytype([],32,30) (default) | numericitytype

Specify the numerator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

**Dependencies**

This property applies only when you set the NumeratorAccumulatorDataType property to Custom.

**DenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths**

Same as product (default) | Same as input | Custom

Specify the denominator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the NumeratorAccumulatorDataType property to the same value.

**CustomDenominatorAccumulatorDataType — Custom denominator accumulator word and fraction lengths**

numericitytype([],32,30) (default) | numericitytype

Specify the denominator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

**Dependencies**

This property applies only when you set the DenominatorAccumulatorDataType property to Custom.

**StateDataType — State word and fraction lengths**

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as Same as input, Same as accumulator, or Custom.

**Dependencies**

This property applies when you set the “Structure” on page 4-0 property to Direct form II or Direct form II transposed.

**CustomStateDataType — Custom state word and fraction lengths**

numericitytype([],16,15) (default) | numericitytype

Specify the state fixed-point type as a scaled numericitytype object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the StateDataType property to Custom.

**NumeratorStateDataType — Numerator state word and fraction lengths**

Same as accumulator (default) | Same as input | Custom

Specify the numerator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the DenominatorStateDataType property to the same value.

**Dependencies**

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

**CustomNumeratorStateDataType — Custom numerator state word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the numerator state fixed-point type as a scaled numerictype object with a Signedness of Auto. The CustomNumeratorProductDataType and CustomDenominatorProductDataType properties must have the same word lengths.

**Dependencies**

This property applies only when you set the StateDataType property to Custom.

**DenominatorStateDataType — Denominator state word and fraction lengths**

Same as accumulator (default) | Same as input | Custom

Specify the denominator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the NumeratorStateDataType property to the same value.

**Dependencies**

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

**CustomDenominatorStateDataType — Custom denominator state word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the denominator state fixed-point type as a scaled numerictype object with a Signedness of Auto. The CustomNumeratorStateDataType and CustomDenominatorStateDataType properties must have the same word lengths.

**Dependencies**

This property applies only when you set the StateDataType property to Custom.

**OutputDataType — Output word and fraction lengths**

Same as accumulator (default) | Same as input | Custom

Specify the output fixed-point data type as Same as input, Same as accumulator, or Custom.

**CustomOutputDataType — Custom output word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

## Usage

### Syntax

```
y = biquad(x)
y = biquad(x,num,den)
y = biquad(x,num,den,g)
```

### Description

`y = biquad(x)` filters the input signal `x`, and outputs the filtered values, `y`. The biquad filter object filters each channel of the input signal over successive calls to the algorithm.

`y = biquad(x,num,den)` filters the input using `num` as the numerator coefficients, and `den` as the denominator coefficients of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`y = biquad(x,num,den,g)` specifies the scale values, `g`, of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

The data type of all the inputs must be the same. If the input is fixed-point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

#### **num** — Numerator coefficients

3-by-*N* matrix

Numerator coefficients, specified as a 3-by-*N* numeric matrix, where *N* is the number of biquad filter sections. The complexity of `x`, `num`, and `den` must be the same.

The data type of all the inputs must be the same. If `num` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

### Dependencies

This input applies only when you set `SOSMatrixSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

#### **den** — Denominator coefficients

2-by-*N* matrix

Denominator coefficients, specified as a 2-by- $N$  numeric matrix, where  $N$  is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1.

The data type of all the inputs must be the same. If `den` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

### Dependencies

This input applies only when you set `SOSMatrixSource` property is `InputPort`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

### **g** — Scale values

1-by- $(N + 1)$  vector

Scale values of the biquad filter, specified as a 1-by- $(N + 1)$  numeric vector, where  $N$  is the number of biquad filter sections.

The data type of all the inputs must be the same. If `g` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

### Dependencies

This input applies when the `SOSMatrixSource` property is `InputPort` and the `ScaleValuesInputPort` property is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.BiquadFilter`

|                     |  |
|---------------------|--|
| <code>freqz</code>  | Frequency response of discrete-time filter System object     |
| <code>fvtool</code> | Visualize frequency response of DSP filters                  |
| <code>impz</code>   | Impulse response of discrete-time filter System object       |
| <code>info</code>   | Information about filter System object                       |
| <code>coeffs</code> | Returns the filter System object coefficients in a structure |
| <code>cost</code>   | Estimate cost of implementing filter System object           |

|             |   |
|-------------|---|
| scale       | Scale second-order sections   |
| scaleopts   | Create an options object for second-order section scaling                     |
| scalecheck  | Check scaling of biquadratic filter   |
| cumsec      | Cumulative second-order section of the biquadratic filter                     |
| generatehdl | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |
| tf          | Convert discrete-time filter System object to transfer function               |
| reorder     | Reorder second-order sections of biquadratic filter System object             |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Filter a Signal Using Biquadratic Filter

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 & amp;
                                     % 3kHz sinusoids
src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4); % Set up the filter
[sosMatrix,scaleValues] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter(sosMatrix,scaleValues,Structure="Direct form I");

sa = spectrumAnalyzer(SampleRate=8e3,...
    Method="welch",...
    PlotAsTwoSidedSpectrum=false,...
    OverlapPercent=80,SpectrumUnits="dBW",...
    YLimits=[-160 -10]);

while ~isDone(src)
    input = src();
    filteredOutput = biquad(input);
    sink(filteredOutput);
    sa(filteredOutput)
end
```

```
filteredResult = sink.Buffer;  
fvtool(biquad,Fs=8000)
```

### Linf-norm Scaling of a Biquadratic SOS Filter

Demonstrate the Linf-norm scaling of a biquadratic SOS filter using the `scale` function.

```
Fs = 8000;
Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2));
[sosMatrix,scaleValues] = zp2sos(z,p,k);
sosFilt = dsp.SOSFilter(Structure='Direct form I', ...
    Numerator=sosMatrix(:,1:3),Denominator=sosMatrix(:,4:6), ...
    HasScaleValues=true,ScaleValues=scaleValues)
```

```
sosFilt =
    dsp.SOSFilter with properties:

## More About

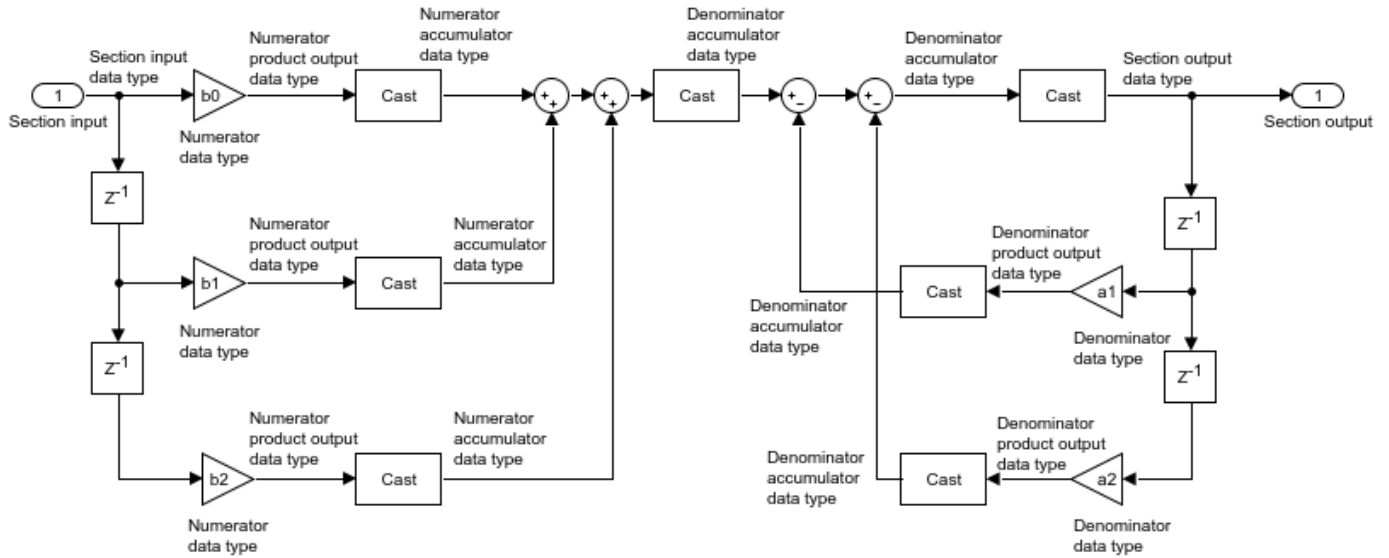

### Fixed Point

The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

#### Direct Form I

The following diagram shows the data types for one section of the filter for fixed-point signals.

The following diagrams show the fixed-point data types between filter sections.

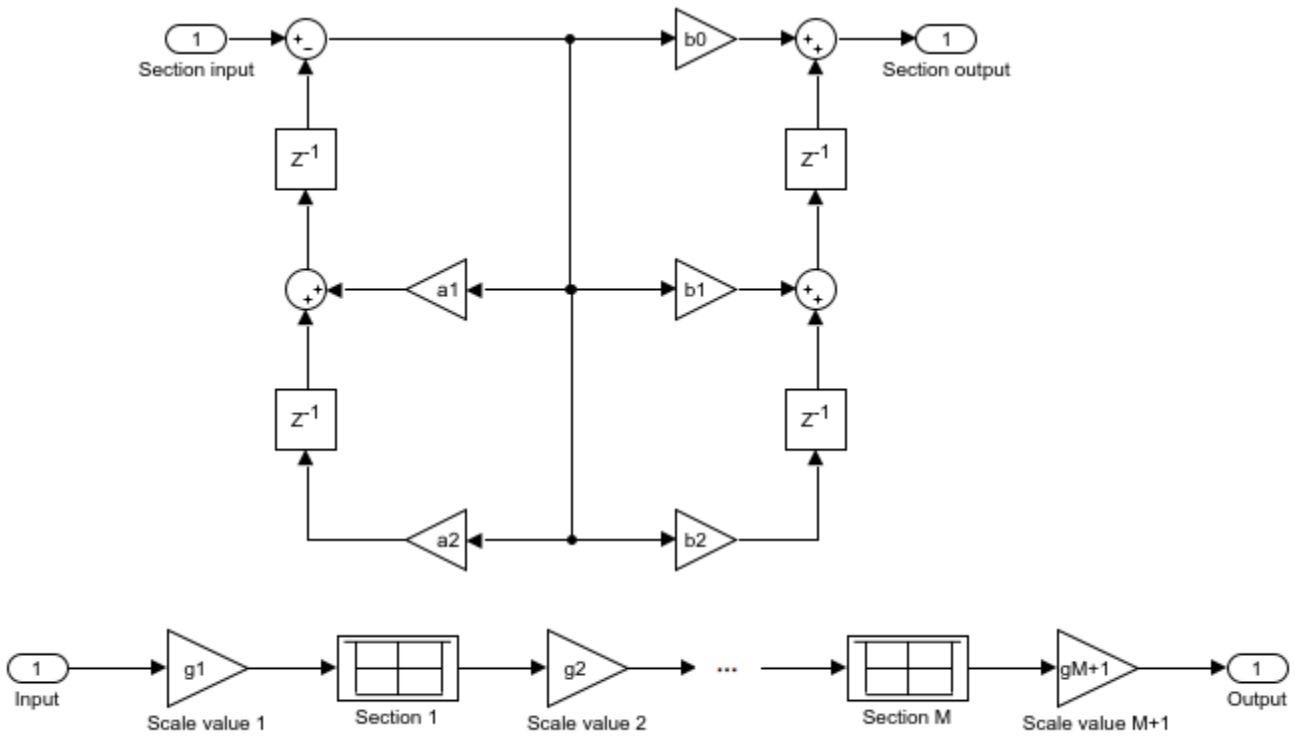

When the data is not optimized:

When you specify OptimizeUnityScaleValues to true, and scale values to 1:

### Direct Form I Transposed

The following diagram shows the data types for one section of the filter for fixed-point signals.

The dashed casts are omitted when you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1.

The following diagrams show the fixed-point data types between filter sections.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the  $a_0$  values of the SOS matrix are not one** - the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the Error or Warn options found in the corresponding block.

Both this object and its corresponding block support variable-size input. When you call the object, it can handle an input argument which is changing in size.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the HDL Coder or Filter Design HDL Coder™ products. For HDL Coder workflows and limitations, see “HDL Code Generation for System Objects” (HDL Coder). For Filter Design HDL Coder workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

**Package:** dsp

Compute output, error, and weights using block LMS adaptive algorithm

## Description

The `dsp.BlockLMSFilter` System object computes output, error, and weights using the block LMS adaptive algorithm.

To compute the output, error, and weights:

- 1 Create the `dsp.BlockLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
blms = dsp.BlockLMSFilter
blms = dsp.BlockLMSFilter(length,blocksize)
blms = dsp.BlockLMSFilter(Name,Value)
```

### Description

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the block least mean squares (LMS) algorithm.

`blms = dsp.BlockLMSFilter(length,blocksize)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length` and the `BlockSize` property set to `blocksize`.

`blms = dsp.BlockLMSFilter(Name,Value)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Length — Length of FIR filter weights vector

32 (default) | positive integer

Specify the length of the FIR filter weights vector as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**BlockSize — Number of samples acquired before weight adaptation**

32 (default) | positive integer

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**StepSizeSource — Source of adaptation step size**

Property (default) | Input port

Specify the source of the adaptation step size factor as Property or Input port.

**StepSize — Adaptation step size**

0.1 (default) | nonnegative scalar

Specify the adaptation step size factor as a scalar, nonnegative numeric value.

**Tunable:** Yes

**Dependencies**

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LeakageFactor — Leakage factor used in leaky LMS algorithm**

1 (default) | scalar

Specify the leakage factor used in leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**InitialWeights — Initial values of filter weights**

0 (default) | scalar | vector

Specify the initial values of the filter weights as a scalar or a vector of length equal to the “Length” on page 4-0 property value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**AdaptInputPort — Additional input to enable adaptation of filter weights**

false (default) | true

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the object. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

**WeightsResetInputPort — Additional input to enable weights reset**`false (default) | true`

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, you must provide a reset control input to the object, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the object algorithm.

**WeightsResetCondition — Condition that triggers the resetting of filter weights**`Non-zero (default) | Rising edge | Falling edge | Either edge`

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset signal input to the object algorithm.

**Dependencies**

This property applies only when you set the `WeightsResetInputPort` property to `true`.

**WeightsOutputPort — Output filter weights**`true (default) | false`

Set this property to `true` to output the adapted filter weights. The default is `true`.

**Usage****Syntax**

```
[y,err,wts] = blms(x,d)
[y,err] = blms(x,d)
[ ___ ] = blms(x,d,mu)
[ ___ ] = blms(x,d,a)
[ ___ ] = blms(x,d,r)
[y,err,wts] = blms(x,d,mu,a,r)
```

**Description**

`[y,err,wts] = blms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y`. The filter error is `err`, and the estimated filter weights is `wts`. The filter weights update once for every block of data that the object processes.

`[y,err] = blms(x,d)` returns only the filtered output `y` and the filter error `err` when the `WeightsOutputPort` property is `false`.

`[ ___ ] = blms(x,d,mu)` uses `mu` as the step size when you set the `StepSizeSource` property to `Input port`. These input arguments can be used with any of the previous sets of output arguments.

`[ ___ ] = blms(x,d,a)` uses `a` as the adaptation control when you set the `AdaptInputPort` property to `true`. When `a` is nonzero, the filter continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

[ \_\_\_ ] = `blms(x,d,r)` uses `r` as a reset signal when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

[`y,err,wts`] = `blms(x,d,mu,a,r)` filters input `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal. The object returns the filtered output `y`, the filter error `err`, and the adapted filter weights `wts`. Set the properties appropriately to provide all possible inputs.

### Input Arguments

#### **x** — Data input

scalar | column vector

The signal to be filtered by the block LMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input length must be an integer multiple of the `BlockSize` property value.

Data Types: `single` | `double`

#### **d** — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

Data Types: `single` | `double`

#### **mu** — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. The data type of the step size input must match the data type of `x` and `d`.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

### Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Input port'.

Data Types: `single` | `double`

#### **a** — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is nonzero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

**Dependencies**

This input is required when the `AdaptInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

**r — Reset signal**

scalar

Reset signal that resets the filter weights based on the values of the `WeightsResetInputPort` property.

**Dependencies**

This input is required when the `WeightsResetInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

**Output Arguments****y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

**err — Difference between output and desired signal**

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

**wts — Adaptive filter weights**

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in the `Length` property.

The data type of `wts` matches the data type of `y`.

Data Types: `single` | `double`

**Object Functions**

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.BlockLMSFilter`

`mse` Estimated mean squared error for adaptive filters  
`maxstep` Maximum step size for LMS adaptive filter convergence

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Remove Noise Using Block LMS Adaptive Algorithm

```
blms = dsp.BlockLMSFilter(10,5);  
blms.StepSize = 0.01;  
blms.WeightsOutputPort = false;  
filt = dsp.FIRFilter;  
filt.Numerator = fir1(10,[.5, .75]);  
x = randn(1000,1); % Noise  
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal  
[y, err] = blms(x, d);  
subplot(2,1,1);  
plot(d);  
title('Noise + Signal');  
subplot(2,1,2);  
plot(err);  
title('Signal');
```

### System Identification of FIR Filter Using Block LMS Filter

```

fir = fir1(31,0.5);
% FIR system to be identified
firFilter = dsp.FIRFilter('Numerator',fir);
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = firFilter(x)+n;
% Filter length
l = 32;
% Block LMS Step size
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 32;
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
% Plot the learning curve for

```

```
% block LMS filter used in system identification  
title('Learning curve')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

## Version History

# dsp.Channelizer

**Package:** dsp

Polyphase FFT analysis filter bank

## Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using a fast Fourier transform (FFT)-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To separate a broadband signal into multiple narrow subbands:

- 1 Create the `dsp.Channelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
channelizer = dsp.Channelizer
channelizer = dsp.Channelizer(M)
channelizer = dsp.Channelizer(M,D)
channelizer = dsp.Channelizer(Name,Value)
```

### Description

`channelizer = dsp.Channelizer` creates a polyphase FFT analysis filter bank System object that separates a broadband input signal into multiple narrowband output signals. This object implements the inverse operation of the `dsp.ChannelSynthesizer` System object.

`channelizer = dsp.Channelizer(M)` creates an  $M$ -band polyphase FFT analysis filter bank, with the `NumFrequencyBands` property set to  $M$ .

Example: `channelizer = dsp.Channelizer(16);`

`channelizer = dsp.Channelizer(M,D)` creates an  $M$ -band polyphase FFT analysis filter bank, with the `DecimationFactor` property set to  $D$ .

Example: `channelizer = dsp.Channelizer(16,8);`

`channelizer = dsp.Channelizer(Name,Value)` creates a polyphase FFT analysis filter bank with each specified property set to the specified value. Enclose each property name in single quotes. For example, you can set `NumTapsPerBand` to 20 and `StopbandAttenuation` to 140.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Main Properties

#### NumFrequencyBands — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands  $M$  into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property corresponds to the number of polyphase branches and the FFT length used in the filter bank.

Example: 16

Example: 64

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### DecimationFactor — Decimation factor

8 (default) | positive integer

Decimation factor  $D$  specified as a positive integer less than or equal to the number of frequency bands  $M$ . The default value of this property equals the number of frequency bands specified.

If the decimation factor  $D$  equals the number of frequency bands  $M$ , then the  $M/D$  ratio equals 1, and the channelizer is known as the maximally decimated channelizer.

If the  $M/D$  ratio is greater than 1, the output sample rate is different from the channel spacing, and the channelizer is known as the non-maximally decimated channelizer. If the ratio is an integer, the channelizer is known as the integer-oversampled channelizer. If the ratio is not an integer, say  $4/3$ , the channelizer is known as the rationally oversampled channelizer. For more details, see "Algorithm" on page 4-200.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### Specification — Filter design parameters or coefficients

"Number of taps per band and stopband attenuation" (default) | "Coefficients"

Filter design parameters or filter coefficients, specified as one of these options:

- "Number of taps per band and stopband attenuation" — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- "Coefficients" — Specify the filter coefficients directly using the `LowpassCoefficients` property.

#### NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients

for the prototype lowpass filter is given by  $\text{NumFrequencyBands} \times \text{NumTapsPerBand}$ . For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 8

Example: 16

**Dependencies**

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**StopbandAttenuation — Stopband attenuation**

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. When the stopband attenuation increases, the passband ripple decreases. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 80

**Dependencies**

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double`

**LowpassCoefficients — Coefficients of prototype lowpass filter**

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,"sqrt")`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s, F_s]$ . For an example, see "Channelizer with Complex Coefficients" on page 4-196.

**Tunable:** Yes

**Dependencies**

This property applies when you set `Specification` to "Coefficients".

Data Types: `single` | `double`

**Code Generation Properties****AllowArbitraryInputLength — Allow arbitrary input length in generated code**

false (default) | true

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as `true` or `false`. When you specify:

- `true` -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.
- `false` -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: `logical`

## Usage

### Syntax

```
channOut = channelizer(input)
```

### Description

`channOut = channelizer(input)` separates the broadband input signal into a number of narrow band signals contained in the columns of the channelizer output.

### Input Arguments

#### **input** — Data input

`vector` | `matrix`

Data input, specified as an  $L$ -by-1 vector or an  $L$ -by- $N$  matrix, with  $N > 1$ .

Under most conditions, the number of inputs rows  $L$  can be arbitrary and does not have to be a multiple of the number of frequency bands. See this table for details.

| Input Signal  | When you Run Object in MATLAB                | When you Generate Code Using MATLAB Coder   |
|---------------|--|---|
| Fixed-size    | Object supports arbitrary input frame length | Object supports arbitrary input frame length when you set <code>AllowArbitraryInputLength</code> to <code>true</code> while generating code |
| Variable-size | Object supports arbitrary input frame length | Object supports arbitrary input frame length  |

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the number of frequency bands.

Data Types: `single` | `double`

## Output Arguments

### channOut — Channelizer output

matrix | 3-D array

Channelizer output, returned as a matrix or a 3-D array.

If the input is an  $L$ -by-1 vector, then the output signal has an upper bound size of  $\text{ceil}(L/M)$ -by- $M$ , where  $M$  is the number of frequency bands. Each narrowband signal forms a column in the output.

If the input has more than one channel, that is, it is of the form  $L$ -by- $N$  with  $N > 1$ , then the output signal has an upper bound size of  $\text{ceil}(L/M)$ -by- $M$ -by- $N$ .

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.Channelizer

|                                  |  |
|----------------------------------|--|
| <code>coeffs</code>              | Coefficients of prototype lowpass filter                     |
| <code>tf</code>                  | Return transfer function of overall prototype lowpass filter |
| <code>polyphase</code>           | Return polyphase matrix                                      |
| <code>freqz</code>               | Frequency response of filters in channelizer                 |

| <code>getFilters</code>          | Return matrix of channelizer FIR filters                     |

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an  $M$ -channel filter bank.

The  $M$ -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The `dsp.Channelizer` object implements the analysis filter bank section. The `dsp.ChannelSynthesizer` object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

## Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = spectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'ChannelNames', {'Input', 'Output'}, ...
    'Title', "Input and Output Spectra");
```

## Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x, v)
end
```

### Channelizer with Complex Coefficients

Create a `dsp.Channelizer` object and set the `LowpassCoefficients` property to a vector of complex coefficients.

#### Complex Coefficients

Using `firpm`, determine the coefficients of a Park-McClellan's optimal equiripple FIR filter of order 30, and frequency and amplitude characteristics described by  $F = [0 \ 0.2 \ 0.4 \ 1.0]$  and  $A = [1 \ 1 \ 0 \ 0]$  vectors, respectively.

Create a complex version of these coefficients by multiplying with a complex exponential. The resultant frequency response is that of a bandpass filter at the specified frequency, in this case 0.4.

```
blowpass = firpm(30,[0 .2 .4 1],[1 1 0 0]);
N = length(blowpass)-1;
Fc = 0.4;
j = complex(0,1);
bbandpass = blowpass.*exp(j*Fc*pi*(0:N));
```

#### Channelizer

Create a `dsp.Channelizer` object with 4 frequency bands and set the `Specification` property to `'Coefficients'`.

```
chann = dsp.Channelizer(4, 'Specification', "Coefficients");
```

Pass the complex coefficients to the channelizer. The prototype filter is a bandpass filter with a center frequency of 0.4. The modulated versions of this filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-Fs Fs]$ .

```
chann.LowpassCoefficients = bbandpass
```

```
chann =
```

```
  dsp.Channelizer with properties:
```

```
    Main
```

```
      NumFrequencyBands: 4
```

```
      DecimationFactor: 4
```

```
      Specification: 'Coefficients'
```

```
      LowpassCoefficients: [0.0019 + 0.0000i 0.0005 + 0.0016i 0.0011 - 0.0008i 0.0051 + 0.0037i -0
```

```
    Show all properties
```

Visualize the frequency response of the channelizer.

```
fvtool(chann)
```

## More About

### Analysis Filter Bank

The generic analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal,  $x[n]$ , into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

Conceptual Diagram of Generic Analysis Filter Bank

## Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter.

The prototype lowpass filter has an impulse response of  $h[n]$ , a normalized two-sided bandwidth of  $2\pi/M$ , and a cutoff frequency of  $\pi/M$ .  $M$  is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses.  $M$  can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter corresponds to  $H_0(z)$  in the filter bank. The first branch of the filter bank contains  $H_0(z)$  followed by the decimator. The other  $M - 1$  branches contain filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k/M, \quad k = 0, 1, \dots, M - 1$$

## Using the Prototype Lowpass Filter

The transfer function of the modulated  $k$ th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of  $M$  filters.

To obtain the frequency response characteristics of the filter  $H_k(z)$ , where  $k = 1, \dots, M-1$ , uniformly shift the frequency response of the prototype filter,  $H_0(z)$ , by multiples of  $2\pi/M$ . Each subband filter,  $H_k(z)$ ,  $\{k = 1, \dots, M - 1\}$ , is derived from the prototype filter.

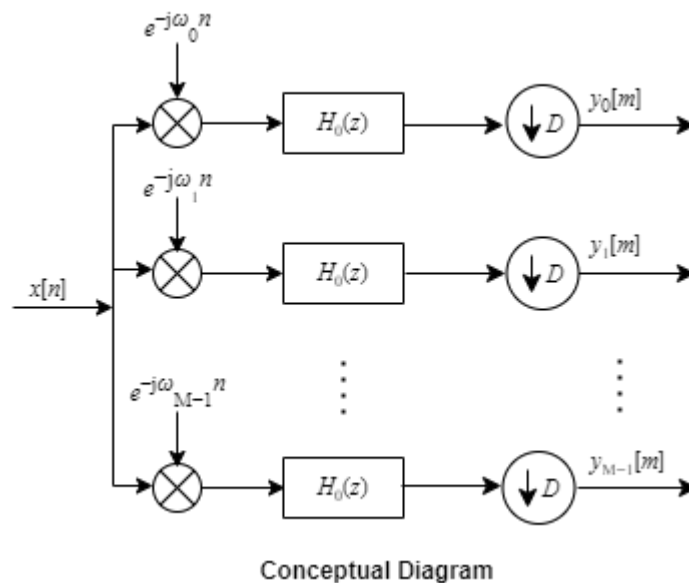

Following is an equivalent representation of the frequency response diagram with  $\omega$  ranging from  $[-\pi, \pi]$ .

### Shift Narrow Subbands to Baseband

The frequency components in the input signal,  $x[n]$ , are translated in frequency to baseband by multiplying  $x[n]$  with the complex exponentials,  $e^{-j\omega_k n}$ ,  $\omega_k = 2\pi k/M$ ,  $k = 1, 2, \dots, M-1$ , where  $\omega_k = 2\pi k/M$ , and  $k = 1, 2, \dots, M-1$ . The resulting product signals are passed through the lowpass filters,  $H_0(z)$ . The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor,  $D \leq M$ , where  $M$  is the number of branches of the analysis filter bank. When  $D < M$ , the channelizer is known as oversampled or non-maximally decimated channelizer.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

$y_1[m], y_2[m], \dots, y_{M-1}[m]$  are narrow subband signals translated into baseband.

## Algorithms

### Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. For more details on the analysis filter bank, see Analysis Filter Bank on page 4-198.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$  is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

$M$  is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$  are polyphase components of the prototype lowpass filter  $H_0(z)$ .

The other filters in the filter bank,  $H_k(z)$ , where  $k = 1, \dots, M-1$ , are modulated versions of this prototype filter.

You can write the transfer function of the  $k^{\text{th}}$  modulated bandpass filter as  $H_k(z) = H_0(z e^{-jw_k})$ .

Replacing  $z$  with  $z e^{jw_k}$ ,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N + 1$  is the length of the  $k^{\text{th}}$  filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all  $M$  channels in the filter bank, the transfer function  $H(z)$  is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

### Maximally decimated channelizer

When  $D = M$ , the channelizer is known as the maximally decimated channelizer or critically sampled channelizer.

Here is the multirate noble identity for decimation, assuming that  $D = M$ .

For example, consider the first branch of the filter bank that contains the lowpass filter.

Replace  $H_0(z)$  with its polyphase representation on page 4-200.

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in the following diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

For all  $M$  channels in the filter bank, the transfer function  $H(z)$  is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches  $M-1$ ,  $M-2$ , all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs  $y_0[m]$ ,  $y_1[m]$ , ...,  $y_{M-1}[m]$ . Each branch in the channelizer effectively outputs one sample for every  $M$  samples it receives. Hence, the sample rate at the output of the channelizer is  $f_s/M$ .

### Non-maximally decimated or oversampled channelizer

When  $D < M$ , the channelizer is known as the non-maximally decimated channelizer or oversampled channelizer. In this configuration, the output sample rate is different from the channel spacing. The non-maximally decimated channelizers offer increased design freedom, but at the expense of increasing computational cost.

If the ratio  $M/D$  equals an integer that is greater than 1 and is less than or equal to  $M-1$ , the channelizer is known as integer-oversampled channelizer. If the ratio  $M/D$  is not an integer, then the channelizer is known as rationally-oversampled channelizer.

In this configuration, when the first input sample is delivered, the switch feeds this input to branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches  $D-1$ ,  $D-2$ , all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs  $y_0[m]$ ,  $y_1[m]$ , ...,  $y_{M-1}[m]$ .

As more data keeps coming in and the switch feeds these samples to the first  $D$  addresses, the formal contents of these addresses are shifted to the next set of  $D$  addresses, and this process of data shift continues every time there is a new set of  $D$  input samples.

For every  $D$  input samples that are fed to the polyphase structure, the channelizer outputs  $M$  samples,  $y_0[m]$ ,  $y_1[m]$ , ...,  $y_{M-1}[m]$ . This process increases the output sample rate from  $f_s/M$  in the case of a maximally decimated channelizer, to  $f_s/D$  in the case of a non-maximally decimated channelizer.

For more details, see [2].

After each  $D$ -point data sequence is delivered to the partitioned  $M$ -stage polyphase filter, the outputs of the  $M$  stages are computed and conditioned for delivery to the  $M$ -point FFT. The data shifting

through the filter introduces frequency-dependent phase shift. To correct for this phase shift and alias all bands to DC, a circular shift buffer is inserted after the polyphase filters and before the  $M$ -point FFT.

With the commutator switch followed by  $M$ -stage polyphase filter, circular shift buffer, and a DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

## Version History

Introduced in R2016b

### R2022b: Support for arbitrary input frame length

Starting in R2022b, this object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the number of frequency bands.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

# dsp.ChannelSynthesizer

**Package:** dsp

Polyphase FFT synthesis filter bank

## Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To merge multiple narrowband signals into a broadband signal:

- 1 Create the `dsp.ChannelSynthesizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
synthesizer = dsp.ChannelSynthesizer  
synthesizer = dsp.ChannelSynthesizer(Name,Value)
```

### Description

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140)`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Specification — Filter design parameters or coefficients

"Number of taps per band and stopband attenuation" (default) | "Coefficients"

Filter design parameters or filter coefficients, specified as one of these options:

- "Number of taps per band and stopband attenuation" — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- "Coefficients" — Specify the filter coefficients directly using `LowpassCoefficients`.

### **NumTapsPerBand — Number of filter coefficients per frequency band**

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

#### **Dependencies**

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **StopbandAttenuation — Stopband attenuation**

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

#### **Dependencies**

This property applies when you set `Specification` to "Number of taps per band and stopband attenuation".

Data Types: `single` | `double`

### **LowpassCoefficients — Coefficients of the prototype lowpass filter**

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,"sqrt")`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range  $[-F_s/2, F_s/2]$ .

**Tunable:** Yes

### Dependencies

This property applies when you set `Specification` to "Coefficients".

Data Types: `single` | `double`

### Usage

### Syntax

```
synthOut = synthesizer(input)
```

### Description

`synthOut = synthesizer(input)` merges the narrowband input signals contained as columns in `input` into broadband signal, `synthOut`.

### Input Arguments

#### **input** — Narrowband signals

matrix | 3-D array

Narrowband signals, specified as a matrix or a 3-D array. Each narrowband signal is stored as a column in the input signal. The number of columns in `input` corresponds to the number of frequency bands of the filter bank. If `input` is three-dimensional, each matrix corresponds to a separate channel. If  $M$  is the number of frequency bands, and `input` is an  $L$ -by- $M$  matrix, then the output signal, `synthOut`, has dimensions  $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions  $L$ -by- $M$ -by- $N$ , then `synthOut` has dimensions  $L \times M$ -by- $N$ .

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change.

Data Types: `single` | `double`

### Output Arguments

#### **synthOut** — Merged broadband signal

matrix | 3-D array

Merged broadband signal, returned as a matrix or a 3-D array. If  $M$  is the number of frequency bands, and `input` is an  $L$ -by- $M$  matrix, then the output signal, `synthOut`, has dimensions  $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions  $L$ -by- $M$ -by- $N$ , then `synthOut` has dimensions  $L \times M$ -by- $N$ .

Data Types: `single` | `double`

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.ChannelSynthesizer

coeffs      Coefficients of prototype lowpass filter  
 tf          Return transfer function of overall prototype lowpass filter  
 polyphase   Return polyphase matrix

## Common to All System Objects

step        Run System object algorithm  
 release    Release resources and allow changes to System object property values and input characteristics  
 reset      Reset internal states of System object

## Examples

### Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an  $M$ -channel filter bank.

The  $M$ -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The dsp.Channelizer object implements the analysis filter bank section. The dsp.ChannelSynthesizer object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

### Initialization

Initialize the dsp.Channelizer and dsp.ChannelSynthesizer System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = spectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'ChannelNames', {'Input', 'Output'}, ...
    'Title', "Input and Output Spectra");
```

### Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
```

```
spectrumAnalyzer(x,v)
end
```

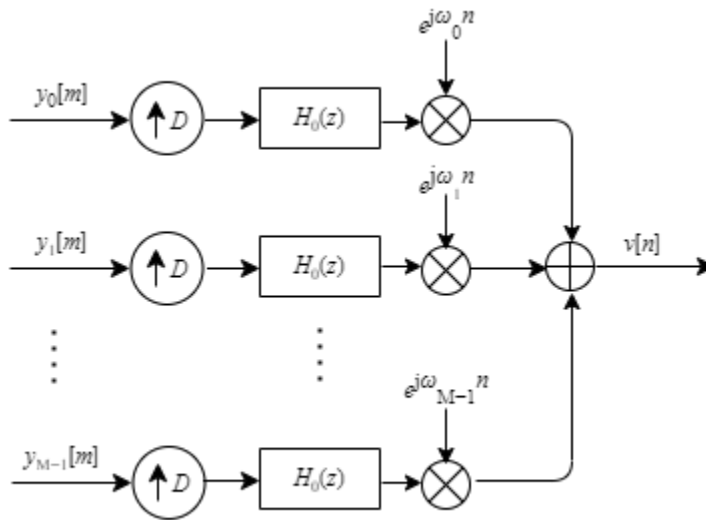

## More About

### Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals,  $y_0[m]$ ,  $y_1[m]$ , ...,  $y_{M-1}[m]$  into a single broadband signal,  $v[n]$ . The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around  $\omega_k$ .

Conceptual Diagram

### Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of  $h[n]$ , a normalized two-sided bandwidth of  $2\pi/M$ , and a cutoff frequency of  $\pi/M$ .  $M$  is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses.  $M$  can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other  $M - 1$  branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by  $e^{jw_k n}$ ,  $w_k = 2\pi k/M$ ,  $k = 0, 1, \dots, M - 1$ .

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal,  $v[n]$ .

## Algorithms

### Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$  is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

$M$  is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$  are polyphase components of the prototype lowpass filter,  $H_0(z)$ .

The other filters in the filter bank,  $H_k(z)$ , where  $k = 1, \dots, M-1$ , are modulated versions of this prototype filter.

You can write the transfer function of the  $k$ th modulated bandpass filter as  $H_k(z) = H_0(z e^{jw_k})$ . Replacing  $z$  with  $z e^{jw_k}$ ,

$$H_k(z) = h_0 + h_1 e^{jw_k} z^{-1} + h_2 e^{j2w_k} z^{-2} \dots + h_N e^{jNw_k} z^{-N}$$

$N + 1$  is the length of the  $k$ th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all  $M$  channels in the filter bank, the MIMO transfer function,  $H(z)$ , is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that  $D = M$ :

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace  $H_0(z)$  with its polyphase representation.

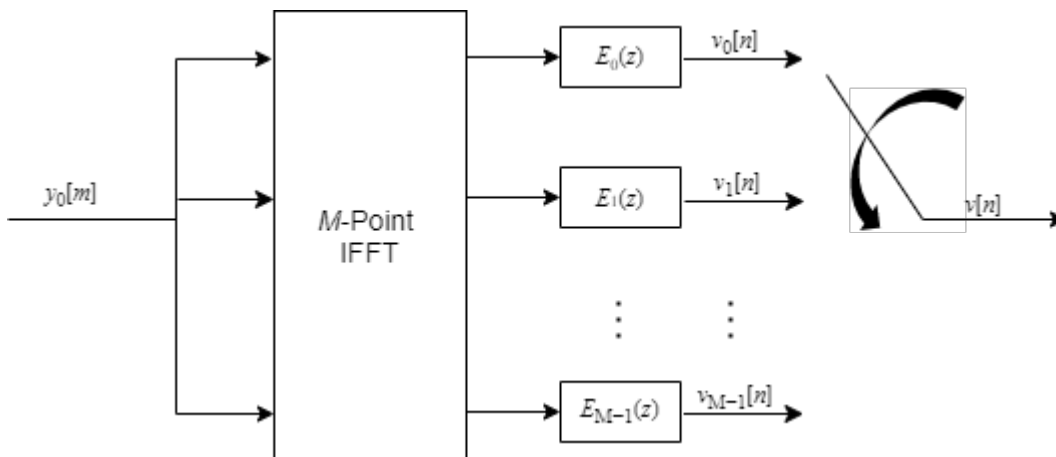

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the  $M$  channels in the filter bank, the MIMO transfer function,  $H(z)$ , is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

## **dsp.Chirp**

**Package:** dsp

Generate swept-frequency cosine (chirp) signal

### **Description**

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

- 1 Create the `dsp.Chirp` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### **Creation**

#### **Syntax**

```
chirp = dsp.Chirp  
chirp = dsp.Chirp(Name,Value)
```

#### **Description**

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp(Name,Value)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

##### **Type — Frequency sweep type**

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time.

##### **SweepDirection — Sweep direction**

`Unidirectional` (default) | `Bidirectional`

Specify the sweep direction as either `Unidirectional` or `Bidirectional`.

### **InitialFrequency — Initial frequency (hertz)**

1000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **TargetFrequency — Target frequency (hertz)**

4000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **TargetTime — Target time**

1 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches  $2f_{tgt} - f_{init}$  Hz, where  $f_{tgt}$  is the `TargetFrequency` and  $f_{init}$  is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SweepTime — Sweep time**

1 (default) | scalar greater than or equal to 0

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InitialPhase — Initial phase**

0 (default) | scalar greater than or equal to 0

Specify initial phase of the output in radians at time  $t = 0$ .

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**SampleRate — Sample rate**

8000 (default) | positive scalar

Specify the sampling rate of the output in hertz as a positive numeric scalar.

Data Types: `single` | `double` | `logical`

**SamplesPerFrame — Samples per output frame**

1 (default) | positive integer

Specify the number of samples to buffer into each output as a positive integer. The default value is 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**OutputDataType — Output data type**

`double` (default) | `single`

Specify the output data type as `double` or `single`. The default value is `double`.

## Usage

## Syntax

```
y = chirp()
```

### Description

`y = chirp()` returns a swept-frequency cosine output, `y`.

### Output Arguments

**y — Swept-frequency cosine output**

scalar | column vector

Swept-frequency cosine output, returned as a scalar or a column vector. The length of the output vector equals the value you specify in the `SamplesPerFrame` property.

Data Types: `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step`      Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### Generate a Bidirectional Swept Chirp Signal

```
chirp = dsp.Chirp(...  
    'SweepDirection', 'Bidirectional', ...  
    'TargetFrequency', 25, ...  
    'InitialFrequency', 0, ...  
    'TargetTime', 1, ...  
    'SweepTime', 1, ...  
    'SamplesPerFrame', 400, ...  
    'SampleRate', 400);  
  
plot(chirp());
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

# dsp.CICCompensationDecimator

**Package:** dsp

Compensate for CIC decimation filter using FIR decimator

## Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

- 1 Create the `dsp.CICCompensationDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```

ciccompdec = dsp.CICCompensationDecimator
ciccompdec = dsp.CICCompensationDecimator(decim)
ciccompdec = dsp.CICCompensationDecimator(cic)
ciccompdec = dsp.CICCompensationDecimator(cic,decim)
ciccompdec = dsp.CICCompensationDecimator( ____,Name,Value)

```

### Description

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(decim)` returns a CIC compensation decimator System object, with the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(cic)` returns a CIC compensation decimator System object, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object, `cic`.

`ciccompdec = dsp.CICCompensationDecimator(cic,decim)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, and the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator( ____,Name,Value)` returns a CIC compensation decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **CICDifferentialDelay** — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CICNumSections** — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CICRateChangeFactor** — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DecimationFactor** — Decimation factor of compensator

2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DesignForMinimumOrder** — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

### **FilterOrder** — Order of decimation compensator filter

12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar.

### **Dependencies**

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PassbandFrequency** — Passband edge frequency in hertz

100000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than  $F_s/2$ , where  $F_s$  is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **PassbandRipple — Filter passband ripple in decibels**

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **SampleRate — Input sample rate in hertz**

1200000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: single | double

#### **StopbandAttenuation — Filter stopband attenuation in decibels**

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### **StopbandFrequency — Stopband edge frequency in hertz**

400000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than  $F_s/2$ , where  $F_s$  is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Fixed-Point Properties**

#### **CoefficientsDataType — Word and fraction lengths of coefficients**

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

#### **RoundingMethod — Rounding method for output fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

## Usage

### Syntax

```
y = ciccompdecim(x)
```

### Description

`y = ciccompdecim(x)` returns the filtered and downsampled values,  $y$ , of the input signal,  $x$ .

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a  $K_i$ -by- $N$  input matrix as  $N$  independent channels, decimating each channel over the first dimension.

The number of input rows  $K_i$  can be arbitrary and does not have to be a multiple of the decimation factor.

This object supports variable-size input signals, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

This object does not support complex unsigned fixed-point data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Output Arguments

#### **y** — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix.

When the input is of size  $K_i$ -by- $N$ , and  $K_i$  is not a multiple of the decimation factor  $M$ , the output signal has an upper bound size of  $\text{ceil}(K_i/M)$ -by- $N$ . If  $K_i$  is a multiple of the decimation factor, then the output is of size  $(K_i/M)$ -by- $N$ . The number of channels (columns) does not change.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.CICCompensationDecimator`

`freqz`            Frequency response of discrete-time filter System object

|             |   |
|-------------|---|
| fvtool      | Visualize frequency response of DSP filters                                   |
| info        | Information about filter System object  |
| cost        | Estimate cost of implementing filter System object                            |
| coeffs      | Returns the filter System object coefficients in a structure                  |
| polyphase   | Polyphase decomposition of multirate filter                                   |
| generatehdl | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Impulse and Frequency Response of CIC Compensation Decimator

Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,...
    'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,...
    'SampleRate',fs);
```

Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompDecim,'Analysis','freq')
```

## Compensation Decimator Design

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);
f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);
```

```
f.NormalizeMagnitudeTo1 = 'on';
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...
       'Overall Response');
```

Apply the design to a 1200-sample random input signal. Store the decimated output along the first dimension of the `y` array.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15),'SamplesPerFrame',120);
```

```
y = fi(zeros(100,1),1,32,20);
```

```
for ind = 1:10
    x2 = CICDecim(x());
    y((ind-1)*10+1:ind*10,1) = CICCompDecim(x2);
end
```

## Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

$R$ ,  $D$ , and  $N$  are the rate change factor, the differential delay, and the number of sections in the CIC filter, respectively.

After decimation, the CIC response has the form:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[ RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where  $\omega_p$  is the passband frequency of the CIC compensation filter.

Notice that when  $\omega/2R \ll \pi$ , the previous equation for  $H_{ciccomp}(\omega)$  can be simplified using the fact that  $\sin(x) \cong x$ :

$$H_{ciccomp}(\omega) \approx \left[ \frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[ \text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

## Version History

### Introduced in R2014b

#### **R2023a: Support for arbitrary input frame length**

This object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the decimation factor.

#### **R2023a: Support for variable-size input signal**

The input signal to this object can be a variable-size signal, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.
- In the code you generate from this object, the decimator output is a fixed-size signal if the input signal is fixed size and is a multiple of the decimation factor. If the input is not a multiple of the decimation factor or if the input is a variable-size signal, then the decimator output is of variable-size.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

# dsp.CICCompensationInterpolator

**Package:** dsp

Compensate for CIC interpolation filter using FIR interpolator

## Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

- 1 Create the `dsp.CICCompensationInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ciccompint = dsp.CICCompensationInterpolator
ciccompint = dsp.CICCompensationInterpolator(interp)
ciccompint = dsp.CICCompensationInterpolator(cic)
ciccompint = dsp.CICCompensationInterpolator(cic,interp)
ciccompint = dsp.CICCompensationInterpolator( ___,Name,Value)
```

### Description

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(cic)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`.

`ciccompint = dsp.CICCompensationInterpolator(cic,interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, and the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator( ___,Name,Value)` returns a CIC compensation interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **CICDifferentialDelay** — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CICNumSections** — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CICRateChangeFactor** — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DesignForMinimumOrder** — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

### **FilterOrder** — Order of interpolation compensator filter

12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar.

#### **Dependencies**

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **InterpolationFactor** — Interpolation factor of compensator

2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PassbandFrequency — Passband edge frequency in hertz**

1000000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than  $F_s/2$ , where  $F_s$  is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PassbandRipple — Filter passband ripple in decibels**

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SampleRate — Input sample rate in hertz**

6000000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: `single` | `double`

### **StopbandAttenuation — Filter stopband attenuation in decibels**

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **StopbandFrequency — Stopband edge frequency in hertz**

4000000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than  $F_s/2$ , where  $F_s$  is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Fixed-Point Properties**

### **CoefficientsDataType — Word and fraction lengths of coefficients**

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

### **RoundingMethod — Rounding method for output fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

## Usage

### Syntax

```
y = ciccompint(x)
```

### Description

`y = ciccompint(x)` outputs the upsampled and filtered values,  $y$ , of the input signal,  $x$ .

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a  $K_i \times N$  input matrix as  $N$  independent channels, interpolating each channel over the first dimension.

This object does not support complex unsigned fixed-point data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **y** — Upsampled and filtered signal

vector | matrix

Upsampled and filtered signal, returned as a vector or matrix. For a  $K_i \times N$  input matrix, the result is a  $K_o \times N$  output matrix, where  $K_o = K_i \times L$  and  $L$  is the interpolation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.CICCompensationInterpolator`

|                          |   |
|--------------------------|---|
| <code>freqz</code>       | Frequency response of discrete-time filter System object                      |
| <code>fvtool</code>      | Visualize frequency response of DSP filters                                   |
| <code>info</code>        | Information about filter System object  |
| <code>cost</code>        | Estimate cost of implementing filter System object                            |
| <code>coeffs</code>      | Returns the filter System object coefficients in a structure                  |
| <code>polyphase</code>   | Polyphase decomposition of multirate filter                                   |
| <code>generatehdl</code> | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |

## Common to All System Objects

step     Run System object algorithm  
release   Release resources and allow changes to System object property values and input characteristics  
reset     Reset internal states of System object

## Examples

### Impulse and Frequency Response of CIC Compensation Interpolator

Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;  
fPass = 200;  
fStop = 500;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(...  
    'InterpolationFactor',2,...  
    'PassbandFrequency',fPass,...  
    'StopbandFrequency',fStop,...  
    'SampleRate',fs);
```

Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp, 'Analysis', 'impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompInterp, 'Analysis', 'freq')
```

### Compensation Interpolator Design

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250 Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;
fPass = 100;
fStop = 250;
ast = 80;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...
    'InterpolationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'StopbandAttenuation',ast, ...
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);
```

```
f = fvtool(CICCompInterp,CICInterp,FC, ...
    'Fs', [fs*2 fs*16*2 fs*16*2]);

f.NormalizeMagnitudeto1 = 'on';
legend(f,'CIC Compensation Interpolator','CIC Interpolator', ...
    'Overall Response');
```

Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15), 'SamplesPerFrame', 100);

y = fi(zeros(32000,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
    y(((ind-1)*3200)+1:ind*3200) = CICInterp(x2);
end
```

## Algorithms

The response of a CIC filter is given by:

$$H_{Cic}(\omega) = \left[ \frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

$R$ ,  $D$ , and  $N$  are the rate change factor, the differential delay, and the number of sections in the CIC filter, respectively.

After decimation, the CIC response has the form:

$$H_{cic}(\omega) = \left[ \frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[ RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where  $\omega_p$  is the passband frequency of the CIC compensation filter.

Notice that when  $\omega/2R \ll \pi$ , the previous equation for  $H_{ciccomp}(\omega)$  can be simplified using the fact that  $\sin(x) \cong x$ :

$$H_{ciccomp}(\omega) \approx \left[ \frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[ \text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

## Version History

Introduced in R2014b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

# dsp.CICDecimator

**Package:** dsp

Decimate signal using cascaded integrator-comb (CIC) filter

## Description

The `dsp.CICDecimator` System object decimates an input signal using a cascaded integrator-comb (CIC) decimation filter. The CIC decimation filter structure consists of  $N$  sections of cascaded integrators, followed by a rate change by a factor of  $R$ , followed by  $N$  sections of cascaded comb filters. For details, see “Algorithms” on page 4-253. The `NumSections` property specifies  $N$ , the number of sections in the CIC filter. The `DecimationFactor` property specifies  $R$ , the decimation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICDecimator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

---

**Note** This object requires a Fixed-Point Designer license.

---

To decimate a signal using a CIC filter:

- 1 Create the `dsp.CICDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
cicDecim = dsp.CICDecimator
cicDecim = dsp.CICDecimator(R,M,N)
cicDecim = dsp.CICDecimator(Name,Value)
```

### Description

`cicDecim = dsp.CICDecimator` creates a CIC decimation System object that applies a CIC decimation filter to the input signal.

`cicDecim = dsp.CICDecimator(R,M,N)` creates a CIC decimation object with the `DecimationFactor` property set to  $R$ , the `DifferentialDelay` property set to  $M$ , and the `NumSections` property set to  $N$ .

`cicDecim = dsp.CICDecimator(Name,Value)` creates a CIC decimation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combination.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **DecimationFactor** — Decimation factor

2 (default) | positive integer

Factor by which the input signal is decimated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DifferentialDelay** — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-253. If the differential delay is a built-in integer data type, the decimation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the decimation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NumSections** — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FixedPointDataType** — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- **Full precision** - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- **Minimum section word lengths** - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicDecimOut` argument.
- **Specify word lengths** - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicDecimOut` argument.
- **Specify word and fraction lengths** - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

**SectionWordLengths — Fixed-point word lengths for each filter section**

[16 16 16 16] (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length  $2 \times \text{NumSections}$ .

Example: 32

Example: [32 32 32 32]

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SectionFractionLengths — Fixed-point fraction lengths for each filter section**

0 (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length  $2 \times \text{NumSections}$ .

Example: -2

Example: [-2 0 5 8]

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OutputWordLength — Fixed-point word length for filter output**

32 (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OutputFractionLength — Fixed-point fraction length for filter output**

0 (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

**Dependencies**

This property applies when you set `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Usage

### Syntax

```
cicDecimOut = cicDecim(input)
```

### Description

`cicDecimOut = cicDecim(input)` decimates the input using a CIC decimator.

### Input Arguments

#### **input** — Data input

vector | matrix

Data input, specified as a vector or matrix. The number of rows in the input must be a multiple of the “DecimationFactor” on page 4-0 . If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **cicDecimOut** — CIC decimator output

vector | matrix

Decimated output, returned as a vector or a matrix. The output frame size equals  $(1 / \text{DecimationFactor}) \times \text{input frame size}$ . The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

### Full precision

When the `FixedPointDataType` is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + \text{NumSect}$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- $WL_{\text{output}}$  -- Word length of the output data.
- $FL_{\text{output}}$  -- Fraction length of the output data.
- $WL_{\text{input}}$  -- Word length of the input data.
- $FL_{\text{input}}$  -- Fraction length of the input data.
- $\text{NumSect}$  -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

The  $WL_{\text{input}}$  and  $FL_{\text{input}}$  are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

### Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in the “OutputWordLength” on page 4-0 property. The output fraction length,  $FL_{\text{output}}$ , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

### Specify word and fraction lengths

When the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the “OutputWordLength” on page 4-0 and “OutputFractionLength” on page 4-0 properties.

### Specify word lengths

When the `FixedPointDataType` property is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length,  $FL_{\text{output}}$ , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Examples

### Decimate a Signal Using a CICDecimator Object

Create a `dsp.CICDecimator System` object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```
cicdec = dsp.CICDecimator(4);  
cicdec.FixedPointDataType = 'Minimum section word lengths';  
cicdec.OutputWordLength = 16;
```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```
Fs = 44.1e3;  
% 0.0232 sec signal  
n = (0:1023)';  
x = fi(sin(2*pi*1e3/Fs*n), true, 16, 15);
```

Create a `dsp.SignalSource` object.

```
src = dsp.SignalSource(x, 64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16, 16);  
for ii = 1:16  
    y(ii, :) = cicdec(src());  
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
D = cicdec.DecimationFactor;  
diffDelay = cicdec.DifferentialDelay;  
NumSect = cicdec.NumSections;  
gainCIC = ...  
    (D*diffDelay)^NumSect;  
stem(n(1:56)/Fs, double(x(4:59)))  
hold on;  
stem(n(1:14)/(Fs/D), double(y(1, 3:end))/gainCIC, ...  
    'r', 'filled')  
xlabel('Time (sec)')  
ylabel('Signal Amplitude')  
legend('Original signal', ...  
    'Decimated signal', ...  
    'Location', 'north')  
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Decimator

```

### Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

#### Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLS vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator

cicD =
  dsp.CICDecimator with properties:

    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numericType(1,16,15)

nt =

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok

WLs = 1x5

    18    18    18    18    18

FLs = 1x5

    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
           Signedness: Signed
           WordLength: 66
        FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
     66     66     66     66     66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

### Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```
DecimationFactor: 2
DifferentialDelay: 1
    NumSections: 2
FixedPointDataType: 'Minimum section word lengths'
OutputWordLength: 32
```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302
```

```
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
```

```
    26    26    26    26    32
```

```
FLs = 1x5
```

```
    15    15    15    15    21
```

### Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```
cicD =
    dsp.CICDecimator with properties:
```

```
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word and fraction lengths'
    SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
    OutputWordLength: 32
    OutputFractionLength: 0
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

### Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    5     5     5     5    21

```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

## More About

### CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC decimation filter is conceptually given by a single rate CIC filter,  $H(z)$  which is a lowpass anti-imaging filter, followed by a downsampler. The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter  $H(z)$  is factorized this way:

$$H(z) = \left[ \sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z)$$

where,

- $H_I$  is the transfer function of the integrator part of the filter containing  $N$  stages of integrators.
- $H_C$  is the transfer function of the  $N$  sections of the cascaded comb filters, each with a width of  $RM$ .
- $N$  is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- $R$  is the decimation factor.
- $M$  is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for decimation and moves the rate change factor,  $R$ , to follow after the  $N$  sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see Algorithms on page 4-253.

### Fixed Point

The fixed-point signal diagram shows the data types that the `dsp.CICDecimator` object uses for fixed-point signals.

where,

- `secNT = numerictype(1,secWL,secFL)`
- `outNT = numerictype(1,outWL,outFL)`
- `secWL` is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- `secFL` is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- `outWL` is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- `outFL` is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of `NumSections` in this diagram is 2.

## Algorithms

### CIC Decimation Filter

The CIC decimation filter in More About on page 4-252 is realized as a cascade of  $N$  sections of the integrators followed by a rate change factor of  $R$ , followed by  $N$  sections of comb filters.

This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

# dsp.CICInterpolator

**Package:** dsp

Interpolate signal using cascaded integrator-comb filter

## Description

The `dsp.CICInterpolator` System object interpolates an input signal using a cascaded integrator-comb (CIC) interpolation filter. The CIC interpolation filter structure consists of  $N$  sections of cascaded comb filters, followed by a rate change by a factor of  $R$ , followed by  $N$  sections of cascaded integrators. For details, see “Algorithms” on page 4-268. The `NumSections` property specifies  $N$ , the number of sections in the CIC filter. The `InterpolationFactor` property specifies  $R$ , the interpolation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICInterpolator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

---

**Note** This object requires a Fixed-Point Designer license.

---

To interpolate a signal using a CIC filter:

- 1 Create the `dsp.CICInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
cicInterp = dsp.CICInterpolator
cicInterp = dsp.CICInterpolator(R,M,N)
cicInterp = dsp.CICInterpolator(Name,Value)
```

### Description

`cicInterp = dsp.CICInterpolator` creates a CIC interpolation System object that applies a CIC interpolation filter to the input signal.

`cicInterp = dsp.CICInterpolator(R,M,N)` creates a CIC interpolation object with the `InterpolationFactor` property set to  $R$ , the `DifferentialDelay` property set to  $M$ , and the `NumSections` property set to  $N$ .

`cicInterp = dsp.CICInterpolator(Name,Value)` creates a CIC interpolation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **InterpolationFactor** — Interpolation factor

2 (default) | positive integer

Factor by which the input signal is interpolated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DifferentialDelay** — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-268. If the differential delay is of built-in integer class data type, the interpolation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the interpolation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NumSections** — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FixedPointDataType** — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- `Full precision` - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- `Minimum section word lengths` - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicInterpOut` argument.
- `Specify word lengths` - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicInterpOut` argument.
- `Specify word and fraction lengths` - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

**SectionWordLengths — Fixed-point word lengths for each filter section**

[16 16 16 16] (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length  $2 \times \text{NumSections}$ .

Example: 32

Example: [32 32 32 32]

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SectionFractionLengths — Fixed-point fraction lengths for each filter section**

0 (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length  $2 \times \text{NumSections}$ .

Example: -2

Example: [-2 0 5 8]

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OutputWordLength — Fixed-point word length for filter output**

32 (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

**Dependencies**

This property applies when you set the `FixedPointDataType` property to one of 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OutputFractionLength — Fixed-point fraction length for filter output**

0 (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

**Dependencies**

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Usage

## Syntax

```
cicInterpOut = cicInterp(input)
```

## Description

`cicInterpOut = cicInterp(input)` interpolates the input using a CIC interpolator.

## Input Arguments

### **input** — Data input

vector | matrix

Data input, specified as a vector or matrix. If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **cicInterpOut** — CIC interpolator output

vector | matrix

Interpolated output, returned as a vector or a matrix. The output frame size equals (“InterpolationFactor” on page 4-0 )  $\times$  input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

## Full precision

When the `FixedPointDataType` property is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- $WL_{\text{output}}$  -- Word length of the output data.
- $FL_{\text{output}}$  -- Fraction length of the output data.
- $WL_{\text{input}}$  -- Word length of the input data.
- $FL_{\text{input}}$  -- Fraction length of the input data.
- $NumSect$  -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

$WL_{input}$  and  $FL_{input}$  are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

### Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in "OutputWordLength" on page 4-0 property. The output fraction length,  $FL_{output}$  is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

### Specify word and fraction lengths

When the `FixedPointDataType` is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the "OutputWordLength" on page 4-0 and "OutputFractionLength" on page 4-0 properties.

### Specify word lengths

When the `FixedPointDataType` is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length,  $FL_{output}$  is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.CICInterpolator

corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

## Examples

### Interpolate Signal Using CICInterpolator System object

Create a `dsp.CICInterpolator` System object™ with `InterpolationFactor` set to 2. Interpolate a fixed-point signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2)

cicint =
  dsp.CICInterpolator with properties:

    InterpolationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

Create a `dsp.SineWave` object with `SampleRate` set to 22.05 kHz, `SamplesPerFrame` set to 32, and `OutputDataType` set to 'Custom'. To generate a fixed-point signal, set the `CustomOutputDataType` property to a `numericType` object. For the purpose of this example, set the value to `numericType([], 16)`. The fraction length is computed based on the values of the generated sinusoidal signal to give the best possible precision.

To generate a fixed-point signal, set the `Method` property of the `dsp.SineWave` object to 'Table lookup'. This method of generating the sinusoidal signal requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is,  $1/f_i T_s = k_i$  must be an integer value for every channel  $i = 1, 2, \dots, N$ . The value of  $T_s$  equals  $1/F_s$ , the variable  $f_i$  is the frequency of the sinusoidal signal, and  $F_s$  is the sample rate of the signal. In other words, the ratio  $F_s/f_i$  must be an integer. For more details, see the “Algorithms” on page 4-1009 section on the `dsp.SineWave` object page.

In this example,  $F_s$  is set to 22050 Hz and  $f_i$  is set to 1050 Hz.

```
Fs = 22.05e3;
sine = dsp.SineWave('Frequency', 1050, ...
    'SampleRate', Fs, ...
    'SamplesPerFrame', 32, ...
    'Method', 'Table lookup', ...
    'OutputDataType', 'Custom')

sine =
  dsp.SineWave with properties:

    Amplitude: 1
    Frequency: 1050
    PhaseOffset: 0
    ComplexOutput: false
    Method: 'Table lookup'
    TableOptimization: 'Speed'
    SamplesPerFrame: 32
```

```

    SampleRate: 22050
    OutputDataType: 'Custom'

```

Show all properties

In each loop of the iteration, stream in a frame of the fixed-point sinusoidal signal sampled at 22.05 kHz. Interpolate the streamed signal by a factor of 2. The interpolated output has 64 samples per frame.

```

for i = 1:16
    x = sine();
    y = cicint(x);
end

```

The output of the CIC interpolation filter is amplified by a specific gain value. You can determine this value using the `gain` function. This gain equals the gain of the  $2N^{\text{th}}$  stage of the CIC interpolation filter and equals  $(I \times D)^N / I$ , where  $I$  is the interpolation factor,  $D$  is the differential delay, and  $N$  is the number of sections of the CIC interpolator.

```

gainCIC = gain(cicint)

gainCIC = 2

```

To adjust this amplified output and to match it to the amplitude of the original signal, divide the CIC interpolated signal with the computed gain value.

Compare the last frames of the original and the interpolated signals. While plotting, account for the output latency of 2 samples.

```

n = (0:63)';
stem(n(1:31)/Fs,double(x(1:31)),'r','filled')
hold on;
I = cicint.InterpolationFactor;
stem(n(1:61)/(Fs*I), ...
     double(y(4:end))/gainCIC,'b')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original Signal',...
       'Interpolated Signal',...
       'location','north')
hold off;

```

Using the `info` function in the 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint, 'long')
```

```

## Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

### Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
cicD =
    dsp.CICDecimator with properties:
        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)
nt =
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok
WLs = 1x5
    18    18    18    18    18
FLs = 1x5
    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
          Signedness: Signed
         WordLength: 66
    FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
    66    66    66    66    66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

### Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32

```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

```

```

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
```

```
    26    26    26    26    32
```

```
FLs = 1x5
```

```
    15    15    15    15    21
```

### Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```
cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Specify word and fraction lengths'
    SectionWordLengths: [16 16 16 16]
    SectionFractionLengths: 0
    OutputWordLength: 32
    OutputFractionLength: 0

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
    16    16    16    16    32
```

```
FLs = 1x5
     0     0     0     0     0
```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1x5
    16    16    16    16    32
```

```
FLs = 1x5
     0     0     0     0     0
```

### Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```
cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32
```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```
WLs = 1x5
    16    16    16    16    32
```

```
FLs = 1x5
     5     5     5     5    21
```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

## More About

### CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC interpolation filter is conceptually given by an upsampler followed by a single rate CIC filter,  $H(z)$ , which is a lowpass anti-imaging filter. The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter  $H(z)$  is factorized this way:

$$H(z) = \left[ \sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{(1 - z^{-RM})^N}{1} \cdot \frac{1}{(1 - z^{-1})^N} = H_C^N(z) \cdot H_I^N(z)$$

where,

- $H_C$  is the transfer function of the  $N$  sections of the cascaded comb filters, each with a width of  $RM$ .
- $H_I$  is the transfer function of the integrator part of the filter containing  $N$  stages of integrators.
- $N$  is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- $R$  is the interpolation factor.
- $M$  is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for interpolation and moves the rate change factor,  $R$ , to follow after the  $N$  sections of the cascaded comb filters.

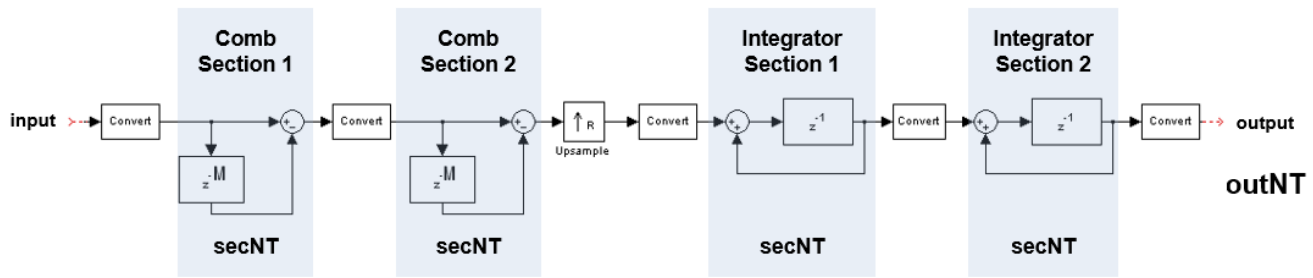

The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see Algorithms on page 4-268.

### Fixed Point

The fixed-point signal diagram shows the data types that the `dsp.CICInterpolator` object uses for fixed-point signals.

where,

- $secNT = numericity(1, secWL, secFL)$
- $outNT = numericity(1, outWL, outFL)$
- $secWL$  is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- $secFL$  is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- $outWL$  is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- $outFL$  is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of NumSections in this diagram is 2.

## Algorithms

### CIC Interpolation Filter

The CIC interpolation filter in More About on page 4-267 is realized as a cascade of  $N$  sections of comb filters followed by a rate change by a factor  $R$ , followed by  $N$  sections of cascaded integrators.

This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This algorithm puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

## dsp.ColoredNoise

**Package:** dsp

Generate colored noise signal

### Description

The `dsp.ColoredNoise` System object generates a colored noise signal with a power spectral density (PSD) of  $1/|f|^\alpha$  over its entire frequency range. The inverse frequency power,  $\alpha$ , can be any value in the interval  $[-2 \ 2]$ . The type of colored noise the object generates depends on the “Color” on page 4-0 you choose. When you set `Color` to 'custom', you can specify the power density of the noise through the “InverseFrequencyPower” on page 4-0 property.

This object uses the default MATLAB random stream, `RandStream`. Reset the default stream for repeatable simulations.

To generate colored noise signal:

- 1 Create the `dsp.ColoredNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
cn = dsp.ColoredNoise
cn = dsp.ColoredNoise(Name=Value)
cn = dsp.ColoredNoise(pow,samp,numChan,Name=Value)
cn = dsp.ColoredNoise(color,samp,numChan,Name=Value)
```

#### Description

`cn = dsp.ColoredNoise` creates a colored noise object, `cn`, that outputs a noise signal one sample or frame at a time, with a  $1/|f|^\alpha$  spectral characteristic over its entire frequency range. Typical values for  $\alpha$  are  $\alpha = 1$  (pink noise) and  $\alpha = 2$  (brownian noise).

`cn = dsp.ColoredNoise(Name=Value)` creates a colored noise object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.ColoredNoise(Color='pink');`

`cn = dsp.ColoredNoise(pow,samp,numChan,Name=Value)` creates a colored noise object with the `InverseFrequencyPower` property set to `pow`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise(1,44.1e3,1,OutputDataType='single');`

`cn = dsp.ColoredNoise(color,samp,numChan,Name=Value)` creates a colored noise object with the `Color` property set to `color`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise('pink',1024,2,OutputDataType='single');`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Color — Noise color

'custom' (default) | 'pink' | 'white' | 'brown' | 'blue' | 'purple'

Noise color, specified as one of the following. Each color is associated with a specific inverse frequency power of the generated noise sequence.

- 'pink' -- The inverse frequency power  $\alpha$  equals 1.
- 'white' --  $\alpha = 0$ .
- 'brown' --  $\alpha = 2$ . Also known as red or Brownian noise.
- 'blue' --  $\alpha = -1$ . Also known as azure noise.
- 'purple' --  $\alpha = -2$ . Also known as violet noise.
- 'custom' -- For noise with a custom inverse frequency power,  $\alpha$  equals the value of the `InverseFrequencyPower` property.

`InverseFrequencyPower`  $\alpha$  can be any value in the interval  $[-2, 2]$ .

Data Types: `char` | `string`

### InverseFrequencyPower — Inverse frequency power

1 (default) | real scalar in  $[-2, 2]$

Inverse frequency power  $\alpha$ , specified as a real scalar in the interval  $[-2, 2]$ . The inverse exponent defines the PSD of the random process as  $1/|f|^\alpha$ . Values of `InverseFrequencyPower` greater than 0 generate lowpass noise with a singularity (pole) at  $f = 0$ . These processes exhibit long memory. Values of `InverseFrequencyPower` less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- 1 -- Pink noise
- 2 -- Brown, red, or Brownian noise
- 0 -- White noise process with a flat PSD
- -1 -- Blue or azure noise
- -2 -- Purple or violet noise

In a log-log plot of power as a function of frequency, processes generated by this object exhibit an approximate linear relationship with slope equal to  $-\alpha$ .

**Dependencies**

This property applies only when you set `Color` to `'custom'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**SamplesPerFrameSource — Samples per frame source**

`'Property'` (default) | `'Input port'`

Source of the number of samples per frame, specified as `'Property'` or `'Input port'`.

Data Types: `char` | `string`

**SamplesPerFrame — Number of samples per output channel**

1024 (default) | positive integer

Number of samples per output channel, specified as a positive integer. This property determines the number of rows in the generated signal.

**Dependencies**

To enable this property, set `SamplesPerFrameSource` to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**MaxSamplesPerFrame — Maximum samples per frame**

192000 (default) | positive integer

Maximum number of samples per frame, specified as a positive integer.

The value you specify in the `MaxSamplesPerFrame` property acts as an upper limit to the number of samples in each frame that the object generates. If you specify a value greater than `MaxSamplesPerFrame`, the number of samples in each frame that the object generates equals the value in the `MaxSamplesPerFrame` property.

**Dependencies**

To enable this property, set `SamplesPerFrameSource` to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**NumChannels — Number of output channels**

1 (default) | positive integer

Number of output channels, specified as an integer. This property determines the number of columns of the generated signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**RandomStream — Source of random number stream**

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as one of the following:

- `'Global stream'` -- The current global random number stream is used for normally distributed random number generation.
- `'mt19937ar with seed'` -- The `mt19937ar` algorithm is used for normally distributed random number generation. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Data Types: char | string

### Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. The reset function reinitializes the random number stream to the value of the Seed property.

### Dependencies

This property applies only when you set the RandomStream property to 'mt19937ar with seed'.

Data Types: double

### BoundedOutput — Set output bounds to +1 and -1

false (default) | true

Specify the output to be bounded between +1 and -1, specified as:

- `true` -- The internal random source that generates the noise is uniform instead of Gaussian, and a gain is applied so that the absolute maximum output never exceeds 1.

If `Color` is set to 'white', there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and -1. The output distribution of filtered noise (such as pink noise) is quasi-Gaussian.

If `Color` is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain which ensures that the absolute maximum output never exceeds 1.

- `false` -- The internal random source is Gaussian. The output is not bounded.

Data Types: logical

### OutputDataType — Output data type

'double' (default) | 'single'

Output data type, specified as either 'double' or 'single'.

Data Types: char | string

## Usage

### Syntax

```
noiseOut = cn()
noiseOut = cn(L)
```

### Description

`noiseOut = cn()` outputs one sample or one frame of colored noise data.

`noiseOut = cn(L)` outputs one frame of colored noise data of length L, where L is a nonnegative integer.

This syntax applies only when you set `SamplesPerFrameSource` to 'Input port'.

## Output Arguments

### **noiseOut** — Colored noise output

vector | matrix

Colored noise output, returned as a vector or a matrix. The `SamplesPerFrame`, `NumChannels`, and the `OutputDataType` properties specify the size and data type of the output.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Measure Pink Noise Power in Octave Bands

The output from this example shows that pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44,100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1)

pinkNoise =
  dsp.ColoredNoise with properties:
           Color: 'custom'
  InverseFrequencyPower: 1
           BoundedOutput: false
           NumChannels: 1
  SamplesPerFrameSource: 'Property'
           SamplesPerFrame: 44100
           OutputDataType: 'double'
           RandomStream: 'Global stream'
```

```
rng default;
x = pinkNoise();
```

Set the sample rate to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
```

```

freqinterval = zeros(7,2);
Pwr = zeros(7,1);
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```

ans=7x2 table
    freqinterval      Pwr
    _____      _____
    100      200      0.17549
    200      400      0.20313
    400      800      0.2438
    800      1600     0.2503
    1600     3200     0.25233
    3200     6400     0.26828
    6400     12800    0.25211

```

The pink noise has roughly equal power in octave bands.

Rerun the preceding code with 'InverseFrequencyPower' equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```

whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();

```

Set the sample rate to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```

beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```

ans=7x2 table
    freqinterval      Pwr
    _____      _____
    100      200      0.0031417
    200      400      0.0073833
    400      800      0.017421

```

|      |       |          |
|------|-------|----------|
| 800  | 1600  | 0.035926 |
| 1600 | 3200  | 0.071139 |
| 3200 | 6400  | 0.15183  |
| 6400 | 12800 | 0.28611  |

White noise has approximately equal power per unit frequency, so octave bands have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for white noise.

### PSD of Pink Noise Realization

Generate a pink noise signal 2048 samples in length. The sample rate is 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

```
cn = dsp.ColoredNoise('pink',SamplesPerFrame=2048);  
x = cn();  
Fs = 1;  
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis with a base-2 logarithmic scale to clearly show the octaves. Plot the PSD estimate in dB,  $10\log_{10}$ .

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)))  
hold on  
plot(log2(F(2:end)),10*log10(PSDPink),'r',linewidth=2)  
xlabel('log_2(Hz)')  
ylabel('dB')  
title('Pink Noise')  
grid on  
legend('PSD estimate','Theoretical pink noise PSD')  
hold off
```

### Two-Channel Brownian Noise

Generate two channels of Brownian noise by setting `Color` to `'brown'` and `NumChannels` to 2. Specify the number of samples in each frame as an input while running the object algorithm.

```
cn = dsp.ColoredNoise('brown',SamplesPerFrameSource='Input port',...
    NumChannels=2)
```

```
cn =
    dsp.ColoredNoise with properties:
        Color: 'brown'
        BoundedOutput: false
        NumChannels: 2
        SamplesPerFrameSource: 'Input port'
        MaxSamplesPerFrame: 192000
        OutputDataType: 'double'
        RandomStream: 'Global stream'
```

```
x = cn(2048);
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;
```

The sample rate is 1 Hz. Obtain Welch PSD estimates for both channels. The fourth argument of `pwelch`, `NFFT`, which is the number of FFT points, is empty. Hence, `NFFT` is set to 256. For even `NFFT`, The number of FFT points used to calculate the PSD estimate is  $(NFFT/2+1)$ , which equals 129.

```
Fs = 1;
Pxx = zeros(129,size(x,2));
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use a base-2 logarithmic scale for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.',linewidth=2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');
```

### Add Pink Noise at 0 dB SNR

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

This example shows how to stream in an audio file and add pink noise at a 0 dB signal-to-noise ratio (SNR). The example reads in frames of an audio file 1024 samples in length, measures the root mean square (RMS) value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set 'SamplesPerFrame' for both the file reader and the colored noise generator to 1024 samples. Set `Color` to 'pink' to generate pink noise with a  $1/|f|$  power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader(FileName='speech_dft.mp3', ...
    SamplesPerFrame=N);
adw = audioDeviceWriter(SampleRate=afr.SampleRate);
cn = dsp.ColoredNoise('pink', SamplesPerFrame=N);
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
```

```
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end
release(afr);
release(adw);
```

### **Averaged Power Spectrum of Pink Noise**

Generate two-channels of pink noise and compute the power density spectrum.

Set up the colored noise generator to generate two channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap.

```
pinkNoise = dsp.ColoredNoise('pink',1024,2);
sa = spectrumAnalyzer(SpectrumType='power-density',...
    Method='welch',...
    AveragingMethod='exponential',...
    ForgettingFactor=0.95,...
    OverlapPercent=50,Window='hamming',...
    PlotAsTwoSidedSpectrum=false, ...
    FrequencyScale='log',YLimits=[-50 30]);
```

Run the simulation for 30 seconds.

```
tic
while toc < 30
    pink = pinkNoise();
    sa(pink);
end
```

## More About

### Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

where  $\alpha$  is a real number in the interval  $[-2, 2]$  and  $L(f)$  is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to  $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If  $\alpha > 0$ ,  $S(f)$  goes to infinity as the frequency,  $f$ , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If  $\alpha < 0$ , the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of  $\frac{1}{|f|^\alpha}$  processes include:

- $\alpha = 0$  — White noise, where  $L(f)$  is a constant proportional to the process variance.
- $\alpha = 1$  — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-274 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$  — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like  $\frac{1}{|f|^2}$ . Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$  — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$  — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

## Algorithms

The figure shows the overall process of generating the colored noise.

The random stream generator produces a stream of white noise that is either Gaussian or uniform in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

When  $\alpha$ , the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and -1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and -1. If  $\alpha$  is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is enabled, a gain  $g$  is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of  $\alpha$  affects the PSD of the colored noise, see “Colored Noise Processes” on page 4-281.

When the inverse frequency power  $\alpha$  is positive, the colored noise is generated using an autoregressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$

$$a_k = (k - 1 - \frac{\alpha}{2}) \frac{a_{k-1}}{k}, \quad k = 1, 2, \dots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power  $\alpha$  is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$

$$b_k = (k - 1 + \frac{\alpha}{2}) \frac{b_{k-1}}{k}, \quad k = 1, 2, \dots, 255$$

Purple noise is generated from a first order filter,  $B = [1 \ -1]$ .

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820-822 in [2].

## Version History

### Introduced in R2014a

### R2022b: Variable-sized output frames in dsp.ColoredNoise object

Starting in R2022b, dsp.ColoredNoise object can generate colored noise signals of variable-sized output frames.

You can specify the frame size of the output colored noise signal as a nonnegative scalar value that is less than or equal to the MaxSamplesPerFrame property.

# dsp.ComplexBandpassDecimator

**Package:** dsp

Extract a frequency subband using a one-sided (complex) bandpass decimator

## Description

The `dsp.ComplexBandpassDecimator` System object extracts a specific sub-band of frequencies using a one-sided, multistage, complex bandpass decimator. The object determines the bandwidth of interest using the specified `CenterFrequency`, `DecimationFactor` and `Bandwidth` values.

To extract a frequency subband using a complex bandpass decimator:

- 1 Create the `dsp.ComplexBandpassDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
bpdecim = dsp.ComplexBandpassDecimator
bpdecim = dsp.ComplexBandpassDecimator(d)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)
bpdecim = dsp.ComplexBandpassDecimator(Name,Value)
```

### Description

`bpdecim = dsp.ComplexBandpassDecimator` creates a System object that filters each channel of the input over time using a one-sided, multistage, complex bandpass decimation filter. The object determines the bandwidth of interest using the default center frequency, decimation factor, and bandwidth values.

`bpdecim = dsp.ComplexBandpassDecimator(d)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, and the `CenterFrequency` property set to `Fc`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, the `CenterFrequency` property set to `Fc`, and the `SampleRate` property set to `Fs`.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3,2e3,48e3);`

`bpdecim = dsp.ComplexBandpassDecimator(Name, Value)` creates a complex bandpass decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3, 2e3, 48e3, 'CenterFrequency', 1e3);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### CenterFrequency — Center frequency in Hz

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range  $[-\text{SampleRate}/2, \text{SampleRate}/2]$ .

**Tunable:** Yes

Data Types: `single` | `double`

### Specification — Filter design parameters

'Decimation factor' (default) | 'Bandwidth' | 'Decimation factor and bandwidth'

Filter design parameters, specified as:

- 'Decimation factor' -- The object specifies the decimation factor through the `Decimation Factor` property. The bandwidth of interest ( $BW$ ) is computed using the following equation:

$$BW = Fs/D$$

where

- $Fs$  -- Sample rate specified through `SampleRate` property.
- $D$  -- Decimation factor.
- 'Bandwidth' -- The object specifies the bandwidth through the `Bandwidth` property. The decimation factor ( $D$ ) is computed using the following equation:

$$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

where

- $Fs$  -- Sample rate specified through `SampleRate` property.
- $BW$  -- Bandwidth of interest.
- $TW$  -- Transition width specified through the `TransitionWidth` property.
- 'Decimation factor and bandwidth' -- The decimation factor and the bandwidth of interest are specified through the `DecimationFactor` and `Bandwidth` properties.

**DecimationFactor — Decimation factor**

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

**Dependencies**

This property applies when you set `Specification` to either 'Decimation factor' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**StopbandAttenuation — Stopband attenuation in dB**

80 (default) | positive scalar

Stopband attenuation of the filter in dB, specified as finite positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**TransitionWidth — Transition width in Hz**

100 (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Bandwidth — Bandwidth (Hz)**

5000 (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

**Dependencies**

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double`

**PassbandRipple — Passband ripple (dB)**

1 (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

**Dependencies**

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**MinimizeComplexCoefficients — Flag to minimize number of complex coefficients**`true` (default) | `false`

Flag to minimize the number of complex filter coefficients, specified as:

- `true` -- The first stage of the multistage filter is bandpass (complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.

- `false` -- The input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if `MixToBaseband` is `true`, and the frequency offset resulting from the decimation is nonzero.

**MixToBaseband — Flag to mix signal to baseband**`true (default) | false`

Flag to mix the signal to baseband, specified as:

- `true` -- The object heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter.
- `false` -- The object skips the mixing stage.

**Dependencies**

This property applies when you set `MinimizeComplexCoefficients` to `false`.

**SampleRate — Input sample rate in Hz**`44100 (default) | real positive scalar`

Sampling rate of the input signal in Hz, specified as a real positive scalar.

Data Types: `single` | `double`

**Usage****Syntax**`y = bpdecim(x)`**Description**

`y = bpdecim(x)` filters the real or complex input signal, `x`, to produce the output, `y`. The output contains the subband of frequencies specified by the System object properties. The System object filters each channel of the input signal independently over time. The frame size (first dimension) of `x` must be a multiple of the decimation factor.

**Input Arguments****x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix of size  $P$ -by- $Q$ . The number of input rows  $P$  can be arbitrary and does not have to be a multiple of the decimation factor.

This object supports variable-size input signals, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

Data Types: `single` | `double`

**Output Arguments****y — Filtered output**`vector | matrix`

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the System object properties.

When the input is of size  $P$ -by- $Q$ , and  $P$  is not a multiple of the decimation factor  $D$ , the output signal has an upper bound size of  $\text{ceil}(P/D)$ -by- $Q$ , where  $D$  is the decimation factor. If  $P$  is a multiple of the decimation factor, then the output is of size  $(P/D)$ -by- $Q$ . The number of channels (columns) does not change.

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.ComplexBandpassDecimator

## Examples

### Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =
```

```
  dsp.ComplexBandpassDecimator with properties:
```

```

        CenterFrequency: 5000
        Specification: 'Decimation factor'
        DecimationFactor: 12
        StopbandAttenuation: 80
        TransitionWidth: 100
        MinimizeComplexCoefficients: true
        SampleRate: 44100
```

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)

c = struct with fields:
    NumCoefficients: 201
    NumStates: 379
    RealMultiplicationsPerInputSample: 44.3333
    RealAdditionsPerInputSample: 43.8333
```

### Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100);
[h,f] = freqz(cbp);
plot(f,20*log10(abs(h)))
grid on
xlabel('Frequency (Hz)')
ylabel('h (dB)')
```

## Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

### Initialization

Create a `dsp.ComplexBandpassDecimator System` object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `spectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;
CF = 2000;
BW = 1000;
D = Fs/BW;
FrameLength = 1200;
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);

sa = spectrumAnalyzer('SampleRate',Fs/D,...
    'Method','welch',...
    'YLimits',[-120 40],...
    'FrequencyOffset',CF);

tones = [1625 2000 2125];
sin = dsp.SineWave('SampleRate',Fs,'Frequency',tones,...
    'SamplesPerFrame',FrameLength);
```

### Visualize Filter Stages

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```

### Display Filter info

The `info` function displays information about the bandpass decimator.

```
fprintf('%s',info(bpdecim))
```

```
Overall Decimation Factor      : 48
Bandwidth                      : 1000 Hz
Number of Filters              : 5
Real multiplications per Input Sample: 14.708333
Real additions per Input Sample  : 13.833333
Number of Coefficients         : 89
Filters:
  Filter 1:
  dsp.FIRDecimator            - Decimation Factor   : 2
  Filter 2:
  dsp.FIRDecimator            - Decimation Factor   : 2
  Filter 3:
  dsp.FIRDecimator            - Decimation Factor   : 2
  Filter 4:
  dsp.FIRDecimator            - Decimation Factor   : 3
  Filter 5:
  dsp.FIRDecimator            - Decimation Factor   : 2
```

### Stream In and Filter Signal

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, sa.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4*randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400

bpdecim =
    dsp.ComplexBandpassDecimator with properties:

        CenterFrequency: 2400
        Specification: 'Decimation factor'
        DecimationFactor: 48
        StopbandAttenuation: 80
```

```

TransitionWidth: 100
MinimizeComplexCoefficients: true
SampleRate: 48000

```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900, 2900] Hz.

```

release(sa)
sa.FrequencyOffset = 2400;

```

Stream in the data and filter the signal.

```

for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end

```

The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

## Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

## Version History

**Introduced in R2018a**

### **R2023a: Support for arbitrary input frame length**

This object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the decimation factor.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- This object also supports SIMD code generation using Intel AVX2 technology under these conditions:
  - Input signal is complex-valued.
  - Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

- In the code you generate from this object, the decimator output is a fixed-size signal if the input signal is fixed size and is a multiple of the decimation factor. If the input is not a multiple of the decimation factor or if the input is a variable-size signal, then the decimator output is of variable-size.

# dsp.Convolver

**Package:** dsp

(Removed) Convolution of two signals

---

**Note** `dsp.Convolver` has been removed. Use `conv` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `dsp.Convolver` System object convolves the first dimension of an  $N$ -D input array,  $u$ , with the first dimension of an  $N$ -D input array,  $v$ . You can convolve the inputs in the time domain or frequency domain. In the time domain, the object convolves the first input with the second input. In the frequency domain, the object multiplies the Fourier transforms of both the inputs, and computes the inverse Fourier transform of the product. In this domain, depending on the input length, the object can require fewer computations. For more information on the two computation methods, see “Algorithms” on page 4-303.

To convolve two inputs:

- 1 Create the `dsp.Convolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
cnv = dsp.Convolver
cnv = dsp.Convolver(Name, Value)
```

### Description

`cnv = dsp.Convolver` creates a convolution System object, `cnv`, to convolve two inputs in the time domain or frequency domain.

`cnv = dsp.Convolver(Name, Value)` creates a convolution System object, `cnv`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `cnv = dsp.Convolver('Method', 'Frequency Domain')`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**Method — Domain for computing convolutions**

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes convolutions, specified as one of the following:

- 'Time Domain' -- Computes the convolutions in the time domain, which minimizes memory usage. For more information, see “Time-Domain Computation” on page 4-303.
- 'Frequency Domain' -- Computes the convolutions in the frequency domain, which can require fewer computations depending on the input length. For more information, see “Frequency-Domain Computation” on page 4-304.
- 'Fastest' -- Computes the convolutions in the domain that minimizes the number of computations.

---

**Note** Fixed-point signals are supported for the time domain only. To use the following fixed-point properties, set Method to 'Time Domain'.

---

**Fixed-Point Properties****FullPrecisionOverride — Full-precision override for fixed-point arithmetic**

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- true -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- false -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

**RoundingMethod — Rounding method**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

**Dependencies**

This property applies when you set the FullprecisionOverride property to false and at least one of the ProductDataType, AccumulatorDataType, and OutputDataType properties to any option other than 'Full precision'.

**OverflowAction — Overflow action**

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.

- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

#### Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than 'Full precision'.

#### ProductDataType — Product output data type

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the output of a product operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and `OverflowAction` properties.
- 'Same as first input' -- The object specifies the product output data type to be the same as the first input data type.

For more information on the product output data type, see the “Fixed Point” on page 4-302 section.

#### CustomProductDataType — Product word and fraction lengths

`numericType([],32,30)` (default)

The product output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

#### Dependencies

This property applies only when you set `ProductDataType` to 'Custom'.

#### AccumulatorDataType — Accumulator data type

'Full precision' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of an accumulation operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the accumulator data type using the full precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the accumulator data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the accumulator data type to be the same as the product data type.

For more information on the accumulator data type, see the “Fixed Point” on page 4-302 section.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

`numericType([],32,30)` (default)

The accumulator data type, specified as an auto signed numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set `AccumulatorDataType` to 'Custom'.

**OutputDataType — Output data type**

'Same as accumulator' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of the `dsp.Convolver` object, specified as one of the following:

- 'Same as accumulator' -- The object specifies the output data type to be the same as the accumulator data type. For more details on the accumulator data type, see the “AccumulatorDataType” on page 4-0 property.
- 'Custom' -- The output data type is specified as a custom numeric type through the `CustomOutputDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the output data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the output data type to be the same as the product data type.

For more information on the output data type, see the “Fixed Point” on page 4-302 section.

**CustomOutputDataType — Output word and fraction lengths**

`numericType([],16,15)` (default)

The output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set `OutputDataType` to 'Custom'.

**Usage****Syntax**

```
cnvOut = cnv(input1, input2)
```

**Description**

`cnvOut = cnv(input1, input2)` convolves the two inputs, `input1` and `input2`, along their first dimensions, and returns the convolved output, `cnvOut`.

## Input Arguments

### input1 — First data input

vector | matrix |  $N$ -D array

First data input, specified as a vector, matrix, or  $N$ -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `ones(10,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

### input2 — Second data input

vector | matrix |  $N$ -D array

Second data input, specified as a vector, matrix, or  $N$ -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `randn(4,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Output Arguments

### cnvOut — Convolved output

vector | matrix |  $N$ -D array

The convolved output of the two inputs, returned as a vector, matrix, or  $N$ -D array.

- When both inputs are  $N$ -D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when  $u$  is an  $M_u$ -by- $N$ -by- $P$  array, and  $v$  is an  $M_v$ -by- $N$ -by- $P$  array, the output is an  $(M_u+M_v-1)$ -by- $N$ -by- $P$  array.
- When one input is a column vector and the other is an  $N$ -D array, the object independently convolves the vector with the first dimension of the  $N$ -D input array. For example, when  $u$  is an  $M_u$ -by-1 column vector and  $v$  is an  $M_v$ -by- $N$  matrix, the output is an  $(M_u+M_v-1)$ -by- $N$  matrix.
- When  $u$  and  $v$  are column vectors with lengths  $M_u$  and  $M_v$ , the object performs the vector convolution. The output is an  $(M_u+M_v-1)$ -by-1 column vector.

When both the inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |

reset     Reset internal states of System object

## Examples

### Convolve Two Rectangular Sequences

Create a `dsp.Convolver` object.

```
conv = dsp.Convolver
conv =
  dsp.Convolver with properties:
    Method: 'Time Domain'
  Show all properties
```

Convolve two rectangular sequences.

```
x = ones(10,1);
y = conv(x,x);
```

Plot the resulting convolved sequence, which is a triangular sequence.

```
plot(y)
```

## More About

### Convolution

The convolution of two signals is the integral that measures the amount of overlap of one signal as it is shifted over another signal.

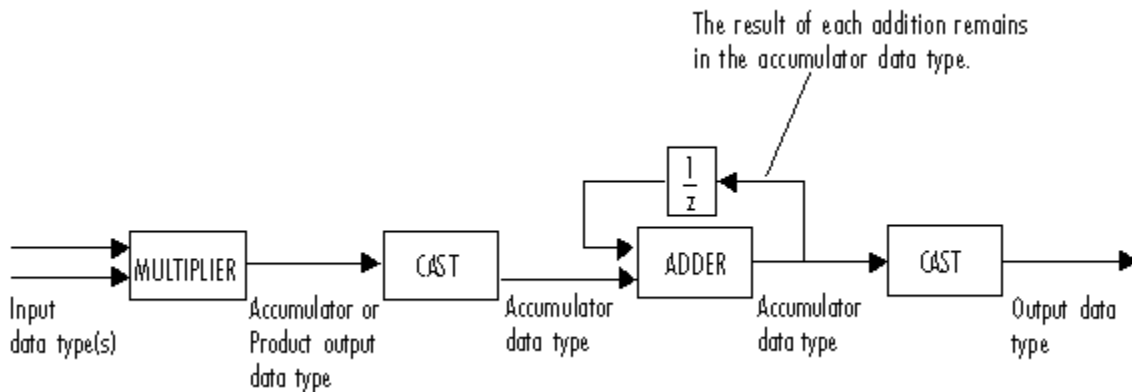

The convolution of two discrete time sequences,  $u[n]$  and  $v[n]$ , is given by the following equation:

$$y(k) = \sum_n u(n-k)v(k)$$

### Fixed Point

The following diagram shows the data types used within the `dsp.Convolver` System object for fixed-point signals.

Fixed-point signals are supported for the time domain only.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

## Algorithms

### Time-Domain Computation

When you set the computation domain to *time*, the algorithm computes the convolution of the two inputs in the time domain.

When the two inputs,  $u$  and  $v$ , are of size  $M_u$ -by- $N$  and  $M_v$ -by- $N$  respectively, the  $j$ th column of the convolution output is given by the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs  $u$  and  $v$  are zero when they are indexed outside their valid ranges.

When  $u$  is an  $M_u$ -by-1 column and  $v$  an  $M_v$ -by- $N$  matrix, the output is an  $(M_u + M_v - 1)$ -by- $N$  matrix whose  $j$ th column is computed using the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

When both the inputs are column vectors with lengths  $M_u$  and  $M_v$ , the object performs the vector convolution given by the following equation:

$$y_i = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is an  $(M_u + M_v - 1)$ -by-1 column vector.

## Frequency-Domain Computation

When you set the computation domain to *frequency*, the algorithm computes the convolution in the frequency domain.

In this domain, the algorithm computes the convolution sequence by taking the Fourier transform of both the input signals, multiplying the Fourier transforms, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

## Version History

### Introduced in R2012a

#### R2021b: `dsp.Convolver` System object will be removed

*Warns starting in R2021b*

`dsp.Convolver` System object will be removed in a future release. Use the `conv` function instead.

#### R2023a: `dsp.Convolver` System object has been removed

*Errors starting in R2023a*

The `dsp.Convolver` System object has been removed. Use the `conv` function instead.

### Update Code

This table shows how to update existing code to use the `conv` function.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre>cv = dsp.Convolver; x = ones(10,1); yobj = cv(x,x);</pre> | <pre>yfn = conv(x,x); isequal(yobj,yfn)  ans =      logical       1</pre> <p>Run the code and plot the vectors <i>yobj</i> and <i>yfn</i> using the <code>plot</code> function. Verify that the plots match.</p> |

# dsp.Counter

**Package:** dsp

(Removed) Count up or down through specified range of numbers

---

**Note** dsp.Counter has been removed. Alternatively, you can create a variable in MATLAB® and increment the variable by 1.

---

## Description

The Counter object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

- 1 Create the dsp.Counter object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
count = dsp.Counter  
count = dsp.Counter(Name, Value)
```

### Description

count = dsp.Counter returns a counter System object, count, that counts up when the input is nonzero.

count = dsp.Counter(Name, Value) returns a counter System object, count, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Direction — Count up or down

Up (default) | Down

Specify the counter direction as Up or Down.

**Tunable:** Yes

### **CountEventInputPort — Add input to specify a count event**

true (default) | false

Set this property to true to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the CountEventCondition property. When you set this property to false, the internal counter is free running, that is, the counter increments or decrements on every call to the object algorithm.

### **CountEventCondition — Condition that increments, decrements, or resets internal counter**

Non-zero (default) | Rising edge | Falling edge | Either edge

Specify the event at the count event input that increments or decrements the counter as Rising edge, Falling edge, Either edge or Non-zero.

If you set the ResetInputPort and CountEventInputPort properties to true, the counter is reset when the event you specify for the CountEventCondition occurs.

#### **Dependencies**

This property applies only when you set the CountEventInputPort property to true.

### **CounterSizeSource — Source of counter size data type**

Property (default) | Input port

Specify the source of the counter size data type as Property or Input port.

### **CounterSize — Range of integer values to count through**

Maximum (default) | 8 bits | 16 bits | 32 bits

Specify the range of integer values to count through before recycling to zero as 8 bits, 16 bits, 32 bits or Maximum.

### **MaximumCount — Counter's maximum value**

255 (default) | 0 | positive integer

Specify the counter's maximum value as a numeric scalar value.

**Tunable:** Yes

#### **Dependencies**

This property applies only when you set the CounterSizeSource property to Property and the CounterSize property to Maximum.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **InitialCount — Counter initial value**

0 (default) | 0 | positive integer

Specify the initial value for the counter.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**CountOutputPort — Output count**`true (default) | false`

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

**HitOutputPort — Output hit events**`true (default) | false`

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

**HitValues — Values whose occurrence in count produce a true hit output**`32 (default) | scalar integer | vector of integers`

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit.

**Dependencies**

This property applies only when you set the `HitOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ResetInputPort — Add input to enable internal counter reset**`true (default) | false`

When you set this property to `true`, specify a reset input to the object algorithm. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

**SamplesPerFrame — Number of samples in each output frame**`1 (default) | positive integer`

Specify the number of samples in each output frame.

**Dependencies**

This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**CountOutputDataType — Data type of count output**`double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32`

Specify the data type of the count output, `cnt`, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`.

**Dependencies**

This property applies when you set the `CountOutputPort` property to `true`.

## Usage

### Syntax

```
[cnt, hit] = count(event, reset)
cnt = count(event, reset)
hit = count(event, reset)
[ ___ ] = count()
[ ___ ] = count(event)
```

### Description

`[cnt, hit] = count(event, reset)` increments, decrements, or resets the internal counter as specified by the values of the `event` and `reset` inputs. The output argument `cnt` denotes the present value of the counter. A trigger event at the `event` input causes the counter to increment or decrement. A trigger event at the `reset` input resets the counter to its initial state.

`cnt = count(event, reset)` returns the current value of the count when you set the `CountOutputPort` property to `true` and the `HitOutputPort` property to `false`.

`hit = count(event, reset)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[ ___ ] = count()` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[ ___ ] = count(event)` increments or decrements the internal counter when the `event` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

### Input Arguments

#### **event** — Event that causes counter to increment or decrement

scalar

Event that causes the counter to increment or decrement, specified as a scalar. The `CountEventCondition` property specifies the event under which the counter value changes.

#### **Dependencies**

This input is valid only when `CountEventInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

#### **reset** — Reset of internal counter

scalar

A trigger event at the reset input resets the counter to the initial state.

#### **Dependencies**

This input is valid only when `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

## Output Arguments

### **cnt** — Present value of counter

scalar | column vector

Current value of the count, returned as a scalar. The data type of this output is set by the `CountOutputDataType` property. If `CountEventInputPort` is false, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

### Dependencies

This output is enabled only when you set the `CountOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### **hit** — Indicates if counter matches hit values

scalar | column vector

Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. If `CountEventInputPort` is false, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

### Dependencies

This output is enabled when you set the `HitOutputPort` property to `true`.

Data Types: `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Count the Rising Edges

Use `dsp.Counter` System object to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...  
    'CountOutputPort', true, ...  
    'HitOutputPort', false, ...  
    'ResetInputPort', false);  
sgnl = [0 1 0 1 0 1 0 1 0 1 0 1];  
cnt = zeros(1,12);  
for ii = 1:length(sgnl)
```

```

        cnt(ii) = count(sgnl(ii));
end
disp(cnt);

    0     1     1     2     2     3     3     4     4     5     5     0

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The CountEventCondition object property does not have a free-running option. Set the CountEventInputPort property to `false` to obtain the free-running option.
- The CounterSizeSource and CounterSize object properties correspond to the **Counter size** block parameter.
- The CountOutputPort and HitOutputPort correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

## dsp.CoupledAllpassFilter

**Package:** dsp

Coupled allpass IIR filter

### Description

The `dsp.CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first.

`dsp.CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

- 1 Create the `dsp.CoupledAllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
caf = dsp.CoupledAllpassFilter
caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(Name,Value)
```

### Description

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to 'Minimum multiplier', `AllpassCoefficients1` set to `AllpassCoeffs1`, and `AllpassCoefficients2` set to `AllpassCoeffs2`.

`caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `struc` and the relevant coefficients set to `AllpassCoeffs1` and `AllpassCoeffs2`. `struc` can be 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'.

`caf = dsp.CoupledAllpassFilter(Name,Value)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Structure — Internal structure of allpass branches

'Minimum multiplier' (default) | 'Wave Digital Filter' | 'Lattice'

Specify the internal structure of allpass branches as one of 'Minimum multiplier', 'Wave Digital Filter', or 'Lattice'. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

### AllpassCoefficients1 — Allpass polynomial coefficients of branch 1

[0 0.5] (default) | row vector | cell array

Specify the polynomial filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

#### Dependencies

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: `single` | `double`

### WDFCoefficients1 — Wave Digital Filter coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

#### Dependencies

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: `single` | `double`

### LatticeCoefficients1 — Lattice coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the allpass lattice coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

**Dependencies**

This property is applicable only if you set the Structure property to 'Lattice'.

Data Types: `single` | `double`

**Delay — Length in samples for branch 1**

0 (default) | positive integer scalar

Integer number of the delay taps in the top branch, specified as a positive integer scalar.

**Tunable:** Yes

**Dependencies**

This property is applicable only if you set the PureDelayBranch property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Gain1 — Independent Branch 1 Phase Gain**

1 (default) | '-1' | '0+i' | '0-i'

Gain1 is the individual branch phase gain. This property can accept only values equal to '1', '-1', '0+i', or '0-i'. This property is nontunable.

Data Types: `char`

**AllpassCoefficients2 — Allpass polynomial coefficients of branch 2**

{[ ]} (default) | row vector | cell array

Specify the polynomial filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

**Dependencies**

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: `single` | `double`

**WDFCoefficients2 — Wave Digital Filter coefficients of branch 2**

{[ ]} (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

**Dependencies**

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: `single` | `double`

**LatticeCoefficients2 — Lattice coefficients of branch 2**

{[ ]} (default) | row vector | cell array

Specify the allpass lattice coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

**Tunable:** Yes

**Dependencies**

This property is applicable only if you set the Structure property to 'Lattice'.

Data Types: single | double

**Gain2 — Independent Branch 2 Phase Gain**

'1' (default) | '-1' | '0+1i' | '0-1i'

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to '1', '-1', '0+i', or '0-i'. This property is nontunable.

Data Types: char

**Beta — Coupled phase gain**

1 (default) | complex value with magnitude equal to 1

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. The absolute value of this property should be 1 and its default value is 1.

**Tunable:** Yes

**Dependencies**

This property is applicable only when the selected Structure property supports complex coefficients.

Data Types: single | double

**PureDelayBranch — Replace allpass filter in first branch with pure delay**

false (default) | true

If you set PureDelayBranch to true, the property holding the coefficients for the first allpass branch is disabled and Delay becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

Data Types: logical

**ComplexConjugateCoefficients — Allow inferring coefficients of second allpass branch as complex conjugate of first**

false (default) | true

When the input signal is real, this property triggers the use of an optimized structural realization. This property enables providing complex coefficients for only the first branch. The coefficients for the second branch are automatically inferred as complex conjugate values of the first branch coefficients

### Dependencies

This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Data Types: `logical`

### Usage

### Syntax

```
y = caf(x)
[y, ypc] = caf(x)
```

### Description

`y = caf(x)` filters the input signal `x` to produce the output `y`. When `x` is a matrix, each column is filtered independently as a separate channel over time.

`[y, ypc] = caf(x)` also returns `ypc`, the power complementary signal to the primary output `y`.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Lowpass filtered output

vector | matrix

Lowpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

#### **ypc** — Highpass filtered output

vector | matrix

Power complimentary highpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.CoupledAllpassFilter

|             |  |
|-------------|--|
| fvtool      | Visualize frequency response of coupled allpass filter       |
| getBranches | Return internal allpass branches                             |
| freqz       | Frequency response of discrete-time filter System object     |
| impz        | Impulse response of discrete-time filter System object       |
| info        | Information about filter System object                       |
| coeffs      | Returns the filter System object coefficients in a structure |
| cost        | Estimate cost of implementing filter System object           |
| grpdelay    | Group delay response of discrete-time filter System object   |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Allpass Realization of a Butterworth Lowpass Filter

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```

Fs = 48000;    % in Hz
Fc = 12000;   % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end

```

### Allpass Realization of an Elliptic Highpass Filter

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

#### Initialize

```

Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
    'SamplesPerFrame',frameLength); % Input composed of two sinusoids.

sa = spectrumAnalyzer('SampleRate',Fs,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
    'Method','welch','AveragingMethod','exponential',...
    'Title','Original (Channel 1) Filtered (Channel 2)',...
    'ChannelNames',{'Original','Filtered'});

```

## Simulate

```

for k = 1:1000
    original = sum(sine(),2); % Add the two sinusoids together
    filtered = hpSpec(original);
    sa([original,filtered]);
end
release(sa)

```

## View Power Complementary Output of Coupled Allpass Filter

Design a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```

Fs = 48000; % in Hz
Fc = 12000; % in Hz
frameLength = 1024;
[b,a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1,c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));

```

Using the 'SubbandView' option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, the power complementary highpass filter output, or both using the `fvtool`.

To view the lowpass filter output, set 'SubbandView' to 1.

```
fvtool(caf, 'SubbandView', 1, 'Fs', Fs)
```

To view the highpass filter output, set 'SubbandView' to 2.

```
fvtool(caf, 'SubbandView', 2, 'Fs', Fs)
```

To view both the outputs, set 'SubbandView' to 'all', [1 2] or [1;2].

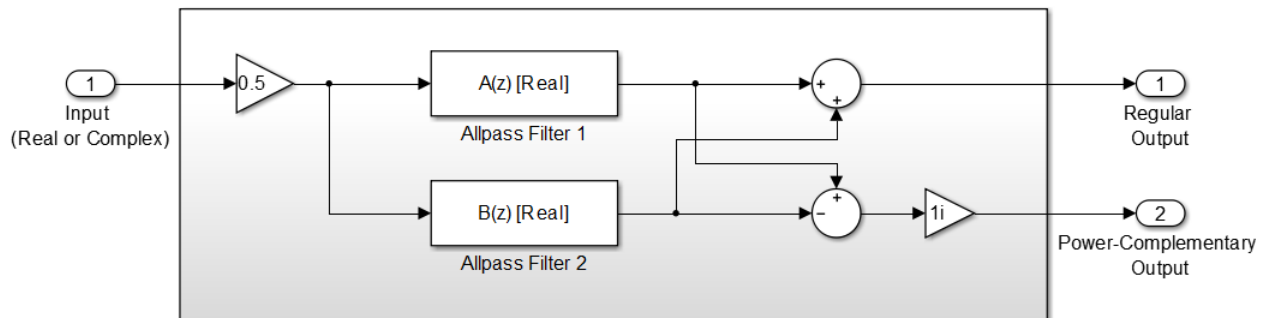

```
fvtool(caf, 'SubbandView', 'all', 'Fs', Fs);
```

## Algorithms

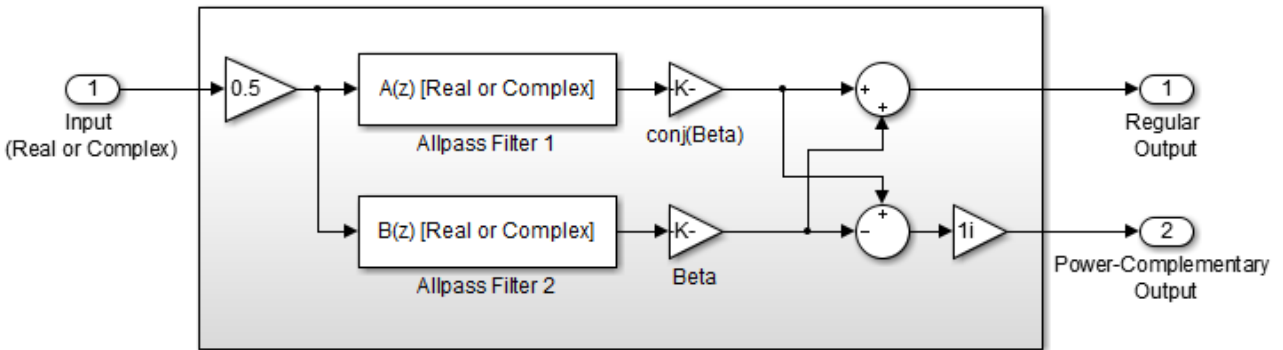

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF

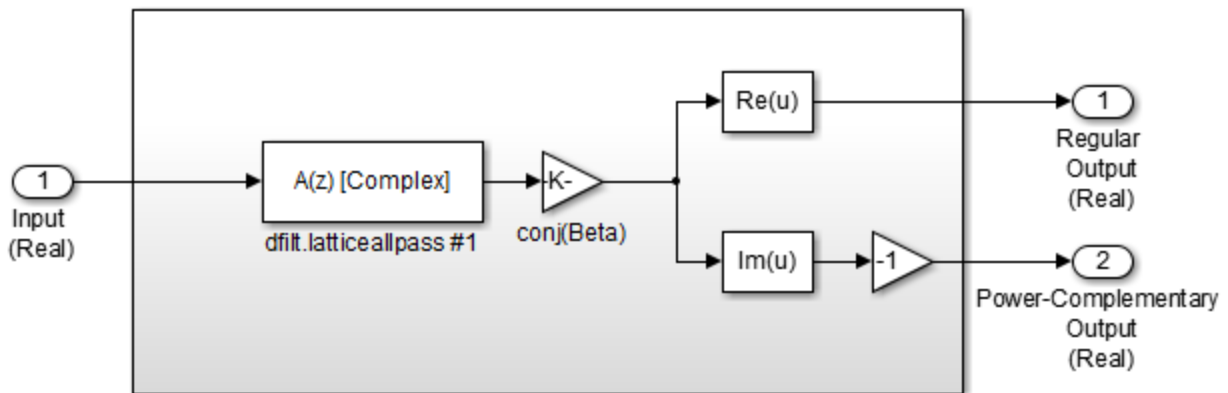

- Lattice

- Lattice with Complex Conjugate Coefficients

## Version History

Introduced in R2013b

# dsp.CrossSpectrumEstimator

**Package:** dsp

Estimate cross-spectral density

## Description

The `dsp.CrossSpectrumEstimator` System object computes the cross-spectrum density of a signal, using the Welch's averaged periodogram method.

To implement the cross-spectrum estimation object:

- 1 Create the `dsp.CrossSpectrumEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
cse = dsp.CrossSpectrumEstimator
cse = dsp.CrossSpectrumEstimator(Name, Value)
```

### Description

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch's averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator(Name, Value)` returns a `dsp.CrossSpectrumEstimator` System object, `cse`, with each specified property name set to the specified value. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### FFTLengthSource — Source of FFT length value

'Auto' (default) | 'Property'

Specify the source of the FFT length value as either 'Auto' or 'Property'. If you set this property to 'Auto', the cross-spectrum estimator sets the FFT length to the input frame size. If you set this property to 'Property', then specify the number of FFT points using the FFTLength property.

**FFTLength — FFT Length**

128 (default) | positive integer

Specify the length of the FFT that the cross-spectrum estimator uses to compute cross-spectral estimates as a positive, integer scalar.

**Dependencies**

This property applies when you set the FFTLengthSource property to 'Property'.

Data Types: double

**Window — Window function**

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser'

Specify a window function for the cross-spectrum estimator as one of 'Rectangular', 'Chebyshev', 'Flat Top', 'Hamming', 'Hann', or 'Kaiser'.

**SidelobeAttenuation — Side lobe attenuation of window**

60 (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

**Dependencies**

This property applies when you set the Window property to 'Chebyshev' or 'Kaiser'.

Data Types: double

**FrequencyRange — Frequency range of the cross-spectrum estimate**

'Twosided' (default) | 'onesided' | 'centered'

Specify the frequency range of the cross-spectrum estimator as one of 'twosided', 'onesided', or 'centered'.

If you set the FrequencyRange to 'onesided', the cross-spectrum estimator computes the one-sided spectrum of real input signals,  $x$  and  $y$ . If the FFT length,  $N_{FFT}$ , is even, the length of the cross-spectral estimate is  $N_{FFT}/2+1$  and is computed over the interval  $[0, SampleRate/2]$ . If  $N_{FFT}$  is odd, the length of the cross-spectrum estimate is equal to  $(N_{FFT}+1)/2$ , and the interval is  $[0, SampleRate/2]$ .

If you set the FrequencyRange to 'twosided', the cross-spectrum estimator computes the two-sided spectrum of complex or real input signals,  $x$  and  $y$ . The length of the cross-spectrum estimate is equal to  $N_{FFT}$ . This value is computed over  $[0, SampleRate]$ .

If you set the FrequencyRange to 'centered', the cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals,  $x$  and  $y$ . The length of the cross-spectrum estimate is equal to  $N_{FFT}$ , and the estimate is computed between  $[-SampleRate/2, SampleRate/2]$  and  $(-SampleRate/2, SampleRate/2)$  for even and odd lengths, respectively.

**AveragingMethod — Averaging method**

'Running' (default) | 'Exponential'

Specify the averaging method as 'Running' or 'Exponential'. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

### **SpectralAverages — Number of spectral averages**

8 (default) | positive integer

Specify the number of spectral averages as a positive, integer scalar. The object computes the current cross-spectral estimate by averaging the last N estimates. N is the number of spectral averages defined in the `SpectralAverages` property.

#### **Dependencies**

This property applies when you set `AveragingMethod` to 'Running'.

Data Types: double

### **ForgettingFactor — Forgetting factor**

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

**Tunable:** Yes

#### **Dependencies**

This property applies when you set `AveragingMethod` to 'Exponential'.

Data Types: single | double

### **SampleRate — Sample rate of input**

1 (default) | positive scalar

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The sample rate is the rate at which the signal is sampled in time.

Data Types: single | double

## **Usage**

### **Syntax**

`pxy = cse(x,y)`

#### **Description**

`pxy = cse(x,y)` computes the cross power spectrum density, `pxy`, of the input signals, `x` and `y`.

#### **Input Arguments**

##### **x — First data input**

vector | matrix

First data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

### **y** — Second data input

`vector` | `matrix`

Second data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

### **Output Arguments**

#### **pxy** — Cross-power spectrum density output

`vector` | `matrix`

Cross-power spectrum density output, returned as a vector or a matrix. The output has the same size and data type as the input signals.

Data Types: `single` | `double`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Specific to `dsp.CrossSpectrumEstimator`**

`getFrequencyVector`    Vector of frequencies at which estimation is done  
`getRBW`                Resolution bandwidth of spectrum

### **Common to All System Objects**

`step`        Run System object algorithm  
`release`    Release resources and allow changes to System object property values and input characteristics  
`reset`      Reset internal states of System object

## **Examples**

### **Compute Cross-Power Spectrum of Two Noisy Sine Waves**

Generate two sine waves.

```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);  
sin1.SamplesPerFrame = 1000;  
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);  
sin2.SamplesPerFrame = 1000;
```

Use the `dsp.CrossSpectrumEstimator` System object™ to compute the cross-spectrum of the signals. Also, use the `dsp.ArrayPlot` object to display the spectra.

```
cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...  
    'FrequencyRange','centered');
```

```

aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
    'XLabel','Frequency (Hz)',...
    'Title','Cross Power Spectrum of Two Signals');

```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```

for ii = 1:10
x = sin1() + 0.05*randn(1000,1);
y = sin2() + 0.05*randn(1000,1);
Pxy = cse(x, y);
aplot(20*log10(abs(Pxy)));
end

```

## Algorithms

### Welch's Method of Averaged Modified Periodograms

Give two signal inputs,  $x$  and  $y$ :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Compute FFT of the signals,  $X$  and  $Y$ , and multiply  $X$  with  $\text{conj}(Y)$  using  $Z = X \cdot \text{conj}(Y)$ .
- 3 Compute the current cross power spectrum estimate by taking the moving average of the last  $N$  number of  $Z$ 's and scaling the answer by the sample rate.

For further information on the algorithms, refer to the “Averaging Method” on page 2-1343 section in Spectrum Analyzer.

# dsp.Crosscorrelator

**Package:** dsp

(Removed) Cross-correlation of two inputs

---

**Note** `dsp.Crosscorrelator` has been removed. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `dsp.Crosscorrelator` System object computes the cross-correlation of two  $N$ -D input arrays along the first dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the “Method” on page 4-0 property. In the time domain, the object convolves the first input signal,  $u$ , with the time-reversed complex conjugate of the second input signal,  $v$ . To compute the cross-correlation in the frequency domain, the object:

- 1 Takes the Fourier transform of both input signals, resulting in  $U$  and  $V$ .
- 2 Multiplies  $U$  and  $V^*$ , where  $*$  denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

If you set `Method` to 'Fastest', the object chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 4-338.

To obtain the cross-correlation for two discrete-time deterministic inputs:

- 1 Create the `dsp.Crosscorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

## Creation

### Syntax

```
xcorr = dsp.Crosscorrelator
xcorr = dsp.Crosscorrelator(Name, Value)
```

### Description

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs in the time domain or frequency domain.

`xcorr = dsp.Crosscorrelator(Name, Value)` returns a cross-correlator object with each specified property set to the specified value. Enclose each property name in single quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Method — Domain for computing correlations

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes the correlation, specified as one of the following:

- 'Time Domain' -- Computes the cross-correlation in the time domain, which minimizes the memory usage.
- 'Frequency Domain' -- Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 4-338.
- 'Fastest' -- Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this property to 'Time Domain'.

### Fixed-Point Properties

---

**Note** Fixed-point signals are supported for the time domain only. To use these properties, set Method to 'Time Domain'.

---

### FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- true -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- false -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

### RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

### Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the RoundingMethod property does not apply.

### **OverflowAction — Overflow action for fixed-point operations**

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

### **Dependencies**

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the OverflowAction property does not apply.

### **ProductDataType — Data type of product output**

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as first input' -- The object specifies the product output data type to be the same as that of the first input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the "CustomProductDataType" on page 4-0 property.

For more information on the product output data type, see "Multiplication Data Types" and the "Fixed Point" on page 4-337 section.

### **Dependencies**

This property applies when you set FullPrecisionOverride to false.

### **CustomProductDataType — Word and fraction lengths of product data type**

numericType([],32,30) (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set `FullPrecisionOverride` to `false` and “`ProductDataType`” on page 4-0 to `'Custom'`.

**AccumulatorDataType — Data type of accumulation operation**

`'Full precision' (default) | 'Same as first input' | 'Same as product' | 'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as first input'` -- The object specifies the accumulator data type to be the same as that of the first input data type.
- `'Custom'` -- The accumulator data type is specified as a custom numeric type through the “`CustomAccumulatorDataType`” on page 4-0 property.

For more information on the accumulator data type this object uses, see the “Fixed Point” on page 4-337 section.

**Dependencies**

This property applies when you set `FullPrecisionOverride` to `false`.

**CustomAccumulatorDataType — Word and fraction lengths of accumulator data type**

`numericType([],32,30) (default)`

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set `FullPrecisionOverride` to `false` and “`AccumulatorDataType`” on page 4-0 to `'Custom'`.

**OutputDataType — Data type of object output**

`'Same as accumulator' (default) | 'Same as first input' | 'Same as product' | 'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` -- The output data type is the same as that of the accumulator output data type.
- `'Same as first input'` -- The output data type is the same as that of the first input data type.
- `'Same as product'` -- The output data type is the same as that of the product output data type.
- `'Custom'` -- The output data type is specified as a custom numeric type through the “`CustomOutputDataType`” on page 4-0 property.

For more information on the output data type this object uses, see the “Fixed Point” on page 4-337 section.

**Dependencies**

This property applies when you set `FullPrecisionOverride` to `false`.

**CustomOutputDataType — Word and fraction lengths of output data type**

`numericType([],16,15)` (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set `FullPrecisionOverride` to `false` and “`OutputDataType`” on page 4-0 to 'Custom'.

**Usage****Syntax**

```
y = xcorr(u,v)
```

**Description**

`y = xcorr(u,v)` computes the cross-correlation of the two input signals, `u` and `v`.

**Input Arguments****u — First data input signal**

vector | matrix | *N*-D array

First data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to 'Time Domain'. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

**v — Second data input signal**

scalar | column vector | matrix

Second data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to 'Time Domain'. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

**Output Arguments****y — Cross-correlated output**

vector | matrix | *N*-D array

Cross-correlated output of the two input signals.

When the inputs are  $N$ -D arrays, the object outputs an  $N$ -D array. All the dimensions of the output array, except for the first dimension, match the input array. For example:

- When the inputs  $u$  and  $v$  have dimensions  $M_u$ -by- $N$ -by- $P$  and  $M_v$ -by- $N$ -by- $P$ , respectively, the object outputs an  $(M_u + M_v - 1)$ -by- $N$ -by- $P$  array.
- When the inputs  $u$  and  $v$  have the dimensions  $M_u$ -by- $N$  and  $M_v$ -by- $N$ , the object outputs an  $(M_u + M_v - 1)$ -by- $N$  matrix.

If one input is a column vector and the other input is an  $N$ -D array, the object computes the cross-correlation of the vector with each column in the  $N$ -D array. For example:

- When the input  $u$  is an  $M_u$ -by-1 column vector and  $v$  is an  $M_v$ -by- $N$  matrix, the object outputs an  $(M_u + M_v - 1)$ -by- $N$  matrix.
- Similarly, when  $u$  and  $v$  are column vectors with lengths  $M_u$  and  $M_v$ , respectively, the object performs the vector cross-correlation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Cross-Correlation of Input Noise and Delayed Version

Compute the cross-correlation of a noisy input signal with its delayed version. The peak of the correlation output occurs at the lag, which corresponds to the delay between the signals.

Use `randn` to create the white Gaussian noisy input, `x`. Create a delayed version of this input, `x1`, using the `dsp.Delay` object.

```
S = rng('default');  
x = randn(100,1);  
delay = dsp.Delay(10);  
x1 = delay(x);
```

Compute the cross-correlation between the two inputs. Plot the correlation output with respect to the lag between the inputs.

```
xcorr = dsp.Crosscorrelator;  
y = xcorr(x1,x);
```

```
lags = 0:99;
stem(lags,y(100:end),'markerfacecolor',[0 0 1])
axis([0 99 -125 125])
xlabel('Lags')
title('Cross-Correlation of Input Noise and Delayed Version')
```

The correlation sequence peaks when the lag is 10, indicating that the correct delay between the two signals is 10 samples.

## More About

### Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length- $N$  deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes,  $x$  and  $y$ , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

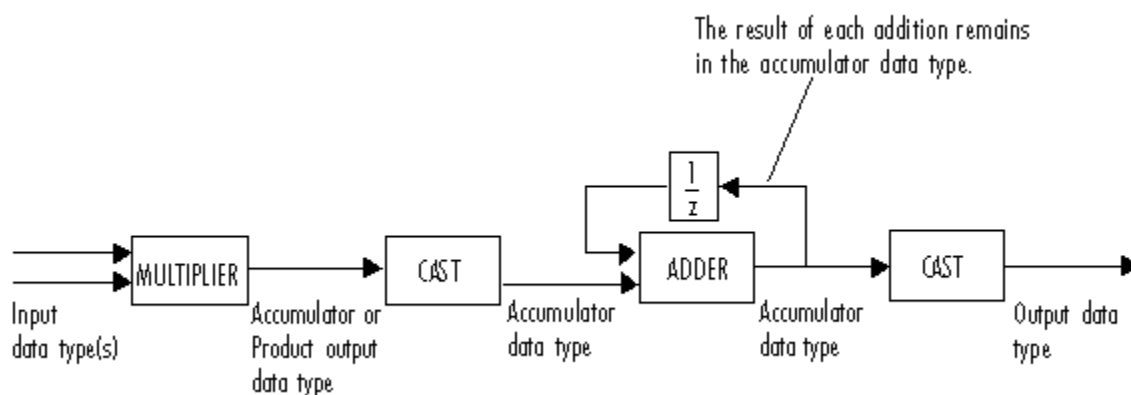

where  $h$  is the lag and  $*$  denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes,  $r_{xy}(h)$  is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where  $E\{ \}$  is the expectation operator.

### Fixed Point

The diagram shows the data types the `dsp.Crosscorrelator` object uses for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types using the corresponding fixed-point properties of the object.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

---

**Note** When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal object data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

---

## Algorithms

### Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

#### Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the  $j$ th column of the output,  $y_{u,v}$ , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k, j}^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- \* denotes the complex conjugate.
- $u$  is an  $M_u$ -by- $N$  input matrix.
- $v$  is an  $M_v$ -by- $N$  input matrix.
- $y_{u,v}$  is an  $(M_u + M_v - 1)$ -by- $N$  matrix.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

#### Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The  $j$ th column of the output,  $y_{u,v}$ , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- \* denotes the complex conjugate.
- $u$  is an  $M_u$ -by-1 column vector.
- $v$  is an  $M_v$ -by- $N$  matrix.

- $y_{uv}$  is an  $(M_u + M_v - 1)$ -by- $N$  matrix.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

### Correlate Two Column Vectors

When the inputs are two column vectors, the  $j$ th column of the output,  $y_{uv}$ , has these elements:

$$y_{uv(i)} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i)} \quad 0 \leq i < M_v$$

$$y_{uv(i)} = y_{vu}^*(-i) \quad -M_u < i < 0$$

where:

- $*$  denotes the complex conjugate.
- $u$  is an  $M_u$ -by-1 column vector.
- $v$  is an  $M_v$ -by-1 column vector.
- $y_{uv}$  is an  $(M_u + M_v - 1)$ -by-1 column vector.

Inputs  $u$  and  $v$  are zero when indexed outside their valid ranges.

### Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals,  $U$  and  $V$ .
- 2 Multiplies  $U$  and  $V^*$ , where  $*$  denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

## Version History

### Introduced in R2012a

#### **R2021b: dsp.Crosscorrelator System object will be removed**

*Warns starting in R2021b*

`dsp.Crosscorrelator` System object will be removed in a future release. Use the `xcorr` function instead.

#### **R2023a: dsp.Crosscorrelator System object has been removed**

*Errors starting in R2023a*

The `dsp.Crosscorrelator` System object has been removed. Use the `xcorr` function instead.

### Update Code

This table shows how to update existing code to use the `xcorr` function.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre> xc0bj = dsp.Crosscorrelator; t = 0:0.001:1; x1 = sin(2*pi*2*t) + 0.05*sin(2*pi*50*t); x2 = sin(2*pi*2*t); % Computes cross-correlation of x1 and x2 y = xc0bj(x1',x2'); figure; plot(t,x1,'b',t,x2,'g'); legend('Input signal 1', 'Input signal 2') figure; plot(y); title('Correlated output') </pre> | <pre> [yfn,lags] = xcorr(x1',x2'); figure; plot(yfn) </pre> <p>Plot the signal with respect to the lags.</p> <pre> figure; plot(lags,yfn) </pre> |

# dsp.CumulativeProduct

**Package:** dsp

(Removed) Cumulative product of channel, column, or row elements

---

**Note** dsp.CumulativeProduct has been removed. Use the cumprod function instead. For more information, see “Compatibility Considerations”.

---

## Description

The dsp.CumulativeProduct System object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

- 1 Create the dsp.CumulativeProduct object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

## Creation

### Syntax

```
cprod = dsp.CumulativeProduct  
cprod = dsp.CumulativeProduct(Name,Value)
```

### Description

cprod = dsp.CumulativeProduct returns a cumulative product object, cprod, that computes the cumulative product of input matrix or input vector elements along the default dimension.

cprod = dsp.CumulativeProduct(Name,Value) returns a cumulative product object with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Dimension — Computation dimension for cumulative product

Channels (running product) (default) | Rows | Columns

Specify the computation dimension as `Channels (running product)`, `Rows`, or `Columns`.

**ResetInputPort — Enable resetting cumulative product through input port**

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the object algorithm to reset the cumulative product.

**Dependencies**

You can access this property when the “Dimension” on page 4-0 property is set to `Channels (running product)`.

**ResetCondition — Reset condition for cumulative product**

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that causes resetting the cumulative product to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

**Dependencies**

This property applies when you set the “ResetInputPort” on page 4-0 property to `true` and the “Dimension” on page 4-0 property to `Channels (running product)`.

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

**OverflowAction — Overflow action for fixed-point operations**

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

**IntermediateProductDataType — Intermediate product word and fraction lengths**

`Same as input` (default) | `Custom`

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`.

**CustomIntermediateProductDataType — Intermediate product word and fraction lengths**

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `IntermediateProductDataType` property to `Custom`.

**ProductDataType — Product output word and fraction lengths**

`Same as input` (default) | `Custom`

Specify the product output fixed-point data type as one of | `Same as input` | `Custom` |.

**CustomProductDataType — Custom product output word and fraction lengths**

numericity([], 32, 30) (default) | numericity

Specify the product output fixed-point type as a scaled numericity object with a Signedness of Auto.

**Dependencies**

This property applies when you set the ProductDataType property to Custom.

**AccumulatorDataType — Accumulator word and fraction lengths**

Same as input (default) | Same as product output | Custom

Specify the accumulator fixed-point data type as Same as product output, Same as input, or Custom.

**CustomAccumulatorDataType — Custom accumulator word and fraction lengths**

numericity([], 32, 30) (default) | numericity

Specify the accumulator fixed-point type as a scaled numericity object with a Signedness of Auto.

**Dependencies**

This property applies when you set the AccumulatorDataType property to Custom.

**OutputDataType — Output word and fraction lengths**

Same as input (default) | Same as product output | Custom

Specify the output fixed-point data type as one of | Same as product output | Same as input | Custom |.

**CustomOutputDataType — Custom output word and fraction lengths**

numericity([], 16, 15) (default) | numericity

Specify the output fixed-point type as a scaled numericity object with a Signedness of Auto.

**Dependencies**

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

**Usage****Syntax**

```
y = cprod(x)
y = cprod(x,r)
```

**Description**

$y = \text{cprod}(x)$  computes the cumulative product along the specified dimension for the input  $x$ .

$y = \text{cprod}(x,r)$  resets the cumulative product object's state based on the ResetCondition property value and the value of the reset signal,  $r$ , when the ResetInputPort property is true.

## Input Arguments

### **x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### **r — Reset signal**

scalar

Reset signal used to reset the running cumulative product, specified as a scalar. The object resets the running cumulative product if the reset signal satisfies the `ResetCondition`.

## Dependencies

This input is applicable only when `Dimension` is set to `'Channels (running product)'` and `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`

## Output Arguments

### **y — Cumulative product**

vector | matrix

Cumulative product of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Cumulative Product of Matrix

Use the `dsp.CumulativeProduct` object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;  
x = magic(2)
```

```
x = 2×2
```

```
    1    3  
    4    2
```

```
y = cprod(x)
```

```
y = 2×2
```

```
    1    3  
    4    6
```

The cumulative product is computed column-wise along each channel.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except the **Reset port** block parameter corresponds to both the ResetCondition and ResetInputPort object properties.

## Version History

### Introduced in R2012a

### R2021b: dsp.CumulativeProduct System object will be removed

*Warns starting in R2021b*

dsp.CumulativeProduct System object will be removed in a future release. Use the cumprod function instead.

### R2023a: dsp.CumulativeProduct System object has been removed

*Errors starting in R2023a*

# dsp.CumulativeSum

**Package:** dsp

(Removed) Cumulative sum of channel, column, or row elements

---

**Note** dsp.CumulativeSum has been removed. Use the cumsum function instead. For more information, see “Compatibility Considerations”.

---

## Description

The dsp.CumulativeSum System object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

- 1 Create the dsp.CumulativeSum object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

## Creation

### Syntax

```
csum = dsp.CumulativeSum  
csum = dsp.CumulativeSum(Name,Value)
```

### Description

csum = dsp.CumulativeSum returns a cumulative sum System object, csum, which computes the running cumulative sum for each channel in the input.

csum = dsp.CumulativeSum(Name,Value) returns a cumulative sum object, csum, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Dimension — Computation dimension for cumulative sum

Channels (running sum) (default) | Rows | Columns

Specify the computation dimension as `Channels` (running `sum`), `Rows`, or `Columns`.

**ResetInputPort — Enable resetting cumulative sum through input port**

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the object algorithm to reset the cumulative sum.

**ResetCondition — Reset condition for cumulative sum**

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that resets the cumulative sum as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

**Dependencies**

This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

**OverflowAction — Overflow action for fixed-point operations**

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

**AccumulatorDataType — Accumulator word and fraction lengths**

`Same as input` (default) | `Custom`

Specify the accumulator fixed-point data type as `Same as input` or `Custom`.

**CustomAccumulatorDataType — Custom accumulator word and fraction lengths**

`numerictype([], 32, 30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `AccumulatorDataType` property to `Custom`.

**OutputDataType — Output word and fraction lengths**

`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as input`, or `Custom`.

**CustomOutputDataType — Custom output word and fraction lengths**

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

**Usage****Syntax**

```
y = csum(x)
y = csum(x, r)
```

**Description**

$y = \text{csum}(x)$  computes the cumulative sum along the specified dimension for the input  $x$ .

$y = \text{csum}(x, r)$  resets the System object state based on the ResetCondition property value and the value of the reset signal,  $r$ . You can only reset the state if the ResetInputPort property is true.

**Input Arguments****x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

**r — Reset signal**

scalar

Reset signal used to reset the running cumulative sum, specified as a scalar. The object resets the running cumulative sum if the reset signal satisfies the ResetCondition.

**Dependencies**

This input is applicable only when Dimension is set to 'Channels (running sum)' and ResetInputPort is set to true.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | fi

**Output Arguments****y — Cumulative sum**

vector | matrix

Cumulative sum of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Cumulative Sum of Matrix

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;  
x = magic(2)
```

```
x = 2×2
```

```
    1    3  
    4    2
```

```
y = csum(x)
```

```
y = 2×2
```

```
    1    3  
    5    5
```

The cumulative sum is computed column-wise along each channel.

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except the **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

## Version History

**Introduced in R2012a**

**R2021b: `dsp.CumulativeSum` System object will be removed**

# dsp.DCBlocker

**Package:** dsp

Block DC component (offset) from input signal

## Description

The `dsp.DCBlocker` System object removes the DC offset from each channel (column) of the input signal. The operation runs over time to continually estimate and remove the DC offset.

To block the DC component of the input signal:

- 1 Create the `dsp.DCBlocker` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
dcblk = dsp.DCBlocker
dcblk = dsp.DCBlocker(Name, Value)
```

### Description

`dcblk = dsp.DCBlocker` creates a DC blocker System object, `dcblk`, to block the DC component from each channel (column) of the input signal.

`dcblk = dsp.DCBlocker(Name, Value)` creates a DC blocker System object, `dcblk`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dcblk = dsp.DCBlocker('Algorithm','FIR')`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Algorithm — Algorithm for estimating DC offset

'IIR' (default) | 'FIR' | 'CIC' | 'Subtract mean'

Algorithm for estimating DC offset, specified as one of the following:

- 'IIR' -- The object uses a recursive estimate based on a narrow, lowpass elliptic filter. The "Order" on page 4-0 property sets the order of the filter, and the "NormalizedBandwidth" on page 4-0 property sets its bandwidth. This algorithm typically uses less memory than the FIR algorithm and is more efficient.
- 'FIR' -- The object uses a nonrecursive, moving average estimate based on a finite number of past input samples. The "Length" on page 4-0 property sets the number of samples. The FIR filter has a linear phase response and does not cause any phase distortion to the signal. The IIR filter requires less memory and is more efficient to implement.
- 'CIC' -- The object uses a CIC decimator, with a decimation factor of 1, whose differential delay is calculated using the NormalizedBandwidth property. It uses two sections to ensure that the first sidelobe attenuation is at least 25 dB below the main lobe of the filter. This algorithm requires fixed-point inputs and can be used for HDL code generation.
- 'Subtract mean' -- The object computes the means of the columns of the input matrix, and subtracts the means from the input. This method does not retain state between inputs.

You can visualize the IIR, FIR, and CIC responses by using the `fvtool` function.

### **NormalizedBandwidth — Normalized bandwidth of lowpass IIR or CIC filter**

0.001 (default) | real scalar greater than 0 and less than 1

Normalized bandwidth of the IIR or CIC filter, specified as a real scalar greater than 0 or less than 1. The normalized bandwidth is used to estimate the DC component of the input signal.

#### **Dependencies**

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR' or 'CIC'.

### **Order — Order of lowpass IIR elliptic filter**

6 (default) | integer greater than 3

Order of the lowpass IIR elliptic filter that is used to estimate the DC level, specified as an integer greater than 3.

#### **Dependencies**

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR'.

### **Length — Number of past input samples used in FIR algorithm**

50 (default) | positive integer

Number of past input samples used in the FIR algorithm to estimate the running mean, specified as a positive integer.

#### **Dependencies**

This property applies only when you set the "Algorithm" on page 4-0 property to 'FIR'.

## **Usage**

### **Syntax**

```
dcblkOut = dcblk(input)
```

## Description

`dcblkerOut = dcblker(input)` removes the DC component from each channel (column) of the input and returns the output.

## Input Arguments

### **input** — Input signal

vector | matrix | *N*-D array

Data input to the DC blocker object, specified as a vector, matrix, or *N*-D array.

Example: `t = (0:0.001:100)'`; `x = sin(30*pi*t) + 1`;

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

## Output Arguments

### **dcblkerOut** — Signal with DC component removed

vector | matrix | *N*-D array

Signal with DC component removed, returned as a vector, matrix, or *N*-D array. The output dimensions match the input dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Visualization Specific to DSP System Toolbox

`fvtool` Visualize frequency response of DSP filters

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Remove DC Component and Display Results

Remove the DC component of an input signal using the IIR, FIR, and subtract mean estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects for the three estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);  
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);  
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1-second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100  
    range = (1:1000) + 1000*(idx-1);  
    y1 = dc1(x(range));           % IIR estimate  
    y2 = dc2(x(range));           % FIR estimate  
    y3 = dc3(x(range));           % Subtract mean  
end
```

Plot the input and output data for the three DC blockers for the first second of time, and show the mean value for each signal. The mean values for the three algorithm types show that the FIR and Subtract mean algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000), ...  
     t(1:1000),y1, ...  
     t(1:1000),y2, ...  
     t(1:1000),y3);  
xlabel('Time (sec)')  
ylabel('Amplitude')  
legend(sprintf('Input DC:%.3f',mean(x)), ...  
        sprintf('IIR DC:%.3f',mean(y1)), ...  
        sprintf('FIR DC:%.3f',mean(y2)), ...  
        sprintf('Subtract mean DC:%.3f',mean(y3)));
```

### Frequency Response Before and After DC Blocker

Compare the spectrum of an input signal with a DC offset to the spectrum of the same signal after applying a DC blocker. Enable the DC blocker to use the FIR estimation algorithm.

Create an input signal composed of three tones and that has a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object that uses the FIR algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a spectrum analyzer with power units set to dBW and a frequency range of [-30 30] to display the frequency response of the input signal. Using the clone function, create a second spectrum analyzer to display the response of the output. Then, use the Title property of the spectrum analyzers to label them.

```
hsa = spectrumAnalyzer('SampleRate',fs, ...
    'Method','welch',...
    'AveragingMethod','exponential',...
```

```
'SpectrumUnits','dBW','FrequencySpan','start-and-stop-frequencies',...
'StartFrequency',-30,'StopFrequency',30,'YLimits',[-200 20],...
'Title','Signal Spectrum');
```

```
hsb = clone(hsa);
hsb.Title = 'Signal Spectrum After DC Blocker';
```

Pass the input signal,  $x$ , through the DC blocker to generate the output signal,  $y$ .

```
y = dcbkcr(x);
```

Use the first spectrum analyzer to display the frequency characteristics of the input signal. The tones at 15, 20, and 25 Hz, and the DC component, are clearly visible.

```
hsa(x)
```

Use the second spectrum analyzer to display the frequency characteristics of the output signal. The DC component has been removed.

```
hsb(y)
```

## Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

### IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

### FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as  $\text{ones}(1, \text{Length}) / \text{Length}$ , where  $\text{Length}$  is the number of past input samples for FIR algorithm. The FIR filter structure is a direct form I transposed structure.

### CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3 dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})} \right|^N$$

- $B_{norm}$  is the normalized bandwidth such that  $0 < B_{norm} < 1$ .
- $M$  is the differential delay in samples.
- $N$  is the number of sections, equal to 2.

Set the differential delay,  $M$ , to the smallest integer such that  $|H(e^{j\omega})| < 1/\sqrt{2}$ . Once  $M$  is known, the gain of the CIC filter is calculated as  $M^N$ . Therefore, to precisely compensate for the filter gain, the multiplier is set to  $(1/M)^N$ .

### Subtract mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

**HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The software supports `double` and `single` data types for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

## dsp.Delay

**Package:** dsp

Delay input signal by fixed samples

### Description

The `dsp.Delay` System object delays the input by a specified number of samples along each channel (column) of the input. You can specify the initial output of the object through the “InitialConditions” on page 4-0 property. To reset the delay, enable the “ResetCondition” on page 4-0 through the “ResetInputPort” on page 4-0 .

To delay the input:

- 1 Create the `dsp.Delay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
delay = dsp.Delay
delay = dsp.Delay(Name,Value)
delay = dsp.Delay(len,Name,Value)
```

#### Description

`delay = dsp.Delay` creates a System object that delays the input by 1 sample.

`delay = dsp.Delay(Name,Value)` creates a delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.Delay('InitialConditionsPerChannel',true);`

`delay = dsp.Delay(len,Name,Value)` creates a delay System object, `delay`, with the `Length` property set to `len`, and other specified properties set to the specified values. Enclose each property name in single quotes.

Example: `delay = dsp.Delay(10,'ResetInputPort',true,'ResetCondition','Rising edge');`

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **Length — Amount of delay to apply to input signal**

1 (default) | scalar positive integer | vector of positive integers

Amount of delay in samples to apply to the input signal, specified as one of the following:

- Scalar positive integer -- The object applies equal delay to all the channels.
- Vector of positive integers -- The length of the vector must equal the number of input channels (columns). The object delays each channel by the amount specified by the respective element in the delay vector.

### **InitialConditionsPerChannel — Enable different initial conditions per channel**

false (default) | true

Enable different initial conditions per channel, specified as either:

- false -- The object applies the same initial conditions for all channels.
- true -- The object applies different initial conditions for each channel.

The value of this property must be the same as the value you choose for the `InitialConditionsPerSample` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

### **InitialConditionsPerSample — Enables different initial conditions per sample**

false (default) | true

Different initial conditions per sample, specified as either:

- false -- The object applies the same initial conditions for all samples.
- true -- The object applies different initial conditions for each sample.

The value of this property must be the same as the value you choose for the `InitialConditionsPerChannel` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

### **InitialConditions — Initial output of the object**

0 (default) | scalar | vector | matrix

Initial output of System object, specified as a scalar, vector, or a matrix. The dimensions of the initial condition matrix must be (Length property value)-by-(number of input channels).

If the input is an  $M$ -by- $N$  matrix, the dimensions of the `InitialConditions` property value must be as follows:

| <code>InitialConditionsPerChannel</code> | <code>InitialConditionsPerSample</code> | <code>InitialConditions</code> |
|--|---|--------------------------------|
| false                                    | false                                   | scalar                         |
| true                                     | true                                    | Length-by- $N$ matrix          |

### **ResetInputPort — Enable reset condition**

false (default) | true

Enable the reset condition so that you can pass the reset control input to the object, specified as either:

- `false` -- The object does not reset the delay states.
- `true` -- You must pass a reset control input to the object by using the “ResetCondition” on page 4-0 property. The object resets the delay states based on the values of the `ResetCondition` property and the reset control that is input to the object.

#### ResetCondition — Event that triggers reset of delay

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Event that triggers the reset of the delay, specified as one of the following. The object resets the delay whenever a reset event is detected in its reset input.

- 'Non-zero' -- Triggers a reset operation at each sample, when the reset input is not zero.
- 'Rising edge' -- Triggers a reset operation when the reset input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- 'Falling edge' -- Triggers a reset operation when the reset input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

## Dependencies

This property applies only when you set the `ResetInputPort` property to `true`.

## Usage

## Syntax

```
delayOut = delay(dataInput)
delayOut = delay(dataInput, resetInput)
```

## Description

`delayOut = delay(dataInput)` adds delay to the data input and returns the delayed output. Each column of the input is treated as an independent channel.

`delayOut = delay(dataInput, resetInput)` adds delay to the data input and selectively resets the state of the System object based on the value of the reset input and the value of the “ResetCondition” on page 4-0 property.

To pass the reset input, set “ResetInputPort” on page 4-0 property to `true`.

```
delay = dsp.Delay('ResetInputPort', true);
...
delayOut = delay(dataInput, resetInput);
```

## Input Arguments

### **dataInput** — Data input

vector | matrix

Data input that is delayed by the object, specified as a vector or a matrix.

Example: `[1;2;3;4;5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

### **resetInput** — Reset input

scalar

Reset input, specified as a scalar.

Example: `2`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

## Output Arguments

### **delayOut** — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size and data type of the output match the size and data type of the data input.

Example: `[0;0;1;2;3]`

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Delay Input

Delay input by four samples by using the `dsp.Delay` System object™. By default, the initial conditions are 0.

```
delay = dsp.Delay(4);  
input = [(1:10)' (11:20)'];  
delayOut = delay(input) %#ok
```

```
delayOut = 10×2
```

```
0     0  
0     0  
0     0  
0     0  
1     11  
2     12  
3     13  
4     14  
5     15  
6     16
```

```
release(delay);
```

Specify initial conditions for each channel and for each sample. The `InitialConditions` property must be a (*Length*)-by-(*NumChannels*) matrix.

```
delay.InitialConditionsPerChannel = true;  
delay.InitialConditionsPerSample = true;  
delay.InitialConditions = [(0.1:0.1:0.4)' (0.5:0.1:0.8)'];  
delayOut = delay(input) %#ok
```

```
delayOut = 10×2
```

```
0.1000    0.5000
```

```

0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000

```

```
release(delay);
```

Reset the delay by setting the reset event to 'Rising edge'. In this mode, a reset event occurs when the reset input:

- Rises from a negative value to 0.
- Rises from a negative value to a positive value.
- Rises from 0 to a positive value, where the rise is not a continuation from a negative value to 0.

Pass an initial reset input of 0.

```

delay.ResetInputPort = true;
delay.ResetCondition = 'Rising edge';
delayOut = delay(input,0) %#ok

```

```
delayOut = 10x2
```

```

0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000

```

Continue to run the delay. The delay samples now contain the rest of the input vector.

```
delayOut = delay(input,0) %#ok
```

```
delayOut = 10x2
```

```

7    17
8    18
9    19
10   20
1    11
2    12
3    13
4    14
5    15
6    16

```

Change the reset input to 2, indicating a rising edge.

```
delayOut = delay(input,2)
```

```
delayOut = 10×2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

The delay values are reset to the initial conditions.

**Package:** dsp

(Removed) Rebuffer sequence of inputs with one-sample shift

---

**Note** `dsp.DelayLine` has been removed. There is no direct replacement. You can use the `dsp.AsyncBuffer` object to achieve a delay line.

---

### **Description**

The `dsp.DelayLine` System object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

- 1 Create the `dsp.DelayLine` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### **Creation**

#### **Syntax**

```
dline = dsp.DelayLine
dline = dsp.DelayLine(delaysize,initial)
dline = dsp.DelayLine(Name,Value)
```

#### **Description**

`dline = dsp.DelayLine` returns a delay line System object, `dline`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`dline = dsp.DelayLine(delaysize,initial)` returns a delay line System object, `dline`, with the `Length` property set to `delaysize` and the `InitialConditions` property set to `initial`.

`dline = dsp.DelayLine(Name,Value)` returns a delay line object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Length — Number of rows in output matrix**

64 (default) | positive integer

Specify the number of rows in the output matrix as a scalar positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**InitialConditions — Initial delay line output**

0 (default) | scalar | vector | matrix

Set the value of the object's initial output as one of `scalar`, `vector`, or `matrix`.

For vector outputs, you can use these options for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, you can use these options for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**DirectFeedthrough — Enable passing input data to output without extra frame delay**`false` (default) | `true`

When you set this property to `true`, the input data is available immediately at the output. When you set this property to `false`, the output has a delay of one frame.

**EnableOutputInputPort — Enable selective output linearization**`false` (default) | `true`

The object uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If the input value is `true`, the object's output is linearized and thus valid. If the input value is `false`, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid.

**HoldPreviousValue — Hold previous valid value for invalid output**`false` (default) | `true`

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data.

**Dependencies**

This property applies only when you set the `EnableOutputInputPort` property to `true`.

## Usage

### Syntax

```
y = dline(x)
y = dline(x,en)
```

### Description

`y = dline(x)` returns the delayed version of input `x`. `y` is an output matrix with the same number of rows as the delay line size. Each column of `x` is treated as a separate channel.

`y = dline(x,en)` selectively outputs the delayed version of input `x` depending on the Boolean input `en`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

#### **en** — Enable output input port

`true` | `false`

Enable output input port signal, specified as a logical value.

If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

### Dependencies

This input is valid only when you set the `EnableOutputInputPort` property to `true`.

Data Types: `logical`

### Output Arguments

#### **y** — Delay line output

vector | matrix

Delay line output, returned as a vector or a matrix.

When the input is an  $M_i$ -by- $N$  matrix, the System object rebuffers the input into a sequence of  $M_o$ -by- $N$  matrix outputs, where  $M_o$  is the output frame size specified by the `Length` property. Depending on whether  $M_o$  is greater than, less than, or equal to the input frame size,  $M_i$ , the output frames can be underlapped or overlapped. Each of the  $N$  input channels is rebuffered independently:

- When  $M_o > M_i$ , the output frame overlap is the difference between the output and input frame size,  $M_o - M_i$ .

- When  $M_o < M_i$ , the output is underlapped; the object discards the first  $M_i - M_o$  samples of each input frame so that only the last  $M_o$  samples are buffered into the corresponding output frame.
- When  $M_o = M_i$ , the output data is identical to the input data, but is delayed by the latency of the object.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Delay Line

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
disp(y)
```

```
-2    -2    -2     1     1
-2    -2    -2     2     2
-2     1     1     3     3
 1     2     2     4     4
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties.

## Version History

**Introduced in R2012a**

### **R2021b: dsp.DelayLine System object will be removed**

*Warns starting in R2021b*

`dsp.DelayLine` System object will be removed in a future release. There is no direct replacement for this object. You can use the `dsp.AsyncBuffer` object to achieve a delay line.

### **R2023a: dsp.DelayLine System object has been removed**

*Errors starting in R2023a*

The `dsp.DelayLine` System object has been removed. To create a delay line, use the `dsp.AsyncBuffer` object.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

`dsp.AsyncBuffer`

# dsp.Differentiator

**Package:** dsp

Direct form FIR fullband differentiator filter

## Description

The `dsp.Differentiator` System object applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is  $D(\omega) = j\omega$  for  $-\pi \leq \omega \leq \pi$ . You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

- 1 Create the `dsp.Differentiator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
DF = dsp.Differentiator
DF = dsp.Differentiator(Name,Value)
```

### Description

`DF = dsp.Differentiator` returns a differentiator, `DF`, which independently filters each channel of the input over time using the given design specifications.

`DF = dsp.Differentiator(Name,Value)` sets each property name to the specified value. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **DesignForMinimumOrder** — Design minimum order filter

true (default) | false

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

### **FilterOrder — Order of the filter**

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer.

This property is not tunable.

#### **Dependencies**

You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PassbandRipple — Maximum passband ripple**

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar.

This property is not tunable.

#### **Dependencies**

You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ScaleCoefficients — Scale filter coefficients**

`false` (default) | `true`

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to `true`, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

#### **Fixed-Point Properties**

### **CoefficientsDataType — Word and fraction lengths of coefficients**

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)`, corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented

without overflow. For details on how the object computes the fraction length of the output, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

### **RoundingMethod — Rounding method for output fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

## **Usage**

### **Syntax**

$y = DF(x)$

### **Description**

$y = DF(x)$  applies a fullband differentiator filter to the input signal,  $x$ .  $y$  is a differentiated version of  $x$ .

### **Input Arguments**

#### **x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### **Output Arguments**

#### **y — Differentiated signal**

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal,  $x$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.Differentiator

getFilter Get underlying FIR filter

## Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

## Examples

### Group Delay Estimation

Estimate the group delay of a linear phase FIR filter using a dsp.TransferFunctionEstimator object followed by dsp.PhaseExtractor and dsp.Differentiator objects. The group delay of a linear phase FIR filter is given by  $GD = -\frac{d\theta(\omega)}{d\omega} = -\frac{N}{2}$ , where  $\theta(\omega)$  is the phase information of the filter,  $\omega$  is the frequency vector, and  $N$  is the order of the filter.

### Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be Hann. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...
    'SpectralAverages',200,'FFTLengthSource','Property',...
    'FFTLength',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase  $\theta$ , create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the input, create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;
Gain2 = -1;
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...
    'SampleRate',Fs);
```

To view the group delay of the filter, create an array plot object.

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

## Run the Algorithm

The for-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
    x = randn(512,1); % Input signal = white Gaussian noise
    y = LPF(x); % Filter noise with Lowpass FIR filter
    H = TFE(x,y); % Compute transfer function estimate
    Phase = PE(H); % Extract the Unwrapped phase
    phaseaftergain1 = Gain1*Phase;
    DiffOut = DF(phaseaftergain1); % Differentiate the phase
    phaseaftergain2 = Gain2 * DiffOut;
    VBFOut = VBFiter(phaseaftergain2); % Smooth the group delay
    AP(VBFOut); % Display the group delay
end
```

As you can see, the group delay of the lowpass filter is 100.

## Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2; % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                        'SamplesPerFrame',1e3,...
                        'SampleRate',Fs);
```

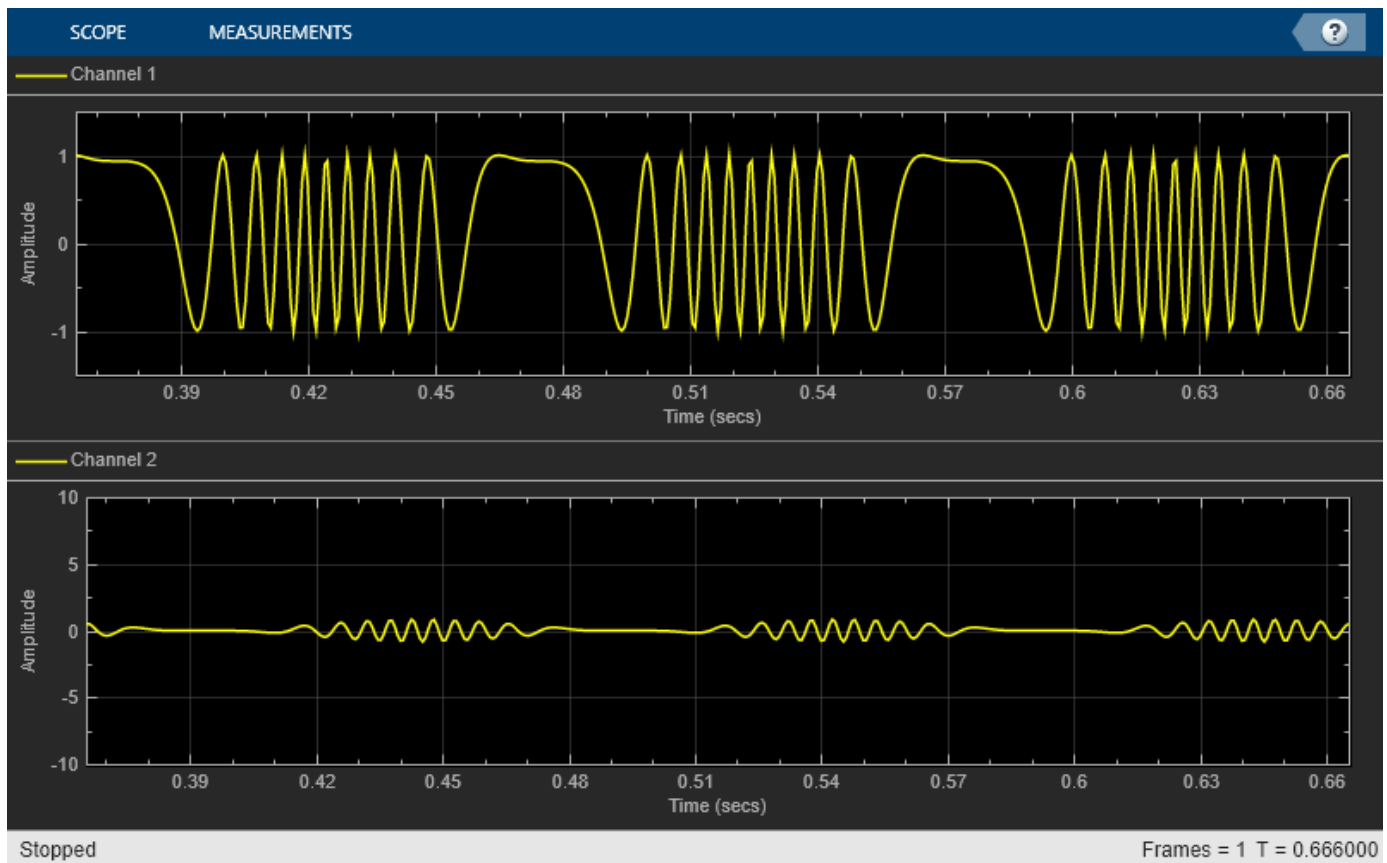

Convert the FM signal to an AM signal.

```
ts = timescope('TimeSpanSource','Property',...
               'TimeSpan',0.3,...
               'BufferLength',10*Fs,...
               'SampleRate',Fs,...
               'ShowGrid',true,...
               'YLimits',[-1.5 1.5],...
               'LayoutDimensions',[2 1]);
```

```
df = dsp.Differentiator;
```

```
tic
while toc<2.2
    x = step(sinewave);
    fm_y = modulate(x,Fc,Fs,'fm');
    am_y = step(df,fm_y);
    step(ts,fm_y,am_y);
end
```

```
release(df);
release(ts);
```

## Algorithms

### Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by  $D(\omega) = j\omega$ , defined over the Nyquist interval  $-\pi \leq \omega \leq \pi$ .

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by  $d(n) = -d(-n)$ . Hence  $d(0) = 0$ . The differentiator must have zero response at zero frequency.

### Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by  $h(n) = -h(M - 1 - n)$ , where  $M$  is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If  $M$  is odd, the real-valued frequency response of the FIR filter,  $H_r(\omega)$ , has the characteristics that  $H_r(0) = 0$  and  $H_r(\pi) = 0$ . This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because  $H_r(\pi) = 0$ . This differentiator has a linear response over the limited frequency range  $[0, 2\pi f_p]$ , where  $f_p$  is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as  $\omega$  increases from 0 to  $2\pi f_p$ .

If  $M$  is even, the real-valued frequency response of the FIR filter,  $H_r(\omega)$ , has the characteristics that  $H_r(0) = 0$  and  $H_r(\pi) \neq 0$ . This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

## Version History

Introduced in R2016a

Differentiator Filter

# **dsp.DigitalDownConverter**

**Package:** dsp

Translate digital signal from intermediate frequency (IF) band to baseband and decimate it

## **Description**

The `dsp.DigitalDownConverter` object translates digital signal from intermediate frequency (IF) band to baseband and decimates it.

To digitally downconvert the input signal:

- 1 Create the `dsp.DigitalDownConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
dwnConv = dsp.DigitalDownConverter  
dwnConv = dsp.DigitalDownConverter(Name,Value)
```

### **Description**

`dwnConv = dsp.DigitalDownConverter` returns a digital downconverter (DDC) System object, `dwnConv`.

`dwnConv = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **SampleRate — Sample rate of input signal**

30000000 (default) | positive scalar

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

### **DecimationFactor — Decimation factor**

100 (default) | positive integer scalar | vector of positive integers

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the  $i$ th element of the vector specifies the decimation factor for the  $i$ th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2.

Data Types: `double`

### **MinimumOrderDesign — Minimum order filter design**

`true` (default) | `false`

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

### **NumCICSections — Number of sections of CIC decimator**

3 (default) | positive integer scalar

Number of sections of CIC decimator, specified as a positive integer scalar.

#### **Dependencies**

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

### **SecondFilterOrder — Order of CIC compensation filter stage**

12 (default) | positive integer scalar

Order of CIC compensation filter stage, specified as a positive integer scalar.

#### **Dependencies**

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

**ThirdFilterOrder — Order of third filter stage**

10 (default) | even positive integer

Order of third filter stage, specified as an even positive integer scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed.

**Dependencies**

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

**Bandwidth — Two-sided bandwidth of input signal in Hz**

200000 (default) | positive integer scalar

Two-sided bandwidth of input signal in Hz, specified as a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. Set the value of this property to less than `SampleRate/DecimationFactor`.

Data Types: `double`

**StopbandFrequencySource — Source of stopband frequency**

Auto (default) | Property

Specify the source of the stopband frequency as one of `Auto` | `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate}/M/2$  Hz, where  $M$  is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as  $F_{stop} = F_c + TW/2$ .  $TW$  is the transition bandwidth of the cascade response computed as  $2 \times (F_c - F_p)$ , and the passband frequency,  $F_p$ , equals `Bandwidth/2`.

**StopbandFrequency — Stopband frequency in Hz**

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

**Dependencies**

This property applies when you set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

**PassbandRipple — Passband ripple of cascade response in dB**

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property.

**Dependencies**

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

**StopbandAttenuation — Stopband attenuation of cascade response in dB**

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property.

#### Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

#### Oscillator — Type of oscillator

`Sine wave` (default) | `NCO` | `Input port` | `None`

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex oscillator signal, `z`, that you pass as an input to the object. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

#### CenterFrequency — Center frequency of input signal in Hz

`14000000` (default) | positive scalar

Center frequency of input signal in Hz, specified as a positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to 0 Hz.

#### Dependencies

This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`.

Data Types: `double`

#### NumAccumulatorBits — Number of NCO accumulator bits

`16` (default) | positive integer

Number of NCO accumulator bits, specified as a positive integer in the range [1 128].

#### Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

#### NumQuantizedAccumulatorBits — Number of NCO quantized accumulator bits

`12` (default) | positive integer

Number of NCO quantized accumulator bits, specified as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property.

#### Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

**Dither — Dither control for NCO**`true (default) | false`

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal.

**Dependencies**

This property applies when you set the `Oscillator` property to `NCO`.

**NumDitherBits — Number of NCO dither bits**`4 (default) | positive integer`

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property.

**Dependencies**

This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

**Fixed-Point Properties****FiltersInputDataType — Data type of input of each filter stage**`Same as input (default) | Custom`

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The object casts the data at the input of each filter stage according to the value you set in this property.

**CustomFiltersInputDataType — Fixed-point data type of input of each filter stage**`numericType([], 16, 15) (default) | numeric type`

Specify the filters input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `FiltersInputDataType` property to `Custom`.

**OutputDataType — Data type of output**`Same as input (default) | Custom`

Specify the data type of output as `Same as input` | `Custom`.

**CustomOutputDataType — Fixed-point data type of output**`numericType([], 16, 15) (default) | numeric type`

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `OutputDataType` property to `Custom`.

## Usage

### Syntax

```
y = dwnConv(x)
y = dwnConv(x,z)
```

### Description

`y = dwnConv(x)` takes an input `x` and outputs a signal, `y` that is frequency downconverted and downsampled.

`y = dwnConv(x,z)` uses the complex input, `z`, as the oscillator signal used to frequency down convert input `x` when you set the `Oscillator` property to `Input port`.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

The input can have multiple channels only if its data type is `double` or `single`. The input can be of data type `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

#### **z** — Oscillator signal

column vector | matrix

Oscillator signal used to frequency down convert the input signal, specified as a column vector or a matrix. This input must be complex. The length of `z` must be equal to the length of `x`. `z` can be `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

### Dependencies

This input applies when you set the `Oscillator` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### Output Arguments

#### **y** — Down converted and down sampled signal

column vector | matrix

Down converted and down sampled signal, returned as a column vector or a matrix. The length of `y` is equal to the length of `x` divided by the `DecimationFactor`. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.DigitalDownConverter`

|                                    |   |
|------------------------------------|---|
| <code>getDecimationFactors</code>  | Get decimation factors of each filter stage of a digital down converter                       |
| <code>getFilterOrders</code>       | Get orders of digital down converter or digital up converter filter cascade                   |
| <code>getFilters</code>            | Get handles to digital down converter or digital up converter filter cascade objects          |
| <code>fvtool</code>                | Visualize frequency response of digital down converter or digital up converter filter cascade |
| <code>groupDelay</code>            | Group delay of digital down converter or digital up converter filter cascade                  |
| <code>visualizeFilterStages</code> | Display response of digital down converter or digital up converter filter cascade             |
| <code>generatehdl</code>           | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)                 |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...
'InterpolationFactor', 20,...
'SampleRate', Fs,...
'Bandwidth', 2e3,...
'StopbandAttenuation', 55,...
'PassbandRipple', 0.2,...
'CenterFrequency', 50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...
    'DecimationFactor',20,...
    'SampleRate', Fs*20,...
    'Bandwidth', 3e3,...
    'StopbandAttenuation', 55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')
```

Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp>window, [], [], 20*Fs, 'centered');
title('Spectrum of up converted signal xUp')
```

Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert  
window = hamming(floor(length(xDown)/10));  
figure; pwelch(xDown,window,[],[],Fs,'centered')  
title('Spectrum of down converted signal xDown')
```

Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```

### Get Decimation Factors

Get decimation factors of each filter stage of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `getDecimationFactors` function, obtain the decimation factors of each stage of the object.

```
dwnConv = dsp.DigitalDownConverter
```

```
dwnConv =  
dsp.DigitalDownConverter with properties:
```

```
DecimationFactor: 100  
MinimumOrderDesign: true  
Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
PassbandRipple: 0.1000  
StopbandAttenuation: 60  
Oscillator: 'Sine wave'  
CenterFrequency: 14000000  
SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv) %#ok
```

```
M = 1×3
```

```
    25     2     2
```

The `DecimationFactor` property of the object is set to 100. The output `M` is by default a 1-by-3 vector, where each element in the vector is a factor of the overall decimation factor.

When you set the `DecimationFactor` to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively.

```
dwnConv.DecimationFactor = [10 10]
```

```
dwnConv =
    dsp.DigitalDownConverter with properties:
```

```
    DecimationFactor: [10 10]
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv)
```

```
M = 1×2
```

```
    10    10
```

The output of the `getDecimationFactors` function is now a 1-by-2 vector.

## More About

### Fixed Point

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the filter input data type. In the `dsp.DigitalDownConverter` object, you can specify the filter input data type through the `FiltersInputDataType` and `CustomFiltersInputDataType` properties. In the Digital Down-Converter block, you can specify the filter input data type through the **Stage input** parameter.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse-gain and fine-gain operations.

If the normalization gain is  $G$  (where  $0 < G \leq 1$ ), then:

- $WLCic$  is the word length of the CIC decimator output and  $FLCic$  is the fraction length of the CIC decimator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved using bit shifts (coarse gain).
- $F2 = \text{fraction length specified by the filter input data type}$ .
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$ , which indicates that the remaining gain cannot be achieved with a bit shift (fine gain).

## Algorithms

The digital down converter downconverts the input signal by multiplying it with a complex exponential that has the specified center frequency. The algorithm downsamples the frequency downconverted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. When you specify an oscillator signal through the input port, the normalization factor does not include the oscillator power factor. Depending on how you set the decimation factor, the block bypasses the third filter stage. When the input data type is double or single, the algorithm implements an  $N$ -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. The algorithm emulates a CIC filter with

an FIR filter so that you can run simulations with floating-point data. When the input data type is fixed-point, the algorithm implements a true CIC filter with actual comb and integrator sections.

This block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

For details about fixed-point operation, see “Fixed Point” on page 4-395.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Interpolate digital signal and translate it from baseband to IF band

## Description

The `dsp.DigitalUpConverter` System object interpolates a digital signal, and translates it from baseband to intermediate frequency (IF) band.

To digitally upconvert the input signal:

- 1 Create the `dsp.DigitalUpConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
upConv = dsp.DigitalUpConverter
upConv = dsp.DigitalUpConverter(Name,Value)
```

### Description

`upConv = dsp.DigitalUpConverter` returns a digital up-converter (DUC) System object, `upConv`.

`upConv = dsp.DigitalUpConverter(Name,Value)` returns a DUC System object with the specified property `Name` set to the specified value `Value`. You can specify one or more name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`. Enclose each property name in single quotes. For example, create an object that upsamples the input signal by a factor of 20, using a filter with the specified qualities.

```
upConv = dsp.DigitalUpConverter('InterpolationFactor',20,...
'SampleRate',Fs,...
'Bandwidth',2e3,...
'StopbandAttenuation',55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**SampleRate — Sample rate of input signal**

30000000 (default) | positive scalar

Set this property to a positive scalar value. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

**InterpolationFactor — Interpolation factor**

100 (default) | positive integer | vector of positive integers

Interpolation factor, specified as a positive integer, or a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. Both elements of this `InterpolationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of this `InterpolationFactor` vector must be greater than 1 and the first element must equal 1 or 2.

Data Types: `double`

**MinimumOrderDesign — Minimum order filter design**

`true` (default) | `false`

Minimum order filter design, specified as `true` or `false`.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

**SecondFilterOrder — Order of CIC compensation filter stage**

12 (default) | positive integer

Order of CIC compensation filter stage, specified as a positive integer.

**Dependencies**

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: double

### **FirstFilterOrder — Order of first filter stage**

10 (default) | positive even integer

Order of first filter stage, specified as a positive even integer.

#### **Dependencies**

To enable this property, set the `MinimumOrderDesign` property to `false`. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property, because the first filter stage is bypassed.

Data Types: double

### **NumCICSections — Number of sections of CIC interpolator**

3 (default) | positive integer

Number of sections of CIC interpolator, specified as a positive integer.

#### **Dependencies**

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: double

### **Bandwidth — Two-sided bandwidth of input signal in Hz**

200000 (default) | positive integer

Two-sided bandwidth of input signal in Hz, specified as a positive integer. The object sets the passband frequency of the cascade of filters to half of the value that you specify in this `Bandwidth` property.

Data Types: double

### **StopbandFrequencySource — Source of stopband frequency**

Auto (default) | Property

Source of stopband frequency, specified as `Auto` or `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately  $F_c = \text{SampleRate}/2$  Hz and computes the stopband frequency as  $F_{\text{stop}} = F_c + TW/2$ .  $TW$  is the transition bandwidth of the cascade response, computed as  $2 \times (F_c - F_p)$ .  $F_p$  is the passband frequency computed by `Bandwidth/2`.

### **StopbandFrequency — Stopband frequency in Hz**

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

#### **Dependencies**

To enable this property, set the `StopbandFrequencySource` property to `Property`.

Data Types: double

**PassbandRipple — Passband ripple of cascade response in dB**

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in this `PassbandRipple` property.

**Dependencies**

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: double

**StopbandAttenuation — Stopband attenuation of cascade response in dB**

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in this `StopbandAttenuation` property.

**Dependencies**

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: double

**Oscillator — Type of oscillator**

Sine wave (default) | NCO

Type of oscillator, specified as `Sine wave` or `NCO`. When you set this property to `Sine wave`, the object frequency-upconverts the output of the interpolation filter cascade by using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object frequency-upconverts the output by using a complex exponential obtained from a numerically controlled oscillator (NCO).

**CenterFrequency — Center frequency of output signal in Hz**

14000000 (default) | positive scalar

Center frequency of output signal in Hz, specified as a positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property and the total interpolation factor. The object up converts the input signal so that the output spectrum centers at this frequency you specify in the `CenterFrequency` property.

Data Types: double

**NCO Properties****NumAccumulatorBits — Number of NCO accumulator bits**

16 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. For more details, see the `dsp.NCO` System object.

**Dependencies**

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

**NumQuantizedAccumulatorBits — Number of NCO accumulator bits**

12 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

**Dependencies**

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

**Dither — Dither control for NCO**

true (default) | false

Dither control for NCO, specified as `true` or `false`. When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. When this property is `false`, the NCO does not apply dither to the signal. For more details, see the `dsp.NCO` System object.

**Dependencies**

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `logical`

**NumDitherBits — Number of NCO dither bits**

4 (default) | positive integer

Number of NCO dither bits, specified as a positive integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

**Dependencies**

To enable this property, set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

**Fixed-Point Properties****FiltersOutputDataType — Data type at output of each filter stage**

Same as `input` (default) | `Custom`

Data type at the output of the first (if it has not been bypassed), second, and third filter stages, specified as `Same as input` or `Custom`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal is scaled by the normalization factor.

**CustomFiltersOutputDataType — Fixed-point data type at output of each filter stage**

`numericType([],16,15)` (default) | `numericType` object

Fixed-point data type at output of each filter stage, specified as a scaled `numericType` object with the `Signedness` property set to `Auto`.

**Dependencies**

To enable this property, set the `FiltersOutputDataType` property to `Custom`.

**OutputDataType — Data type of output**

`Same as input` (default) | `Custom`

Data type of output, specified as `Same as input` or `Custom`.

**CustomOutputDataType — Fixed-point data type of output**

`numericType([],16,15)` (default) | `numericType` object

Fixed-point data type of output, specified as a scaled `numericType` object the `Signedness` property set to `Auto`.

**Dependencies**

To enable this property, set the `OutputDataType` property to `Custom`.

**Usage****Syntax**

`y = upConv(x)`

**Description**

`y = upConv(x)` returns an upsampled and frequency-upconvertedred signal `y`, for a real or complex input column vector `x`.

**Input Arguments****x — Input signal**

column vector

Input signal, specified as a column vector of real or complex values.

When the data type of `x` is `double` or `single`, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Output Arguments

### y — Upconverted and upsampled signal

column vector

Upconverted and upsampled signal, returned as a column vector. The length of y is equal to the length of x multiplied by the value in the `InterpolationFactor` property. When the data type of x is `double` or `single`, the data type of y is the same as that of x. When the data type of x is of a fixed-point type, the data type of y is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.DigitalUpConverter

| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Upconvert Sine Wave Signal

Create a DUC System object™ that upsamples a 1-kHz sinusoidal signal by a factor of 20 and upconverts it to 50 kHz.

Create a sine wave generator to obtain the 1-kHz sinusoidal signal with a sample rate of 6 kHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,...
    'SampleRate',Fs,...
    'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a DUC System object. Use minimum order filter designs and set the passband ripple to 0.2 dB and stopband attenuation to 55 dB. Set the double-sided signal bandwidth to 2 kHz.

```
upConv = dsp.DigitalUpConverter(...
    'InterpolationFactor',20,...
    'SampleRate',Fs,...
    'Bandwidth',2e3,...
    'StopbandAttenuation',55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before and after upconverting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')
```

Upconvert the signal and visualize the spectrum.

```
xUp = upConv(x);
window = hamming(floor(length(xUp)/10));
figure;
pwelch(xUp>window, [], [], 20*Fs, 'centered')

## More About

### Fixed Point

The block diagram represents the DUC arithmetic with signed fixed-point inputs.

- $WL$  is the word length of the input, and  $FL$  is the fraction length of the input.
- The output of each filter is cast to the filter output data type. In the `dsp.DigitalUpConverter` object, you can specify the filter output data type through the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties. In the Digital Up-Converter block, you can specify the filter output data type through the **Stage output** parameter. The casting of the CIC output occurs after the scaling factor is applied.

- The oscillator output is cast to a word length equal to the filter output data type word length plus one. The fraction length is equal to the filter output data type word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse-gain and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The figure shows the coarse-gain and fine-gain operations.

If the normalization gain is  $G$  (where  $0 < G \leq 1$ ), then:

- $WL_{cic}$  is the word length of the CIC interpolator output, and  $FL_{cic}$  is the fraction length of the CIC interpolator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$ , indicating the part of  $G$  achieved by using bit shifts (coarse gain).
- $F2$  is the fraction length specified by the filter output data type.
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$ , which indicates that the remaining gain cannot be achieved with a bit shift (fine gain).

## Algorithms

The digital up converter upsamples the input signal using a cascade of three interpolation filters. This algorithm frequency-upconverts the upsampled signal by multiplying it with a complex exponential that has the specified center frequency. In this case, the filter cascade consists of an FIR interpolation stage, a second stage for CIC compensation, and a CIC interpolator. The block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. Depending on how you set the interpolation factor, the block bypasses the first filter stage. When the input data type is floating point, the algorithm implements an  $N$ -section CIC interpolation filter as a FIR filter with a response that corresponds to a cascade of  $N$  boxcar filters. The algorithm emulates a CIC filter with an FIR filter so that you can run simulations with floating-point data. When the input data type is a fixed-point type, the algorithm implements a true CIC filter with actual comb and integrator sections.

This block diagram represents the DUC arithmetic with floating-point inputs.

For details about fixed-point operation, see “Fixed Point” on page 4-408.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

# getInterpolationFactors

**Package:** dsp

Get interpolation factors of each filter stage of digital upconverter

## Syntax

```
M = getInterpolationFactors(upConv)
```

## Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage of digital up converter `upConv`. If the first filter stage is bypassed, then `M` is a 1-by-2 vector that contains the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

## Examples

### Get Interpolation Factors

Get interpolation factors of each filter stage of a `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings. Using the `getInterpolationFactors` function, obtain the interpolation factors of each stage of the object.

```
upConv = dsp.DigitalUpConverter

upConv =
  dsp.DigitalUpConverter with properties:

    InterpolationFactor: 100
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 300000
```

Show all properties

```
M = getInterpolationFactors(upConv) %#ok
```

```
M = 1×3
     2     2    25
```

The `InterpolationFactor` property of the object is set to 100. By default, the output `M` is a 1-by-3 vector, where each element in the vector is a factor of the overall interpolation factor.

When you set the `InterpolationFactor` property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. The output of the `getInterpolationFactors` function is now a 1-by-2 vector.

```
upConv.InterpolationFactor = [10 10]
```

```
upConv =  
dsp.DigitalUpConverter with properties:
```

```
    InterpolationFactor: [10 10]  
    MinimumOrderDesign: true  
                Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
    StopbandAttenuation: 60  
                Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
    SampleRate: 300000
```

```
Show all properties
```

```
M = getInterpolationFactors(upConv)
```

```
M = 1×2
```

```
    10    10
```

## Input Arguments

### **upConv** — Digital up converter

`dsp.DigitalUpConverter` System object

Digital up converter, specified as a `dsp.DigitalUpConverter` System object.

## Output Arguments

### **M** — Interpolation factors

vector

Interpolation factors of each filter stage, returned as a 1-by-2 or 1-by-3 vector. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Data Types: double

# **dsp.DyadicAnalysisFilterBank**

**Package:** dsp

Dyadic analysis filter bank

## **Description**

The `dsp.DyadicAnalysisFilterBank` System object decomposes a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The System object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

- 1 Create the `dsp.DyadicAnalysisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
dydan = dsp.DyadicAnalysisFilterBank  
dydan = dsp.DyadicAnalysisFilterBank(Name, Value)
```

### **Description**

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`dydan = dsp.DyadicAnalysisFilterBank(Name, Value)` returns a dyadic analysis filter bank object, with each property set to the specified value.

### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Filter — Type of filter used in subband decomposition**

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse Biorthogonal, or Discrete Meyer. All property values except Custom require Wavelet Toolbox software. If the value of this property is Custom, the filter coefficients are specified by the values of the CustomLowpassFilter and CustomHighpassFilter properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

| Filter                                | Example Setting                   | Syntax for Analysis Filters                                      |
|---------------------------------------|-----------------------------------|--|
| Haar                                  | N/A                               | <code>[Lo_D,Hi_D]=wfilters('haar');</code>                       |
| Daubechies extremal phase             | <code>WaveletOrder=3;</code>      | <code>[Lo_D,Hi_D]=wfilters('db3');</code>                        |
| Symlets (Daubechies least-asymmetric) | <code>WaveletOrder=4;</code>      | <code>[Lo_D,Hi_D]=wfilters('sym4');</code>                       |
| Coiflets                              | <code>WaveletOrder=1;</code>      | <code>[Lo_D,Hi_D]=wfilters('coif1');</code>                      |
| Biorthogonal                          | <code>FilterOrder='[3/1]';</code> | <code>[Lo_D,Hi_D,Lo_R,Hi_R]=...<br/>wfilters('bior3.1');</code>  |
| Reverse biorthogonal                  | <code>FilterOrder='[3/1]';</code> | <code>[Lo_D,Hi_D,Lo_R,Hi_R]=...<br/>wfilters('rbior3.1');</code> |
| Discrete Meyer                        | N/A                               | <code>[Lo_D,Hi_D]=wfilters('dmey');</code>                       |

**CustomLowpassFilter — Lowpass FIR filter coefficients**

`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in powers of  $z^{-1}$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

**Dependencies**

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**CustomHighpassFilter — Highpass FIR filter coefficients**

`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in powers of  $z^{-1}$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

**Dependencies**

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**WaveletOrder — Order for orthogonal wavelets**

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

#### Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

#### FilterOrder — Analysis and synthesis filter orders for biorthogonal filters

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, 5 / 5, or 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter.

#### Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

#### NumLevels — Number of filter bank levels used in analysis (decomposition)

2 (default) | integer greater than or equal to 1

Specify the number of filter bank analysis levels a positive integer greater than or equal to 1. A level- $N$  asymmetric structure produces  $N+1$  output subbands. A level- $N$  symmetric structure produces  $2^N$  output subbands. The size of the input along the first dimension must be a multiple of  $2^N$ , where  $N$  is the number of levels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has  $2^N$  subbands each of size  $M/2^N$ . In this case,  $M$  is the length of the input along the first dimension and  $N$  is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has  $N+1$  subbands. The following equation gives the length of the output in the  $k$ th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

## Usage

### Syntax

```
y = dydan(x)
```

### Description

`y = dydan(x)` computes the subband decomposition of the input `x` and outputs the dyadic subband decomposition in `y` as a single concatenated column vector or matrix of coefficients.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of `x` is treated as an independent input, and the number of rows of `x` must be a multiple of  $2^N$ , where  $N$  is the number of levels specified by the `NumLevels` property.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Dyadic subband decomposition output

column vector | matrix

Dyadic subband decomposition output, returned as a column vector or a matrix. The elements of `y` are ordered with the highest-frequency subband first followed by subbands in decreasing frequency.

When `TreeStructure` is set to `Symmetric`, the output has  $2^N$  subbands each of size  $M/2^N$ . In this case,  $M$  is the length of the input along the first dimension, and  $N$  is the value of the `NumLevels` property. When `TreeStructure` is set to `Asymmetric`, the output has  $N+1$  subbands. The following equation gives the length of the output in the  $k$ th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### Filter Square Wave Using Dyadic Filter Banks

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;  
x= square(2*pi*30*t);  
xn = x' + 0.08*randn(length(x),1);  
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];  
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];  
dydsyn = dsp.DyadicSynthesisFilterBank;  
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];  
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];  
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...  
              zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');  
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

### Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

### Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);

dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except: The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

# dsp.DyadicSynthesisFilterBank

**Package:** dsp

Reconstruct signals from subbands

## Description

The `dsp.DyadicSynthesisFilterBank` System object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

- 1 Create the `dsp.DyadicSynthesisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
dydsyn = dsp.DyadicSynthesisFilterBank
dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)
```

### Description

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)` returns a dyadic synthesis filter bank object, with each property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### Filter — Type of filter used in filter bank

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse

Biorthogonal, or Discrete Meyer. If you set this property to Custom, the CustomLowpassFilter and CustomHighpassFilter properties specify the filter coefficients. Otherwise, the object uses the wfilters function to construct the filters. Depending on the filter, the WaveletOrder or “FilterOrder” on page 4-0 property might apply. For a list of the supported wavelets, see the following table.

| Filter               | Sample Setting for Related Filter Specification Properties | Corresponding Wavelet Toolbox Function Syntax |
|----------------------|--|---|
| Haar                 | None   | wfilters('haar')                              |
| Daubechies           | H.WaveletOrder = 4   | wfilters('db4')                               |
| Symlets              | H.WaveletOrder = 3   | wfilters('sym3')                              |
| Coiflets             | H.WaveletOrder = 1   | wfilters('coif1')                             |
| Biorthogonal         | H.FilterOrder = '[3/1]'                                    | wfilters('bior3.1')                           |
| Reverse Biorthogonal | H.FilterOrder = '[3/1]'                                    | wfilters('rbior3.1')                          |
| Discrete Meyer       | None   | wfilters('dmey')                              |

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the CustomLowpassFilter and CustomHighpassFilter properties to specify lowpass and highpass FIR filters.

#### CustomLowpassFilter — Lowpass FIR filter coefficients

[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352] (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

#### Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### CustomHighpassFilter — Highpass FIR filter coefficients

[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327] (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

#### Dependencies

This property applies when you set the Filter property to Custom.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### WaveletOrder — Wavelet order

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

#### Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

### FilterOrder — Wavelet order for synthesis filter stage

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.
- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

#### Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

### NumLevels — Number of filter bank levels

2 (default) | integer greater than or equal to 1

Specify the number of filter bank levels as a scalar integer. An  $N$ -level asymmetric structure has  $N + 1$  input subbands, and an  $N$ -level symmetric structure has  $2^N$  input subbands.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level.

## Usage

### Syntax

```
y = dydsyn(x)
```

### Description

`y = dydsyn(x)` reconstructs the concatenated subband input `x` to output `y`. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `x` must be a multiple of  $2^N$ , where  $N$  is the value of the `NumLevels` property.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Reconstructed signal

column vector | matrix

Reconstructed signal, returned as a column vector or a matrix.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Filter Square Wave Using Dyadic Filter Banks

Denoise square wave input using dyadic analysis and synthesis filter banks.

```

t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;

```

The filter coefficients correspond to a haar wavelet.

```

dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);

```

Subband outputs.

```

C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

```

Set higher frequency coefficients to zero to remove the noise.

```

x_den = dydsyn([zeros(length(C1),1);...
               zeros(length(C2),1);C3]);

```

Plot the original and denoised signals.

```

subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');

```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except: The object only receives data as a vector or matrix of concatenated subbands.

### Version History

Introduced in R2012a

# dsp.FarrowRateConverter

**Package:** dsp

Polynomial sample rate converter with arbitrary conversion factor

## Description

The `dsp.FarrowRateConverter` System object implements a polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

- 1 Create the `dsp.FarrowRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
frc = dsp.FarrowRateConverter
frc = dsp.FarrowRateConverter(Name,Value)
frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)
```

### Description

`frc = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `frc`. For each channel of an input signal, `frc` converts the input sample rate to the output sample rate.

`frc = dsp.FarrowRateConverter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `frc = dsp.FarrowRateConverter('Specification','Coefficients','Coefficients',[1 2; 3 4])` returns a filter that converts from 44.1 kHz to 48 kHz using custom coefficients that implement a 2nd-order polynomial filter.

`frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)` returns a sample rate converter System object, `frc`, with `InputSampleRate` property set to `fsIn`, `OutputSampleRate` property set to `fsOut`, `OutputRateTolerance` property set to `tol`, and `PolynomialOrder` property set to `np`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Filter Properties

#### **InputSampleRate — Sample rate of input signal**

44100 (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **OutputSampleRate — Sample rate of output signal**

48000 (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can represent an upsample or downsample of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **OutputRateTolerance — Maximum tolerance for output sample rate**

0 (default) | positive scalar

Maximum tolerance for the output sample rate, specified as a positive scalar from 0 through 0.5, inclusive.

The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range `OutputSampleRate ± 1%`. This flexibility often enables a simpler filter design.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **Specification — Method for specifying filter coefficients**

'Polynomial order' (default) | 'Coefficients'

Method for specifying filter coefficients for the interpolator filter, specified as one of the following:

- 'Polynomial order' — Use the `PolynomialOrder` property to specify the order of the Lagrange-interpolation-filter polynomial. The object calculates coefficients that meet the rate and tolerance properties.
- 'Coefficients' — Use the `Coefficients` property to specify the polynomial coefficients directly.

#### **PolynomialOrder — Order of Lagrange-interpolation-filter polynomial**

3 (default) | positive integer less than or equal to 4

Order of the Lagrange-interpolation-filter polynomial, specified as a positive integer less than or equal to 4. The object calculates coefficients that meet the rate and tolerance properties.

**Dependencies**

This property applies only when you set Specification to 'Polynomial order'.

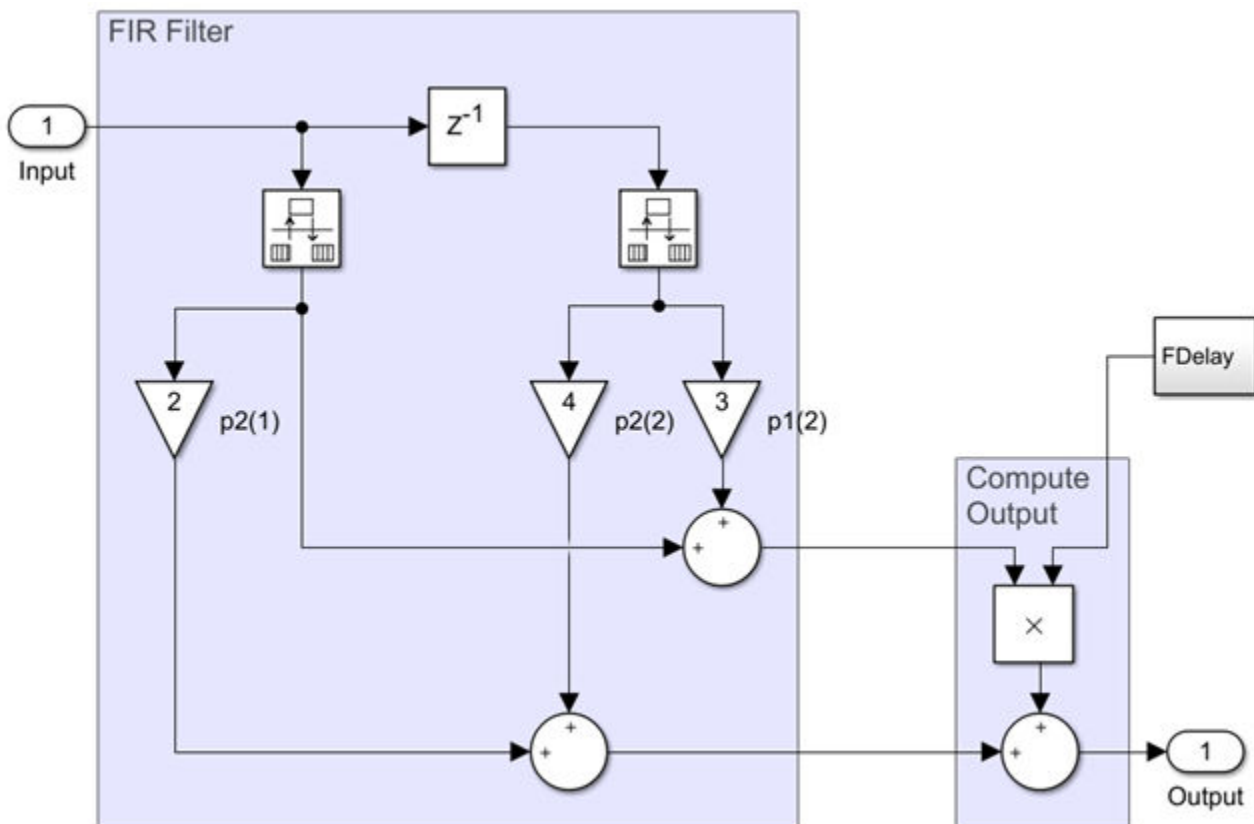

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Coefficients — Filter polynomial coefficients**

[-1 1; 1 0] (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued  $M$ -by- $M$  matrix, where  $M$  is the polynomial order.

The diagram shows the signal flow graph for a dsp.FarrowRateConverter object with coefficients set to [1 2; 3 4].

Each branch of the FIR filter corresponds to a row of the coefficient matrix.

**Dependencies**

This property applies only when you set Specification to 'Coefficients'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding method for fixed-point operations, specified as a character vector. For more information on the rounding methods see “Rounding Modes”.

**OverflowAction — Overflow action for fixed-point operations**

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as either 'Wrap' or 'Saturate'. For more details on the overflow actions, see “Overflow Handling”.

**CoefficientsDataType — Data type of filter coefficients**

numerictype(1,16) (default) | numerictype object

Data type of the filter coefficients, specified as a signed numerictype object. The default data type is a signed, 16-bit numerictype object. You must specify a numerictype object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the coefficient values.

**FractionalDelayDataType — Data type of fractional delay**

numerictype(0,8) (default) | numerictype object

Data type of the fractional delay, specified as an unsigned numerictype object. The default data type is an unsigned, 8-bit numerictype object. You must specify a numerictype object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the fractional delay values.

**MultiplicandDataType — Data type of multiplicand**

numerictype(1,16,13) (default) | numerictype object

Data type of the multiplicand, specified as a signed numerictype object. The default data type is a signed 16-bit numerictype object with 13-bit fraction length. You must specify a numerictype object that has a specific binary point scaling.

**OutputDataType — Data type of output**

'Same word length as input' (default) | 'Same as accumulator' | numerictype object

Data type of the output, specified as one of the following:

- 'Same word length as input' — Output word length and fraction length are the same as the input.
- 'Same as accumulator' — Output word length and fraction length are the same as the accumulator.
- numerictype object — Signed fixed-point output data type. If you do not specify a fraction length, the object computes the fraction length based on the input range. The object preserves the dynamic range of the input.

## Usage

### Syntax

```
y = frc(x)
```

### Description

$y = \text{frc}(x)$  resamples input  $x$  to create output  $y$  according to the rate conversion defined by  $\text{frc}$ .

### Input Arguments

#### **x** — Input signal

vector | matrix

Input signal, specified as a vector or a matrix. Each column of the input is treated as a separate channel.

### Output Arguments

#### **y** — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.FarrowRateConverter

|  |   |
|--|---|
| <code>getPolynomialCoefficients</code> | Get polynomial coefficients of farrow rate conversion filter                  |
| <code>getActualOutputRate</code>       | Get actual output rate  |
| <code>getRateChangeFactors</code>      | Get overall interpolation and decimation factors                              |
| <code>generatehdl</code>               | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |

### Filter Analysis

|                     |  |
|---------------------|--|
| <code>freqz</code>  | Frequency response of discrete-time filter System object |
| <code>fvtool</code> | Visualize frequency response of DSP filters              |
| <code>info</code>   | Information about filter System object                   |
| <code>cost</code>   | Estimate cost of implementing filter System object       |

### Common to All System Objects

|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Upsample an Audio Signal Using `dsp.FarrowRateConverter`

**Note:** The `dsp.AudioFileWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.FarrowRateConverter` System object™ to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the filter.

```
FsIn = 44.1e3;
FsOut = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',FsIn,...
                              'OutputSampleRate',FsOut,...
                              'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',FsOut);
```

Check the resulting interpolation and decimation factors.

```
[interp,decim] = getRateChangeFactors(frc)
```

```
interp = 320
```

```
decim = 147
```

Display the polynomial that the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs = 3x3
```

```
    0.5000    -0.5000         0
   -1.0000         0     1.0000
    0.5000     0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
    x = ar();
    y = frc(x);
    aw(y);
end
```

Release the `dsp.AudioFileWriter` System object™ to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals. The latency of the Farrow rate converter introduces a delay in the output signal.

```
tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
```

```
figure
```

```

subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')

```

Use the `outputDelay` function to determine this delay value. To account for this delay, shift the output by this delay value.

```
[delay,~,~] = outputDelay(frc,Fc=0)
```

```
delay = 4.5351e-05
```

```
tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
```

figure

```
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty-delay,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty-delay,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Zoom in to see the difference in sample rates.

```
figure
subplot(2,1,1)
plot(tx,x(:,1),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,1),'ro')
plot(ty-delay,y(:,1),'b.')
xlim([0.0105 0.0107])
```

```

legend('Interpolated input','Input samples','Output samples')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,2),'ro')
plot(ty-delay,y(:,2),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 2')

```

### Reduce Input Size Restriction by Adjusting Tolerance

Create a `dsp.FarrowRateConverter` System object™ with 0% tolerance. The output rate is equal to the `OutputSampleRate` property. The input size must be a multiple of the decimation factor,  $M$ . In this case  $M$  is 320.

```

frc = dsp.FarrowRateConverter('InputSampleRate',96e3,...
    'OutputSampleRate',44.1e3);
FsOut = getActualOutputRate(frc)

FsOut = 44100

[L,M] = getRateChangeFactors(frc)

L = 147

```

```
M = 320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor.

```
frc.OutputRateTolerance = 0.01;  
FsOut2 = getActualOutputRate(frc)
```

```
FsOut2 = 4.4308e+04
```

```
[L2,M2] = getRateChangeFactors(frc)
```

```
L2 = 6
```

```
M2 = 13
```

The decimation factor is now only 13. The lower the decimation factor, the more flexibility in input size. The output rate is within the range `OutputSampleRate ± 1%`.

### Frequency Response of `dsp.FarrowRateConverter`

Create a `dsp.FarrowRateConverter` System object™ with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;  
[h,f] = freqz(frc);  
plot(f,20*log10(abs(h)))  
ylabel('Filter Response')  
xlabel('Frequency (rad/s)')
```

## Determine Computational Cost of dsp.FarrowRateConverter

Create a dsp.FarrowRateConverter System object™ with default values. Determine its computational cost: the number of coefficients, number of states, multiplications per input sample, and additions per input sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)

cst = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 13.0612
    AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)

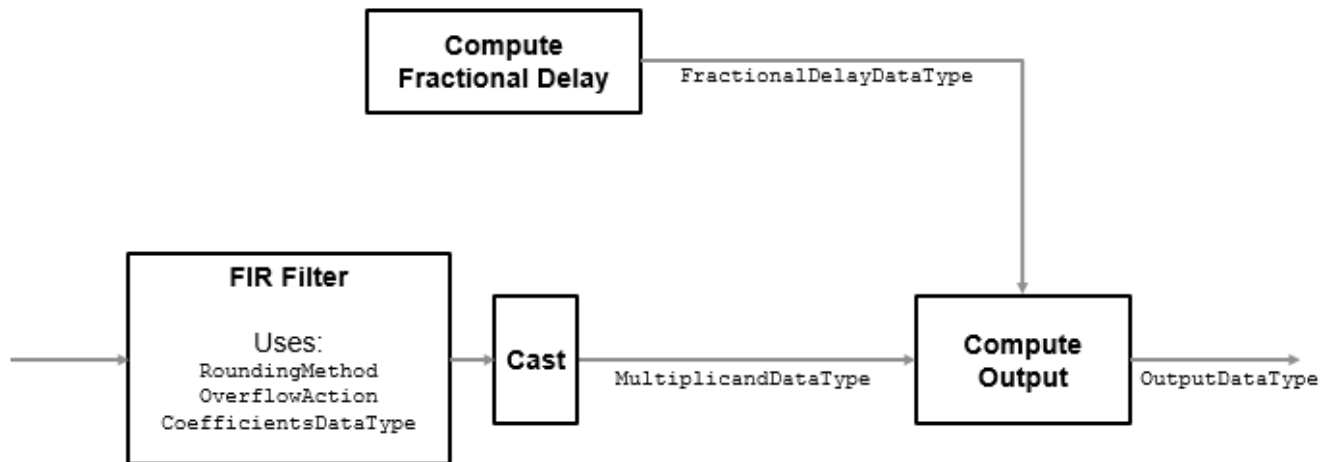

ctl = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 12
    AdditionsPerInputSample: 11
```

## More About

### Fixed Point

If the input is fixed point, it must be a signed integer or a signed fixed point value with a power-of-two slope and zero bias.

The diagram shows the data types that the dsp.FarrowRateConverter object uses for fixed-point signals and floating-point signals. You can specify these data types using the properties of the object, see “Fixed-Point Properties” on page 4-0 . If the input is floating point, all data types in filter are the same as the input data type, single or double.

If the input is fixed point, the FIR filter defines internal data types using the `RoundingMode`, `OverflowMode`, and `CoefficientsDataType` properties. The accumulators and products within the FIR filter use full precision data types. The object casts the output of the FIR filter to `MultiplicandDataType`.

## Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner's rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The algorithm computes interpolated values at the desired locations by varying only the fractional delay  $\mu$ . This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using  $M + 1$  FIR filters, where  $M$  is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay,  $\mu$ .
- The output is the sum of the multiplication results.

## Version History

Introduced in R2014b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `getRateChangeFactors` function supports C and C++ code generation.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

# **dsp.FastTransversalFilter**

**Package:** dsp

Fast transversal least-squares FIR adaptive filter

## **Description**

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FastTransversalFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
ftf = dsp.FastTransversalFilter  
ftf = dsp.FastTransversalFilter(len)  
ftf = dsp.FastTransversalFilter(Name,Value)
```

### **Description**

`ftf = dsp.FastTransversalFilter` returns a System object, `ftf`, which is a fast transversal, least-squares FIR adaptive filter. This System object computes the filtered output and the filter error for a given input and desired signal.

`ftf = dsp.FastTransversalFilter(len)` returns a `dsp.FastTrasversalFilter` System object with the `Length` property set to `len`.

`ftf = dsp.FastTransversalFilter(Name,Value)` returns a `dsp.FastTransversalFilter` System object with each specified property set to the specified value.

### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Method — Method to calculate filter coefficients**

'Fast transversal least-squares' (default) | 'Sliding-window fast transversal least-squares'

Specify the method used to calculate filter coefficients as either 'Fast transversal least-squares' or 'Sliding-window fast transversal least-squares'. For algorithms used to implement these two different methods, refer to [1]. This property is nontunable.

**Length — Length of filter coefficients vector**

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value.

Data Types: double

**SlidingWindowBlockLength — Width of sliding window**

32 (default) | positive integer

Specify the width of the sliding window as a positive integer value greater than or equal to the Length property value. The default value is the value of the Length property.

**Dependencies**

This property applies only if the Method property is set to 'Sliding-window fast transversal least-squares'.

Data Types: double

**ForgettingFactor — Fast transversal filter forgetting factor**

1 (default) | positive scalar

Specify the fast transversal filter forgetting factor as a positive scalar in the range (0,1]. Setting this value to 1 denotes infinite memory while filter adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range  $[1 - 0.5/L, 1]$ , where L is the Length property value.

**Tunable:** Yes

**Dependencies**

This property applies only if the Method property is set to 'Fast transversal least-squares'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**InitialPredictionErrorPower — Initial prediction error power**

10 (default) | positive scalar

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InitialConversionFactor — Initial conversion factor (gamma)**

1 (default) | scalar | 2-element row vector

Specify the initial value of the conversion factor of the fast transversal filter.

The value of this property depends on the `Method` property. If `Method` is set to:

- `'Fast transversal least-squares'` -- This property must be a positive numeric value less than or equal to 1
- `'Sliding-window fast transversal least-squares'` -- This property must be a two-element numeric vector. The first element of this vector must lie within the range `[0, 1]`, and the second element must be less than or equal to `-1`. In this case, the default value is `[1, -1]`.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **InitialCoefficients** — Initial coefficients of filter

`0` (default) | `scalar` | `vector`

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LockCoefficients** — Locked status of coefficient updates

`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update, and their values remain the same.

**Tunable:** Yes

## **Usage**

### **Syntax**

```
[y,err] = ftf(x,d)
```

### **Description**

`[y,err] = ftf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

### **Input Arguments**

#### **x** — Data input

`scalar` | `column vector`

The signal to be filtered by the fast transversal filter. The input, `x`, and the desired signal, `d` must have the same size and data type.

The data input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

### **d — Desired signal**

scalar | column vector

The fast transversal filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible. You can access the current filter weights by calling `ftf.Coefficients`, where `ftf` is the fast transversal filter object.

The input and the desired signal must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

### **Output Arguments**

#### **y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

#### **err — Difference between output and desired signal**

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge toward optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

### **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Specific to dsp.FastTransversalFilter**

`mseSim` Estimated mean squared error for adaptive filters

### **Common to All System Objects**

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### System Identification of FIR Filter Using Fast Transversal Filter

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `fir1` is the unknown system.
- Appropriate input data to exercise the adaptation process. In a generic system identification model, the desired signal  $d(k)$  and the input signal  $x(k)$  are used to exercise the adaptation process.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter  $y(k)$  and the output of the unknown system (or the system to be identified)  $d(k)$ . Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

### Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `fir1` function to design the filter coefficients. The designed filter is a 10th order lowpass digital filter with a cutoff frequency of 0.25.

```
filt = dsp.FIRFilter;  
filt.Numerator = fir1(10, .25)
```

```
filt =  
dsp.FIRFilter with properties:  
  
Structure: 'Direct form'  
NumeratorSource: 'Property'  
Numerator: [-0.0039 1.7585e-18 0.0321 0.1167 0.2207 0.2687 0.2207 0.1167 0.0321 1.7585e-18]  
InitialConditions: 0
```

Show all properties

Pass the signal  $x$  to the FIR filter. The desired signal  $d$  is the sum of the output of the unknown system (FIR filter) and an additive noise signal  $n$ .

```
x = randn(1000,1);  
d = filt(x) + 0.01*randn(1000,1);
```

### Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the fast transversal filter object to identify the unknown filter.

Create a `dsp.FastTransversalFilter` object to represent an adaptive filter. Set the length of the adaptive filter to 11 taps and a forgetting factor of 0.99.

```
ftf1 = dsp.FastTransversalFilter(11,...
    'ForgettingFactor',0.99)

ftf1 =
    dsp.FastTransversalFilter with properties:

                Method: 'Fast transversal least-squares'
                Length: 11
        ForgettingFactor: 0.9900
    InitialPredictionErrorPower: 10
        InitialCoefficients: 0
    InitialConversionFactor: 1
        LockCoefficients: false
```

Pass the primary input signal  $x$  and the desired signal  $d$  to the fast transversal filter. Run the adaptive filter to determine the unknown system. The output  $y$  of the adaptive filter is the signal converged to the desired signal  $d$ , thereby minimizing the error  $e$  between the two signals.

```
[y,e] = ftf1(x,d);
w = ftf1.Coefficients
```

```
w = 1×11
```

```
    -0.0043    0.0016    0.0308    0.1171    0.2204    0.2677    0.2210    0.1181    0.0323    0.0000
```

Plot the results. The output signal matches the desired signal very closely making the error between the two close to zero.

```
subplot(2,1,1);
plot(1:1000,[d,y,e])
title('System Identification of an FIR filter');
legend('Desired','Output','Error');
xlabel('time index');
ylabel('signal value');
```

The coefficients of the FIR filter match very closely with the coefficients of the adapted filter, thereby confirming the convergence.

```
subplot(2,1,2);
stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

# dsp.FFT

**Package:** dsp

Discrete Fourier transform

## Description

The `dsp.FFT` System object computes the discrete Fourier transform (DFT) of an input using fast Fourier transform (FFT). The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the DFT of an input:

- 1 Create the `dsp.FFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ft = dsp.FFT
ft = dsp.FFT(Name, Value)
```

### Description

`ft = dsp.FFT` returns a FFT object that computes the discrete Fourier transform (DFT) of a real or complex  $N$ -D array input along the first dimension using fast Fourier transform (FFT).

`ft = dsp.FFT(Name, Value)` returns a FFT object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**FFTImplementation — FFT implementation**

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as one of Auto, Radix-2, or FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

**BitReversedOutput — Order of output elements relative to input elements**

false (default) | true

Designate order of output channel elements relative to order of input elements. Set this property to true to output the frequency indices in bit-reversed order. The default is false, which corresponds to a linear ordering of frequency indices.

**Normalize — Divide butterfly outputs by two**

false (default) | true

Set this property to true if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is false with no scaling.

**FFTLengthSource — Source of FFT length**

Auto (default) | Property

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal.

**FFTLength — FFT length**

64 (default) | integer

FFT length, specified as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The BitReversedOutput property is true.
- The FFTImplementation property is Radix-2.

**Dependencies**

This property applies when you set the FFTLengthSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**WrapInput — Boolean value of wrapping or truncating input**

true (default) | false

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation.

## Fixed-Point Properties

### **RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

### **OverflowAction — Overflow action for fixed-point operations**

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

### **SineTableDataType — Sine table word and fraction lengths**

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

### **CustomSineTableDataType — Sine table word and fraction lengths**

numericType([],16) (default) | numericType

Specify the sine table fixed-point type as an unscaled numericType object with a Signedness of Auto.

#### **Dependencies**

This property applies when you set the SineTableDataType property to Custom.

### **ProductDataType — Product word and fraction lengths**

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

### **CustomProductDataType — Product word and fraction lengths**

numericType([],32,30) (default) | numericType

Specify the product fixed-point type as a scaled numericType object with a Signedness of Auto.

#### **Dependencies**

This property applies when you set the ProductDataType property to Custom.

### **AccumulatorDataType — Accumulator word and fraction lengths**

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator data type as Full precision, Same as input, Same as product, or Custom.

### **CustomAccumulatorDataType — Accumulator word and fraction lengths**

numericType([],32,30) (default) | numericType

Specify the accumulator fixed-point type as a scaled numericType object with a Signedness of Auto.

#### **Dependencies**

This property applies when you set the AccumulatorDataType property to Custom.

**OutputDataType — Output word and fraction lengths**

Full precision (default) | Same as input | Custom

Specify the output data type as one of Full precision, Same as input, Custom.

**CustomOutputDataType — Output word and fraction lengths**

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

**Usage****Syntax** $y = ft(x)$ **Description**

$y = ft(x)$  computes the DFT,  $y$ , of the input  $x$  along the first dimension of  $x$ .

**Input Arguments****x — Time-domain input signal**vector | matrix |  $N$ -D array

Time-domain input signal, specified as a vector, matrix, or  $N$ -D array.

When the FFTLengthSource property is set to 'Auto', the length of  $x$  along the first dimension must be a positive integer power of two. This length is also the FFT length. When the FFTLengthSource property is 'Property', the value you specify in FFTLength property must be a positive integer power of two.

Variable-size input signals are only supported when the FFTLengthSource property is set to 'Auto'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

**Output Arguments****y — Discrete Fourier transform of input signal**vector | matrix |  $N$ -D array

Discrete Fourier transform of input signal, returned as a vector, matrix, or an  $N$ -D array. When FFTLengthSource property is set to 'Auto', the FFT length is same as the number of rows in the input signal. When FFTLengthSource property is set to 'Property', the FFT length is specified through the FFTLength property.

To support non-power-of-two transform lengths with variable-size data, set the FFTImplementation property to 'FFTW'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Single-Sided Amplitude Spectrum of Signal

Find frequency components of a signal in additive noise.

```
Fs = 800; L = 1000;
t = (0:L-1)/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal
ft = dsp.FFT('FFTLengthSource','Property', ...
    'FFTLength',1024);
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512))/1024)
title('Single-sided amplitude spectrum of noisy signal y(t)')
xlabel('Frequency (Hz)'); ylabel('|Y(f)|')
```

### Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Consider a time-domain signal  $x[n]$ , which is defined over the finite time interval  $0 \leq n \leq N - 1$ . The energy of the signal  $x[n]$  is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients,  $X[k]$ , are considered signal values in the frequency domain. The energy of the signal  $x[n]$  in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

## Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

## Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq,...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');  
hold on;  
plot(ReconstrSignal, 'o');  
hold off;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
  - FFTImplementation is set to 'FFTW'.
  - FFTImplementation is set to 'Auto', FFTLengthSource is set to 'Property', and FFTLength is not a power of two.

Use the packNGo function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

dsp.IFFT

# **dsp.FilterCascade**

**Package:** dsp

Create cascade of filter System objects

## **Description**

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. This object operates similar to the `cascade` function. However, the `cascade` function does not support delay as a filter stage.

You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function.

When you call the object, the size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

To filter a signal with a cascade of filters:

- 1 Create the `dsp.FilterCascade` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Alternatively, you can generate a MATLAB function from the filter cascade object, and call that function to filter a signal. The generated function supports C/C++ code generation. For more details, see the `generateFilteringCode` function.

## **Creation**

### **Syntax**

```
FC = dsp.FilterCascade
FC = dsp.FilterCascade(filt1,filt2,...,filtn)
```

### **Description**

`FC = dsp.FilterCascade` returns a System object, `FC` that has a single stage, a `dsp.FIRFilter` System object with default properties.

`FC = dsp.FilterCascade(filt1,filt2,...,filtn)` returns a multistage System object, `FC`, with the first stage set to `filt1`, the second stage set to `filt2`, and so on. Each stage can be a filter System object, a `dsp.FilterCascade` System object, a `dsp.Delay` System object, or a scalar gain value.

For example, create a filter cascade that includes a lowpass filter, a highpass filter, and a gain stage.

```

lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
                           'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
                             'PassbandFrequency',8000);
gain = 2;
bpFilt = dsp.FilterCascade(lpFilt, hpFilt, 2);

```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Stage*i* — Filter stage

`dsp.FIRFilter` System object with default properties (default) | filter System object | delay System object | scalar gain value

Filter stage, specified as a filter System object, delay System object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can modify an existing stage by modifying the associated property. For example:

```
FC = dsp.FilterCascade(dsp.FIRFilter,5)
```

```
FC =
```

```
  dsp.FilterCascade with properties:
```

```
  Stage1: [1×1 dsp.FIRFilter]
  Stage2: 5
```

```
K>> FC.Stage2 = dsp.FIRDecimator
```

```
FC =
```

```
  dsp.FilterCascade with properties:
```

```
  Stage1: [1×1 dsp.FIRFilter]
  Stage2: [1×1 dsp.FIRDecimator]
```

To change the number of stages in a cascade, use the `addStage` and `removeStage` functions.

## Usage

### Syntax

```
y = FC(x)
```

**Description**

$y = FC(x)$  filters input signal  $x$  by using the filter cascade defined in  $FC$  and returns filtered output  $y$ . The size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

**Input Arguments****x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. When the input is a matrix, each column of the matrix represents an independent data channel.

Data Types: `single` | `double`

**Output Arguments****y — Filtered output data**

vector | matrix

Filtered output data, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Specific to `dsp.FilterCascade`**

|                                    |   |
|------------------------------------|---|
| <code>addStage</code>              | Add filter stage to cascade                   |
| <code>generateFilteringCode</code> | Generate MATLAB code for a filter cascade     |
| <code>getNumStages</code>          | Get number of stages in filter cascade        |
| <code>releaseStages</code>         | Release locked state of all stages in cascade |
| <code>removeStage</code>           | Remove stage from filter cascade              |

**Common to All System Objects**

|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

**Examples****Filter Signal Using Cascaded Lowpass and Highpass Filters**

Design a bandpass filter by cascading:

- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
    'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
    'PassbandFrequency',8000);

bpFilt = dsp.FilterCascade(lpFilt,hpFilt);

hvft = fvtool(bpFilt);
legend(hvft,'Bandpass filter');
```

Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

```
Sine1 = dsp.SinWave('Frequency',3e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);
Sine2 = dsp.SinWave('Frequency',10e3,...
    'SampleRate',48e3,...
```

```

        'SamplesPerFrame',6000);
Sine3 = dsp.SineWave('Frequency',15e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);

SpecAna = spectrumAnalyzer(...
    'PlotAsTwoSidedSpectrum',false,...
    'SampleRate',Sine1.SampleRate, ...
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1:1000
    x = Sine1()+Sine2()+Sine3()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);
end
release(SpecAna)

```

### Design Compensation Decimator for CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

```

cicdecim = dsp.CICDecimator(...
    'DecimationFactor',6,...
    'NumSections',6);
decimcasc = dsp.FilterCascade(cicdecim,...
    1/gain(cicdecim));

```

Design a compensation decimator and cascade it with the filter cascade, `decimcasc`. This operation nests a `dsp.FilterCascade` object as a stage in another filter cascade. The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. The factor of `1/gain(cicdecim)` from the decimation filter cascade, `decimcasc`, compensates for the compensation filter gain.

```

% Sample rate of input of compensation decimator
fs = 16e3;
% Passband frequency
fPass = 4e3;
% Stopband frequency
fStop = 4.5e3;
ciccomp = dsp.CICCompensationDecimator(cicdecim,...
    'DecimationFactor',2, ...
    'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop, ...
    'SampleRate',fs);
filtchain = dsp.FilterCascade(decimcasc,ciccomp);

```

Visualize the frequency response of the cascade of cascades.

```

f = fvtool(decimcasc,ciccomp,...
    filtchain,'Fs',[fs*6,fs,fs*6],...
    'Arithmetic','fixed');
legend(f,'CIC Decimator',...
    'CIC Compensation Decimator',...
    'Overall Response');

```

### Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
filtCasc = designMultistageDecimator(4,2000,100,60)
```

```
filtCasc =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    CloneStages: false
```

Verify your design by using `fvtool`.

```
info(filtCasc)

ans =
  'Discrete-Time Filter Cascade
  -----
  Number of stages: 2
  Stage cloning: disabled
```

```
Stage1: dsp.FIRDecimator

,
```

```
fvtool(filtCasc)
```

Generate code to filter data using this design. You cannot generate C/C++ code from the `dsp.FilterCascade` object directly, but you can generate C/C++ code from the generated function. The function defines the filter stages and calls them in sequence. The function is saved in a file called `myDecimator.m` in the current directory.

```
generateFilteringCode(filtCasc, 'myDecimator');
```

The `myDecimator` function creates a filter cascade and calls each stage object in turn.

```
type myDecimator
```

```
function y = myDecimator(x)
%MYDECIMATOR Construct filter cascade and process each stage

% MATLAB Code
% Generated by MATLAB(R) 9.14 and DSP System Toolbox 9.16.
% Generated on: 03-Mar-2023 11:31:17

% To generate C/C++ code from this function use the codegen command.
% Type 'help codegen' for more information.
%#codegen

%% Process  
y1 = filter1( x );  
y = filter2( y1);
```

## Version History

Introduced in R2014b

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You cannot generate code directly from `dsp.FilterCascade`. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

## See Also

### Objects

`dsp.FIRFilter` | `dsp.Delay`

### Functions

`cascade`

## addStage

**Package:** dsp

Add filter stage to cascade

### Syntax

```
addStage(FC,newFilt)
addStage(FC,newFilt,stageId)
```

### Description

`addStage(FC,newFilt)` adds a filter stage represented by the `newFilt` System object as the final stage of the `dsp.FilterCascade` System object, `FC`. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC,newFilt,stageId)` adds `newFilt` at stage position `stageId` of the filter cascade `FC`. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when `newFilt` is added.

### Examples

#### Add Filter Stage to Filter Cascade

Call `addStage` with only the System object™ arguments,. The function adds the new filter stage as the final stage in the filter cascade.

```
FC = dsp.FilterCascade
```

```
FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRFilter]
    CloneStages: true
```

```
addStage(FC,dsp.IIRFilter)
FC
```

```
FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
    CloneStages: true
```

Call `addStage` with an index argument. The function adds the new filter stage at the specified index. This example creates a filter cascade with three stages, and then adds a filter as the second stage of the cascade.

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter)
```

```
FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.CICDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    Stage3: [1x1 dsp.FIRFilter]
    CloneStages: true
```

```
addStage(FC,dsp.IIRFilter,2)
```

```
FC
```

```
FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.CICDecimator]
    Stage2: [1x1 dsp.IIRFilter]
    Stage3: [1x1 dsp.FIRDecimator]
    Stage4: [1x1 dsp.FIRFilter]
    CloneStages: true
```

## Input Arguments

### **FC — Filter cascade**

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

### **newFilt — Filter stage to add**

filter System object | delay System object | scalar gain value

Filter stage to add, specified as one of the supported System objects or a scalar gain value. Each stage can be a filter or delay object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

### **stageId — Index of filter stage to be added**

positive integer

Index of filter stage to be added, specified as a positive integer. The object adds this stage to the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the new filter is added.

## Version History

# generateFilteringCode

**Package:** dsp

Generate MATLAB code for a filter cascade

## Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC, fileName)
```

## Description

`generateFilteringCode(FC)` creates a MATLAB function that contains code to create the stages of a filter cascade, `FC`, and calls each stage in sequence. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.

`generateFilteringCode(FC, fileName)` generates code and saves the resulting function to the file specified in `fileName`.

## Examples

### Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
filtCasc = designMultistageDecimator(4,2000,100,60)
```

```
filtCasc =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRDecimator]
        Stage2: [1x1 dsp.FIRDecimator]
        CloneStages: false
```

Verify your design by using `fvtool`.

%% Process
y1 = filter1( x );
y = filter2( y1);
```

## Input Arguments

### FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

### fileName — File name

character vector | string scalar

File name where the generated function is saved, specified as a character vector or string scalar.

Data Types: `char` | `string`

## Version History

Introduced in R2014b

# getNumStages

**Package:** dsp

Get number of stages in filter cascade

## Syntax

```
getNumStages(FC)
```

## Description

getNumStages(FC) returns the number of stages in the dsp.FilterCascade object, FC.

## Examples

### Find Number of Stages

This example shows how to query the number of stages in a filter cascade.

Create a filter cascade with two stages and call getNumStages on the cascade object.

```
FC = cascade(dsp.FIRFilter,dsp.IIRFilter)

FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
    CloneStages: true

FCstages = getNumStages(FC)

FCstages = 2
```

## Input Arguments

### FC — Filter cascade

dsp.FilterCascade System object

Filter cascade, specified as a dsp.FilterCascade System object.

## Version History

**Introduced in R2014b**

## **See Also**

### **Objects**

`dsp.FilterCascade`

### **Functions**

`addStage` | `generateFilteringCode` | `releaseStages` | `removeStage`

# releaseStages

**Package:** dsp

Release locked state of all stages in cascade

## Syntax

```
releaseStages(FC)
```

## Description

releaseStages(FC) calls the release function of each individual stage in the dsp.FilterCascade System object FC.

For instance, if a dsp.FilterCascade object consists of a dsp.FIRFilter and a dsp.FIRInterpolator object, the releaseStages function calls the:

- release function of the dsp.FIRFilter object
- release function of the dsp.FIRInterpolator object

## Examples

### Release Stages of a Filter Cascade

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;  
y = firfilt(randn);  
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);  
isLocked(FC.Stage2)
```

```
ans = logical  
     1
```

```
releaseStages(FC);  
isLocked(FC.Stage2)
```

```
ans = logical  
     0
```

## Input Arguments

### FC — Filter cascade

dsp.FilterCascade System object

Filter cascade, specified as a dsp.FilterCascade System object.

## **Version History**

**Introduced in R2014b**

### **See Also**

#### **Objects**

`dsp.FilterCascade`

#### **Functions**

`addStage` | `generateFilteringCode` | `getNumStages` | `removeStage`

# removeStage

**Package:** dsp

Remove stage from filter cascade

## Syntax

```
removeStage(FC)
removeStage(FC, stageId)
```

## Description

`removeStage(FC)` removes the final stage of the `dsp.FilterCascade` System object `FC`.

`removeStage(FC, stageId)` removes the stage from stage position `stageId` of the filter cascade `FC`. All existing filter stages from `stageId` to the end of the cascade are shifted down in the cascade when the stage is removed.

## Examples

### Remove Filter Stage

Call `removeStage` with no arguments other than the filter cascade System object™. The function removes the last stage in the filter cascade.

```
FC2= dsp.FilterCascade(dsp.FIRFilter,...
    dsp.IIRFilter)
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
    CloneStages: true
```

```
removeStage(FC2);
FC2
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    CloneStages: true
```

To remove a specific stage of the cascade, specify the index for that stage as an input argument. This example creates a filter cascade that has four stages, and then removes the third stage.

```
FC4 = cascade(dsp.FIRInterpolator,...
    dsp.FIRInterpolator,...
```

```
    dsp.FIRDecimator, ...
    dsp.FIRDecimator)

FC4 =
    dsp.FilterCascade with properties:

        Stage1: [1x1 dsp.FIRInterpolator]
        Stage2: [1x1 dsp.FIRInterpolator]
        Stage3: [1x1 dsp.FIRDecimator]
        Stage4: [1x1 dsp.FIRDecimator]
    CloneStages: true

removeStage(FC4,3);
FC4

FC4 =
    dsp.FilterCascade with properties:

        Stage1: [1x1 dsp.FIRInterpolator]
        Stage2: [1x1 dsp.FIRInterpolator]
        Stage3: [1x1 dsp.FIRDecimator]
    CloneStages: true
```

## Input Arguments

### FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

### stageId — Index of filter stage to be removed

positive integer

Index of filter stage to be removed, specified as a positive integer. The function removes this stage from the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the filter is removed.

# dsp.FilteredXLMSFilter

**Package:** dsp

Filtered XLMS filter

## Description

The `dsp.FilteredXLMSFilter` System object computes output, error and coefficients using filtered-x least mean square FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FilteredXLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fxlms = dsp.FilteredXLMSFilter
fxlms = dsp.FilteredXLMSFilter(len)
fxlms = dsp.FilteredXLMSFilter(Name,Value)
```

### Description

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x least mean square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter(len)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the `Length` property set to `len`.

`fxlms = dsp.FilteredXLMSFilter(Name,Value)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Length — Length of filter coefficients vector**

10 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**StepSize — Adaptation step size**

0.1 (default) | positive scalar

Specify the adaptation step size factor as a positive numeric scalar.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**LeakageFactor — Adaptation leakage factor**

1 (default) | scalar

Specify the leakage factor used in a leaky adaptive filter as a numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default value is 1, providing no leakage in the adapting method.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**SecondaryPathCoefficients — Coefficients of the secondary path filter model**

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SecondaryPathEstimate — Estimate of secondary path filter model**

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the SecondaryPathCoefficients property value. This property is not tunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InitialCoefficients — Initial coefficients of filter**

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the Length property.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

**Tunable:** Yes

## Usage

## Syntax

```
[y,err] = fxlms(x,d)
```

### Description

`[y,err] = fxlms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output `y` and the filter error `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `fxlms` filter, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

### Input Arguments

#### **x** — Data input

scalar | column vector

The signal to be filtered by the filtered XLMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

#### **d** — Desired signal

scalar | column vector

The filtered XLMS filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal, `d`, can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **y** — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal  $x$  to match the desired signal  $d$ . The filter outputs the converged signal.

Data Types: `single` | `double`

### **err** — Difference between output and desired signal

scalar | column vector

Difference between the output signal  $y$  and the desired signal  $d$ , returned as a scalar or a column vector. The objective of the filtered XLMS filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the filtered XLMS filter coefficients, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.FilteredXLMSFilter`

`msesim` Estimated mean squared error for adaptive filters

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Active Noise Control of Random Noise Signal

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

```
x = randn(1000,1);  
g = fir1(47,0.4);  
n = 0.1*randn(1000,1);  
d = filter(g,1,x) + n;  
b = fir1(31,0.5);
```

Use the `dsp.FilteredXLMSFilter` System object™ to compute the filtered output and the filter error for the input and the signal to be canceled.

```

mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
    1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);

```

Plot the results.

```

### System Identification of FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-x LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

#### Initialization

Create a `dsp.FIRFilter` System object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```

num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;

```

## Adaptive Filter

Create a `dsp.FilteredXLMSFilter` System object to create an adaptive filter that uses the filtered-x LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```
l = 32;
mu = 0.008;
m = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
% Plot the learning curve for filtered-x LMS filter
% used in system identification
title('Learning curve')
```

With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

**Package:** `dsp`

Perform polyphase FIR decimation

### Description

The `dsp.FIRDecimator` System object performs an efficient polyphase decimation using an integer downsampling factor  $M$  along the first dimension.

Conceptually, the FIR decimator (as shown in the schematic) consists of an anti-aliasing FIR filter followed by a downsampler.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The FIR filter coefficients can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. The `designMultirateFIR` function designs an anti-aliasing FIR filter. The downsampler that follows the FIR filter downsamples each channel of filtered data by taking every  $M$ -th sample and discarding the  $M - 1$  samples that follow.  $M$  is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is  $1/M$  times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see "Algorithms" on page 4-500.

To resample vector or matrix inputs along the first dimension:

- 1 Create the `dsp.FIRDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see "Code Generation" on page 4-503.

## Creation

### Syntax

```

firdecim = dsp.FIRDecimator
firdecim = dsp.FIRDecimator(M)
firdecim = dsp.FIRDecimator(M,'Auto')
firdecim = dsp.FIRDecimator(M,num)
firdecim = dsp.FIRDecimator( ____,Name,Value)
firdecim = dsp.FIRDecimator(M,'legacy')

```

### Description

`firdecim = dsp.FIRDecimator` returns an FIR decimator object with a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(1,2)` function.

`firdecim = dsp.FIRDecimator(M)` returns an FIR decimator with the integer-valued `DecimationFactor` property set to `M`. The object designs its filter coefficients based on the decimation factor `M` that you specify while creating the object, using the `designMultirateFIR(1,M)` function. The designed filter corresponds to a lowpass with a cutoff at  $\pi/M$  in radial frequency units.

`firdecim = dsp.FIRDecimator(M,'Auto')` returns an FIR decimator with the `NumeratorSource` property set to `'Auto'`. In this mode, every time there is an update in the decimation factor, the object redesigns the filter using `designMultirateFIR(1,M)`.

`firdecim = dsp.FIRDecimator(M,num)` returns an FIR decimator with the `DecimationFactor` property set to `M` and the `Numerator` property set to `num`.

`firdecim = dsp.FIRDecimator( ____,Name,Value)` returns an FIR decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firdecim = dsp.FIRDecimator(M,'legacy')` returns an FIR decimator where the filter coefficients are designed using `fir1(35,0.4)`. The designed filter has a cutoff frequency of  $0.4\pi$  radians/sample.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Main Properties

#### DecimationFactor — Decimation factor

2 (default) | positive integer

Decimation factor  $M$ , specified as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The number of input rows must be a multiple of the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the `designMultirateFIR(1,M)` function.

### Numerator — FIR filter coefficients

`designMultirateFIR(1,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of  $z^{-1}$ . The following equation defines the system function for a filter of length  $N+1$ :

$$H(z) = \sum_{l=0}^N b_l z^{-l}$$

The vector  $\mathbf{b} = [b_0, b_1, \dots, b_N]$  represents the vector of filter coefficients.

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than  $1/M$ . To design an effective anti-aliasing filter, use the `designMultirateFIR` function. For an example, see "Decimate Sum of Sine Waves" on page 4-493.

### Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using `designMultirateFIR(1,M)`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Structure — Filter structure

'Direct form' (default) | 'Direct form transposed'

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`.

### Code Generation Properties

#### AllowArbitraryInputLength — Allow arbitrary input length in generated code

`false` (default) | `true`

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as `true` or `false`. When you specify:

- `true` -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.

- `false` -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: `logical`

### Fixed-Point Properties

#### FullPrecisionOverride — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

#### RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

#### Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `ProductDataType` set to 'Full precision', `AccumulatorDataType` set to 'Full precision', and `OutputDataType` set to 'Same as accumulator'.

Under these conditions, the object operates in full precision mode.

#### OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

#### Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

### **CoefficientsDataType — Data type of FIR filter coefficients**

Same word length as input (default) | Custom

Data type of the FIR filter coefficients, specified as:

- Same word length as input -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- Custom -- The coefficients data type is specified as a custom numeric type through the CustomCoefficientsDataType property.

### **CustomCoefficientsDataType — Word and fraction lengths of coefficients data type**

numerictype([],16,15) (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

#### **Dependencies**

This property applies when you set the CoefficientsDataType property to Custom.

### **ProductDataType — Data type of product output**

'Full precision' (default) | 'Custom' | 'Same as input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as input' -- The object specifies the product output data type to be the same as that of the input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the CustomProductDataType property.

For more information on the product output data type, see “Multiplication Data Types”.

#### **Dependencies**

This property applies when you set FullPrecisionOverride to false.

### **CustomProductDataType — Word and fraction lengths of product data type**

numerictype([],32,30) (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

#### **Dependencies**

This property applies only when you set FullPrecisionOverride to false and ProductDataType to 'Custom'.

**AccumulatorDataType — Data type of accumulation operation**

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- 'Full precision' -- The accumulation operation has full precision.
- 'Same as product' -- The object specifies the accumulator data type to be the same as that of the product output data type.
- 'Same as input' -- The object specifies the accumulator data type to be the same as that of the input data type.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the CustomAccumulatorDataType property.

**Dependencies**

This property applies when you set FullPrecisionOverride to false.

**CustomAccumulatorDataType — Word and fraction lengths of accumulator data type**

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set FullPrecisionOverride to false and AccumulatorDataType to 'Custom'.

**OutputDataType — Data type of object output**

'Same as accumulator' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The output data type is the same as that of the accumulator output data type.
- 'Same as input' -- The output data type is the same as that of the input data type.
- 'Same as product' -- The output data type is the same as that of the product output data type.
- 'Custom' -- The output data type is specified as a custom numeric type through the CustomOutputDataType property.

**Dependencies**

This property applies when you set FullPrecisionOverride to false.

**CustomOutputDataType — Word and fraction lengths of output data type**

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set FullPrecisionOverride to false and OutputDataType to 'Custom'.

## Usage

### Syntax

```
y = firdecim(x)
y = firdecim(x,num)
```

### Description

`y = firdecim(x)` outputs the filtered and downsampled values, `y`, of the input signal, `x`.

`y = firdecim(x,num)` uses the FIR filter, `num`, to decimate the input signal. This configuration is valid only when the 'NumeratorSource' property is set to 'Input port'.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix of size  $P$ -by- $Q$ . The columns in the input signal represent  $Q$  independent channels.

Under most conditions, the number of inputs rows  $P$  can be arbitrary and does not have to be a multiple of the `DecimationFactor` property. See this table for details.

| Input Signal  | When you Run Object in MATLAB                | When you Generate Code Using MATLAB Coder   |
|---------------|--|---|
| Fixed-size    | Object supports arbitrary input frame length | Object supports arbitrary input frame length when you set <code>AllowArbitraryInputLength</code> to <code>true</code> while generating code |
| Variable-size | Object supports arbitrary input frame length | Object supports arbitrary input frame length  |

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the `DecimationFactor` property.

This object does not support complex unsigned fixed-point inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

#### **num** — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

### Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### y — FIR decimator output

column vector | matrix

FIR decimator output, returned as a column vector or a matrix. When the input is of size  $P$ -by- $Q$ , and  $P$  is not a multiple of the decimation factor  $M$ , the output signal has an upper bound size of  $\text{ceil}(P/M)$ -by- $Q$ . If  $P$  is a multiple of the decimation factor, then the output is of size  $(P/M)$ -by- $Q$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.FIRDecimator

|             |   |
|-------------|---|
| freqz       | Frequency response of discrete-time filter System object                      |
| fvtool      | Visualize frequency response of DSP filters                                   |
| info        | Information about filter System object  |
| cost        | Estimate cost of implementing filter System object                            |
| polyphase   | Polyphase decomposition of multirate filter                                   |
| generatehdl | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |
| impz        | Impulse response of discrete-time filter System object                        |
| coeffs      | Returns the filter System object coefficients in a structure                  |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Decimate Sum of Sine Waves

Decimate a sum of sine waves by a factor of 2 and by a factor of 4.

Start with a cosine wave that has an angular frequency of  $\frac{\pi}{4}$  radians/sample.

```
x = cos(pi/4*(0:95)');
```

### Design Default Filter

Create a `dsp.FIRDecimator` object. To prevent aliasing, the object uses an anti-aliasing lowpass filter before downsampling. By default, the anti-aliasing lowpass filter is designed using the `designMultirateFIR` function. The function designs the filter based on the decimation factor that

you specify, and stores the coefficients in the Numerator property. For a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(1,2)`.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =  
dsp.FIRDecimator with properties:
```

```
Main
```

```
DecimationFactor: 2
```

```
NumeratorSource: 'Property'
```

```
Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 -0.0043 0 0.0077 0 -0.012
```

```
Structure: 'Direct form'
```

```
Show all properties
```

Visualize the filter response using `fvtool`. The designed filter meets the ideal filter constraints that are marked in red. The cutoff frequency is approximately half the spectrum.

```
fvtool(firdecim)
```

### Decimate by 2

Decimate the cosine signal by a factor of 2.

```
y = firdecim(x);
```

Plot the original and the decimated signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR decimator and the scaling introduced by the filter. Use the `outputDelay` function to compute the delay value introduced by the decimator. Shift the output by this delay value.

Visualize the input and the resampled signals. After a short transition, the output converges to a cosine of frequency  $\frac{\pi}{2}$  as expected, which is twice the frequency of the input signal  $\frac{\pi}{4}$ . Due to the decimation factor of 2, the output samples coincide with every other input sample.

```
[delay,FsOut] = outputDelay(firdecim);
nx = (0:length(x)-1);
ty = (0:length(y)-1)/FsOut-delay;
stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (y)','Input signal (x)');
```

### Add a High Frequency Component to Input and Decimate

Add another frequency component to the input signal, a sine with an angular frequency of  $\frac{2\pi}{3}$  radians/sample. Since  $\omega = \frac{2\pi}{3}$  is above the FIR lowpass cutoff,  $\frac{\pi}{2}$ , the frequency  $\frac{2\pi}{3}$  radians/sample is filtered out from the signal.

```
xhigh = x + 0.2*sin(2*pi/3*(0:95));
release(firdecim)
yhigh = firdecim(xhigh);
```

Plot the input signal, decimated signal, and the output of the low frequency component. The decimated signal `yhigh` has the high frequency component filtered out. `yhigh` is almost identical to the output of the low frequency component `y`.

```
stem(ty,yhigh,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(ty,y,'m',MarkerSize=7);
hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (yhigh)',...
       'Input signal with the high tone added (xhigh)',...
       'Decimated by 2 - low tone only (y)');
```

### Decimate by 4 in Automatic Filter Design Mode

Now decimate by a factor of 4. In order for the filter design to be updated automatically based on the new decimation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass `'Auto'` as the keyword while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the decimation factor, the object updates the filter design.

```

release(firdecim)
firdecim.NumeratorSource = 'Auto';
firdecim.DecimationFactor = 4

firdecim =
    dsp.FIRDecimator with properties:

    Main
        DecimationFactor: 4
        NumeratorSource: 'Auto'
        Structure: 'Direct form'

    Show all properties

```

To access the filter coefficients in the automatic mode, type `firdecim.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firdecim)
```

Decimate the cosine signal by a factor of 4. After a short transition, the output converges to a cosine of frequency  $\pi$  as expected, which is four times the lower frequency component of the input signal  $\frac{\pi}{4}$ . This time, the amplitude of the output is half the amplitude of the input since the gain of the FIR at

$\omega = \frac{\pi}{4}$  is exactly  $\frac{1}{2}$ . The high frequency component  $\frac{2\pi}{3}$  diminishes by the lowpass FIR whose cutoff frequency is  $\frac{\pi}{4}$ .

```
yAuto = firdecim(xhigh);
```

Plot the input signal with the high frequency component added, low frequency component scaled by 1/2, and the decimated signal. Recalculate the output delay and the output sample rate since the decimation factor has changed.

```
[delay,FsOut] = outputDelay(firdecim);
```

```
tyAuto = (0:length(yAuto)-1)/FsOut-delay;
stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(nx,x/2,'m:',MarkerSize=7); hold off;
```

```
xlim([-20,36])
```

```
ylim([-2.5 2.5])
```

```
legend('Decimated by 4 (yAuto)',...
```

```
'Input signal with the high frequency component added (xhigh)',...
```

```
'Low tone input scaled by 1/2');
```

## Reduce Sample Rate of Audio Signal

Reduce the sample rate of an audio signal by a factor of 2 and play the decimated signal using the `audioDeviceWriter` object.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The default audio file read by the object has a sample rate of 22050 Hz.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'single');
```

Create a `dsp.FIRDecimator` object and specify the decimation factor to be 2. The object designs the filter using `designMultirateFIR(1,2)` and stores the coefficients in the `Numerator` property of the object.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =
    dsp.FIRDecimator with properties:
```

```
    Main
```

```
    DecimationFactor: 2
```

```
    NumeratorSource: 'Property'
```

```
        Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 -0.0043 0 0.0077 0 -0.012
```

```
        Structure: 'Direct form'
```

```
Show all properties
```

Create an `audioDeviceWriter` object. Specify the sample rate to be 22050/2.

```
adw = audioDeviceWriter(22050/2)
```

```
adw =
```

```
    audioDeviceWriter with properties:
```

```
        Driver: 'DirectSound'
```

```
        Device: 'Default'
```

```
        SampleRate: 11025
```

```
Show all properties
```

Read the audio signal using the file reader object, decimate the signal by a factor of 2, and play the decimated signal.

```
while ~isDone(afr)
    frame = afr();
    y = firdecim(frame);
    adw(y);
end

release(afr);
pause(0.5);
release(adw);
```

## More About

### Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into  $M$  different subfilters, where  $M$  is the downsampling or decimation factor. For more details on the polyphase implementation, see “Algorithms” on page 4-500.

Let  $h(n)$  denote the FIR filter impulse response of length  $N+1$  and  $x(n)$  the input signal. Decimating the filter output by a factor of  $M$  is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting  $M = 2$ , the input values  $x(0), x(2), x(4), \dots$  are combined only with the filter coefficients  $h(0), h(2), h(4), \dots$ , and the input values  $x(1), x(3), x(5), \dots$  are combined only with the filter coefficients  $h(1), h(3), h(5), \dots$ . By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of  $M$ , there are  $M$  phases and therefore  $M$  subfilters.

## Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see Polyphase Subfilters on page 4-500.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H(z) = & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\
 & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\
 & \vdots \\
 & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)})
 \end{aligned}$$

$M$  is the number of polyphase components, and its value equals the decimation factor that you specify.

You can write this equation as:

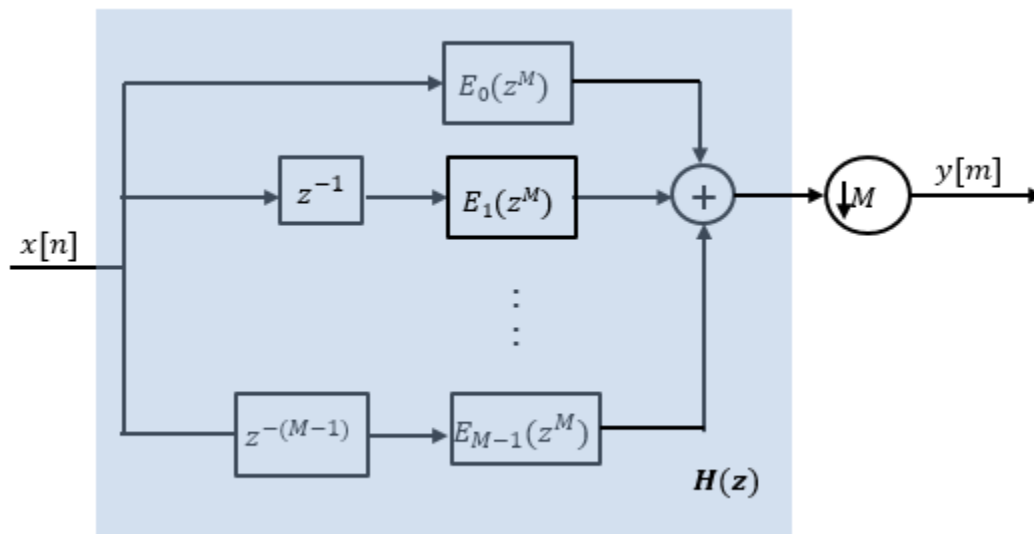

$$H(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$  are the polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

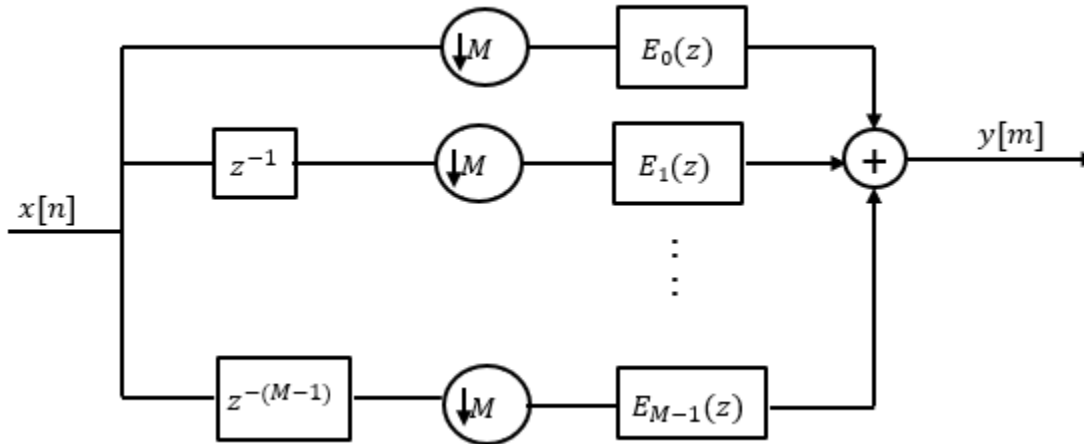

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches  $M-1$ ,  $M-2$ , and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch comes to the branch 0, the decimator outputs  $y[m]$ . The decimator effectively outputs one sample for every  $M$  samples it receives. Hence the sample rate at the output of the FIR decimation filter is  $f_s/M$ .

## Version History

Introduced in R2012a

### R2022b: Support for arbitrary input frame length

Starting in R2022b, this object supports an input signal with an arbitrary frame length. so the input frame length does not have to be a multiple of the decimation factor.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRDecimator` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Filter structure is set to 'Direct form'.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

## **dsp.FIRFilter**

**Package:** dsp

Static or time-varying FIR filter

### **Description**

The `dsp.FIRFilter` System object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.FIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-514.

### **Creation**

#### **Syntax**

```
fir = dsp.FIRFilter
fir = dsp.FIRFilter(num)
fir = dsp.FIRFilter(Name,Value)
```

#### **Description**

`fir = dsp.FIRFilter` returns a finite impulse response (FIR) filter object, `fir`, which independently filters each channel of the input over time using a specified FIR filter implementation.

`fir = dsp.FIRFilter(num)` returns an FIR filter System object, `fir`, with the `Numerator` property set to `num`.

`fir = dsp.FIRFilter(Name,Value)` returns an FIR filter System object, `fir`, with each property set to the specified value.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Structure – Filter structure**

Direct form (default) | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA

Specify the filter structure. You can specify the filter structure as one of Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA.

**NumeratorSource – Source of filter coefficients**

Property (default) | Input port

Specify the source of the filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

**Dependencies**

This applies when you set the Structure to Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed.

**ReflectionCoefficientsSource – Source of filter coefficients**

Property (default) | Input port

Specify the source of the Lattice filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

**Dependencies**

This applies when you set the Structure to Lattice MA.

**Numerator – Numerator coefficients**

[0.5 0.5] (default) | row vector

Specify the filter coefficients as a real or complex numeric row vector.

**Tunable:** Yes

**Dependencies**

This property applies when you set the NumeratorSource property to Property, and the “Structure” on page 4-0 property is set to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ReflectionCoefficients – Reflection coefficients of lattice filter structure**

[0.5 0.5] (default) | row vector

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector.

**Tunable:** Yes

**Dependencies**

This property applies when you set the “Structure” on page 4-0 property to Lattice MA, and the ReflectionCoefficientsSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InitialConditions — Initial conditions for the FIR filter**`0 (default) | scalar | vector | matrix`

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients-1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

**Tunable:** Yes

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**Fixed-Point Properties****FullPrecisionOverride — Full precision override for fixed-point arithmetic**`true (default) | false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

**RoundingMethod — Rounding method for fixed-point operations**`Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero`

Specify the rounding method.

**Dependencies**

This property applies only if the object is not in full precision mode.

**OverflowAction — Overflow action for fixed-point operations**`Wrap (default) | Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

**Dependencies**

This property applies only if the object is not in full precision mode.

**CoefficientsDataType — Coefficients word and fraction lengths**

Same word length as input (default) | Custom

Specify the coefficients fixed-point data type as Same word length as input or Custom.

**Dependencies**

This property applies when you set the NumeratorSource property to Property.

**CustomCoefficientsDataType — Custom coefficients word and fraction lengths**

numerictype(true,16,15) (default) | numerictype

Specify the coefficients fixed-point type as a signed or unsigned numerictype object.

**Dependencies**

This property applies when you set the CoefficientsDataType property to Custom.

**ReflectionCoefficientsDataType — Reflection coefficients word and fraction lengths**

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as Same word length as input or Custom.

**Dependencies**

This property applies when you set the ReflectionCoefficientsSource property to Property.

**CustomReflectionCoefficientsDataType — Custom reflection coefficients word and fraction lengths**

numerictype(true,16,15) (default) | numerictype

Specify the reflection coefficients fixed-point type as a signed or unsigned numerictype object.

**Dependencies**

This property applies when you set the ReflectionCoefficientsDataType property to Custom.

**ProductDataType — Product word and fraction lengths**

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as Full precision, Same as input, or Custom.

**CustomProductDataType — Custom product word and fraction lengths**

numerictype(true,32,30) (default) | numerictype

Specify the product fixed-point type as a signed or unsigned scaled numerictype object.

**Dependencies**

This property applies when you set the ProductDataType property to Custom.

**AccumulatorDataType — Accumulator word and fraction lengths**

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to Full precision, Same as input, Same as product, or Custom.

**CustomAccumulatorDataType — Custom accumulator word and fraction lengths**`numerictype(true,32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a signed or unsigned scaled `numerictype` object.

**Dependencies**

This property applies when you set the `AccumulatorDataType` property to `Custom`.

**StateDataType — State word and fraction lengths**`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the state fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

**Dependencies**

This property does not apply to any of the direct form or direct form I filter structures.

**CustomStateDataType — Custom state word and fraction lengths**`numerictype(true,16,15)` (default) | `numerictype`

Specify the state fixed-point type as a signed or unsigned scaled `numerictype` object.

**Dependencies**

This property applies when you set the `StateDataType` property to `Custom`.

**OutputDataType — Output word and fraction lengths**`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

**CustomOutputDataType — Custom output word and fraction lengths**`numerictype(true,16,15)` (default) | `numerictype`

Specify the output fixed-point type as a signed or unsigned scaled `numerictype` object.

**Dependencies**

This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`.

**Usage****Syntax**

```
y = fir(x)
y = fir(x,coeff)
```

**Description**

`y = fir(x)` applies an FIR filter to the real or complex input signal `x` to produce the output `y`.

$y = \text{fir}(x, \text{coeff})$  uses the time-varying coefficients, `coeff`, to filter the input signal `x` and produce the output `y`. You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

## Input Arguments

### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to the object.

This System object supports variable-size input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

### **coeff** — Filter coefficients

row vector

Time-varying filter coefficients, specified as a row vector. The data and coefficient inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Complex Number Support: Yes

## Output Arguments

### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.FIRFilter`

|                          |   |
|--------------------------|---|
| <code>freqz</code>       | Frequency response of discrete-time filter System object                      |
| <code>fvtool</code>      | Visualize frequency response of DSP filters                                   |
| <code>impz</code>        | Impulse response of discrete-time filter System object                        |
| <code>info</code>        | Information about filter System object  |
| <code>coeffs</code>      | Returns the filter System object coefficients in a structure                  |
| <code>cost</code>        | Estimate cost of implementing filter System object                            |
| <code>grpdelay</code>    | Group delay response of discrete-time filter System object                    |
| <code>generatehdl</code> | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```
t = (0:1000)'/8e3;  
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);  
  
sr = dsp.SignalSource;  
sr.Signal = xin;  
sink = dsp.SignalSink;  
  
fir = dsp.FIRFilter(fir1(10,0.5));  
  
sa = spectrumAnalyzer(...  
    'SampleRate',8e3,...  
    'Method','welch',...  
    'PlotAsTwoSidedSpectrum',false,...  
    'OverlapPercent',80,...  
    'SpectrumUnits','dBW',...  
    'YLimits',[-150 -10]);  
  
while ~isDone(sr)  
    input = sr();  
    filteredOutput = fir(input);  
    sink(filteredOutput);  
    sa(filteredOutput)  
end
```

```
filteredResult = sink.Buffer;  
fvtool(fir,'Fs',8000)
```

Design an FIR filter as a System object.

```
N = 10;  
Fc = 0.4;  
B = fir1(N,Fc);  
fir1 = dsp.FIRFilter(B);  
fvtool(fir1)
```

This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;
Fc = 0.4;
specLowpass = fdesign.lowpass('N,Fc',...
    N,Fc);
fir2 = design(specLowpass,...
    'systemobject',true)

fir2 =
    dsp.FIRFilter with properties:

        Structure: 'Direct form'
        NumeratorSource: 'Property'
        Numerator: [-1.2414e-18 -0.0126 -0.0247 0.0635 0.2748 0.3981 0.2748 0.0635 -0.0247 -
        InitialConditions: 0

    Show all properties

fvtool(fir2);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Filter structure is set to 'Direct form' or 'Direct form transposed'.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the HDL Coder or Filter Design HDL Coder products. For HDL Coder workflow and limitations, see “HDL Code Generation for System Objects” (HDL Coder). # dsp.FIRHalfbandDecimator

**Package:** dsp

Halfband decimator

## Description

The `dsp.FIRHalfbandDecimator` System object performs an efficient polyphase decimation of the input signal by a factor of two. You can use `dsp.FIRHalfbandDecimator` to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

`dsp.FIRHalfbandDecimator` uses an FIR equiripple design or a Kaiser window design to construct the halfband filters and a polyphase implementation to filter the input.

To filter and downsample your data:

- 1 Create the `dsp.FIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
firhalfbanddecim = dsp.FIRHalfbandDecimator  
firhalfbanddecim = dsp.FIRHalfbandDecimator(Name=Value)
```

### Description

`firhalfbanddecim = dsp.FIRHalfbandDecimator` returns a halfband decimator, `firhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB. The design method is set to "Auto".

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name=Value)` returns a halfband decimator, with additional properties specified by one or more `Name=Value` pair arguments.

Example: `firhalfbanddecim = dsp.FIRHalfbandDecimator(Specification="Filter order and stopband attenuation")` creates an FIR halfband decimator object with filter order set to 52 and stopband attenuation set to 80 dB.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Specification — Filter design parameters

"Transition width and stopband attenuation" (default) | "Filter order and stopband attenuation" | "Filter order and transition width" | "Coefficients"

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- "Transition width and stopband attenuation" -- Transition width and stopband attenuation are the design parameters.
- "Filter order and stopband attenuation" -- Filter order and stopband attenuation are the design parameters.
- "Filter order and transition width" -- Filter order and transition width are the design parameters.

The filter is designed using the optimal equiripple filter design method or the kaiser-window-based design method.

When you set `Specification` to "Coefficients", you specify the halfband filter coefficients directly through the `Numerator` property.

### FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

#### Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Filter order and transition width".

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

#### Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Transition width and stopband attenuation".

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

#### Dependencies

This property applies when you set `Specification` to either "Transition width and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Numerator — FIR halfband filter coefficients**

`firhalfband('minororder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-528 and “FIR Halfband Filter Design”. If half the order of the filter,  $(\text{length}(\text{Numerator}) - 1)/2$ , is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 0.5. If half the order of the filter is odd, the sequence of alternating zeros with a 0.5 at the center starts at the second coefficient.

#### **Dependencies**

This property applies when you set `Specification` to “Coefficients”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DesignMethod — Filter design method**

“Auto” (default) | “Equiripple” | “Kaiser”

Specify the filter design method as one of the following:

- “Auto” -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the `DesignMethod` property to “Auto”, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the object used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the object chooses in the “Auto” mode is not suitable for your application, manually specify the `DesignMethod` as “Equiripple” or “Kaiser”.

- “Equiripple” -- The algorithm uses the equiripple method.
- “Kaiser” -- The algorithm uses the Kaiser window method.

For more details on these two methods, see “Algorithms” on page 4-529.

#### **Dependencies**

To enable this property, set `Specification` to “Transition width and stopband attenuation”, “Filter order and stopband attenuation”, or “Filter order and transition width”.

Data Types: `char` | `string`

### **SampleRate — Input sample rate**

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

### Fixed-Point Properties

#### CoefficientsDataType — Word and fraction lengths of coefficients

`numericity(1,16)` (default) | `numericity` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericity` object. The default, `numericity(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

#### RoundingMethod — Rounding method for output fixed-point operations

"Floor" (default) | "Ceiling" | "Convergent" | "Nearest" | "Round" | "Simplest" | "Zero"

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

## Usage

### Syntax

```
y_low = firhalfbanddecim(x)
[y_low,y_high] = firhalfbanddecim(x)
```

### Description

`y_low = firhalfbanddecim(x)` filters the input signal `x` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2.

`[y_low,y_high] = firhalfbanddecim(x)` computes the `y_low` and `y_high`, of the analysis filter bank, `firhalfbanddecim` for input `x`. A  $K_i$ -by- $N$  input matrix is treated as  $N$  independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `y_low` and `y_high` are of the same size ( $K_o$ -by- $N$ ) and data type.  $K_o = K_i/2$ , where 2 is the decimation factor.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

This object supports variable-size input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **y<sub>low</sub>** — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

#### **y<sub>high</sub>** — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.FIRHalfbandDecimator`

|                        |  |
|------------------------|--|
| <code>freqz</code>     | Frequency response of discrete-time filter System object     |
| <code>fvtool</code>    | Visualize frequency response of DSP filters                  |
| <code>info</code>      | Information about filter System object                       |
| <code>cost</code>      | Estimate cost of implementing filter System object           |
| <code>coeffs</code>    | Returns the filter System object coefficients in a structure |
| <code>polyphase</code> | Polyphase decomposition of multirate filter                  |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Impulse and Frequency Response of Halfband Decimation Filter

Create two lowpass halfband decimation filters for data sampled at 44.1 kHz. The design method in the first filter is set to "Equiripple" and in the second filter is set to "Kaiser".

The output data rate is 1/2 the input sample rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = "Filter order and transition width";
Order = 52;
TW = 4.1e3;
firhalfbanddecimEquiripple = dsp.FIRHalfbandDecimator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Equiripple",...
    SampleRate=Fs);
firhalfbanddecimKaiser = dsp.FIRHalfbandDecimator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Kaiser",...
    SampleRate=Fs);
```

Plot the impulse response of both the filters. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
hfvt = fvtool(firhalfbanddecimEquiripple,firhalfbanddecimKaiser,...
    Analysis="impulse");
legend(hfvt,{'Equiripple','Kaiser'})
```

Plot the magnitude and phase response.

If the filter specifications are tight, say a very high filter order with a very narrow transition width, the filter designed using the "Kaiser" method converges more effectively.

```

hvftMag = fvtool(firhalfbanddecimEquiripple, firhalfbanddecimKaiser, ...
    Analysis="Magnitude");
legend(hvftMag, {'Equiripple', 'Kaiser'})

```

```
hvftPhase = fvtool(firhalfbanddecimEqui, firhalfbanddecimKaiser, ...  
    Analysis="Phase");  
legend(hvftPhase, {'Equiripple', 'Kaiser'})
```

### Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sample rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the design parameters of the filter.

```
afr = dsp.AudioFileReader(...
    "speech_dft.mp3",...
    SamplesPerFrame=1024);

filtSpec = "Filter order and transition width";
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification=filtSpec,...
```

```

FilterOrder=Order,...
TransitionWidth=TW,...
DesignMethod="Auto",...
SampleRate=afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate/2);

adw = audioDeviceWriter(SampleRate=afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end

```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);  
release(adw);
```

### Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader("speech_dft.mp3", SamplesPerFrame=1024);  
AP = audioDeviceWriter(SampleRate=AF.SampleRate);
```

```
filterspec = "Filter order and transition width";  
Order = 52;  
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    Specification=filterspec, FilterOrder=Order, ...  
    TransitionWidth=TW, DesignMethod="Auto", ...  
    SampleRate=AF.SampleRate);
```

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    Specification=filterspec, FilterOrder=Order, ...  
    TransitionWidth=TW, SampleRate=AF.SampleRate/2, ...  
    DesignMethod="Auto", ...  
    FilterBankInputPort=true);
```

```
SpecAna = spectrumAnalyzer(SampleRate=AF.SampleRate, ...  
    PlotAsTwoSidedSpectrum=false, ...  
    ShowLegend=true, ...  
    ChannelNames={'Input signal', 'Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)  
    audioInput = AF();  
    [xlo, xhigh] = firhalfbanddecim(audioInput);  
    audioOutput = firhalfbandinterp(xlo, xhigh);  
    spectrumInput = [audioInput audioOutput];  
    SpecAna(spectrumInput);  
    AP(audioOutput);
```

```
end
```

```
release(AF);
```

```
release(AP);
release(SpecAna);
```

### Filter Input into Lowpass and Highpass Subbands Using FIR Halfband Decimator

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the specified filter design parameters.

```
hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification="Transition width and stopband attenuation",...
    TransitionWidth=2000,...
    StopbandAttenuation=60,...
    DesignMethod="Auto",...
    SampleRate=44.1e3);
```

Filter a two-channel input into low and highpass subbands.

```
x = randn(1024,2);
[ylow,yhigh] = hfirhalfbanddecim(x);
```

## More About

### Halfband Filters

An ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

An ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of an ideal lowpass filter possesses some important properties that are required in a realizable approximation. The impulse response of an ideal lowpass halfband filter is:

- Equal to 0 for all even-indexed samples.
- Equal to 1/2 at  $n=0$  as shown by L'Hôpital's rule on the continuous-valued equivalent of the discrete-time impulse response

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The impulse response of an ideal highpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$

The FIR halfband decimator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the  $\ell^\infty$  norm of the error (minimax). See "Algorithms" on page 4-529 for more information.

### Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta \sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of  $\alpha$  dB, use this  $\beta$ .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order  $n$  is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where  $\Delta\omega$  is the transition width.

## Algorithms

### Filter Design Method

The FIR halfband decimator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to `Auto`. In this mode, the algorithm automatically chooses a design method that optimally meets the specified filter constraints.

### Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to  $1/2$ . This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 4-528. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

### Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 4-528, then it applies a Kaiser window defined in “Kaiser Window” on page 4-528. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

### Polyphase Implementation with Halfband Filters

The FIR halfband decimator uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response  $h(n)$  into two polyphase components results in an even polyphase component with  $z$ -transform of

$$H_0(z) = \sum_n h(2n)z^{-n},$$

and an odd polyphase component with  $z$ -transform of

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The  $z$ -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

You can represent filtering the input signal and then downsampling it by 2 using this figure.

Using the multirate noble identity for downsampling, you can move the downsampling operation before the filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to  $z^0$ . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately  $z^{-N/4}$  where  $N$  is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, the algorithm replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters.

```
filterspec = "Filter order and stopband attenuation";
halfOrderEven = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=64,StopbandAttenuation=80,DesignMethod="Auto");
halfOrderOdd = dsp.FIRHalfbandDecimator(Specification=filterspec,...
    FilterOrder=54,StopbandAttenuation=80,DesignMethod="Auto");
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, the FIR halfband decimator:

- Decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

# **dsp.FIRHalfbandInterpolator**

**Package:** dsp

Halfband interpolator

## **Description**

The `dsp.FIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design or a Kaiser window design to construct the halfband filters and a polyphase implementation to filter the input. For more details, see “Algorithms” on page 4-547.

To upsample and interpolate your data:

- 1 Create the `dsp.FIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name=Value)
```

### **Description**

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB. The design method is set to "Auto".

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name=Value)` returns a halfband interpolator, with additional properties specified by one or more `Name=Value` pair arguments.

Example: `firhalfbandinterp = dsp.FIRHalfbandInterpolator(Specification="Filter order and stopband attenuation")` creates an FIR halfband interpolator object with filter order set to 52 and stopband attenuation set to 80 dB.

## **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Specification — Filter design parameters

"Transition width and stopband attenuation" (default) | "Filter order and stopband attenuation" | "Filter order and transition width" | "Coefficients"

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- "Transition width and stopband attenuation" -- Transition width and stopband attenuation are the design parameters.
- "Filter order and stopband attenuation" -- Filter order and stopband attenuation are the design parameters.
- "Filter order and transition width" -- Filter order and transition width are the design parameters.

The filter is designed using optimal equiripple filter design method.

When you set `Specification` to "Coefficients", you specify the halfband filter coefficients directly through the `Numerator` property.

### FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

#### Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Filter order and transition width".

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

#### Dependencies

This property applies when you set `Specification` to either "Filter order and stopband attenuation" or "Transition width and stopband attenuation".

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

#### Dependencies

This property applies when you set `Specification` to either "Transition width and stopband attenuation" or "Filter order and transition width".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Numerator — FIR halfband filter coefficients**

`2*firhalfband("minorder",0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-546 and “FIR Halfband Filter Design”. If half the order of the filter,  $(\text{length}(\text{Numerator}) - 1)/2$  is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 1.0. If half the order of the filter is odd, the sequence of alternating zeros with a 1.0 at the center starts at the second coefficient.

**Dependencies**

This property applies when you set `Specification` to “Coefficients”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**DesignMethod — Filter design method**

“Auto” (default) | “Equiripple” | “Kaiser”

Specify the filter design method as one of the following:

- “Auto” -- The algorithm automatically chooses the filter design method depending on the filter design parameters. The algorithm uses the equiripple or the Kaiser window method to design the filter.

If the design constraints are very tight, such as very high stopband attenuation or very narrow transition width, then the algorithm automatically chooses the Kaiser method, as this method is optimal for designing filters with very tight specifications. However, if the design constraints are not tight, then the algorithm chooses the equiripple method.

When you set the `DesignMethod` property to “Auto”, you can determine the method used by the algorithm by examining the passband and stopband ripple characteristics of the designed filter. If the object used the equiripple method, the passband and stopband ripples of the designed filter have a constant amplitude in the frequency response. If the filter design method the object chooses in the “Auto” mode is not suitable for your application, manually specify the `DesignMethod` as “Equiripple” or “Kaiser”.

- “Equiripple” -- The algorithm uses the equiripple method.
- “Kaiser” -- The algorithm uses the Kaiser window method.

For more details on these two methods, see “Algorithms” on page 4-547.

**Dependencies**

To enable this property, set `Specification` to “Transition width and stopband attenuation”, “Filter order and stopband attenuation”, or “Filter order and transition width”.

Data Types: `char` | `string`

**SampleRate — Input sample rate**

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

### **FilterBankInputPort — Synthesis filter bank**

`false` (default) | `true`

Synthesis filter bank, specified as either `false` or `true`. If this property is `false`, `dsp.FIRHalfbandInterpolator` is an interpolation filter for a single vector- or matrix-valued input when you call the algorithm. If this property is `true`, `dsp.FIRHalfbandInterpolator` is a synthesis filter bank and the algorithm accepts two inputs, the lowpass and highpass subbands to synthesize.

### **Fixed-Point Properties**

#### **CoefficientsDataType — Word and fraction lengths of coefficients**

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

#### **RoundingMethod — Rounding method for output fixed-point operations**

`"Floor"` (default) | `"Ceiling"` | `"Convergent"` | `"Nearest"` | `"Round"` | `"Simplest"` | `"Zero"`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

## **Usage**

### **Syntax**

```
y = firhalfbandinterp(x1)
y = firhalfbandinterp(x1,x2)
```

### **Description**

`y = firhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the FIR halfband interpolator, `firhalfbandinterp`.

`y = firhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is set to `true`.

## Input Arguments

### **x1 — Data input**

column vector | matrix

Data input to the FIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### **x2 — Second data input**

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **y — Output of interpolator**

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.FIRHalfbandInterpolator`

## Examples

### Impulse and Frequency Response of Halfband Interpolation Filter

Create two lowpass halfband interpolation filters for upsampling data to 44.1 kHz. The design method in the first filter is set to "Equiripple" and in the second filter is set to "Kaiser".

Specify a filter order of 52 and a transition width of 4.1 kHz.

```
Fs = 44.1e3;
InputSampleRate = Fs/2;
Order = 52;
TW = 4.1e3;
filterspec = "Filter order and transition width";

firhalfbandinterpEqui = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,FilterOrder=Order,...
    TransitionWidth=TW,DesignMethod="Equiripple",...
    SampleRate=InputSampleRate);

firhalfbandinterpKaiser = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,FilterOrder=Order,...
    TransitionWidth=TW,DesignMethod="Kaiser",...
    SampleRate=InputSampleRate);
```

Plot the impulse response of both the filters. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
hfvt = fvtool(firhalfbandinterpEqui,firhalfbandinterpKaiser,...
    Analysis="Impulse");
legend(hfvt,{'Equiripple','Kaiser'})
```

Plot the magnitude and phase response.

If the filter specifications are tight, say a very high filter order with a very narrow transition width, the filter designed using the "Kaiser" method converges more effectively.

```

hvftMag = fvtool(firhalfbandinterpEqui,firhalfbandinterpKaiser,...
    Analysis="Magnitude");
legend(hvftMag,{'Equiripple','Kaiser'})

```

```
hvftPhase = fvtool(firhalfbandinterpEqui, firhalfbandinterpKaiser, ...  
    Analysis="Phase");  
legend(hvftPhase, {'Equiripple', 'Kaiser'})
```

### Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sample rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the design parameters of the filter.

```

afr = dsp.AudioFileReader(...
    "speech_dft.mp3",...
    SamplesPerFrame=1024);

filtSpec = "Filter order and transition width";
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    Specification=filtSpec,...

```

```

    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filtSpec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=afr.SampleRate/2);

adw = audioDeviceWriter(SampleRate=afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end

```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);  
release(adw);
```

### Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader("speech_dft.mp3", SamplesPerFrame=1024);  
AP = audioDeviceWriter(SampleRate=AF.SampleRate);
```

```
filterspec = "Filter order and transition width";  
Order = 52;  
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    Specification=filterspec, FilterOrder=Order, ...  
    TransitionWidth=TW, DesignMethod="Auto", ...  
    SampleRate=AF.SampleRate);
```

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    Specification=filterspec, FilterOrder=Order, ...  
    TransitionWidth=TW, SampleRate=AF.SampleRate/2, ...  
    DesignMethod="Auto", ...  
    FilterBankInputPort=true);
```

```
SpecAna = spectrumAnalyzer(SampleRate=AF.SampleRate, ...  
    PlotAsTwoSidedSpectrum=false, ...  
    ShowLegend=true, ...  
    ChannelNames={'Input signal', 'Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)  
    audioInput = AF();  
    [xlo, xhigh] = firhalfbanddecim(audioInput);  
    audioOutput = firhalfbandinterp(xlo, xhigh);  
    spectrumInput = [audioInput audioOutput];  
    SpecAna(spectrumInput);  
    AP(audioOutput);
```

```
end
```

```
release(AF);
```

```
release(AP);
release(SpecAna);
```

### Upsample and Interpolate Multichannel Input Using FIR Halfband Interpolator

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

Set the design method to "Auto". This mode chooses one of the filter design methods, equiripple or Kaiser, based on the specified filter design parameters.

```
Fs = 44.1e3;
filterspec = "Filter order and transition width";
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Auto",...
    SampleRate=Fs);

x = randn(1024,4);
y = firhalfbandinterp(x);
```

## More About

### Halfband Filters

An ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

An ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of an ideal lowpass filter possesses some important properties that are required in a realizable approximation. The impulse response of an ideal lowpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$  as shown by L'Hôpital's rule on the continuous-valued equivalent of the discrete-time impulse response

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The impulse response of an ideal highpass halfband filter is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$

The FIR halfband interpolator uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the  $\ell^\infty$  norm of the error (minimax). See "Algorithms" on page 4-547 for more information.

### Kaiser Window

The coefficients of a Kaiser window are computed from this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of  $\alpha$  dB, use this  $\beta$ .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order  $n$  is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where  $\Delta\omega$  is the transition width.

## Algorithms

### Filter Design Method

The FIR halfband interpolator algorithm uses the equiripple or the Kaiser window method to design the FIR halfband filter. When the design constraints are tight, such as very high stopband attenuation or very narrow transition width, use the Kaiser window method. When the design constraints are not tight, use the equiripple method. If you are not sure of which method to use, set the design method to `Auto`. In this mode, the algorithm automatically chooses a design method that optimally meets the specified filter constraints.

### Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to  $1/2$ . This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in “Halfband Filters” on page 4-546. See [1] for a description of this filter design method using the Remez exchange algorithm. Since you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

### Kaiser Window Design

In the Kaiser window method, the algorithm first truncates the ideal halfband filter defined in “Halfband Filters” on page 4-546, then it applies a Kaiser window defined in “Kaiser Window” on page 4-546. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter.

The coefficients of the designed halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

For more information on designing FIR halfband filters, see “FIR Halfband Filter Design”.

### Polyphase Implementation with Halfband Filters

The FIR halfband interpolator uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter’s impulse response  $h(n)$  into two polyphase components results in an even polyphase component with  $z$ -transform of

$$H_0(z) = \sum_n h(2n)z^{-n},$$

and an odd polyphase component with  $z$ -transform of

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

The  $z$ -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

You can represent the upsampling by 2 and then filtering the signal using this figure.

Using the multirate noble identity for upsampling, you can move the upsampling operation after the filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to  $z^0$ . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately  $z^{-N/4}$ , where  $N$  is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, the algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order.

To confirm this behavior, run the following code in the MATLAB command prompt and inspect the polyphase components of the following filters.

```
filterspec = "Filter order and stopband attenuation";  
halfOrderEven = dsp.FIRHalfbandInterpolator(Specification=filterspec,...  
    FilterOrder=64,StopbandAttenuation=80);  
halfOrderOdd = dsp.FIRHalfbandInterpolator(Specification=filterspec,...  
    FilterOrder=54,StopbandAttenuation=80);  
polyphase(halfOrderEven)  
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;  
hfirdecim = dsp.FIRHalfbandDecimator;  
polyphase(hfirdecim)  
polyphase(hfirinterp)
```

To summarize, the FIR halfband interpolator:

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

## dsp.FIRInterpolator

**Package:** dsp

Perform polyphase FIR interpolation

### Description

The `dsp.FIRInterpolator` System object performs an efficient polyphase interpolation using an integer upsampling factor  $L$  along the first dimension.

Conceptually, the FIR interpolator (as shown in the schematic) consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. The coefficients of the anti-imaging filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function.

The upsampler upsamples each channel of the input to a higher rate by inserting  $L-1$  zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is  $L$  times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see "Algorithms" on page 4-566.

To upsample an input:

- 1 Create the `dsp.FIRInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see "Code Generation" on page 4-569.

## Creation

### Syntax

```
firinterp = dsp.FIRInterpolator
firinterp = dsp.FIRInterpolator(L)
```

```

firinterp = dsp.FIRInterpolator(L, 'Auto')
firinterp = dsp.FIRInterpolator(L,num)
firinterp = dsp.FIRInterpolator(L,method)
firinterp = dsp.FIRInterpolator( ____,Name,Value)
firinterp = dsp.FIRInterpolator(L, 'legacy')

```

## Description

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator with an interpolation factor of 3. The object designs the FIR filter coefficients using the `designMultirateFIR(3,1)` function.

`firinterp = dsp.FIRInterpolator(L)` returns an FIR interpolator with the `InterpolationFactor` property set to `L`. The object designs its filter coefficients based on the interpolation factor `L` that you specify while creating the object using the `designMultirateFIR(L,1)` function. The designed filter corresponds to a lowpass with a cutoff at  $\pi/L$  in radial frequency units.

`firinterp = dsp.FIRInterpolator(L, 'Auto')` returns an FIR interpolator with the `NumeratorSource` property set to `'Auto'`. In this mode, every time there is an update in the interpolation factor, the object redesigns the filter using the design method specified in `DesignMethod`.

`firinterp = dsp.FIRInterpolator(L,num)` returns an FIR interpolator with the `InterpolationFactor` property set to `L` and the `Numerator` property set to `num`.

`firinterp = dsp.FIRInterpolator(L,method)` returns an FIR interpolator with the `InterpolationFactor` property set to `L` and the `DesignMethod` property set to `method`. When you pass the design method as an input, the `NumeratorSource` property is automatically set to `'Auto'`.

`firinterp = dsp.FIRInterpolator( ____,Name,Value)` returns an FIR interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firinterp = dsp.FIRInterpolator(L, 'legacy')` returns an FIR interpolator where the filter coefficients are designed using `fir1(15,0.25)`. The designed filter has a cutoff frequency of  $0.25\pi$  radians/sample.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### InterpolationFactor — Interpolation factor

3 (default) | positive integer

Specify the integer factor,  $L$ , by which to increase the sampling rate of the input signal. The polyphase implementation uses  $L$  polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NumeratorSource — FIR filter coefficient source**

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as either:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

### **Numerator — FIR filter coefficients**

`designMultirateFIR(L,1)` (default) | row vector

Numerator coefficients of the anti-imaging FIR filter, specified as a row vector in powers of  $z^{-1}$ . The following equation defines the system function for a filter of length  $N+1$ :

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector  $\mathbf{b} = [b(0), b(1), \dots, b(N)]$  represents the vector of filter coefficients.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. Use `designMultirateFIR` to design such a filter. More generally, any complex bandpass filter can be used. For an example, see “Double the Sample Rate Using FIR Interpolator” on page 4-565.

The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the  $L$  polyphase subfilters, `Numerator` is appended with zeros if necessary.

### **Dependencies**

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **DesignMethod — Auto design method**

'Kaiser' (default) | 'ZOH' | 'Linear'

Design method of the FIR filter coefficients, specified as one of the following:

- 'Kaiser' -- Kaiser method. Approximate anti-imaging lowpass filter using the `designMultirateFIR` function.
- 'ZOH' -- Zero order hold method. Hold the input sequence values.
- 'Linear' -- Linear interpolation method.

### **Dependencies**

This property is visible only when you set the `NumeratorSource` property to 'Auto', or if you pass the 'auto' keyword as an input while creating the object.

## Fixed-Point Properties

### FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

### RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

#### Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `ProductDataType` set to `'Full precision'`, `AccumulatorDataType` set to `'Full precision'`, and `OutputDataType` set to `'Same as accumulator'`.

Under these conditions, the object operates in full precision mode.

### OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` -- The object wraps the result of its fixed-point operations.
- `'Saturate'` -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

#### Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- `FullPrecisionOverride` set to `true`.
- `FullPrecisionOverride` set to `false`, `OutputDataType` set to `'Same as accumulator'`, `ProductDataType` set to `'Full precision'`, and `AccumulatorDataType` set to `'Full precision'`.

Under these conditions, the object operates in full precision mode.

**CoefficientsDataType — Data type of FIR filter coefficients**

Same word length as input (default) | Custom

Data type of the FIR filter coefficients, specified as:

- `Same word length as input` -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- `Custom` -- The coefficients data type is specified as a custom numeric type through the `CustomCoefficientsDataType` property.

**CustomCoefficientsDataType — Word and fraction lengths of coefficients data type**

`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned `numerictype` with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies when you set the `CoefficientsDataType` property to `Custom`.

**ProductDataType — Data type of product output**

'Full precision' (default) | 'Custom' | 'Same as input'

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` -- The product output data type has full precision.
- `'Same as input'` -- The object specifies the product output data type to be the same as that of the input data type.
- `'Custom'` -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

**Dependencies**

This property applies when you set `FullPrecisionOverride` to `false`.

**CustomProductDataType — Word and fraction lengths of product data type**

`numerictype([],32,30)` (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.

**AccumulatorDataType — Data type of accumulation operation**

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.

- 'Same as input' -- The object specifies the accumulator data type to be the same as that of the input data type.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the CustomAccumulatorDataType property.

#### Dependencies

This property applies when you set FullPrecisionOverride to false.

#### CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

#### Dependencies

This property applies only when you set FullPrecisionOverride to false and AccumulatorDataType to 'Custom'.

#### OutputDataType — Data type of object output

'Same as accumulator' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The output data type is the same as that of the accumulator output data type.
- 'Same as input' -- The output data type is the same as that of the input data type.
- 'Same as product' -- The output data type is the same as that of the product output data type.
- 'Custom' -- The output data type is specified as a custom numeric type through the CustomOutputDataType property.

#### Dependencies

This property applies when you set FullPrecisionOverride to false.

#### CustomOutputDataType — Word and fraction lengths of output data type

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

#### Dependencies

This property applies only when you set FullPrecisionOverride to false and OutputDataType to 'Custom'.

## Usage

### Syntax

```
y = firinterp(x)
y = firinterp(x,num)
```

### Description

`y = firinterp(x)` interpolates the input signal `x` along the first dimension, and outputs the upsampled and filtered values, `y`.

`y = firinterp(x,num)` uses the FIR filter, `num`, to interpolate the input signal. This configuration is valid only when the 'NumeratorSource' property is set to 'Input port'.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. A  $P$ -by- $Q$  input matrix is treated as  $Q$  independent channels, and the System object interpolates each channel over the first dimension and generates a  $P*L$ -by- $Q$  output matrix, where  $L$  is the interpolation factor.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

#### **num** — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

### Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Output Arguments

#### **y** — FIR interpolator output

vector | matrix

FIR interpolator output, returned as a vector or a matrix of size  $P*L$ -by- $Q$ , where  $L$  is the interpolation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.FIRInterpolator

`freqz`            Frequency response of discrete-time filter System object  
`fvtool`          Visualize frequency response of DSP filters

### Interpolate by 2

Interpolate the cosine signal by a factor of 2.

```
y = firinterp(x);
```

Plot the original and interpolated signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR interpolator and the scaling introduced by the filter. Use the `outputDelay` function to compute the delay value introduced by the interpolator. Shift the output by this delay value.

Visualize the input and the resampled signals. The input and output values coincide every other sample, due to the interpolation factor of 2.

```
[delay,FsOut] = outputDelay(firinterp)
```

```
delay = 12
```

```
FsOut = 2
```

```
nx = (0:length(x)-1);
ty = (0:length(y)-1)/FsOut-delay;
stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,20])
ylim([-2.5 2.5])
legend('Interpolated by 2','Input signal','Location','best');
```

### Interpolate by 4 in Automatic Filter Design Mode

Now interpolate by a factor of 4. In order for the filter design to be updated automatically based on the new interpolation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'Auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the interpolation factor, the object updates the filter design.

```
release(firinterp)
firinterp.NumeratorSource = 'Auto';
firinterp.InterpolationFactor = 4

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Kaiser'

Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firinterp.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firinterp)
```

Interpolate the cosine signal by a factor of 4.

```
yAuto = firinterp(x);
```

Plot the original and resampled signals. Recalculate the delay and the output sample rate values since the interpolation factor has changed. The input and output values coincide every 4 output samples, owing to the interpolation factor of 4.

```
[delay,FsOut] = outputDelay(firinterp);
```

```
nx = (0:length(x)-1);
tyAuto = (0:length(yAuto)-1)/FsOut-delay;
stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,10])
ylim([-2.5 2.5])
legend('Interpolated by 4','Input signal');
```

### Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

### Set `DesignMethod` to 'linear'

If you set the `DesignMethod` to 'linear', the object uses the linear interpolation model.

```
release(firinterp)
firinterp.DesignMethod = 'linear'

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Linear'

Show all properties
```

Interpolate the signal using the linear interpolation model.

```
ylinear = firinterp(x);
```

Plot the original and the linearly interpolated signal.

```

[delay,FsOut] = outputDelay(firinterp);
nx = (0:length(x)-1);

% Calculate output times for vector ylinear in input units
tylinear = (0:length(ylinear)-1)/FsOut-delay;

stem(tylinear,ylinear,'filled',MarkerSize=4); hold on;
stem(nx,x);
hold off;
xlim([0,10])
ylim([-2.5 2.5])
legend('Linear Interpolation by 4','Input signal');

```

### Set DesignMethod to 'ZOH' and Change InterpolationFactor to 5

If you set the DesignMethod to 'ZOH', the object uses the zero order hold method. Change the interpolation factor to 5.

```

release(firinterp)
firinterp.DesignMethod = 'ZOH';
firinterp.InterpolationFactor = 5

firinterp =
    dsp.FIRInterpolator with properties:
        InterpolationFactor: 5
        NumeratorSource: 'Auto'
        DesignMethod: 'ZOH'

```

Show all properties

Interpolate the signal using the zero order hold method.

```
yzoh = firinterp(x);
```

Plot the original and ZOH interpolated signal.

```
[delay,FsOut] = outputDelay(firinterp);
nx = (0:length(x)-1);
```

```
% Calculate output times for vector yzoh in input units
tyzoh = (0:length(yzoh)-1)/FsOut-delay;
```

```
stem(tyzoh,yzoh,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([0,10])
ylim([-1.5 1.5])
legend('ZOH Interpolation by 4','Input signal');
```

### Double the Sample Rate Using FIR Interpolator

Double the sample rate of an audio signal and play the interpolated signal using the `audioDeviceWriter` object.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \dots + z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)})$$

$L$  is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

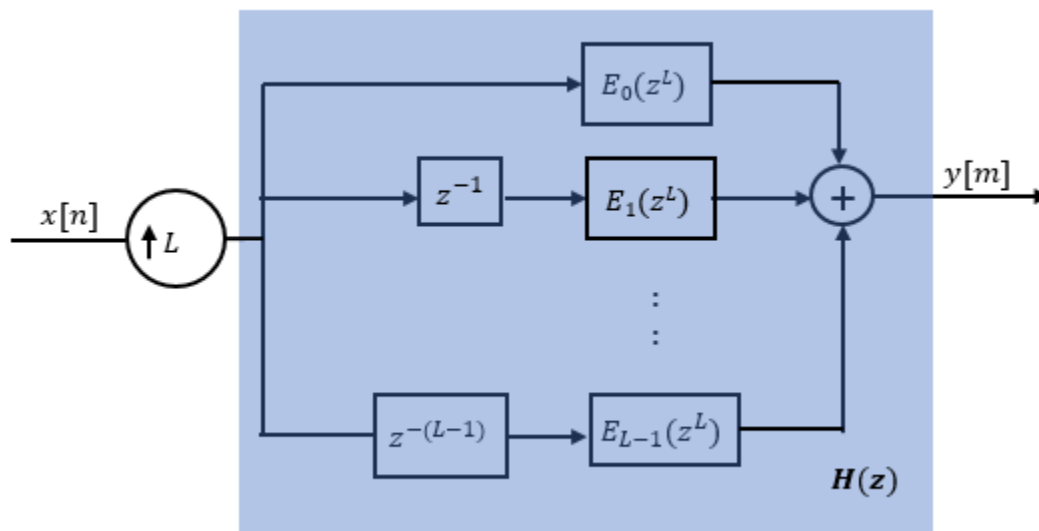

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$  are polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter  $H(z)$ .

**Conceptual Operation  
of FIR Interpolator**

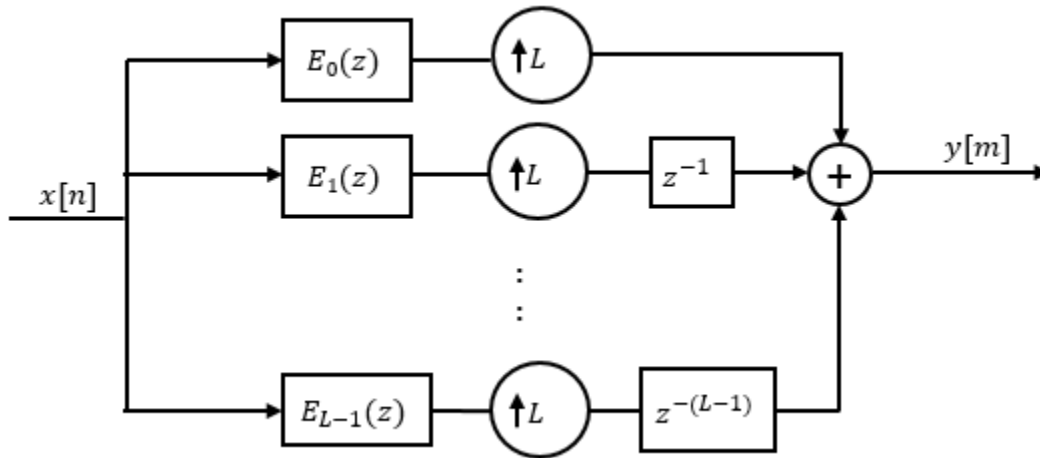

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving one sample from each branch. The interpolator effectively outputs  $L$  samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is  $Lf_s$ .

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRInterpolator` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

## dsp.FIRRateConverter

**Package:** dsp

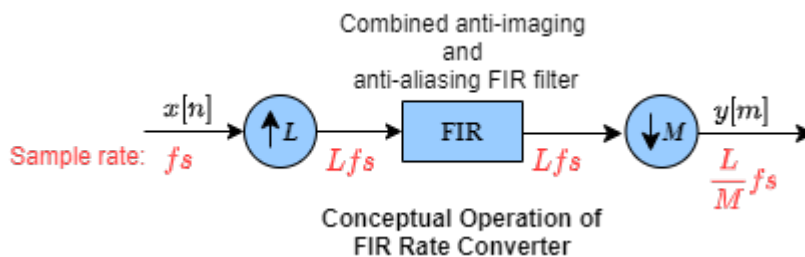

Perform polyphase FIR sample rate conversion

### Description

The `dsp.FIRRateConverter` System object performs an efficient polyphase sample rate conversion using a rational factor  $L/M$  along the first dimension.

The FIR rate converter cascades an interpolator with a decimator. Conceptually, the rate converter (as shown in the schematic) consists of an upsampler, followed by a combined anti-imaging and anti-aliasing FIR filter, followed by a downsampler. The coefficients of the anti-imaging and anti-aliasing FIR filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. For an example, see “Resample Signal Using FIR Rate Converter” on page 4-576.

The upsampler increases the sample rate of the signal by a factor  $L$  and the downsampler reduces the sample rate of the signal by a factor  $M$ . Use upsampling and downsampling factors that are relatively prime or coprime. The resulting discrete-time signal has a sample rate that is  $L/M$  times the original sample rate.

Note that the actual object algorithm implements a polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 4-581.

To perform sampling rate conversion:

- 1 Create the `dsp.FIRRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
firrc = dsp.FIRRateConverter
firrc = dsp.FIRRateConverter(L,M)
firrc = dsp.FIRRateConverter(L,M,'Auto')
```

```

firrc = dsp.FIRRateConverter(L,M,num)
firrc = dsp.FIRRateConverter(L,M,method)
firrc = dsp.FIRRateConverter( ____,Name,Value)
firrc = dsp.FIRRateConverter(L,M,'legacy')

```

## Description

`firrc = dsp.FIRRateConverter` returns an FIR sample rate converter object with an interpolation factor of 3 and a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(3,2)` function.

`firrc = dsp.FIRRateConverter(L,M)` returns an FIR sample rate converter with the integer-valued `InterpolationFactor` property set to `L` and the `DecimationFactor` property set to `M`. The object designs its filter coefficients based on the rate conversion factors that you specify while creating the object, using the `designMultirateFIR(L,M)` function. The designed filter corresponds to a lowpass filter with normalized cutoff frequency no greater than  $\min(\pi/L, \pi/M)$  in radial frequency units.

`firrc = dsp.FIRRateConverter(L,M,'Auto')` returns an FIR sample rate converter where the `NumeratorSource` property is set to `'Auto'`. In this mode, every time there is an update in the rate conversion factors, the object redesigns the filter using the design method specified in `DesignMethod`.

`firrc = dsp.FIRRateConverter(L,M,num)` returns an FIR sample rate converter with the `Numerator` property set to `num`.

`firrc = dsp.FIRRateConverter(L,M,method)` returns an FIR sample rate converter with the `DesignMethod` property set to `method`. When you pass the design method as an input, the `NumeratorSource` property is automatically set to `'Auto'`.

`firrc = dsp.FIRRateConverter( ____,Name,Value)` returns an FIR sample rate converter with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `firrc = dsp.FIRRateConverter('FullPrecisionOverride','false')` enables the fixed-point data types to be controlled through the individual fixed-point property settings.

`firrc = dsp.FIRRateConverter(L,M,'legacy')` returns an FIR sample rate converter where the filter coefficients are designed using `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`. The designed filter has a cutoff frequency of  $\pi/3$  radians/sample.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Main Properties

#### InterpolationFactor — Interpolation factor

3 (default) | positive integer

Interpolation factor  $L$ , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **DecimationFactor — Decimation factor**

2 (default) | positive integer

Decimation factor  $M$ , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **NumeratorSource — FIR filter coefficient source**

'Property' (default) | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

#### **Numerator — FIR filter coefficients**

`designMultirateFIR(L,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of  $z^{-1}$ .

The following equation defines the transfer function of the filter:

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector  $\mathbf{b} = [b(0), b(1), \dots, b(N)]$  represents the vector of filter coefficients.

Use a lowpass filter with normalized cutoff frequency no greater than  $\min(1/L, 1/M)$ , where  $L$  is the interpolation factor and  $M$  is the decimation factor. The gain of the lowpass filter should equal  $L$ , the interpolation factor. Choose the length of the filter to be a multiple of the interpolation factor. To design such a filter, use the `designMultirateFIR` function. For an example, see "Resample Signal Using FIR Rate Converter" on page 4-576. All initial filter states are zero.

#### **Dependencies**

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **DesignMethod — Auto design method**

'Kaiser' (default) | 'ZOH' | 'Linear'

Design method of the FIR filter coefficients, specified as one of the following:

- 'Kaiser' -- Kaiser method. Approximate combined anti-aliasing and anti-imaging lowpass filter using the `designMultirateFIR` function.

- 'ZOH' -- Zero order hold method. Hold the input sequence values.
- 'Linear' -- Linear interpolation method.

### Dependencies

This property is visible only when you set the `NumeratorSource` property to 'Auto', or if you pass the 'auto' keyword as an input while creating the object.

### Code Generation Properties

#### AllowArbitraryInputLength — Allow arbitrary input length in generated code

false (default) | true

Allow arbitrary frame length for fixed-size input signals in the generated code, specified as true or false. When you specify:

- true -- The input frame length does not have to be a multiple of the decimation factor. The output of the object in the generated code is a variable-size array.
- false -- The input frame length must be a multiple of the decimation factor.

When you specify variable-size signals, the input frame length can be arbitrary and the object ignores this property in the generated code. When you run this object in MATLAB, the object supports arbitrary input frame lengths for fixed-size and variable-size signals and this property does not affect the object behavior.

Data Types: logical

### Fixed-Point Properties

#### FullPrecisionOverride — Full precision override for fixed-point arithmetic

true (default) | false

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

#### RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |.

### Dependencies

This property applies only if the object is not in full precision mode.

#### OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as one of | Wrap | Saturate |.

**Dependencies**

This property applies only if the object is not in full precision mode.

**CoefficientsDataType — Word and fraction lengths of filter coefficients**

Same word length as input (default) | Custom

Specify the filter coefficient fixed-point data type as one of | Same word length as input | Custom |.

**CustomCoefficientsDataType — Word and fraction lengths of filter coefficients**

numerictype([],16,15) (default) | numerictype

Specify the filter coefficient fixed-point type as a numerictype object with a Signedness of Auto.

**Dependencies**

This property applies only when the CoefficientsDataType property is Custom.

**ProductDataType — Product word and fraction lengths**

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |.

**CustomProductDataType — Product word and fraction lengths**

numerictype([],32,30) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

**Dependencies**

This property applies only when the ProductDataType property is Custom.

**AccumulatorDataType — Accumulator word and fraction lengths**

Full precision (default) | Same as product | Same as input | Custom

Specify the accumulator fixed-point data type as one of | Full precision | Same as product | Same as input | Custom |.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

numerictype([],32,30) (default) | numerictype

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto.

**Dependencies**

This property applies only when the AccumulatorDataType property is Custom.

**OutputDataType — Output word and fraction lengths**

Same as accumulator (default) | Same as product | Same as input | Custom

Specify the output fixed-point data type as one of | Same as accumulator | Same as product | Same as input | Custom |.

**CustomOutputDataType — Output word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the output fixed-point type as a scaled numeric type object with a Signedness of Auto.

### Dependencies

This property applies only when the OutputDataType property is Custom.

## Usage

### Syntax

```
y = firrc(x)
```

### Description

`y = firrc(x)` resamples the input `x` and returns the resampled signal `y`.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix of size  $P$ -by- $Q$ . The columns in the input signal represent  $Q$  independent channels.

Under most conditions, the number of inputs rows  $P$  can be arbitrary and does not have to be a multiple of the DecimationFactor property. See this table for details.

| Input Signal  | When you Run Object in MATLAB                | When you Generate Code Using MATLAB Coder   |
|---------------|--|---|
| Fixed-size    | Object supports arbitrary input frame length | Object supports arbitrary input frame length when you set AllowArbitraryInputLength to true while generating code |
| Variable-size | Object supports arbitrary input frame length | Object supports arbitrary input frame length  |

Variable-size signals change in frame length once you lock the object while the fixed-size signals remain constant. When the object does not support arbitrary frame length, the input frame length must be a multiple of the DecimationFactor property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Output Arguments

#### **y** — Resampled output

column vector | matrix

Resampled output, returned as a column vector or a matrix. When the input is of size  $P$ -by- $Q$ , and  $P$  is not a multiple of the decimation factor  $M$ , the output signal has an upper bound size of  $\text{ceil}(LP/M)$ -by- $Q$ . If  $P$  is a multiple of the decimation factor, then the output is of size  $(LP/M)$ -by- $Q$ .

The number of rows in the output signal is given by  $LP/M$ , where  $P$  is the number of input rows,  $L$  is the interpolation factor, and  $M$  is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.FIRRateConverter`

|                          |   |
|--------------------------|---|
| <code>freqz</code>       | Frequency response of discrete-time filter System object                      |
| <code>fvtool</code>      | Visualize frequency response of DSP filters                                   |
| <code>info</code>        | Information about filter System object  |
| <code>cost</code>        | Estimate cost of implementing filter System object                            |
| <code>coeffs</code>      | Returns the filter System object coefficients in a structure                  |
| <code>polyphase</code>   | Polyphase decomposition of multirate filter                                   |
| <code>generatehdl</code> | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Resample Signal Using FIR Rate Converter

Resample a 100 Hz sine wave signal by a factor of 3/2.

Create a `dsp.SineWave` object which generates a sinusoidal signal with 54 samples per frame, contains a tone at 100 Hz, and has a sample rate of 1250 Hz.

```
sine = dsp.SineWave(1,100, 'SampleRate',1250, 'SamplesPerFrame',54);
```

```
% Grab a frame
```

```
x = sine();
```

```
% Calculate input time vector
```

```
tx = (0:length(x)-1)/sine.SampleRate;
```

### Design Default Filter

Create a `dsp.FIRRateConverter` object. The object uses a combined anti-imaging and anti-aliasing FIR filter. By default, this filter is designed using the `designMultirateFIR` function. The function designs the filter based on the rate conversion factors that you specify, and stores the coefficients in the `Numerator` property. For an interpolation factor of 3 and a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(3,2)`.

```
firrc = dsp.FIRRateConverter(3,2);
```

### Resample by a Factor of 3/2

Resample the signal by a factor of 3/2.

```
y = firrc(x);
```

Plot the original and resampled signals. In order to plot the two signals on the same plot, you must account for the output delay of the FIR rate converter and the scaling introduced by the filter. Use the `outputDelay` function to compute the delay value introduced by the rate converter. Shift the output by this delay value.

Visualize the input and the resampled signals. The input and output values coincide every 3 output samples, and every other input sample, owing to the conversion rate of 3/2.

```
FsIn = sine.SampleRate;
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector y in input units
ty = (0:length(y)-1)/FsOut-delay;

stem(tx,x,'filled',MarkerSize=4)
hold on
stem(ty,y)
hold off
xlim([0.0 0.0145])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

### Resample by a Factor of 5/3 in Automatic Filter Design Mode

Now change the interpolation factor to 5 and the decimation factor to 3. In order for the filter design to be updated automatically based on the new rate conversion factors, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the rate conversion factors, the object updates the filter design accordingly.

```
release(firrc)
firrc.NumeratorSource = 'Auto';
firrc.InterpolationFactor = 5;
firrc.DecimationFactor = 3

firrc =
    dsp.FIRRateConverter with properties:

    Main
        InterpolationFactor: 5
        DecimationFactor: 3
        NumeratorSource: 'Auto'
        DesignMethod: 'Kaiser'

    Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firrc.Numerator` in the MATLAB command prompt.

Resample the signal with the updated rate conversion values.

```
yAuto = firrc(x);
```

Plot the original and resampled signals. Recalculate the output delay and the output sample rate since the rate conversion factors have changed. Note that the input and output coincide every 3 input samples, and every 5 output samples, owing to the 5/3 conversion factor.

```
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector yAuto in input units
tyAuto = (0:length(yAuto)-1)/FsOut-delay;

stem(tx,x,'filled',MarkerSize=4)
hold on
stem(tyAuto,yAuto,'r')
hold off
xlim([0.0 0.015])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

### Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

Set `DesignMethod` to `'linear'` and change the interpolation factor to 11.

```
release(firrc)
firrc.DesignMethod = 'linear';
firrc.InterpolationFactor = 11;
```

Resample the signal using the linear interpolation model.

```
yLinear = firrc(x);
```

Plot the original and resampled signals. The output samples lie on a piecewise-linear curve. Note that the input and output coincide every three input samples and every 11 output samples as expected from the ratio 11/3.

```
[delay,FsOut] = outputDelay(firrc,FsIn=FsIn);
% Calculate output times for vector yLinear in input units
tyLinear = (0:length(yLinear)-1)/FsOut-delay;
```

```
stem(tx,x,'filled',MarkerSize=4)
hold on
stem(tyLinear,yLinear)
plot(tyLinear,yLinear,Color=[1 0 0 0.3])
hold off
```

```
xlim([0.0 0.009])
ylim([-1.5 1.5])
legend('Original input','Resampled')
```

### Resample and Play Audio Signal

Resample an audio signal from 48 kHz to 44 kHz and play the resampled signal using the `audioDeviceWriter` object.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The object reads an audio file that has a sample rate of 48 kHz.

```
L = 11;
M = 12;
afr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType','single', ...
    'SamplesPerFrame',4*M);
```

Create a `dsp.FIRRateConverter` object with an interpolation factor of  $L = 11$  and a decimation factor of  $M = 12$  (the co-prime representation of the ratio  $44k/48k$ ), a reasonable approximation of the standard 44.1 kHz rate. The object designs the filter using `designMultirateFIR(11,12)` and stores the coefficients in the `Numerator` property of the object.

```
firrc = dsp.FIRRateConverter(L,M)
```

```
firrc =
  dsp.FIRRateConverter with properties:

  Main
    InterpolationFactor: 11
    DecimationFactor: 12
    NumeratorSource: 'Property'
    Numerator: [0 2.3076e-05 5.4790e-05 9.3620e-05 1.3665e-04 1.7959e-04 2.1699e-04 2.4...
```

Show all properties

Create an `audioDeviceWriter` object. Specify the sample rate to be 44100 Hz.

```
adw = audioDeviceWriter(44100);
```

Read the audio file, convert the sample rate of the audio signal, and play the resampled audio.

```
while ~isDone(afr)
    audio1 = afr();
    audio2 = firrc(audio1);
    adw(audio2);
end
release(afr)
release(adw)
```

## Algorithms

The FIR rate converter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter: This FIR filter is a combined anti-imaging and anti-aliasing filter.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$  is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\ & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\ & \quad \vdots \\ & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)}) \end{aligned}$$

$L$  is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$  are polyphase components of the FIR filter  $H(z)$ .

Conceptually, the FIR rate converter contains an upsampler, followed by a combined anti-imaging, anti-aliasing FIR filter  $H(z)$ , which is followed by a downsampler.

Replace  $H(z)$  with its polyphase representation.

Here is the multirate noble identity for interpolation.

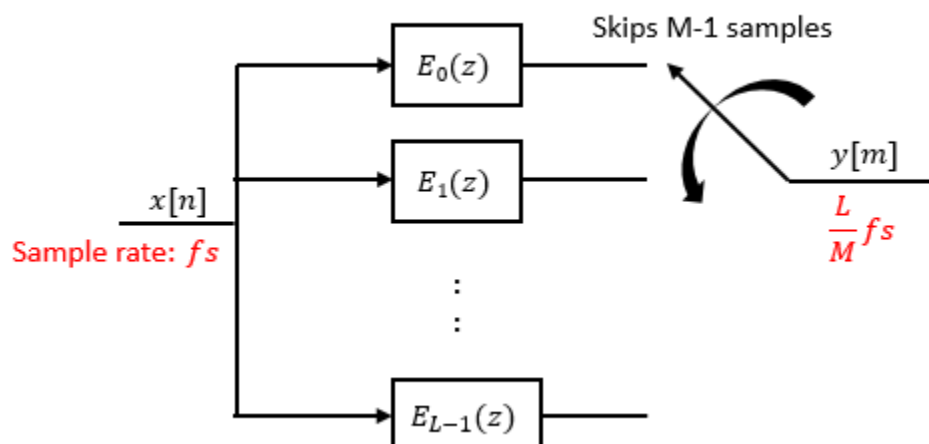

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and the adder with a commutator switch. To account for the downsampler that follows, the switch moves in steps of size  $M$ . The switch receives the first sample from branch 0 and moves in the counter clockwise direction, each time skipping  $M-1$  branches.

As an example, consider a rate converter with  $L$  set to 5 and  $M$  set to 3. The polyphase components are  $E_0(z)$ ,  $E_1(z)$ ,  $E_2(z)$ ,  $E_3(z)$ , and  $E_4(z)$ . The switch starts on the first branch 0, skips branches 1 and 2, receives the next sample from branch 3, then skips branches 4 and 0, receives the next sample from branch 2, and so on. The sequence of branches from which the switch receives the data sample is [0, 3, 1, 4, 2, 0, 3, 1, ...].

The rate converter implements the  $L/M$  conversion by first applying the interpolation factor  $L$  to the incoming data, and using the commutator switch at the end to receive only 1 in  $M$  samples, effectively accounting for the downsampling factor  $M$ . Hence, the sample rate at the output of the FIR rate converter is  $Lfs/M$ .

## Version History

Introduced in R2012a

### **R2022b: Support for arbitrary input frame length**

Starting in R2022b, this object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the decimation factor.

When you generate code, to support arbitrary frame length for fixed-size signals, you must set the `AllowArbitraryInputLength` property to `true` while generating code.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

**Package:** dsp

Compute output, error, and coefficients using frequency-domain FIR adaptive filter

## Description

The `dsp.FrequencyDomainAdaptiveFilter` System object implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The “Length” on page 4-0 and the “BlockLength” on page 4-0 properties specify the filter length and the block length values the algorithm uses. The “FFTCoefficients” on page 4-0 property contains the discrete Fourier transform of the current filter coefficients. The object offers the constrained and unconstrained versions of the algorithm with partitioned and non-partitioned modes. For details, see “Algorithms” on page 4-598.

To filter a signal using frequency-domain FIR adaptive filter:

- 1 Create the `dsp.FrequencyDomainAdaptiveFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
fdaf = dsp.FrequencyDomainAdaptiveFilter
fdaf = dsp.FrequencyDomainAdaptiveFilter(len)
fdaf = dsp.FrequencyDomainAdaptiveFilter( ___,Name,Value)
```

### Description

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(len)` returns a frequency domain FIR adaptive filter object with the `Length` property set to `len`.

`fdaf = dsp.FrequencyDomainAdaptiveFilter( ___,Name,Value)` returns a frequency domain FIR adaptive filter object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',0.1)` models a frequency-domain adaptive filter with a length of 32 taps and a step size of 0.1.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Method — Method to calculate filter coefficients

'Constrained FDAF' (default) | 'Unconstrained FDAF' | 'Partitioned constrained FDAF' | 'Partitioned unconstrained FDAF'

Method used to calculate the filter coefficients, specified as:

- 'Constrained FDAF' -- Imposes a gradient constraint on the filter tap weights.
- 'Unconstrained FDAF' -- No gradient constraint is imposed on the filter tap weights.
- 'Partitioned constrained FDAF' -- Partitions the impulse response of the filter to reduce latency.
- 'Partitioned unconstrained FDAF' -- Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 4-598.

### Length — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### BlockLength — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficient updates, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this property. For details on how this data is processed by the filter, see “Algorithms” on page 4-598. The length of the input vector must be divisible by the `BlockLength` property value. The default value of the `BlockLength` property is set to the value of the `Length` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### StepSize — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is 1, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **LeakageFactor — Adaptation leakage factor**

1 (default) | scalar in the range [0,1]

Leakage factor used when implementing a leaky adaptive filter, specified as a scalar numeric value in the range [0,1]. When the value is less than 1, the System object implements a leaky adaptive algorithm. When the value is 1, the object provides no leakage in the adapting method.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **AveragingFactor — Averaging factor for signal power**

0.9 (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Offset — Offset for normalization terms**

0 (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. This property value is used to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **InitialPower — Initial FFT input signal power**

1 (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar.

If you change this value once the object is locked, the change takes effect only after you reset the object.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **InitialCoefficients — Initial time-domain coefficients of filter**

0 (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value once the object is locked, the change takes effect only after you reset the object.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **LockCoefficients — Locked status of coefficient updates**

`false` (default) | `true`

Locked status of the coefficient updates, specified as:

- `false` -- The object continuously updates the filter coefficients.
- `true` -- The filter coefficients do not get updated and their values remain at the current value.

**Tunable:** Yes

Data Types: `logical`

### **FFTCoefficients — Current FFT coefficients of filter**

`[]` (default) | row vector

This property is read-only.

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For 'Constrained FDAF' and 'Unconstrained FDAF' algorithms, the length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Data Types: `single` | `double`

Complex Number Support: Yes

## **Usage**

### **Syntax**

```
[y,err] = fdaf(x,d)
```

### **Description**

`[y,err] = fdaf(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. The FFT of these filter weights can be obtained by accessing the `FFTCoefficients` property after calling the object algorithm.

### **Input Arguments**

#### **x — Data input**

column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The input, `x`, and the desired signal, `d`, must have the same size and data type. The length of the input vector must be divisible by the “`BlockLength`” on page 4-0 property value.

The input,  $x$ , can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

### **d — Desired signal**

column vector

The frequency domain adaptive filter adapts its filter weights to minimize the error, `err`, and converge the input signal,  $x$ , to the desired signal,  $d$ , as closely as possible.

The input signal and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the `BlockLength` property value.

The input signal can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

### **Output Arguments**

#### **y — Filtered output**

column vector

Filtered output, returned as a column vector. The object adapts its filter weights to converge the input signal,  $x$ , to match the desired signal,  $d$ . The filter outputs the converged signal.

Data Types: `single` | `double`

#### **err — Difference between output and desired signal**

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how `err` is computed, see [2].

Data Types: `single` | `double`

Complex Number Support: Yes

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### QPSK Adaptive Equalization With FIR Filter

Transmit a quadrature phase shift keying (QPSK) signal across a noisy transmission channel. Minimize the noise in the received signal using a frequency-domain adaptive filter.

The QPSK signal,  $s$ , is transmitted across a noisy channel. The numerator and the denominator coefficients of the channel are contained in the vectors  $b$  and  $a$ , respectively. The received signal,  $r$ , obtained at the end of the transmission channel contains the transmitted QPSK signal and the noise added to the channel,  $n$ . The adaptive filter is used to extract the QPSK signal from the received noisy input. The desired signal,  $d$ , is the delayed version of the QPSK signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1024;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Create a `dsp.FrequencyDomainAdaptiveFilter` object to model a frequency-domain adaptive filter of length 32 taps and a step size of 0.1. The adaptive filter accepts the delayed version of the received signal and the desired signal as inputs. The output of the adaptive filter is compared to the desired signal. The error between the two signals represents the noise added to the transmission channel. The adaptive filter updates its coefficients until this error becomes minimal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the `FFTCoefficients` property of this object.

```
mu = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients

fftCoeffs = 1x64 complex

    0.6802 - 0.6847i  -0.2485 - 0.9427i  -0.9675 - 0.2123i  -0.5605 + 0.8002i   0.5748 + 0.7593i
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
plot(1:ntr,real([d;y;e]))
legend('Desired','Output','Error')
title('In-Phase Components')
xlabel('Time Index'); ylabel('signal value')
```

```
plot(1:ntr,imag([d;y;e]))  
legend('Desired','Output','Error')  
title('Quadrature Components')  
xlabel('Time Index')  
ylabel('signal value')
```

Create scatter plots of the received signal and the desired signal.

```
plot(x(ntr-100:ntr),'.')
axis([-3 3 -3 3])
title('Received Signal Scatter Plot')
axis('square')
xlabel('Real[x]')
ylabel('Imag[x]')
grid on
```

```
plot(d(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Desired Signal Scatter Plot')  
axis('square')  
xlabel('Real[y]')  
ylabel('Imag[y]')  
grid on
```

The adaptive filter equalizes the received signal to eliminate noise. Plot the scatter plot of the equalized signal.

```
plot(y(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Equalized Signal Scatter Plot')  
axis('square')  
xlabel('Real[y]')  
ylabel('Imag[y]')  
grid on
```

### Estimate Coefficients of long FIR Filter using Frequency-Domain Adaptive Filter

Use a frequency-domain adaptive filter to estimate the coefficients of a long FIR filter. The FIR filter models the impulse response of a room. Use the partitioned mode in the frequency-domain adaptive filter to reduce filter latency.

**Note:** This example runs only in R2018a or later.

#### Initialization

Generate a long FIR impulse response of 8192 samples and assign the impulse response to a `dsp.FIRFilter` object, `room`. This object models the impulse response of a room. Create a `dsp.FrequencyDomainAdaptiveFilter` filter, `lmsfilt`, in partitioned constrained mode. Set the length of the filter to one-fourth the length of the impulse response of the room. Set the block length of the filter to 128 samples. Set the step size to 0.025, initial power to 0.01, averaging factor to 0.98, offset to 1, and the leakage factor to 1. Initialize a `dsp.ArrayPlot` object to view the filter coefficients. Initialize a `timescope` object to show the mean-squared error between the filter output and the desired signal.

```
fs = 16e3;
m = 8192;
[b,a] = cheby2(4,20,[0.1 0.7]);
impulseResponseGenerator = dsp.IIRFilter(...
    'Numerator', [zeros(1,6) b], ...
```

```

    'Denominator', a);
roomImpulseResponse = impulseResponseGenerator( ...
    (log(0.99*rand(1,m)+0.01).*sign(randn(1,m)).*exp(-0.002*(1:m)))');
roomImpulseResponse = roomImpulseResponse/norm(roomImpulseResponse);
room = dsp.FIRFilter('Numerator',roomImpulseResponse');

lmsfilt = dsp.FrequencyDomainAdaptiveFilter(...
    'Method','Partitioned constrained FDAF',...
    'Length',m/4, ...
    'BlockLength',128,...
    'StepSize',0.025, ...
    'InitialPower',0.01, ...
    'AveragingFactor',0.98,...
    'Offset',1,...
    'LeakageFactor',1);

FrameSize = lmsfilt.BlockLength; NIter = 2000;

AP = dsp.ArrayPlot('YLimits',[-0.2 .2],'ShowLegend',true, ...
    'Position',[0 0 560 420],'ChannelNames', ...
    {'Actual Coefficients','Estimated Coefficients'});

TS = timescope('SampleRate',fs,'TimeSpanSource','property',...
    'TimeSpan',FrameSize*NIter/fs,...
    'TimeUnits','Seconds',...
    'YLimits',[-50 0],'Title','Learning curve',...
    'YLabel','dB', ...
    'BufferLength',FrameSize*NIter,...
    'ShowGrid',true);

signalmean = dsp.MovingAverage('SpecifyWindowLength',false);

```

### Streaming

Generate a random input signal using the `randn` function. The frame size of the input matches the block length of the adaptive filter. The desired signal is the sum of the output of the FIR filter (`room`) and a white Gaussian noise signal. Pass the input signal and the desired signal to the adaptive filter. Compute the adaptive filter output and the error between the output and the desired signal.

Estimate the time-domain coefficients of the adaptive filter by taking the IFFT of the frequency-domain coefficients vector returned by the `lmsfilt.FFTCoefficients` property. Compare the estimated coefficients with the actual coefficients assigned to the FIR filter (`room`). Once the adaptive filter has converged its output to the desired signal, and minimized the error signal, the estimated coefficients match closely with the actual coefficients. This means that the adaptive filter has successfully adapted itself to model the impulse response of the FIR filter (`room`).

```

for k = 1:NIter
    x = randn(FrameSize,1);
    d = room(x) + 0.01*randn(FrameSize,1);
    [y,e] = lmsfilt(x,d);
    FFTCoeffs = lmsfilt.FFTCoefficients;
    w = ifft(FFTCoeffs,[],2,'symmetric');
    w = w(:,1:FrameSize) + w(:,FrameSize+1:end);
    w = reshape(w.',1,m/4);
    AP([roomImpulseResponse(1:m/4),w.']);
    TS(10*log10(signalmean(abs(e).^2)));
end

```

As the filter adapts with time, you can see in the time scope that the mean-squared error becomes minimal. Simultaneously, the estimated coefficients match the actual coefficients closely in the array plot.

## Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the "Algorithms" on page 4-611 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

### Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.

where:

- $N$  -- Filter length
- $L$  -- Block length
- $\mu$  -- Step size parameter
- $x(n)$  -- Input signal
- $X(k)$  -- Transformed input signal in the frequency domain
- $d(n)$  -- Desired signal
- $e(n)$  -- Error between the desired signal and the filter output
- $E(k)$  -- Transformed error signal in the frequency domain
- $W(k)$  -- Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

## Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

## Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

**Package:** dsp

Filter input signal in frequency domain

## **Description**

The `dsp.FrequencyDomainFIRFilter` System object implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering is efficient when the impulse response is very long. You can specify the filter coefficients directly in the frequency domain by setting `NumeratorDomain` to 'Frequency'.

This object uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the `dsp.FrequencyDomainFIRFilter` object partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, set the "PartitionForReducedLatency" on page 4-0 property to `true`. For more details on these two methods and on reducing latency through impulse response partitioning, see "Algorithms" on page 4-611.

To filter the input signal in the frequency domain:

- 1 Create the `dsp.FrequencyDomainFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
fdf = dsp.FrequencyDomainFIRFilter
fdf = dsp.FrequencyDomainFIRFilter(num)
fdf = dsp.FrequencyDomainFIRFilter(Name,Value)
```

### **Description**

`fdf = dsp.FrequencyDomainFIRFilter` creates a frequency domain FIR filter System object that filters each channel of the input signal independently over time in the frequency domain using the overlap-save or overlap-add method.

`fdf = dsp.FrequencyDomainFIRFilter(num)` creates a frequency domain FIR filter object with the "Numerator" on page 4-0 property set to `num`.

Example: `dsp.FrequencyDomainFIRFilter(fir1(400,2 * 2000 / 8000));`

`fdf = dsp.FrequencyDomainFIRFilter(Name, Value)` creates a frequency domain FIR filter System object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.FrequencyDomainFIRFilter('Method', 'Overlap-add');`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Method — Frequency-domain filter method

'Overlap-save' (default) | 'Overlap-add'

Frequency-domain filter method, specified as either 'Overlap-save' or 'Overlap-add'. For more details on these two methods, see “Algorithms” on page 4-611.

### NumeratorDomain — Numerator domain

'Time' (default) | 'Frequency'

Domain of the filter coefficients, specified as one of the following:

- 'Time' -- Specify the time-domain filter numerator in the Numerator property.
- 'Frequency' -- Specify the filter's frequency response in the FrequencyResponse property.

### Numerator — FIR filter coefficients

`fir1(100, 0.3)` (default) | row vector

FIR filter coefficients, specified as a row vector.

**Tunable:** Yes

#### Dependencies

This property applies when NumeratorDomain is set to 'Time'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`  
Complex Number Support: Yes

### FrequencyResponse — Filter frequency response

`fft(fir1(100, 0.3), 202)` (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When `PartitionForReducedLatency` is `false`, `FrequencyResponse` must be a row vector. The FFT length is equal to the length of the `FrequencyResponse` vector. When `PartitionForReducedLatency` is `true`, `FrequencyResponse` must be a  $2P$ -by- $N$  matrix, where  $P$  is the partition size, and  $N$  is the number of partitions.

**Tunable:** Yes

**Dependencies**

This property applies when `NumeratorDomain` is set to 'Frequency'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`  
Complex Number Support: Yes

**NumeratorLength — Time-domain numerator length**

101 (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

**Dependencies**

This property applies when `NumeratorDomain` is set to 'Frequency' and `PartitionForReducedLatency` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**FilterIsReal — Flag to specify if filter is real**

`true` (default) | `false`

Flag to specify if the filter coefficients are all real, specified as `true` or `false`.

**Dependencies**

This property applies when `NumeratorDomain` is set to 'Frequency'.

**PartitionForReducedLatency — Flag to partition numerator to reduce latency**

`false` (default) | `true`

Flag to partition numerator to reduce latency, specified as one of the following:

- `false` -- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is “`FFTLength`” on page 4-0 - `length(“Numerator” on page 4-0 ) + 1`.
- `true` -- In this mode, the object partitions the numerator into segments of length specified by the “`PartitionLength`” on page 4-0 property. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

**FFTLength — FFT length**

[ ] (default) | positive integer

FFT length, specified as a positive integer. The default value of this property, [ ], indicates that the FFT length is equal to twice the numerator length. The FFT length must be greater than or equal to the numerator length.

Example: 64

**Dependencies**

This property applies when you set `NumeratorDomain` property to 'Time' and “`PartitionForReducedLatency`” on page 4-0 property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**PartitionLength — Numerator partition length**

32 (default) | positive integer

Numerator partition length, specified as a positive integer less than or equal to the length of the numerator.

Example: 40

Example: 60

### Dependencies

This property applies when you set the `NumeratorDomain` property to 'Time' and "PartitionForReducedLatency" on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Latency — Filter latency

102 (default) | positive integer

This property is read-only.

Filter latency in samples, returned as an integer greater than 0. When "PartitionForReducedLatency" on page 4-0 is `false`, the latency is equal to "FFTLength" on page 4-0 - length("Numerator" on page 4-0) + 1. When `PartitionForReducedLatency` is `true`, the latency is equal to the partition length.

Data Types: `uint32`

## Usage

### Syntax

```
fdfOut = fdf(input)
```

### Description

`fdfOut = fdf(input)` filters the input signal and outputs the filtered signal. The object filters each channel of the input signal independently over time in the frequency domain.

### Input Arguments

#### input — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(164,4)`

Data Types: `single` | `double`

### Output Arguments

#### fdfOut — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.FrequencyDomainFIRFilter`

`fvtool` Visualize frequency response of DSP filters

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Frequency Domain Filtering Using Overlap-Add and Overlap-Save

Filter input signal using overlap-add and overlap-save methods, and compare the outputs to the output of a FIR filter.

#### Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The impulse response has a length of 400.

```
impL = 400;  
Fs = 8000;  
Fcutoff = 2000;  
imp = fir1(impL, 2*Fcutoff/Fs);
```

Create two `dsp.FrequencyDomainFIRFilter` objects and a `dsp.FIRFilter` object. Set the numerator of all the three filters to `imp`. Delay the FIR output by the latency of the frequency-domain filter.

```
fdf0A = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-add');  
fdf0S = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');  
fir = dsp.FIRFilter('Numerator', imp);  
dly = dsp.Delay('Length', fdf0A.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```
frameLen = 256;  
sin_100Hz = dsp.SineWave('Frequency', 100, 'SampleRate', Fs, ...  
    'SamplesPerFrame', frameLen);
```

```

sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = timescope('TimeSpanOvverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Overlap-save','Direct-form FIR'});

```

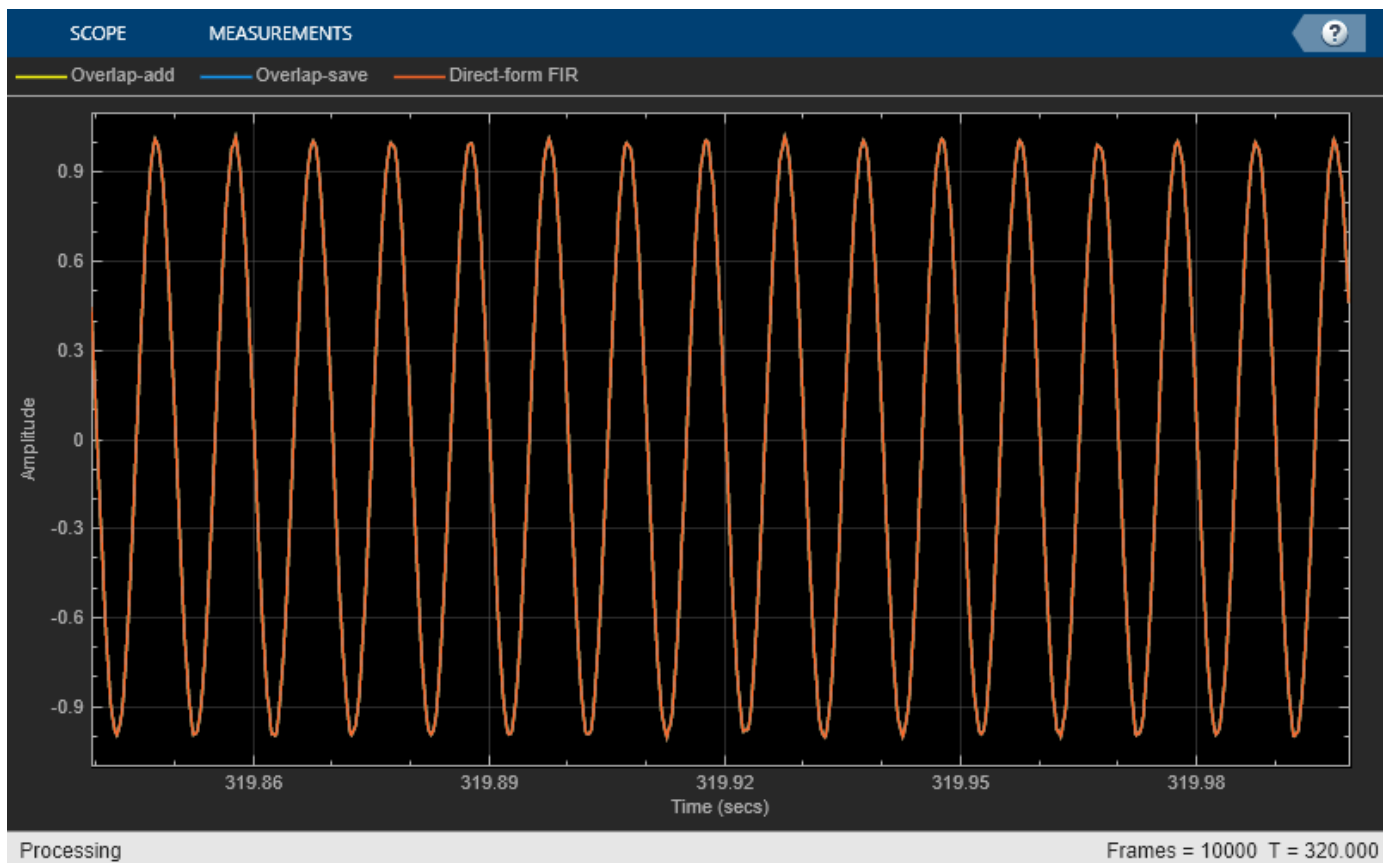

## Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency domain filters and the FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01*randn(frameLen,1);
    yOA = fdfOA(x);
    yOS = fdfOS(x);
    yFIR = fir(dly(x));
    ts([yOA,yOS,yFIR]);
end

```

The outputs of all the three filters match exactly.

## Reduce Latency Through Partitioned Numerator

Partition the impulse response length of a frequency domain FIR filter. Compare the outputs of the partitioned filter and the original filter.

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz and the cutoff frequency of the filter is 2 kHz. The impulse response is of length 4000.

```
impL    = 4000;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL, 2 * Fcutoff / Fs);
```

Create a `dsp.FrequencyDomainFIRFilter` with coefficients set to the `imp` vector. The latency of this filter is given by  $FFTLength - Length(Numerator) + 1$ , which is equal to 4002. By default, FFT length is equal to twice the numerator length. This makes the latency proportional to the impulse response length.

```
fdf0S = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');
fprintf('Frequency domain filter latency is %d samples\n', fdf0S.Latency);
```

```
Frequency domain filter latency is 4002 samples
```

Partition the impulse response to blocks of length 256. The latency after partitioning is proportional to the block length.

```
fdfRL = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save', ...
    'PartitionForReducedLatency', true, ...
    'PartitionLength', 256);
fprintf('Frequency domain filter latency is %d samples\n', fdfRL.Latency);
```

```
Frequency domain filter latency is 256 samples
```

Compare the outputs of the two frequency domain filters. The latency of `fdf0S` is 4002, and the latency of `fdfRL` is 256. To compare the two outputs, delay the input to `fdfRL` by 4002 - 256 samples.

```
dly = dsp.Delay('Length', (fdf0S.Latency - fdfRL.Latency));
```

Create two `dsp.SineWave` objects. The sine waves have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

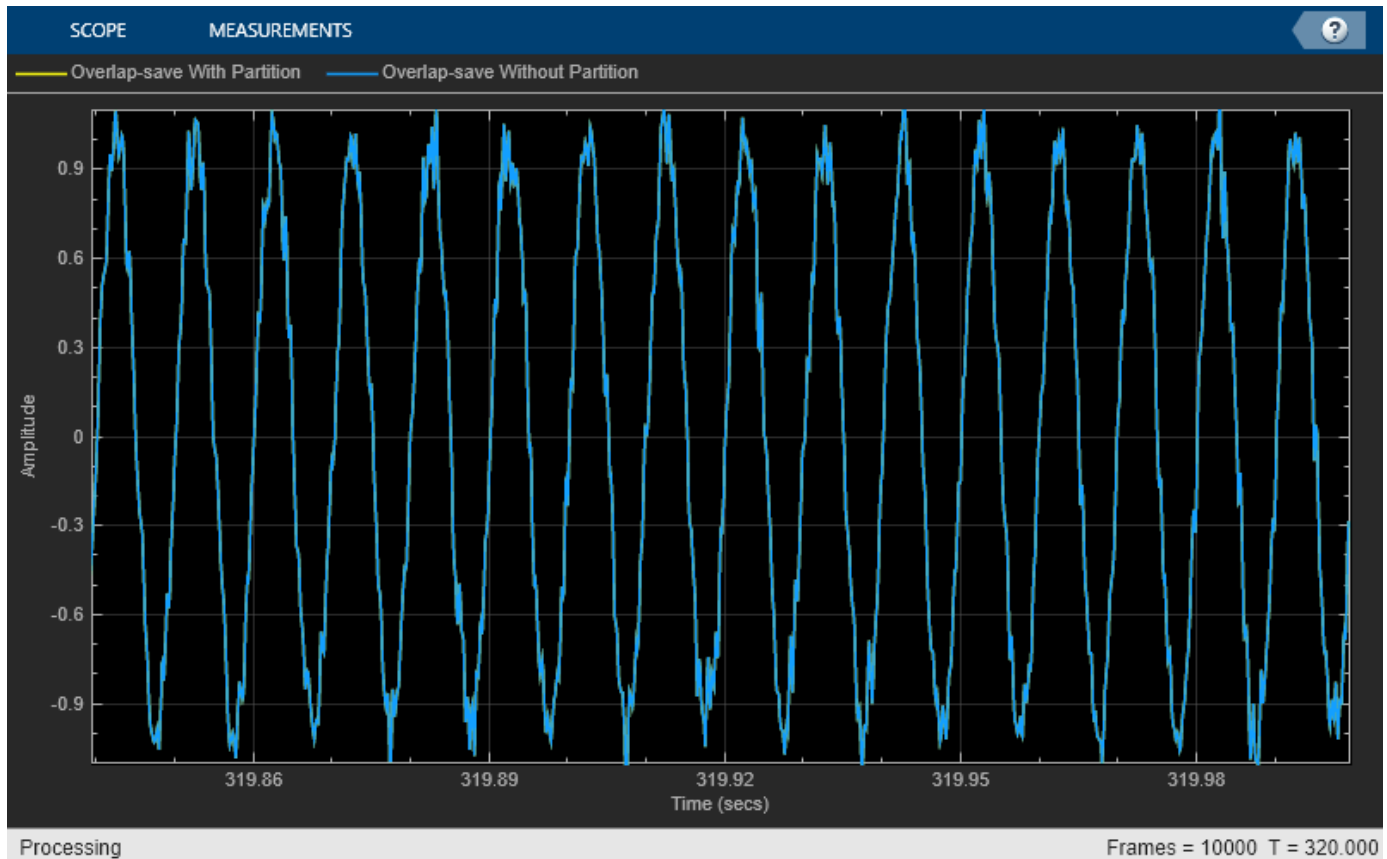

```
frameLen = 256;
sin_100Hz = dsp.SineWave('Frequency', 100, 'SampleRate', Fs, ...
    'SamplesPerFrame', frameLen);
sin_3KHz = dsp.SineWave('Frequency', 3e3, 'SampleRate', Fs, ...
    'SamplesPerFrame', frameLen);
ts = timescope('TimeSpanOvverrunAction', 'Scroll', 'ShowGrid', true, ...
    'TimeSpanSource', 'Property', 'TimeSpan', 5 * frameLen / Fs, ...
    'YLimits', [-1.1 1.1], ...
    'ShowLegend', true, ...
    'SampleRate', Fs, ...
    'ChannelNames', {'Overlap-save With Partition', 'Overlap-save Without Partition'});
```

Stream 1e4 frames of noisy input data. Pass this data through the two frequency domain filters. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + .1 * randn(frameLen,1);
    yRL = fdfRL(dly(x));
    yOS = fdfOS(x);
    ts([yRL,yOS]);
end

```

The outputs match exactly.

### Specify Frequency Response of the Frequency-Domain FIR Filter

Specify the numerator coefficients of the frequency-domain FIR filter in the frequency domain. Filter the input signal using the overlap-add method. Compare the frequency-domain FIR filter output to the corresponding time-domain FIR filter output.

#### Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The time-domain impulse response has a length of 400. Compute the FFT of this impulse response and specify this response as the frequency response of the frequency-domain FIR filter. Set the time-domain numerator length, specified by the `NumeratorLength` property, to the number of elements in the time-domain impulse response.

```

impL    = 400;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
H       = fft(imp , 2 * numel(imp));
oa      = dsp.FrequencyDomainFIRFilter('NumeratorDomain','Frequency',...
    'FrequencyResponse', H,...
    'NumeratorLength',numel(imp),...
    'Method','overlap-add');
fprintf('Frequency domain filter latency is %d samples\n',oa.Latency);

```

```
Frequency domain filter latency is 402 samples
```

Create a `dsp.FIRFilter` System object? and specify the numerator as the time-domain coefficients computed using the `fir1` function, `imp`. Delay the FIR output by the latency of the frequency-domain FIR filter.

```

fir = dsp.FIRFilter('Numerator',imp);
dly = dsp.Delay('Length',oa.Latency);

```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```

frameLen = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);

ts = timescope('TimeSpanOvrrunAction','Scroll',...
    'ShowGrid',true,'YLimits',[-1.1 1.1],...
    'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Direct-form FIR'});

```

### Streaming

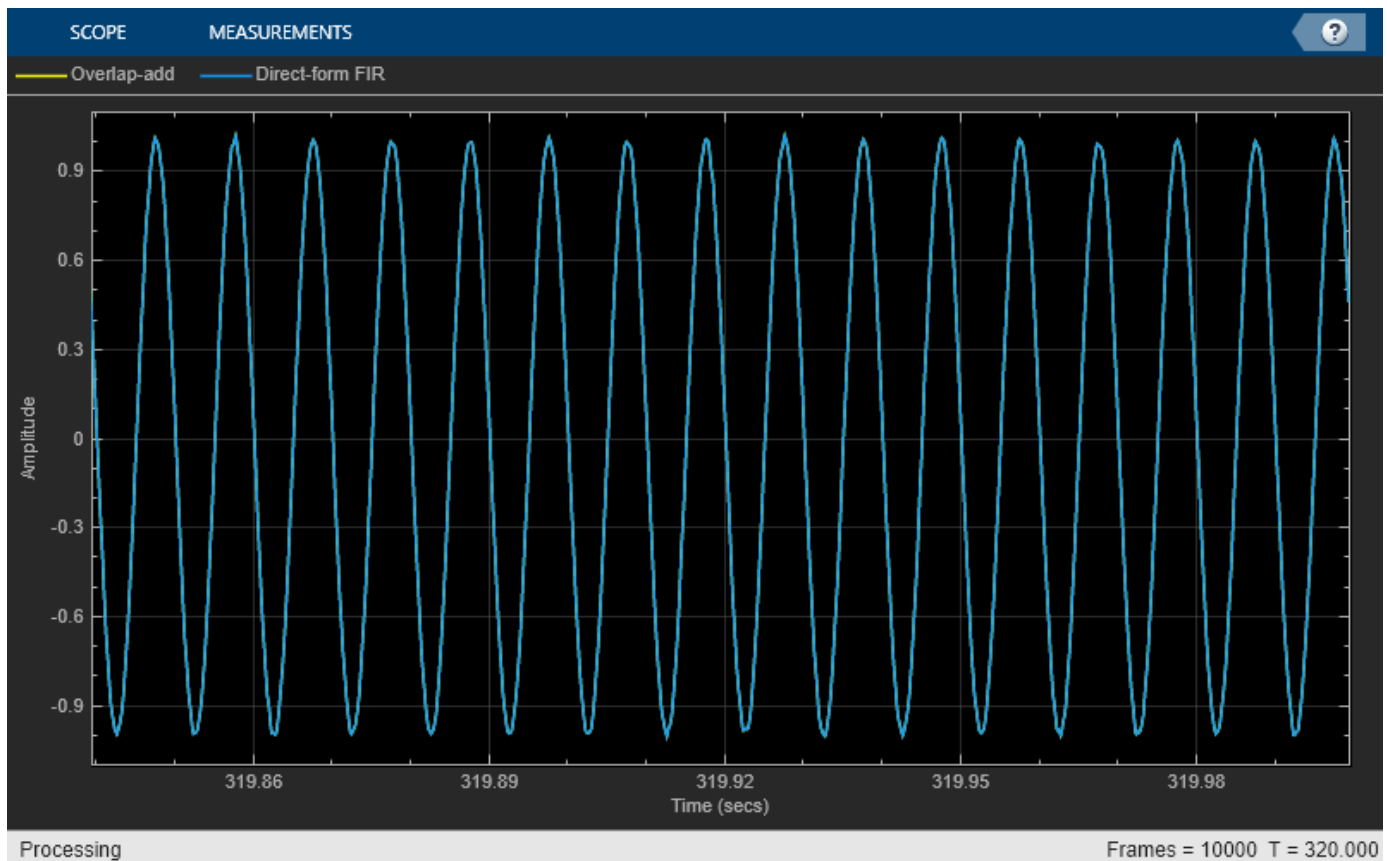

Stream 1e4 frames of noisy input data. Pass this data through the frequency-domain FIR filter and the time-domain FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01 * randn(frameLen,1);
    y1 = oa(x);
    y2 = fir(dly(x));
    ts([y1,y2]);
end

```

The outputs of both the filters match exactly.

## Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

### Overlap-Save

The overlap-save method is implemented using the following approach:

The input stream is partitioned into overlapping blocks of size  $FFTLen$ , with an overlap factor of  $NumLen - 1$  samples.  $FFTLen$  is the FFT length and  $NumLen$  is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$  FFT of

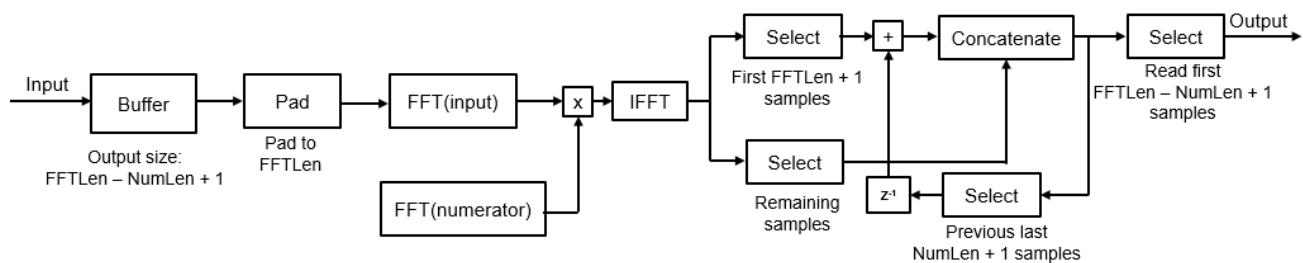

the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last  $FFTLen - NumLen + 1$  samples are saved. The remaining samples are dropped.

The latency of overlap-save is  $FFTLen - NumLen + 1$ . The first  $FFTLen - NumLen + 1$  samples are equal to zero. The filtered value of the first input sample appears as the  $FFTLen - NumLen + 2$  output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than  $NumLen$ .

### Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length  $FFLen - NumLen + 1$ , with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first  $NumLen + 1$  samples are modified by adding the values of the last  $NumLen + 1$  samples from the previous computed IFFT.

The latency of overlap-add is  $FFTLen - NumLen + 1$ . The first  $FFTLen - NumLen + 1$  samples are equal to zero. The filtered value of the first input sample appears as the  $FFTLen - NumLen + 2$  output sample.

### Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

## Version History

Introduced in R2017b

## dsp.HampelFilter

**Package:** dsp

Filter outliers using Hampel identifier

### Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and  $\frac{Len-1}{2}$  adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 4-621.

To filter the input signal using a Hampel identifier:

- 1 Create the `dsp.HampelFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
hampFilt = dsp.HampelFilter
hampFilt = dsp.HampelFilter(Len)
hampFilt = dsp.HampelFilter(Len, Lim)
hampFilt = dsp.HampelFilter(Name,Value)
```

#### Description

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

Example: `hampFilt = dsp.HampelFilter(11,2);`

`hampFilt = dsp.HampelFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

If a property is listed as *tunable*, then you can change its value even when the object is locked.

### WindowLength — Length of the sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

Data Types: `single` | `double`

### Threshold — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 4-621.

**Tunable:** Yes

Data Types: `single` | `double`

## Usage

### Syntax

```
y = hampFilt(x)
[y,isOutlier] = hampFilt(x)
```

### Description

`y = hampFilt(x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the Hampel filter.

`[y,isOutlier] = hampFilt(x)` returns a logical array, `isOutlier`, in which each true element indicates that the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. The object accepts multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$ , and  $n > 1$ .  $m$  is the number of samples in each frame (channel), and  $n$  is the

number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Filtered data

`vector` | `matrix`

Filtered data, returned as a vector or a matrix.

Data Types: `single` | `double`

#### **isOutlier** — Indicate outlier

`true` | `false`

Logical array whose elements indicate if the corresponding element in the input array is an outlier. If an element in `isOutlier` is `true`, the corresponding element in the input array is an outlier.

Data Types: `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

#### Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```
Fs = 1000;  
hampFilt = dsp.HampelFilter(7);  
medFilt = dsp.MedianFilter(7);  
scope = timescope('SampleRate',Fs, ...  
    'TimeSpanOvverrunAction','Scroll', ...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1,'ShowGrid',true, ...
```

```

        'LayoutDimensions',[3 1], ...
        'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.YLimits = [-1 3];
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];

```

### Filter the Noisy Sine Wave Using a Window of Length 7

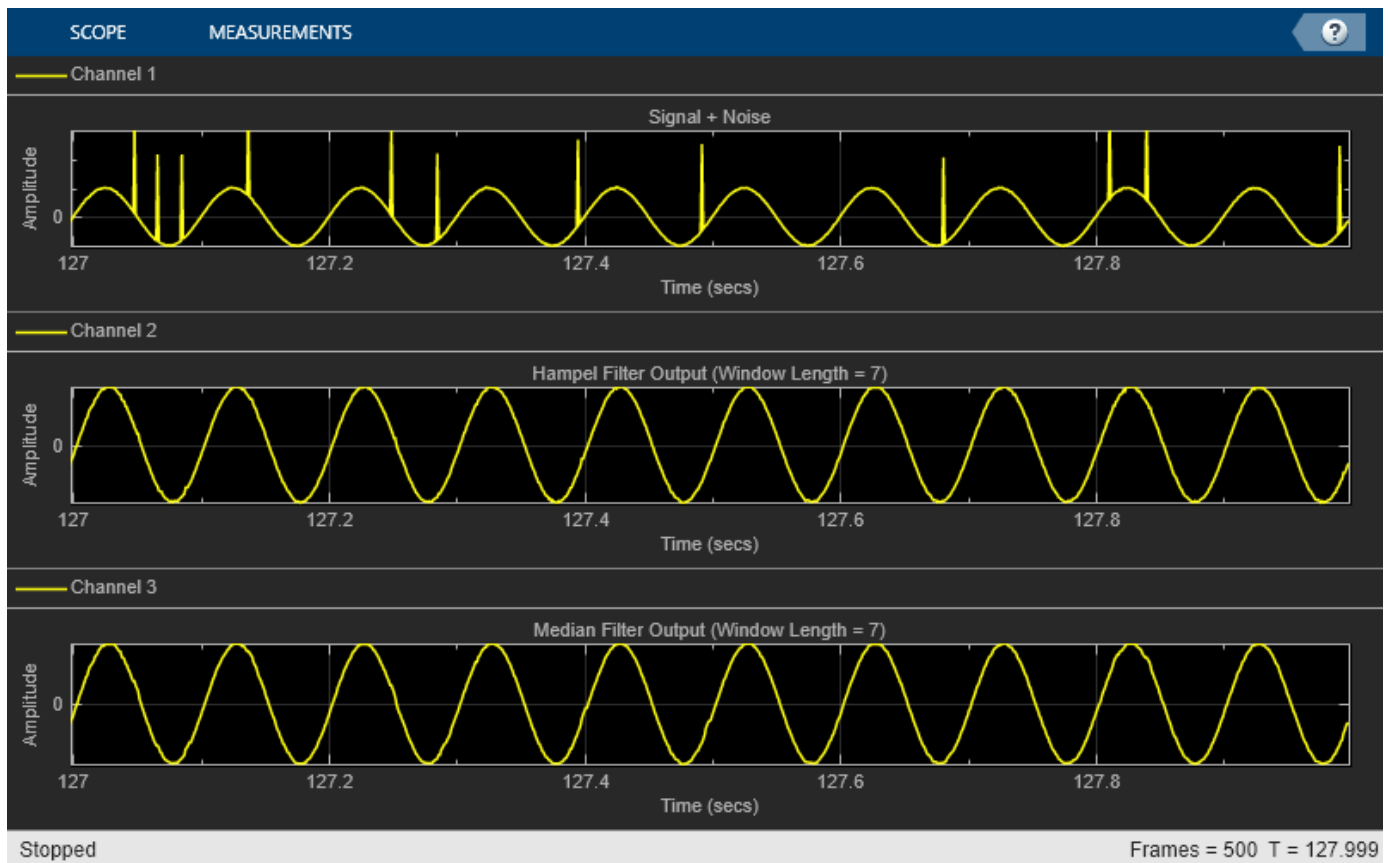

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```

FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
release(scope)

```

Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

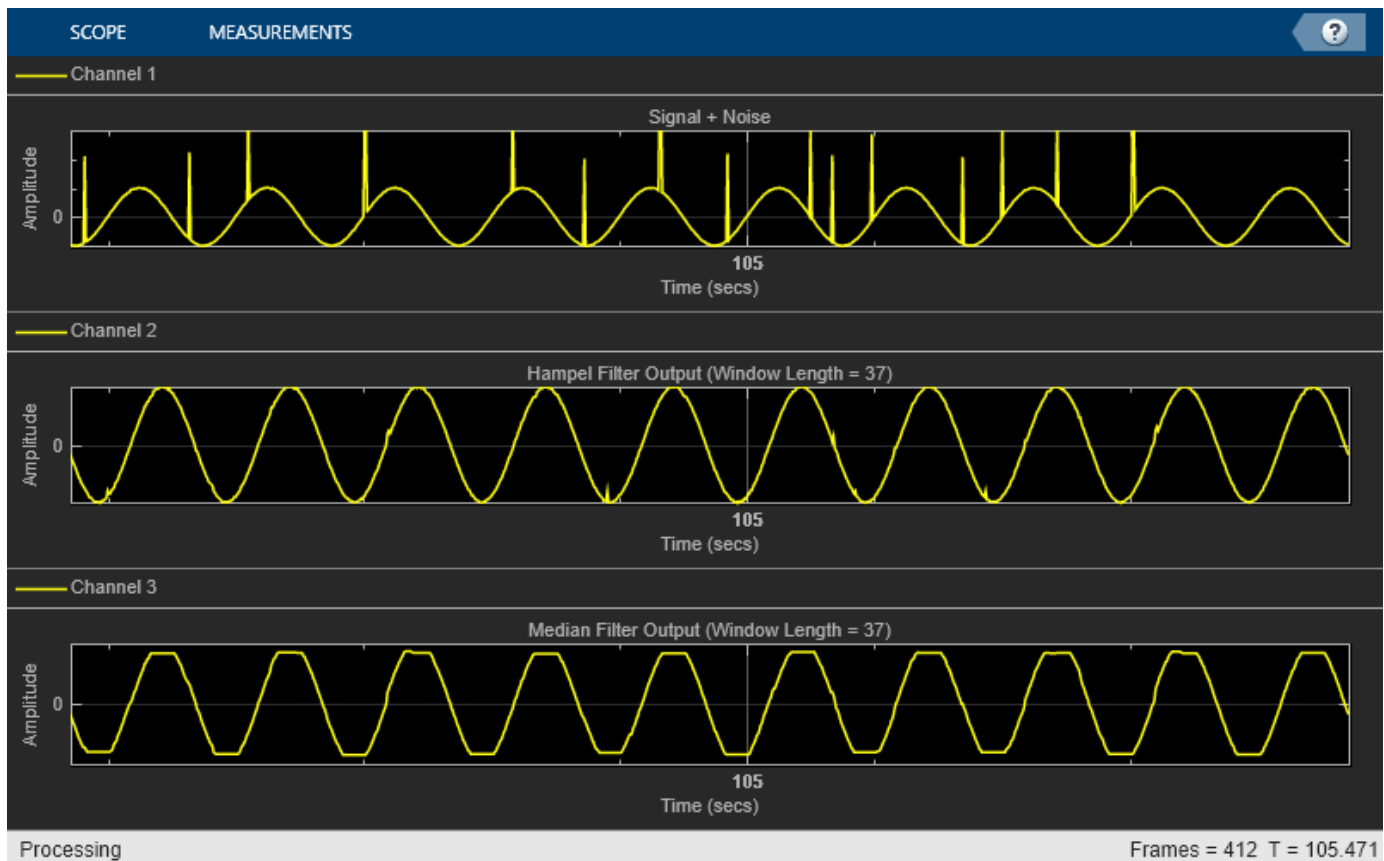

### Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

```
end
release(scope)
```

The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

### Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the x-axis, y-axis, and z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `timescope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.mat', ...
    'VariableName','data');
hampFilt = dsp.HampelFilter(11);
scope = timescope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...
    'ChannelNames',{'Input','Filtered Output'},...
    'TimeSpanSource','Property','TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampelFilter` System object. View the filtered z-axis data in the Time Scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = hampFilt(gyroData);
    scope([gyroData(:,3), filteredData(:,3)]);
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

## More About

### Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence  $x_1, x_2, x_3, \dots, x_n$  and a sliding window of length  $k$ , define point-to-point median and standard-deviation estimates using:

- Local median —  $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation —  $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$ , where  $\kappa = \frac{1}{\sqrt{2} \text{erfc}^{-1}(1/2)} \approx 1.4826$

The quantity  $\sigma_i / \kappa$  is known as the median absolute deviation (MAD).

If a sample  $x_i$  is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold  $n_\sigma$ , then the Hampel identifier declares  $x_i$  an outlier and replaces it with  $m_i$ . If  $n_\sigma$  is 0, then the Hampel filter behaves as a regular median filter.

## Algorithms

For a given sample of data,  $x_s$ , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median,  $m_i$ , and standard deviation,  $\sigma_i$ , over the current window of data.
- Compares the current sample with  $n_\sigma \times \sigma_i$ , where  $n_\sigma$  is the threshold value. If  $|x_s - m_i| > n_\sigma \times \sigma_i$ , the filter identifies the current sample,  $x_s$ , as an outlier and replaces it with the median value,  $m_i$ .

Consider a frame of data that is passed into the Hampel filter.

|   |   |   |   |    |   |    |   |   |
|---|---|---|---|----|---|----|---|---|
| 1 | 2 | 4 | 9 | 23 | 8 | 12 | 4 | 2 |
|---|---|---|---|----|---|----|---|---|

In this example, the Hampel filter slides a window of length 5 ( $Len$ ) over the data. The filter has a threshold value of 2 ( $n_\sigma$ ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with  $Len - 1$  zeros. To compute the first sample of the output, the window centers on the  $\left[\frac{Len - 1}{2} + 1\right]^{\text{th}}$  sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample:  $x_s = 0$ .
- Window of data:  $win = [0\ 0\ 0\ 0\ 1]$ .

- Local median:  $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$ .
- Median absolute deviation:  $mad_i = \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$ . For this window of data,  $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$ .
- Standard deviation:  $\sigma_i = \kappa \times mad_i = 0$ , where  $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$ .
- The current sample,  $x_s = 0$ , does not obey the relation for outlier detection.  
 $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

Therefore, the Hampel filter outputs the current input sample,  $x_s = 0$ .

Repeat this procedure for every succeeding sample until the algorithm centers the window on the  $\left[End - \frac{Len - 1}{2}\right]^{\text{th}}$  sample, marked as End. Because the window centered on the last  $\frac{Len - 1}{2}$  samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

# dsp.HighpassFilter

**Package:** dsp

FIR or IIR highpass filter

## Description

The `dsp.HighpassFilter` System object independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.HighpassFilter` to 'FIR' or 'IIR' to implement the object as an FIR or IIR highpass filter.

When the `FilterType` property is set to 'FIR', using this object is an alternative to using the `firceqrip` and `firgr` functions with `dsp.FIRFilter`. The `dsp.HighpassFilter` object condenses the two-step process into one. You can use `measure` to verify that the design meets the prescribed specifications.

To filter each channel of your input:

- 1 Create the `dsp.HighpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
HPF = dsp.HighpassFilter  
HPF = dsp.HighpassFilter(Name=Value)
```

### Description

`HPF = dsp.HighpassFilter` returns a minimum order FIR highpass filter, `HPF`, with the default filter settings. Calling the object with the default property settings filters the input data with a stopband frequency of 8 kHz, a passband frequency of 12 kHz, a stopband attenuation of 80 dB, and a passband ripple of 0.1 dB.

`HPF = dsp.HighpassFilter(Name=Value)` returns a highpass filter with additional properties specified by one or more `Name-Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. For example, `StopbandFrequency=8000` sets the stopband frequency specification of the filter to 8000 Hz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### FilterType — Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of these options:

- 'FIR' — The object designs an FIR highpass filter.
- 'IIR' — The object designs an IIR highpass (biquad) filter.

### DesignForMinimumOrder — Flag to design minimum order filter

true (default) | false

Flag to design minimum order filter, specified as:

- true -- The object designs the minimum order filter that meets the filter design specifications.
- false -- The object designs the filter with the order that you specify in the FilterOrder property.

### FilterOrder — Order of the FIR or IIR filter

50 (default) | positive integer

Order of the FIR or IIR filter, specified as a positive integer.

#### Dependencies

To enable this property, set DesignForMinimumOrder to false.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### StopbandFrequency — Filter stopband edge frequency

8000 (default) | real positive scalar

Filter stopband edge frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the NormalizedFrequency property to:

- false -- The value of the stopband edge frequency is in Hz. The value must be less than the passband edge frequency and half the SampleRate property value.
- true -- The value of the stopband edge frequency is in normalized frequency units. The value must be a positive scalar less than the passband edge frequency and less than 1.0.

#### Dependencies

To enable this property, set the DesignForMinimumOrder property to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### PassbandFrequency — Filter passband edge frequency

12000 (default) | real positive scalar

Filter passband edge frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the NormalizedFrequency property to:

- `false` -- The value of the passband edge frequency is in Hz. The value must be less than half the `SampleRate` property value and greater than the `StopbandFrequency` property value.
- `true` -- The value of the passband edge frequency is in normalized frequency units. The value must be a positive scalar less than `1.0` and greater than the `StopbandFrequency` property value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **StopbandAttenuation — Minimum attenuation in the stopband**

`80` (default) | real positive scalar

Minimum attenuation in the stopband, specified as a real positive scalar in dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PassbandRipple — Maximum ripple of filter response in the passband**

`0.1` (default) | real positive scalar

Maximum ripple of filter response in the passband, specified as a real positive scalar in dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NormalizedFrequency — Flag to set frequencies in normalized units**

`false` (default) | `true`

Flag to set frequencies in normalized units, specified as one of these values:

- `true` -- The passband edge and stopband edge frequencies must be in the normalized frequency units and less than `1.0`.
- `false` -- The passband edge and stopband edge frequencies are in Hz. You can specify the input sample rate through the `SampleRate` property.

Data Types: `logical`

### **SampleRate — Input sample rate**

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar.

#### **Dependency**

To enable this property, set `NormalizedFrequency` to `false`.

Data Types: `single` | `double`

#### **Fixed-Point Properties**

### **RoundingMethod — Rounding method for output fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

### **CoefficientsDataType — Word and fraction lengths of coefficients**

`numericType([],16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

## Usage

### Syntax

`y = HPF(x)`

### Description

`y = HPF(x)` highpass filters the input signal, `x`. `y` is a highpass-filtered version of `x`.

### Input Arguments

#### **x** — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

### Specific to `dsp.HighpassFilter`

|                          |   |
|--------------------------|---|
| <code>freqz</code>       | Frequency response of discrete-time filter System object                      |
| <code>fvtool</code>      | Visualize frequency response of DSP filters                                   |
| <code>impz</code>        | Impulse response of discrete-time filter System object                        |
| <code>info</code>        | Information about filter System object  |
| <code>coeffs</code>      | Returns the filter System object coefficients in a structure                  |
| <code>cost</code>        | Estimate cost of implementing filter System object                            |
| <code>grpdelay</code>    | Group delay response of discrete-time filter System object                    |
| <code>generatehdl</code> | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |
| <code>measure</code>     | Measure frequency response characteristics of filter System object            |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
FIRHPF = dsp.HighpassFilter(SampleRate=Fs,...
                           FilterType=filtertype,...
                           PassbandFrequency=Fpass,...
                           StopbandFrequency=Fstop,...
                           PassbandRipple=Rp,...
                           StopbandAttenuation=Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to IIR.

```
IIRHPF = clone(FIRHPF);
IIRHPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,Analysis='impulse')
```

Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF,Analysis='impulse')
```

Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF,Analysis='freq')
```

Calculate the cost of implementing the FIR highpass filter.

```
cost(FIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```

Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```

### Filter White Gaussian Noise Signal With FIR Highpass Filter

Create a highpass filter using the `dsp.HighpassFilter` object. Setting the `NormalizedFrequency` property to `true` designs the filter with frequency specifications in normalized frequency units.

```
LPF = dsp.HighpassFilter(NormalizedFrequency=true)
```

```
LPF =  
dsp.HighpassFilter with properties:
```

```
    FilterType: 'FIR'  
DesignForMinimumOrder: true  
    StopbandFrequency: 0.3628  
    PassbandFrequency: 0.5442  
    StopbandAttenuation: 80  
    PassbandRipple: 0.1000  
    NormalizedFrequency: true
```

```
Show all properties
```

Create a `spectrumAnalyzer` object to visualize the input and output signal spectra. With a sample rate of  $44.1 \times 10^3$  Hz, the stopband frequency and the passband frequency of the filter translate to 8000 Hz and 12000 Hz, respectively.

```
SA = spectrumAnalyzer(SampleRate=44.1e3,...
    PlotAsTwoSidedSpectrum=false,ShowLegend=true,...
    YLimits=[-150 30],...
    Title='Input Signal and Output Signal of Lowpass Filter');
SA.ChannelNames = {'Input','Output'};
```

Run the highpass filter algorithm to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    SA([Input,Output]);
end
```

### Filter White Gaussian Noise with an IIR Highpass Filter

Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
```

```

Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
hpf = dsp.HighpassFilter(SampleRate=Fs,...
    FilterType=filtertype,...
    PassbandFrequency=Fpass,...
    StopbandFrequency=Fstop,...
    PassbandRipple=Rp,...
    StopbandAttenuation=Astop);

```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```

Create a spectrum analyzer object.

```

sa = spectrumAnalyzer(SampleRate=44.1e3,...
    PlotAsTwoSidedSpectrum=false,ShowLegend=true,...
    YLimits=[-150 30],...
    Title='Input Signal and Output Signal of IIR Highpass Filter');
sa.ChannelNames = {'Input','Output'};

```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```

for k = 1:100
    Input = randn(1024,1);

```

```

Output = hpf(Input);
sa([Input,Output]);
end

```

### Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
```

```
HPF =
dsp.HighpassFilter with properties:
```

```

    FilterType: 'FIR'
DesignForMinimumOrder: true
  StopbandFrequency: 8000
  PassbandFrequency: 12000
  StopbandAttenuation: 80
    PassbandRipple: 0.1000
  NormalizedFrequency: false
    SampleRate: 44100

```

```
Show all properties
```

```
HPFMeas = measure(HPF)
```

```
HPFMeas =  
Sample Rate      : 44.1 kHz  
Stopband Edge    : 8 kHz  
6-dB Point       : 10.418 kHz  
3-dB Point       : 10.8594 kHz  
Passband Edge    : 12 kHz  
Stopband Atten.  : 81.8558 dB  
Passband Ripple  : 0.08066 dB  
Transition Width : 4 kHz
```

## Algorithms

### FIR Highpass Filter

For the minimum order design, the algorithm uses generalized Remez FIR filter design algorithm. For the specified order design, the algorithm uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct` form structure.

### IIR Highpass Filter

In the IIR configuration, the algorithm uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The algorithm uses the SOS and scale values to setup a `Direct` form I biquadratic IIR filter, which forms the basis of the IIR version of the highpass filter.

## Version History

### Introduced in R2015a

#### R2023a: Support for normalized frequencies

When you set the `NormalizedFrequency` property to `true`, you must specify the passband and stopband frequencies in normalized frequency units (0 to 1).

When you set the `NormalizedFrequency` property to `true` while creating the object, the passband and stopband frequency values are automatically set to normalized frequency units using the default sample rate of 44100 Hz.

```
hpFilter = dsp.HighpassFilter(NormalizedFrequency=true)
```

```
hpFilter =  
    dsp.HighpassFilter with properties:  
  
        FilterType: 'FIR'  
    DesignForMinimumOrder: true  
        StopbandFrequency: 0.3628  
        PassbandFrequency: 0.5442  
    StopbandAttenuation: 80  
        PassbandRipple: 0.1000  
    NormalizedFrequency: true
```

When you set the `NormalizedFrequency` property to `true` after you create the object, the passband and stopband frequencies must be manually set to the normalized frequency values before you run the object algorithm.

```
hpFilter = dsp.HighpassFilter

hpFilter =
  dsp.HighpassFilter with properties:
      FilterType: 'FIR'
  DesignForMinimumOrder: true
      StopbandFrequency: 8000
      PassbandFrequency: 12000
  StopbandAttenuation: 80
      PassbandRipple: 0.1000
  NormalizedFrequency: false
      SampleRate: 44100
```

To specify the normalized frequency values, set `NormalizedFrequency` to `true` and manually convert the frequency values in Hz to normalized values using the input sample rate in Hz. For example, if the input sample rate is 44100 Hz, the corresponding values in normalized units are computed using these equations.

```
hpFilter.NormalizedFrequency = true;
hpFilter.StopbandFrequency = 8000/(44100/2);
hpFilter.PassbandFrequency = 12000/(44100/2)

hpFilter =
  dsp.HighpassFilter with properties:
      FilterType: 'FIR'
  DesignForMinimumOrder: true
      StopbandFrequency: 0.3628
      PassbandFrequency: 0.5442
  StopbandAttenuation: 80
      PassbandRipple: 0.1000
  NormalizedFrequency: true
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- `FilterType` is set to 'FIR'.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

**Package:** dsp

Inverse discrete Fourier transform (IDFT)

## Description

The `dsp.IFFT` System object computes the inverse discrete Fourier transform (IDFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the IFFT of the input:

- 1 Create the `dsp.IFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ift = dsp.IFFT
ift = dsp.IFFT(Name,Value)
```

### Description

`ift = dsp.IFFT` returns an IFFT object, `ift`, that computes the IDFT of a column vector or  $N$ -D array. For column vectors or  $N$ -D arrays, the IFFT object computes the IDFT along the first dimension of the array. If the input is a row vector, the IFFT object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT(Name,Value)` returns an IFFT object, `ift`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **FFTImplementation — FFT implementation**

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as Auto, Radix-2, or FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

### **BitReversedInput — Enable bit-reversed order interpretation of input elements**

false (default) | true

Set this property to true if the order of Fourier transformed input elements to the IFFT object are in bit-reversed order. The default is false, which denotes linear ordering.

#### **Dependencies**

This property applies only when the FFTLengthSource property is Auto.

### **ConjugateSymmetricInput — Enable conjugate symmetric interpretation of input**

false (default) | true

Set this property to true if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to true optimizes the IDFT computation method. Setting this property to false for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to true for nonconjugate symmetric inputs results in invalid outputs.

#### **Dependencies**

This property applies only when the FFTLengthSource property is Auto.

### **Normalize — Enable dividing output by FFT length**

true (default) | false

Specify whether to divide the IFFT output by the FFT length. The default is true and each element of the output is divided by the FFT length.

### **FFTLengthSource — Source of FFT length**

Auto (default) | Property

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal.

#### **Dependencies**

This property applies only when both the BitReversedInput and ConjugateSymmetricInput properties are false.

### **FFTLength — FFT length**

64 (default) | integer

Specify the FFT length as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The FFTImplementation property is Radix-2.

#### Dependencies

This property applies when you set the BitReversedInput and ConjugateSymmetricInput properties to false, and the FFTLengthSource property to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

#### WrapInput — Boolean value of wrapping or truncating input

true (default) | false

Wrap input data when FFTLength is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFTLength is shorter than the input length. If this property is set to false, truncation of the input data to the FFTLength occurs before the FFT operation.

#### Fixed-Point Properties

##### RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

##### OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

##### SineTableDataType — Sine table word and fraction lengths

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

##### CustomSineTableDataType — Sine table word and fraction lengths

numericType([],16) (default) | numericType

Specify the sine table fixed-point type as an unscaled numericType object with a Signedness of Auto.

#### Dependencies

This property applies when you set the SineTableDataType property to Custom.

##### ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

##### CustomProductDataType — Product word and fraction lengths

numericType([],32,30) (default) | numericType

Specify the product fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies when you set the `ProductDataType` property to `Custom`.

**AccumulatorDataType — Accumulator word and fraction lengths**

`Full precision (default) | Same as input | Same as product | Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `AccumulatorDataType` property to `Custom`.

**OutputDataType — Output word and fraction lengths**

`Full precision (default) | Same as input | Custom`

Specify the output data type as `Full precision`, `Same as input`, or `Custom`.

**CustomOutputDataType — Output word and fraction lengths**

`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

**Dependencies**

This property applies when you set the `OutputDataType` property to `Custom`.

**Usage****Syntax**

`y = ift(x)`

**Description**

`y = ift(x)` computes the inverse discrete Fourier transform (IDFT) , `y`, of the input `x` along the first dimension of `x`.

**Input Arguments****x — Data input**

`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or *N*-D array.

When the `FFTLengthSource` property is `Auto`, the length of `x` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `x` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Variable-size input signals are only supported when the `FFTLengthSource` property is set to `'Auto'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **y** — Inverse discrete Fourier transform of input signal

vector | matrix |  $N$ -D array

Inverse discrete Fourier transform of input signal, returned as a vector, matrix, or  $N$ -D array.

When `FFTLengthSource` property is set to `'Auto'`, the FFT length is same as the number of rows in the input signal. When `FFTLengthSource` property is set to `'Property'`, the FFT length is specified through the `FFTLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Consider a time-domain signal  $x[n]$ , which is defined over the finite time interval  $0 \leq n \leq N - 1$ . The energy of the signal  $x[n]$  is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients,  $X[k]$ , are considered signal values in the frequency domain. The energy of the signal  $x[n]$  in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

### Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

### Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq), ...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReonstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');
hold on;
plot(ReconstrSignal, 'o');
hold off;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except the **Output sampling mode** parameter is not supported by `dsp.IFFT`.

## Version History

Introduced in R2012a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See "System Objects in MATLAB Code Generation" (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
  - `FFTImplementation` is set to 'FFTW'.
  - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

# dsp.IIRFilter

**Package:** dsp

Infinite impulse response (IIR) filter

## Description

The `dsp.IIRFilter` System object filters each channel of the input using the specified filter. You can specify the filter to have a 'Direct form I', 'Direct form I transposed', 'Direct form II', or a 'Direct form II transposed' structure.

Use the “Numerator” on page 4-0 and “Denominator” on page 4-0 properties to specify the coefficients of the filter numerator and denominator coefficients. In addition to these coefficients, you can also specify nonzero initial filter states through the “InitialConditions” on page 4-0 property.

To filter a signal using an IIR filter:

- 1 Create the `dsp.IIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
iir = dsp.IIRFilter
iir = dsp.IIRFilter(Name,Value)
```

### Description

`iir = dsp.IIRFilter` creates an infinite impulse response (IIR) filter System object that independently filters each channel of the input over time using a specified IIR filter implementation.

`iir = dsp.IIRFilter(Name,Value)` creates an IIR filter object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `iir = dsp.IIRFilter('Structure','Direct form I');`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Structure — IIR filter structure**

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

IIR filter structure, specified as 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

**Numerator — Numerator coefficients**

[1 1] (default) | row vector

Numerator coefficients, specified as a row vector.

Example: [0.0296 0.1775 0.4438 0.5918 0.4438 0.1775 0.0296]

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64  
Complex Number Support: Yes

**Denominator — Denominator coefficients**

[1 0.1] (default) | row vector

Denominator coefficients, specified as a row vector. The leading denominator coefficient must equal 1.

Example: [1.0000 -0.0000 0.7777 -0.0000 0.1142 -0.0000 0.0018]

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64  
Complex Number Support: Yes

**InitialConditions — Initial conditions**

0 (default) | scalar | vector | matrix

Initial conditions of the filter states, specified as one of the following:

- scalar -- The object initializes all delay elements in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements in the filter. Each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements in the filter. The number of columns in the matrix must equal the number of channels in the input. Each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

The number of filter states equals  $\max(N,M) - 1$ , where  $N$  is the number of poles, and  $M$  is the number of zeros.

**Tunable:** Yes

**Dependencies**

This property applies only when you set the "Structure" on page 4-0 property to 'Direct form II' or 'Direct form II transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

### **NumeratorInitialConditions — Initial conditions on zeros side**

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the zeros, specified as one of the following:

- scalar -- The object initializes all delay elements on the zeros side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the zeros side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the zeros side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the zeros side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

The number of filter states equals  $\max(N,M) - 1$ , where  $N$  is the number of poles, and  $M$  is the number of zeros, respectively.

**Tunable:** Yes

#### **Dependencies**

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64  
Complex Number Support: Yes

### **DenominatorInitialConditions — Initial conditions on poles side**

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the poles, specified as one of the following:

- scalar -- The object initializes all delay elements on the poles side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the poles side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the poles side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the poles side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

The number of filter states equals  $\max(N,M) - 1$ , where  $N$  is the number of poles, and  $M$  is the number of zeros, respectively.

**Tunable:** Yes

**Dependencies**

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`  
Complex Number Support: Yes

**Fixed-Point Properties****RoundingMethod — Rounding method**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

**OverflowAction — Overflow action**

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

**StateDataType — State data type**

'Same as input' (default) | 'Custom'

State data type, specified as one of the following:

- 'Same as input' -- The state data type is same as the input data type.
- 'Custom' -- The state output data type is an autosigned numeric type through the “CustomStateDataType” on page 4-0 property.

**CustomStateDataType — State word and fraction lengths**

`numericType([],16,15)` (default)

State word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set “StateDataType” on page 4-0 to 'Custom'.

**NumeratorCoefficientsDataType — Data type of numerator coefficients**

'Same word length as input' (default) | 'Custom'

Data type of numerator coefficients, specified as one of the following:

- 'Same word length as input' -- The word length of the numerator coefficients is the same as the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' -- The data type of the numerator coefficients is the autosigned numeric type specified by the “CustomNumeratorCoefficientsDataType” on page 4-0 property.

### **CustomNumeratorCoefficientsDataType — Word and fraction lengths of the numerator coefficients**

`numericType([],16,15)` (default)

Word and fraction lengths of the numerator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

#### **Dependencies**

This property applies only when you set “NumeratorCoefficientsDataType” on page 4-0 to 'Custom'.

### **DenominatorCoefficientsDataType — Data type of the denominator coefficients**

`'Same word length as input'` (default) | `'Custom'`

Data type of the denominator coefficients, specified as one of the following:

- `'Same word length as input'` -- The word length of the denominator coefficients is the same as that of the input word length. The fraction length is chosen to give the best possible precision.
- `'Custom'` -- The data type of the denominator coefficients is the autosigned numeric type specified by the “CustomDenominatorCoefficientsDataType” on page 4-0 property.

### **CustomDenominatorCoefficientsDataType — Word and fraction lengths of denominator coefficients**

`numericType([],16,15)` (default)

Word and fraction lengths of denominator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

#### **Dependencies**

This property applies only when you set “DenominatorCoefficientsDataType” on page 4-0 to 'Custom'.

### **NumeratorProductDataType — Numerator product data type**

`'Full precision'` (default) | `'Same as input'` | `'Custom'`

Data type of the output of a product operation in the numerator polynomial of the IIR filter, specified as one of the following:

- `'Full precision'` -- The object computes the numerator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `'Same as input'` -- The product output data type is the same as the input data type.
- `'Custom'` -- The product output data type is the custom numeric type specified by the “CustomNumeratorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

### **CustomNumeratorProductDataType — Numerator product word and fraction lengths**

`numericType([],32,30)` (default)

Numerator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set “NumeratorProductDataType” on page 4-0 to 'Custom'.

**DenominatorProductDataType — Denominator product data type**

'Full precision' (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The product output data type is the same as the input data type.
- 'Custom' -- The product output data type is custom numeric type specified by the “CustomDenominatorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

**CustomDenominatorProductDataType — Denominator product word and fraction lengths**

numericity([],32,30) (default)

Denominator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set “DenominatorProductDataType” on page 4-0 to 'Custom'.

**NumeratorAccumulatorDataType — Numerator accumulator data type**

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the numerator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomNumeratorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

**CustomNumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths**

numericity([],32,30) (default)

Numerator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set “NumeratorAccumulatorDataType” on page 4-0 to 'Custom'.

**DenominatorAccumulatorDataType — Denominator accumulator data type**

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomDenominatorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

**CustomDenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths**

numericType([],32,30) (default)

Denominator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

**Dependencies**

This property applies only when you set “DenominatorAccumulatorDataType” on page 4-0 to 'Custom'.

**OutputDataType — Output data type**

'Same as input' (default) | 'Full precision' | 'Custom'

Data type of the output of the dsp.IIRFilter object, specified as one of the following:

- 'Same as input' -- The output data type is the same as the input data type.
- 'Full precision' -- The object computes the output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The output data type is the custom numeric type specified by the “CustomOutputDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

**CustomOutputDataType — Output word and fraction lengths**

numericType([],16,15) (default)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set “OutputDataType” on page 4-0 to 'Custom'.

**MultiplicandDataType — Multiplicand data type**

'Same as input' (default) | 'Custom'

Multiplicand data type, specified as one of the following:

- 'Same as input' -- The multiplicand data type is the same as the input data type.
- 'Custom' -- The multiplicand data type is the autosigned numeric type specifies by the “CustomMultiplicandDataType” on page 4-0 property.

**CustomMultiplicandDataType — Multiplicand output word and fraction lengths**

numericType([],16,15) (default)

Multiplicand output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

**Dependencies**

This property applies only when you set “MultiplicandDataType” on page 4-0 to 'Custom'.

**Usage****Syntax**

```
iirOut = iir(input)
```

**Description**

`iirOut = iir(input)` filters the input signal using the specified filter to produce the filtered output. The System object filters each column of the input signal independently over time.

**Input Arguments****input — Data input**

vector | matrix

Data input that is filtered, specified as a vector or matrix.

Example: `randn(34,24)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**Output Arguments****iirOut — Filtered output**

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output match that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.IIRFilter

|                     |  |
|---------------------|--|
| <code>freqz</code>  | Frequency response of discrete-time filter System object         |
| <code>fvtool</code> | Visualize frequency response of DSP filters                      |
| <code>impz</code>   | Impulse response of discrete-time filter System object           |
| <code>phasez</code> | Phase response of discrete-time filter System object (unwrapped) |
| <code>sos</code>    | Convert to second order sections                                 |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

For a list of filter analysis methods this object supports, type `dsp.IIRFilter.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

## Examples

### Filter Noisy Signal Using IIR Filter

Filter a noisy sinusoidal signal using a lowpass butterworth IIR filter.

#### Input Signal

The input signal has three tones, 1 kHz, 5 kHz, and 12 kHz.

```
Sine1 = dsp.SineWave('Frequency',1e3,...
    'SampleRate',44.1e3);
Sine2 = dsp.SineWave('Frequency',5e3,...
    'SampleRate',44.1e3);
Sine3 = dsp.SineWave('Frequency',12e3,...
    'SampleRate',44.1e3);
```

#### Filter Design

Use the `butter` function to design a 10th order lowpass Butterworth filter.

```
N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
```

Create a `dsp.IIRFilter` object and assign the designed coefficients to the Numerator and the Denominator properties.

```
iir = dsp.IIRFilter('Numerator',b,...
    'Denominator',a);
```

View the magnitude response of the filter. The cutoff frequency is at  $0.4\pi$  rad/sample, which, with a sample rate of 44.1 kHz, translates to  $0.4 \times 44100/2$  or 8.82 kHz.

```
fvtool(iir,'Fs',Sine1.SampleRate)
```

View the power spectrum of the input and output signal using the Spectrum Analyzer.

```
sa = spectrumAnalyzer('SampleRate',Sine1.SampleRate,...
    'Method','welch',...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,...
    'SpectrumUnits','dBW',...
    'YLimits',[-220 -10]);
```

### Streaming

Add zero-mean white Gaussian noise with a standard deviation of 0.01 to the sum of sine waves. Filter the signal using the IIR filter.

The tones at 1 kHz and 5 kHz are unaffected since they fall in the passband. The frequency at 12 kHz is attenuated since it falls in the transition band of the filter.

```
for i = 1:1000
    input = Sine1()+Sine2()+Sine3()+...
        0.01*randn(Sine1.SamplesPerFrame,1);
```

```

output = iir(input);
sa(input,output)
end

```

## Design an IIR Filter

Design a notching comb filter with 8 notches, and a notch bandwidth of 0.02 referenced to a -3 dB level.

Create a comb filter design specification object using the `fdesign.comb` function and specify these design parameters.

```
combSpecs = fdesign.comb('notch','N,BW',8,0.02);
```

Design the notching comb filter using the `design` function. The resulting filter is a `dsp.IIRFilter System` object™. For details on how to apply this filter on streaming data, refer to `dsp.IIRFilter`.

```
iirFilt = design(combSpecs,'Systemobject',true)
```

```
iirFilt =
dsp.IIRFilter with properties:
```

```

Structure: 'Direct form II'
Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]
Denominator: [1 0 0 0 0 0 0 0 -0.7757]

```

InitialConditions: 0

Show all properties

View magnitude response of the designed filter using `fvtool`.

```
fvtool(iirFilt)
```

## More About

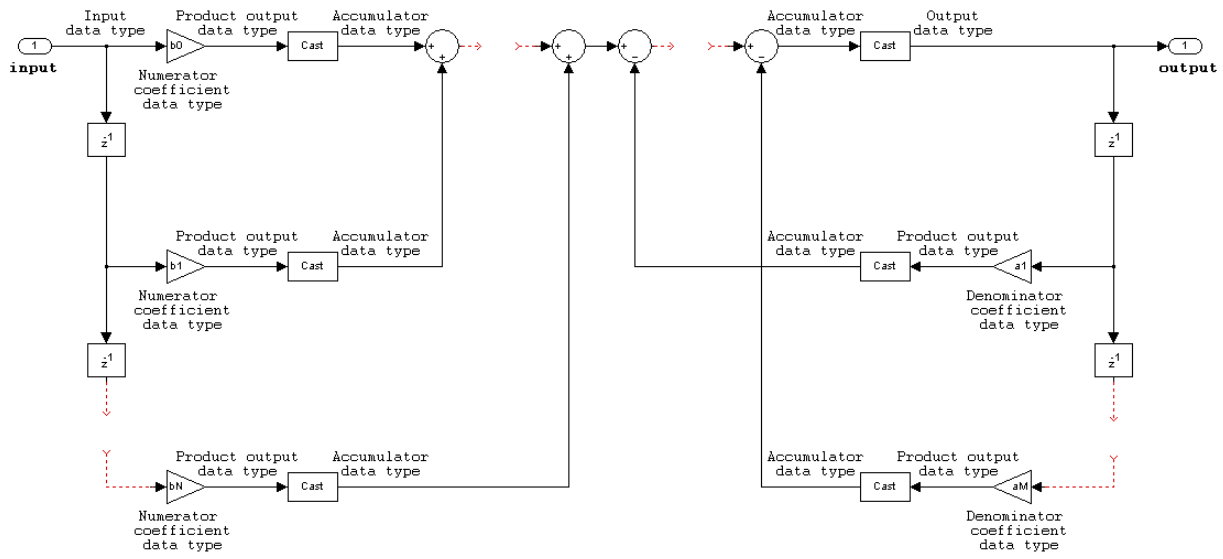

### Fixed Point

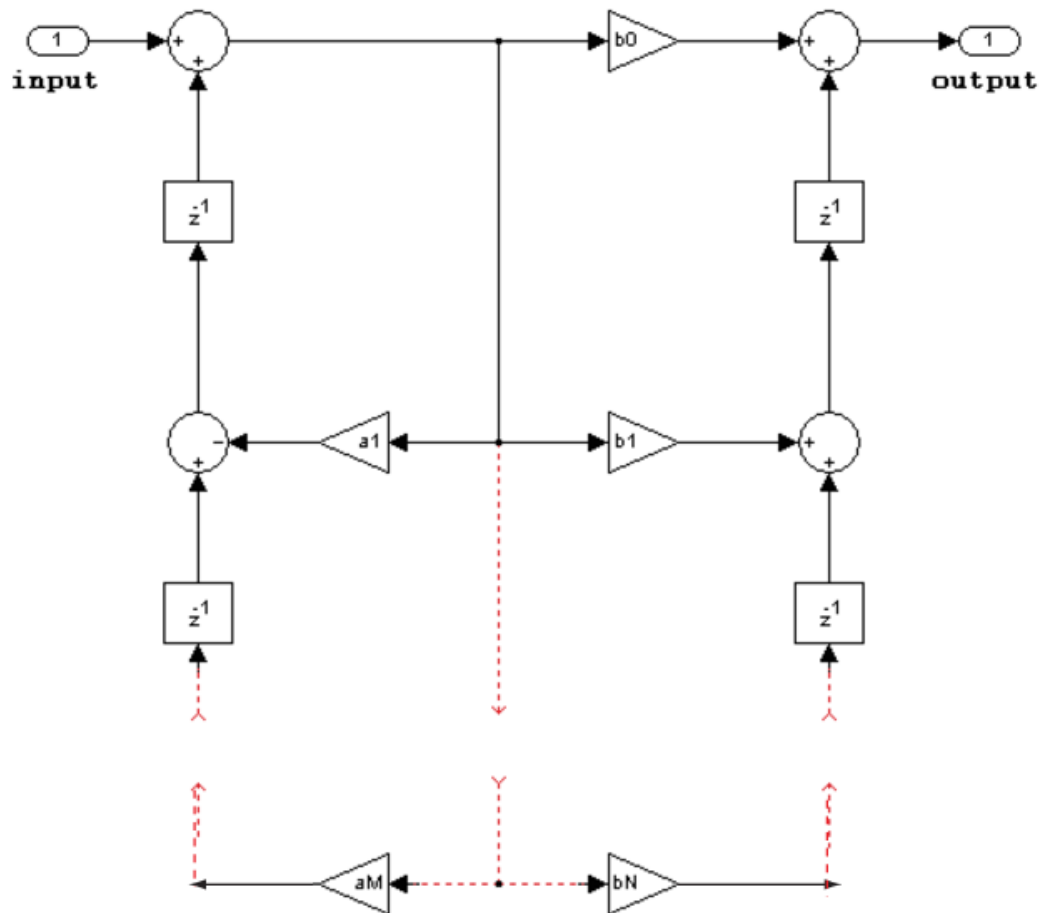

The `dsp.IIRFilter` System object supports the following filter structures. The diagrams in each section show the data types used in the filter structures for fixed-point signals. You can set the data types using the fixed-point properties of the object.

**Direct form I**

The following constraints apply when the Structure property is set to 'Direct form I':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- The State data type cannot be specified for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

**Direct form I transposed**

The following constraints apply when the Structure property is set to 'Direct form I transposed':

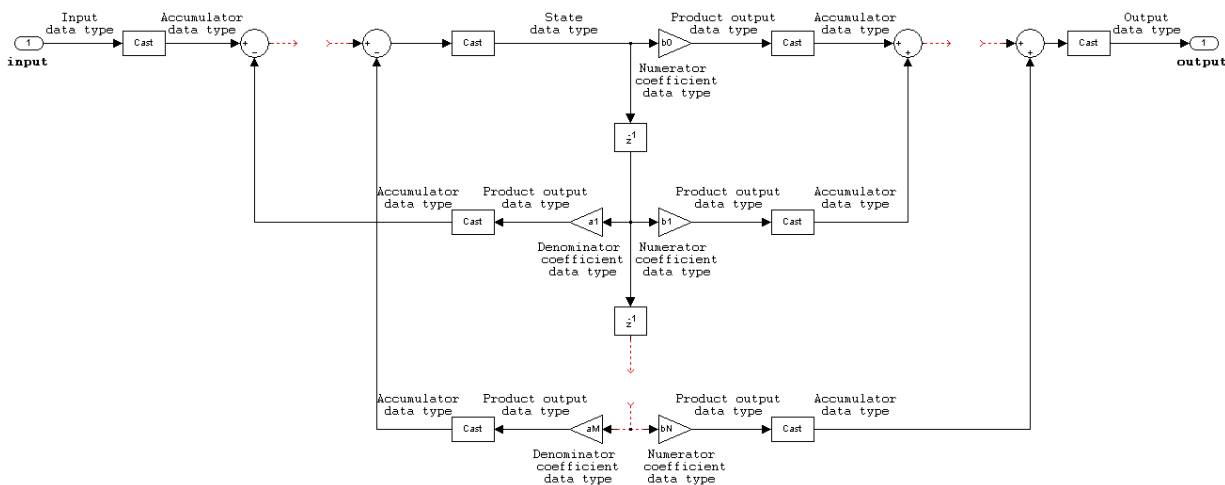

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.

**Direct form II**

The following constraints apply when the Structure property is set to 'Direct form II':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

**Direct form II transposed**

The following constraints apply when the Structure property is set to 'Direct form II transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

## Version History

Introduced in R2012b

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` and `Denominator` properties are tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.IIRHalfbandDecimator

**Package:** dsp

Decimate by factor of two using polyphase IIR

## Description

The `dsp.IIRHalfbandDecimator` System object performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

To filter and downsample your data:

- 1 Create the `dsp.IIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
iirhalfbanddecim = dsp.IIRHalfbandDecimator
iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name, Value)
```

### Description

`iirhalfbanddecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `iirhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name, Value)` returns an IIR halfband decimator, with additional properties specified by one or more `Name, Value` pair arguments.

Example: `iirhalfbanddecim = dsp.IIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an IIR halfband decimator object with filter order set to 9 and stopband attenuation set to 80 dB.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

### FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

#### Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

#### Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

### TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

**Dependencies**

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

**DesignMethod — Design method**

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

**Dependencies**

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

**SampleRate — Input sample rate**

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

**Dependencies**

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

**Structure — Internal allpass filter implementation structure**

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'.

This property is not tunable.

**Dependencies**

This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

**AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch**

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections.

**Tunable:** Yes

**Dependencies**

This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Minimum multiplier'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch**`[0.4295667] (default) | [0.7906755 0.1534]`

Allpass polynomial filter coefficients of the second branch, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections.

**Tunable:** Yes

**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form**`[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]`

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form**`[0.4295667] (default) | [0.7906755 0.1534]`

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of 'WDFCoefficients2' and a  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

**Dependencies**

This property applies only when you set 'Specification' to 'Coefficients' and 'Structure' to 'Wave Digital Filter'.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**HasPureDelayBranch — Make first branch a pure delay**`false (default) | true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties AllpassCoefficients1 and WDFCoefficients1 do not apply.

This property is not tunable.

**Dependencies**

This property applies only when you set `Specification` to `'Coefficients'`.

**Delay — Length of delay**

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

**Dependencies**

This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

**HasTrailingFirstOrderSection — Treat the last section of the second branch as first order**

false (default) | true

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an  $N$ -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an  $N$ -by-1 matrix, this property is ignored.

This property is not tunable.

**Dependencies**

This property applies only when you set `Specification` to `'Coefficients'`.

**Usage****Syntax**

```
y_low = iirhalfbanddecim(x)
[y_low,y_high] = iirhalfbanddecim(x)
```

**Description**

`y_low = iirhalfbanddecim(x)` filters the input signal, `x`, using the IIR halfband filter, `iirhalfbanddecim`, and downsamples the output by a factor of 2.

`[y_low,y_high] = iirhalfbanddecim(x)` computes the `y_low` and `y_high`, of the analysis filter bank, `iirhalfbanddecim` for input `x`. A  $K_i$ -by- $N$  input matrix is treated as  $N$  independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `y_low` and `y_high` are of the same size ( $K_o$ -by- $N$ ) and data type.  $K_o = K_i/2$ , where 2 is the decimation factor.

## Input Arguments

### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of rows in the input signal must be even since the decimation factor is always 2 for this object. If the input is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double`

## Output Arguments

### **y<sub>low</sub>** — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

### **y<sub>high</sub>** — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.IIRHalfbandDecimator`

|                        |  |
|------------------------|--|
| <code>freqz</code>     | Frequency response of discrete-time filter System object |
| <code>fvtool</code>    | Visualize frequency response of DSP filters              |
| <code>info</code>      | Information about filter System object                   |
| <code>cost</code>      | Estimate cost of implementing filter System object       |

## Examples

## Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim, 'Analysis', 'freq')
```

## Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end

```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```

release(afr);
release(ap);

```

## Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```

AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

```

```

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

```

```

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

```

```

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

```

```

SpecAna = spectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});

```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```

while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];

```

```

    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);

```

### Filter Input into Lowpass and Highpass Subbands

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```

IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);

```

Filter a two-channel input into lowpass and highpass subbands.

```

x = randn(1024,2);
[ylow,yhigh] = IIRHalfbanddecim(x);

```

## Algorithms

### Polyphase Implementation with Halfband Filters

When you filter your signal, the IIR halfband decimator uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at a lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

### Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

### Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where  $k$  is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where  $N$  is the order of the IIR halfband filter.

You can represent filtering the input signal and then downsampling it by 2 using this figure.

Using the multirate noble identity for downsampling, you can move the downsampling operation before the filtering operation. This change enables you to filter at a lower rate.

To implement the halfband decimator efficiently, this algorithm replaces the delay block and downsampling operator with a commutator switch.

### Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

You can represent the analysis filter bank as in this diagram.

The IIR halfband decimator generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, the IIR halfband decimator:

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has a nonlinear phase response and uses few coefficients with the elliptic design method.
- Has near-linear phase response at the cost of additional coefficients with the quasi-linear phase design method, where one of the branches is a pure delay

# **dsp.IIRHalfbandInterpolator**

**Package:** dsp

Interpolate by a factor of two using polyphase IIR

## **Description**

The `dsp.IIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To upsample and interpolate your data:

- 1 Create the `dsp.IIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
iirhalfbandinterp = dsp.IIRHalfbandInterpolator  
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)
```

### **Description**

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `iirhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)` returns an IIR halfband interpolator, with additional properties specified by one or more `Name, Value` pair arguments.

Example: `iirhalfbandinterp = dsp.IIRHalfbandInterpolator('Specification','Filter order and stopband`

`attenuation'`) creates an IIR halfband interpolator object with filter order set to 9 and stopband attenuation set to 80 dB.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

### FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

#### Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

#### Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

### TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

**Dependencies**

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

**DesignMethod — Design method**

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

**Dependencies**

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

**SampleRate — Input sample rate**

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

**Dependencies**

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

**FilterBankInputPort — Option to use object as synthesis filter bank**

false (default) | true

Option to use object as synthesis filter bank, specified as a logical value. If this property is false, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is true, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and the algorithm accepts two inputs: the lowpass and highpass subbands.

**Dependencies**

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

**Structure — Filter structure used in coefficient mode**

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

**Dependencies**

This property applies only when you set 'Specification' to 'Coefficients'.

**AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch**

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections.

**Tunable:** Yes**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch**

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections.

**Tunable:** Yes**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form**

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form**

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an  $N$ -by-1 or  $N$ -by-2 matrix.  $N$  is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

**Dependencies**

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **HasPureDelayBranch — Make the first branch a pure delay**

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

#### **Dependencies**

This property applies only when you set `Specification` to `'Coefficients'`.

### **Delay — Length of the delay**

`1` (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

#### **Dependencies**

This property is applicable only when you set `'Specification'` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

### **HasTrailingFirstOrderSection — Make the last section of the second branch as first order**

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an  $N$ -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an  $N$ -by-1 matrix, this property is ignored.

This property is not tunable.

#### **Dependencies**

This property applies only when you set `Specification` to `'Coefficients'`.

## **Usage**

## **Syntax**

```
y = iirhalfbandinterp(x1)
y = iirhalfbandinterp(x1,x2)
```

## Description

`y = iirhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the IIR halfband interpolator, `iirhalfbandinterp`.

`y = iirhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

## Input Arguments

### **x1** — Data input

column vector | matrix

Data input to the IIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double`

### **x2** — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double`

## Output Arguments

### **y** — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Examples

### Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp, 'Analysis', 'freq')
```

## Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';  
Order = 21;  
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

### Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

**Note:** The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);
```

```
SpecAna = spectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

### Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```

Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',Fs);

x = randn(1024,4);
y = iirhalfbandinterp(x);

```

## Algorithms

### Polyphase Implementation with Halfband Filters

When you filter your signal, the IIR halfband interpolator uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at a lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

### Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

### Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where,  $k$  is the length of the delay.

$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where  $N$  is the order of the IIR halfband filter.

You can represent the upsampling-by-2 operation followed by the filtering operation using this figure.

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at a lower rate.

To efficiently implement the halfband interpolator, this algorithm replaces the upsampling operator, delay block, and adder with a commutator switch. The commutator switch operates at twice the input sample rate. This is shown in the following figure.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

### Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

You can represent the synthesis filter bank as in this diagram.

The IIR halfband interpolator implements the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, the IIR halfband interpolator:

- Filters the input before upsampling
- Acts as a synthesis filter bank
- Has a nonlinear phase response and uses few coefficients with the elliptic design method

- Has near-linear phase response at the cost of additional coefficients with the quasi-linear phase design method, where one of the branches is a pure delay

## dsp.Interpolator

**Package:** dsp

(Removed) Linear or polyphase FIR interpolation

---

**Note** `dsp.Interpolator` has been removed. Use `dsp.FIRInterpolator`, `interp1` instead. For more information, see “Compatibility Considerations”.

---

### Description

The `dsp.Interpolator` System object interpolates values between real-valued input samples using linear or polyphase FIR interpolation. Specify which values to interpolate by providing a vector of interpolation points. An interpolation point of 1 refers to the first sample in the input. To interpolate the value halfway between the second and third sample in the input, specify an interpolation point of 2.5. Interpolation points that are not within the valid range are replaced with the closest value in the valid range.

To interpolate a real-valued input signal:

- 1 Create the `dsp.Interpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
interp = dsp.Interpolator  
interp = dsp.Interpolator(Name, Value)
```

#### Description

`interp = dsp.Interpolator` creates an interpolation System object, `interp`, to interpolate values between real-valued input samples using linear interpolation.

`interp = dsp.Interpolator(Name, Value)` creates an interpolation System object, `interp`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `interp = dsp.Interpolator('InterpolationPointsSource', 'Input port')`

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### InterpolationPointsSource — Source of interpolation points

'Property' (default) | 'Input port'

Method to specify the interpolation points, specified as one of the following:

- 'Property' — Specify the interpolation points through the “InterpolationPoints” on page 4-0 property.
- 'Input port' — Pass the interpolation points as an input to the System object algorithm.

### InterpolationPoints — Interpolation points

[1.1;4.8;2.67;1.6;3.2] (default) | vector | matrix |  $N$ -D array

Interpolation points, specified as a vector, matrix, or an  $N$ -D array. The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2;3.1;-2.1], the valid range of interpolation points is from 1 to 3. If you specify a [-1;1.5;2;2.5;3;3.5] vector of interpolation points, the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3].

For details on the dimension of the interpolation points array and how that influences the dimension of the output, see the tables in the “*ipts*” on page 4-0 input of the System object.

**Tunable:** Yes

### Dependencies

This property applies only when you set the “InterpolationPointsSource” on page 4-0 property to 'Property'.

### Method — Interpolation method

'Linear' (default) | 'FIR'

Interpolation method, specified as one of the following:

- 'Linear' -- The object interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.
