- 'FIR' -- The object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. If the input has insufficient low-rate samples to perform FIR interpolation, the interpolator object performs linear interpolation. For more details, see the “FilterHalfLength” on page 4-0 property.

### FilterHalfLength — Half-length of interpolation filter

3 (default) | integer scalar greater than 0

For a filter half-length of  $P$ , the polyphase FIR subfilters have length  $2P$ . FIR interpolation always requires  $2P$  low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires  $P$  low-rate samples below and  $P$  low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the  $2P$ -sample requirement includes the low-rate sample.

- If the input has less than  $2P$  neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input `[1 4 1 4 1 4 1 4]`, upsampling by a factor of 4 results in equally spaced interpolation points, `InterP = [1:0.25:8]`. The points `InterP(9:12)` are `[3.0 3.25 3.5 3.75]`. If you set `FilterHalfLength` to 2, interpolating at these points uses the 4 low-rate samples from the input with indices `(2,3,4,5)`. If you set `FilterHalfLength` to 4, the interpolator object uses linear interpolation, because the input does not have enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, increasing the filter half-length increases computation time and requires more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides a reasonably accurate interpolation.

### Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

### InterpolationPointsPerSample — Upsampling factor

3 (default) | integer scalar greater than 0

Upsampling factor, specified as an integer scalar greater than 0. An upsampling factor of  $L$  inserts  $L - 1$  zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length  $2P$ , where  $P$  is the value you specify in the “FilterHalfLength” on page 4-0 property. For  $nL$  low-rate samples in the upsampled input, where  $n=1,2,\dots$ , the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters to interpolate at the points  $nL+i/L$ , where  $i = 0, 1, 2, \dots, L - 1$ .

If you specify interpolation points that do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. Suppose you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points `[3 3.2 3.4 3.6 3.8]`. The interpolator object uses the first polyphase subfilter for the points `[3.0 3.2]`, the second subfilter for the point 3.4, the third subfilter for the point 3.6, and the fourth subfilter for the point 3.8.

### Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

### Bandwidth — Normalized input bandwidth

0.5 (default) | real scalar greater than 0 and less than or equal to 1

Bandwidth to which the interpolated output samples must be constrained, specified as a real scalar greater than 0 and less than or equal to 1. A value of 1 equals the Nyquist frequency, or half the sampling frequency,  $F_s$ . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above  $F_s/4$ , you can specify a value of 0.5 for the `Bandwidth` property.

### Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

## Usage

### Syntax

```
interpOut = interp(input)
interpOut = interp(input, ipts)
```

### Description

`interpOut = interp(input)` outputs the interpolated sequence, `interpOut`, of the input vector or matrix `input`, as specified in the “InterpolationPoints” on page 4-0 property. Each column of `input` is treated as an independent channel of the input.

`interpOut = interp(input, ipts)` outputs the interpolated sequence as specified by `ipts`.

To specify the interpolation points, set the “InterpolationPointsSource” on page 4-0 property to 'Input port'.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
ipts = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource', 'Input port');
interpOut = interp(x1', ipts');
```

### Input Arguments

#### **input** — Data input

vector | matrix | *N*-D array

Input that is interpolated by the object, specified as a vector, matrix, or *N*-D array.

Example: `t = 0:0.0001:0.0511; input = sin(2*pi*20*t);`

Data Types: `single` | `double`

#### **ipts** — Interpolation points

vector | matrix | *N*-D array

Interpolation array  $I_{pts}$ , specified as a vector, matrix, or *N*-D array. The interpolation array represents the points in time at which to interpolate values of the input signal. An entry of 1 in  $I_{pts}$  refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when  $I_{pts}$  is a vector, it can be of any length.

Valid values in the interpolation array  $I_{pts}$  range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector  $D$ , all entries of  $I_{pts}$  must range from 1 to 5.  $I_{pts}$  cannot contain entries such as 7 or -9, because  $D$  does not have a seventh or ninth entry.

The algorithm replaces any out-of-range values in  $I_{pts}$  with the closest value in the valid range (from 1 to the number of input samples). Then it performs the interpolation using the clipped version of  $I_{pts}$ .

Consider the following input data and interpolation points vector:

- `D = [11 22 33 44]'`

- $I_{Pts} = [10 \ 2.6 \ -3]'$

Because D has four samples, valid interpolation points range from 1 to 4. The algorithm clips interpolation point 10 down to 4 and the point -3 up to 1. The result is the clipped interpolation vector  $I_{PtsClipped} = [4 \ 2.6 \ 1]'$ .

Depending on the dimension of the input and the dimension of  $I_{Pts}$ , the algorithm applies  $I_{Pts}$  to the input in one of the following ways:

- If  $I_{Pts}$  is an array, the object applies  $I_{Pts}$  across the first dimension of an  $N$ -D array, resulting in an  $N$ -D array output.
- If  $I_{Pts}$  is a vector, the object applies  $I_{Pts}$  to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the object applies the interpolation array  $I_{Pts}$  to all the possible types of inputs. The table also shows the resulting output dimensions.

This table describes the behavior when InterpolationPointsSource is set to 'Property'.

| Input Dimensions                   | Valid Dimensions of Interpolation Array $I_{Pts}$             | How Object Applies $I_{Pts}$ to Input  | Output Dimensions   |
|------------------------------------|---|--|---|
| $M$ -by- $N$ -by- $K$ matrix       | $P$ -by-1 column  | Applies $I_{Pts}$ to the first dimension of the input                                    | $P$ -by- $N$ -by- $K$ array                                       |
|                                    | $P$ -by- $N$ -by- $K$ matrix                                  | Applies each column element of $I_{Pts}$ to the corresponding column of the input matrix | $P$ -by- $N$ -by- $K$ array                                       |
| $M$ -by- $N$ matrix                | 1-by- $N$ row   | Applies each column element of $I_{Pts}$ to the corresponding column of the input matrix | 1-by- $N$ row   |
|                                    | $P$ -by-1 column  | Applies $I_{Pts}$ to each input column   | $P$ -by- $N$ matrix   |
|                                    | $P$ -by- $N$ matrix   | Applies the columns of $I_{Pts}$ to the corresponding columns of the input matrix        |   |
| $M$ -by-1 column                   | 1-by- $P$ row<br>(the algorithm treats $I_{Pts}$ as a column) | Applies $I_{Pts}$ to the input column  | $P$ -by-1 column  |
|                                    | $P$ -by-1 column  |  |   |
| 1-by- $N$ row<br>(not recommended) | 1-by- $N$ row   | Not applicable. Object copies input vector.  | 1-by- $N$ row, a copy of the input vector                         |
|                                    | $P$ -by-1 column  |  | $P$ -by- $N$ matrix, where each row is a copy of the input vector |
|                                    | $P$ -by- $N$ matrix   |  |   |

This table describes the behavior when InterpolationPointsSource is set to 'Input port'.

| Input Dimensions                   | Valid Dimensions of Interpolation Array $I_{pts}$ | How Object Applies $I_{pts}$ to Input  | Output Dimensions   |
|------------------------------------|---|--|---|
| $M$ -by- $N$ -by- $K$ matrix       | Column vector of length $P$                       | Applies $I_{pts}$ to the first dimension of the input                                    | $P$ -by- $N$ -by- $K$ array                                       |
|                                    | $P$ -by- $N$ -by- $K$ matrix                      | Applies each column element of $I_{pts}$ to the corresponding column of the input matrix | $P$ -by- $N$ -by- $K$ array                                       |
| $M$ -by- $N$ matrix                | 1-by- $N$ row                                     | Applies each column element of $I_{pts}$ to the corresponding column of the input matrix | 1-by- $N$ row   |
|                                    | $P$ -by-1 column                                  | Applies $I_{pts}$ to each input column   | $P$ -by- $N$ matrix   |
|                                    | $P$ -by- $N$ matrix                               | Applies the columns of $I_{pts}$ to the corresponding columns of the input matrix        |   |
| $M$ -by-1 column                   | 1-by- $P$ row                                     | Applies $I_{pts}$ to the input column  | $P$ -by-1 column  |
|                                    | $P$ -by-1 column                                  |  |   |
| 1-by- $N$ row<br>(not recommended) | 1-by- $N$ row                                     | Not applicable. Object copies input vector.  | 1-by- $N$ row, a copy of the input vector                         |
|                                    | $P$ -by-1 column                                  |  | $P$ -by- $N$ matrix, where each row is a copy of the input vector |
|                                    | $P$ -by- $N$ matrix                               |  |   |

Example: `ipts = [1:10];`

Data Types: `single` | `double`

## Output Arguments

### **interpOut** — Interpolated sequence

vector | matrix |  $N$ -D array

Interpolated sequence, returned as a vector, matrix, or  $N$ -D array. The dimension of the output depends on the dimensions of the input and the interpolation points array. For more details on the dimensions, see the tables in “`ipts`” on page 4-0 .

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Interpolate a Sum of Sinusoids

Interpolate a sum of sinusoids with FIR interpolation, and with 'Input port' as the source of interpolation points.

```

Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
interp = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1,I);
stem(I,y,'r');
hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');

```

## Algorithms

### Linear Interpolation Mode

In the linear interpolation mode, the algorithm interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

Suppose the input signal is  $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$ . The left plot shows the samples in D and the right plot shows the linearly interpolated values between the samples in D.

When the interpolation points are out of range, the algorithm clips the invalid interpolation points. Consider an input signal,  $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$ , and an interpolation vector,  $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$ . The interpolated output is given by  $[1 \ 1.65 \ 2.175 \ 0.25]'$ .

### Interpolated Values of D at Clipped Interpolation Points

### FIR Interpolation Mode

In the FIR interpolation mode, the algorithm interpolates data values using an FIR interpolation filter. The FIR filter is implemented using a polyphase structure. A polyphase implementation *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let  $L$  represent the number of interpolation points per sample, or the upsampling factor. Let  $P$  represent the half length of the polyphase subfilters. Indexing from zero, if  $h(n)$  is the impulse response of the FIR filter, the  $k$ th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \dots, L - 1 \quad n = 0, 1, \dots, 2P - 1$$

The table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object.

| Coefficients                     | Polyphase Subfilter |
|----------------------------------|---------------------|
| $h(0), h(3), h(6), \dots, h(15)$ | $h_0(n)$            |
| $h(1), h(4), h(7), \dots, h(16)$ | $h_1(n)$            |
| $h(2), h(5), h(8), \dots, h(17)$ | $h_2(n)$            |

An upsampling factor of  $L$  inserts  $L - 1$  zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter.

## Version History

### Introduced in R2012a

#### R2021b: `dsp.Interpolator` System object will be removed

*Warns starting in R2021b*

`dsp.Interpolator` System object will be removed in a future release. Use `dsp.FIRInterpolator`, `interp1` instead.

#### R2023a: `dsp.Interpolator` System object has been removed

*Errors starting in R2023a*

The `dsp.Interpolator` System object has been removed. Use `dsp.FIRInterpolator`, `interp1` instead.

### Update Code

This table shows how to update existing code to use the replacement features.

| Discouraged Usage   | Replacement using <code>dsp.FIRInterpolator</code>   |

# dsp.KalmanFilter

**Package:** dsp

(Removed) Estimate system measurements and states using Kalman filter

---

**Note** dsp.KalmanFilter has been removed. Use the Kalman filter functionality in Sensor Fusion and Tracking Toolbox™ instead.

---

## Description

The dsp.KalmanFilter System object is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state,  $x$ , at the  $k^{\text{th}}$  time-step:  $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$  (state equation). This measurement,  $z$ , is given as:  $z(k) = Hx(k) + v(k)$  (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters  $x$  (state) and  $P$  (state error covariance) are estimated using the previous state.
- Correction: The state and error covariance are corrected using the current measurement.

To filter each channel of the input:

- 1 Create the dsp.KalmanFilter object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
kalman = dsp.KalmanFilter
kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance,
CIMatrix)
kalman = dsp.KalmanFilter(Name,Value)
```

### Description

kalman = dsp.KalmanFilter returns the Kalman filter System object, kalman, with default values for the parameters.

kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix) returns a Kalman filter System object, kalman. The StateTransitionMatrix property is set to STMatrix, the MeasurementMatrix property is set to MMatrix, the ProcessNoiseCovariance property is set to PNCovariance, the

MeasurementNoiseCovariance property is set to MNCovariance, and the ControlInputMatrix property is set to CIMatrix.

`kalman = dsp.KalmanFilter(Name,Value)` returns an Kalman filter System object, `kalman`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### StateTransitionMatrix — Model of state transition

1 (default) | scalar | square matrix

Specify  $A$  in the state equation that relates the state at the previous time step to the state at current time step.  $A$  is a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ControlInputMatrix — Model of relation between control input and states

1 (default) | column vector

Specify  $B$  in the state equation that relates the control input to the state.  $B$  is a column vector with a number of rows equal to the number of states.

### Dependencies

This property is activated only when the `ControlInputPort` property value is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### MeasurementMatrix — Model of relation between states and measurement output

1 (default) | row vector

Specify  $H$  in the measurement equation that relates the states to the measurements.  $H$  is a row vector with a number of columns equal to the number of measurements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ProcessNoiseCovariance — Covariance of process noise

0.1 (default) | scalar | square matrix

Specify  $Q$  as a square matrix with each dimension equal to the number of states.  $Q$  is the covariance of the white Gaussian process noise,  $w$ , in the state equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### MeasurementNoiseCovariance — Covariance of measurement noise

0.1 (default) | scalar | square matrix

Specify  $R$  as a square matrix with each dimension equal to the number of states.  $R$  is the covariance of the white Gaussian process noise,  $v$ , in the measurement equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **InitialStateEstimate — Initial value for states**

0 (default) | scalar | column vector

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **InitialErrorCovarianceEstimate — Initial value for state error covariance**

0.1 (default) | scalar | square matrix

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **DisableCorrection — Disable port for filters**

false (default) | true

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm.

#### **ControlInputPort — Presence of a control input**

true (default) | false

Specify if the control input is present, using a scalar logical value. The default value is true.

## Usage

### Syntax

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)
```

### Description

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)` carries out the iterative Kalman filter algorithm over measurements  $z$  and control inputs  $u$ . The columns in  $z$  and  $u$  are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `zEst`, estimated states `xEst`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred`, and MSE of predicted states `MSE_Pred`.

### Input Arguments

#### **z — Measurement input**

vector | matrix

Measurement input, specified as a vector or a matrix.

The ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property must be equal to the ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property.

The measurement signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

### **u — Control input**

vector | matrix

Control input, specified as a vector or a matrix.

The ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property must be equal to the ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property.

The control signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

### **Output Arguments**

#### **zEst — Estimated measurements**

vector | matrix

Estimated measurements, returned as a vector or matrix.

Data Types: `single` | `double`

#### **xEst — Estimated state**

vector | matrix

Estimated state, returned as a vector or matrix.

Data Types: `single` | `double`

#### **MSE\_Est — MSE of estimated states**

scalar | column vector

Mean-squared error of estimated states, returned as a scalar or column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

#### **zPred — Predicted measurements**

vector | matrix

Predicted measurements, returned as a vector or a matrix.

Data Types: `single` | `double`

#### **xPred — Predicted states**

vector | matrix

Predicted states, returned as a vector or a matrix.

Data Types: `single` | `double`

### MSE\_Pred — MSE of predicted states

scalar | column vector

Mean-squared error of predicted states, returned as a scalar or a column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step`     Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

## Examples

### Estimate Changing Scalar

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ones(numSamples/4,1); -3*ones(numSamples/4,1); ...
    4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = timescope('NumInputPorts',3,...
    'TimeSpanSource','Property','TimeSpan',numSamples, ...
    'TimeUnits','Seconds','YLimits',[-5 5], ...
    'ShowLegend',true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance',R,...
    'InitialStateEstimate',5,...
    'InitialErrorCovarianceEstimate',1,...
    'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal);
```

```
tScope(noisyVal,trueVal,estVal);  
end
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

### Version History

#### Introduced in R2013b

#### **R2021b: dsp.KalmanFilter System object will be removed**

*Warns starting in R2021b*

`dsp.KalmanFilter` System object will be removed in a future release. Use the Kalman filter functionality in the Sensor Fusion and Tracking Toolbox instead.

#### **R2023a: dsp.KalmanFilter System object has been removed**

*Errors starting in R2023a*

The `dsp.KalmanFilter` System object has been removed. Use the Kalman filter functionality in Sensor Fusion and Tracking Toolbox instead.

# dsp.LDLFactor

**Package:** dsp

(Removed) Factor square Hermitian positive definite matrices into components

---

**Note** dsp.LDLFactor has been removed. Use `ldl` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of  $S$ .

To factor these matrices into lower, upper, and diagonal components:

- 1 Define and set up your LDL factor object. See “Construction” on page 4-713.
- 2 Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular  $L$  and diagonal  $D$  such that  $S = LDL$  for square, symmetric/Hermitian, positive definite input matrix  $S$ .

`ldl = dsp.LDLFactor('PropertyName', PropertyValue, ...)` returns an LDL factor System object, `ldl`, with each specified property set to the specified value.

## Properties

### Fixed-Point Properties

#### AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

#### CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **CustomIntermediateProductDataType**

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType(true, 16, 15)`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **IntermediateProductDataType**

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

## Methods

`step`      Decompose matrix into components

| Common to All System Objects |  |
|------------------------------|--|
| <code>release</code>         | Allow System object property value changes |

## Examples

### Decompose a Matrix

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A)
```

```
y = 5x5
 1.0000  -0.3884   0.0296  -0.6152  -0.3903
-0.3884   0.8491  -0.6386  -0.4901   0.3137
 0.0296  -0.6386   0.6529   0.3611   0.5770
-0.6152  -0.4901   0.3611   0.3324   0.5660
-0.3903   0.3137   0.5770   0.5660   0.4403
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except: No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

## Version History

Introduced in R2012a

### R2021b: dsp.LDLFactor System object will be removed

Warns starting in R2021b

`dsp.LDLFactor` System object will be removed in a future release. Use the `ldl` function instead.

### R2023a: dsp.LDLFactor System object has been removed

Errors starting in R2023a

The `dsp.LDLFactor` System object has been removed. Use the `ldl` function instead.

### Update Code

This table shows how to update existing code to use the `ldl` function.

| Discouraged Usage   | Recommended Replacement   |
|---|---|

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## See Also

ldl

## step

**System object:** dsp.LDLFactor

**Package:** dsp

Decompose matrix into components

### Syntax

```
Y = step(ldl,S)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LevinsonSolver

**Package:** dsp

(Removed) Solve linear system of equations using Levinson-Durbin recursion

---

**Note** `dsp.LevinsonSolver` has been removed. Use `levinson` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

- 1 Define and set up your System object. See “Construction” on page 4-719.
- 2 Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

## Construction

`levinson = dsp.LevinsonSolver` returns a System object, `levinson`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`levinson = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `levinson`, with each specified property set to the specified value.

## Properties

### AOutputPort

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

### KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients  $K$ . You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

### **PredictionErrorOutputPort**

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

### **ZerothLagZeroAction**

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

### **Fixed-Point Properties**

#### **RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

#### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

#### **ACoefficientDataType**

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

#### **CustomACoefficientDataType**

A coefficient word and fraction lengths

Specify the A coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

#### **KCoefficientDataType**

K coefficient word and fraction lengths

This constant property has a value of Custom.

### **CustomKCoefficientDataType**

*K* coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

### **PredictionErrorDataType**

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

### **CustomPredictionErrorDataType**

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

## Methods

`step` Reflection coefficients corresponding to columns of input

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>release</code> | Allow System object property value changes |
|----------------------|--|

## Examples

### Compute Polynomial Coefficients

---

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

---

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
lev = dsp.LevinsonSolver;
lev.AOutputPort = true;
lev.KOutputPort = false;
x = (1:100)';
a = xcorr(x,10);
% Consider the autocorrelation computed over nonnegative lags [0 10].
c = lev(a(11:end)); % Compute polynomial coefficients
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except: **Output(s)** block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

## Version History

### Introduced in R2012a

#### R2021b: `dsp.LevinsonSolver` System object will be removed

*Warns starting in R2021b*

`dsp.LevinsonSolver` System object will be removed in a future release. Use the `levinson` function instead.

#### R2023a: `dsp.LevinsonSolver` System object has been removed

*Errors starting in R2023a*

The `dsp.LevinsonSolver` System object has been removed. Use the `levinson` function instead.

## Update Code

This table shows how to update existing code to use the `levinson` function.

| Discouraged Usage  | Recommended Replacement   |
|--|---|
| <pre>lev = dsp.LevinsonSolver; lev.AOutputPort = true; lev.KOutputPort = false; x = (1:100)';</pre> <p>The System object computes autocorrelation over the lags [-10 10].</p> <pre>a = xcorr(x,10);</pre> <p>Display the autocorrelation computed over nonnegative lags [0 10].</p> <pre>c = lev(a(11:end));</pre> <pre>c = 10x1  1.0000 -0.9920  0.0001  0.0001  0.0001  0.0001  0.0001  0.0001  0.0001  0.0001  0.0001  0.0070</pre> | <p>The function returns the polynomial coefficients in the form of a row vector.</p> <pre>cfn = levinson(a(11:end))</pre> <pre>cfn = 1x10  1.0000 -0.9920 0.0001 0.0001 0.0001 0.0001 0.0001...  0.0001 0.0001 0.0001 0.0001 0.0070</pre> |

## Extended Capabilities

### C/C++ Code Generation

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

`levinson`

## step

**System object:** dsp.LevinsonSolver

**Package:** dsp

Reflection coefficients corresponding to columns of input

### Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[... , P] = step(levinson,X)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag  $\theta$  as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[... , P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.LMSFilter

**Package:** dsp

Compute output, error, and weights of LMS adaptive filter

## Description

The `dsp.LMSFilter` System object implements an adaptive finite impulse response (FIR) filter that converges an input signal to the desired signal using one of the following algorithms:

- LMS
- Normalized LMS
- Sign-Data LMS
- Sign-Error LMS
- Sign-Sign LMS

For more details on each of these methods, see “Algorithms” on page 4-768.

The filter adapts its weights until the error between the primary input signal and the desired signal is minimal. The mean square of this error (MSE) is computed using the `mseim` function. The predicted version of the MSE is determined using a Wiener filter in the `msepred` function. The `maxstep` function computes the maximum adaptation step size, which controls the speed of convergence.

For an overview of the adaptive filter methodology, and the most common applications the adaptive filters are used in, see “Overview of Adaptive Filters and Applications”.

To filter a signal using an adaptive FIR filter:

- 1 Create the `dsp.LMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-769.

## Creation

### Syntax

```
lms = dsp.LMSFilter
lms = dsp.LMSFilter(L)
lms = dsp.LMSFilter(Name,Value)
```

## Description

`lms = dsp.LMSFilter` returns an LMS filter object, `lms`, that computes the filtered output, filter error, and the filter weights for a given input and a desired signal using the least mean squares (LMS) algorithm.

`lms = dsp.LMSFilter(L)` returns an LMS filter object with the “Length” on page 4-0 property set to `L`.

`lms = dsp.LMSFilter(Name, Value)` returns an LMS filter object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with the previous input argument.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Method — Method to calculate filter weights

'LMS' (default) | 'Normalized LMS' | 'Sign-Data LMS' | 'Sign-Error LMS' | 'Sign-Sign LMS'

Method to calculate filter weights, specified as one of the following:

- 'LMS' -- Solves the Wiener-Hopf equation and finds the filter coefficients for an adaptive filter.
- 'Normalized LMS' -- Normalized variation of the LMS algorithm.
- 'Sign-Data LMS' -- Correction to the filter weights at each iteration depends on the sign of the input `x`.
- 'Sign-Error LMS' -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error, `err`.
- 'Sign-Sign LMS' -- Correction applied to the current filter weights for each successive iteration depends on both the sign of `x` and the sign of `err`.

For more details on the algorithms, see “Algorithms” on page 4-768.

### Length — Length of FIR filter weights vector

32 (default) | positive integer

Length of the FIR filter weights vector, specified as a positive integer.

Example: 64

Example: 16

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### StepSizeSource — Method to specify adaptation step size

'Property' (default) | 'Input port'

Method to specify the adaptation step size, specified as one of the following:

- 'Property' -- The property "StepSize" on page 4-0 specifies the size of each adaptation step.
- 'Input port' -- Specify the adaptation step size as one of the inputs to the object.

### StepSize — Adaptation step size

0.1 (default) | non-negative scalar

Adaptation step size factor, specified as a non-negative scalar. For convergence of the normalized LMS method, the step size must be greater than 0 and less than 2.

A small step size ensures a small steady state error between the output "y" on page 4-0 and the desired signal "d" on page 4-0. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

**Tunable:** Yes

### Dependencies

This property applies when you set "StepSizeSource" on page 4-0 to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### LeakageFactor — Leakage factor used in leaky LMS method

1 (default) | [0 1]

Leakage factor used when implementing the leaky LMS method, specified as a scalar in the range [0 1]. When the value equals 1, there is no leakage in the adapting method. When the value is less than 1, the filter implements a leaky LMS method.

Example: 0.5

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### InitialConditions — Initial conditions of filter weights

0 (default) | scalar | vector

Initial conditions of filter weights, specified as a scalar or a vector of length equal to the value of the "Length" on page 4-0 property. When the input is real, the value of this property must be real.

Example: 0

Example: [1 3 1 2 7 8 9 0 2 2 8 2]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

### AdaptInputPort — Flag to adapt filter weights

false (default) | true

Flag to adapt filter weights, specified as one of the following:

- false -- The object continuously updates the filter weights.

- `true` -- An adaptation control input is provided to the object when you call its algorithm. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

### WeightsResetInputPort — Flag to reset filter weights

`false` (default) | `true`

Flag to reset filter weights, specified as one of the following:

- `false` -- The object does not reset weights.
- `true` -- A reset control input is provided to the object when you call its algorithm. This setting enables the “WeightsResetCondition” on page 4-0 property. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input provided to the object algorithm.

### WeightsResetCondition — Event to reset filter weights

`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Event that triggers the reset of the filter weights, specified as one of the following. The object resets the filter weights whenever a reset event is detected in its reset input.

- `'Non-zero'` -- Triggers a reset operation at each sample, when the reset input is not zero.
- `'Rising edge'` -- Triggers a reset operation when the reset input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- `'Falling edge'` -- Triggers a reset operation when the reset input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

The object resets the filter weights based on the value of this property and the reset input `r` provided to the object algorithm.

#### Dependencies

This property applies when you set the “WeightsResetInputPort” on page 4-0 property to `true`.

#### WeightsOutput — Method to output adapted filter weights

'Last' (default) | 'None' | 'All'

Method to output adapted filter weights, specified as one of the following:

- 'Last' (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the “Length” on page 4-0 property.
- 'All' — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- 'None' — This setting disables the weights output.

#### Fixed-Point Properties

##### RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

##### OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

##### StepSizeDataType — Step size word length and fraction length settings

'Same word length as first input' (default) | 'Custom'

Step size word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of step size to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The step size data type is specified as a custom numeric type through the "CustomStepSizeDataType" on page 4-0 property.

For more information on the step size data type this object uses, see the "Fixed Point" on page 4-765 section.

#### **CustomStepSizeDataType — Word and fraction lengths of step size**

`numerictype([],16,15)` (default)

Word and fraction lengths of the step size, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numerictype([],32)`

#### **Dependencies**

This property applies under the following conditions:

- "StepSizeSource" on page 4-0 property set to 'Property' and "StepSizeDataType" on page 4-0 set to 'Custom'.
- StepSizeSource property set to 'Input port'.

#### **LeakageFactorDataType — Leakage factor word length and fraction length settings**

'Same word length as first input' (default) | 'Custom'

Leakage factor word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of leakage factor to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The leakage factor data type is specified as a custom numeric type through the "CustomLeakageFactorDataType" on page 4-0 property.

For more information on the leakage factor data type this object uses, see the "Fixed Point" on page 4-765 section.

#### **CustomLeakageFactorDataType — Word and fraction lengths of the leakage factor**

`numerictype([],16,15)` (default)

Word and fraction lengths of the leakage factor, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numerictype([],32)`

#### **Dependencies**

This property applies when you set the "LeakageFactorDataType" on page 4-0 property to 'Custom'.

#### **WeightsDataType — Weights word length and fraction length settings**

'Same as first input' (default) | 'Custom'

Weights word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights to be the same as that of the first input.
- 'Custom' -- The data type of filter weights is specified as a custom numeric type through the "CustomWeightsDataType" on page 4-0 property.

For more information on the filter weights data type this object uses, see the "Fixed Point" on page 4-765 section.

### **CustomWeightsDataType — Word and fraction lengths of filter weights**

`numericType([],16,15)` (default)

Word and fraction lengths of the filter weights, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numericType([],32,20)`

#### **Dependencies**

This property applies when you set the "WeightsDataType" on page 4-0 property to 'Custom'.

### **EnergyProductDataType — Energy product word length and fraction length settings**

'Same as first input' (default) | 'Custom'

Energy product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy product to be the same as that of the first input.
- 'Custom' -- The data type of the energy product is specified as a custom numeric type through the "CustomEnergyProductDataType" on page 4-0 property.

For more information on the energy product data type this object uses, see the "Fixed Point" on page 4-765 section.

#### **Dependencies**

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS'.

### **CustomEnergyProductDataType — Word and fraction lengths of energy product**

`numericType([],32,20)` (default)

Word and fraction lengths of the energy product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

#### **Dependencies**

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS' and "EnergyProductDataType" on page 4-0 property to 'Custom'.

### **EnergyAccumulatorDataType — Energy accumulator word length and fraction length settings**

'Same as first input' (default) | 'Custom'

Energy accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy accumulator to be the same as that of the first input.
- 'Custom' -- The data type of the energy accumulator is specified as a custom numeric type through the “CustomEnergyAccumulatorDataType” on page 4-0 property.

For more information on the energy accumulator data type this object uses, see the “Fixed Point” on page 4-765 section.

### Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

### CustomEnergyAccumulatorDataType — Word and fraction lengths of energy accumulator

numericity([],32,20) (default)

Word and fraction lengths of the energy accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

### Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “EnergyAccumulatorDataType” on page 4-0 property to 'Custom'.

### ConvolutionProductDataType — Convolution product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution product to be the same as that of the first input.
- 'Custom' -- The data type of the convolution product is specified as a custom numeric type through the “CustomConvolutionProductDataType” on page 4-0 property.

For more information on the convolution product data type this object uses, see the “Fixed Point” on page 4-765 section.

### CustomConvolutionProductDataType — Word and fraction lengths of convolution product

numericity([],32,20) (default)

Word and fraction lengths of the convolution product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

### Dependencies

This property applies when you set the “ConvolutionProductDataType” on page 4-0 property to 'Custom'.

### ConvolutionAccumulatorDataType — Convolution accumulator word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution accumulator to be the same as that of the first input.

- 'Custom' -- The data type of the convolution accumulator is specified as a custom numeric type through the “CustomConvolutionAccumulatorDataType” on page 4-0 property.

For more information on the convolution accumulator data type this object uses, see the “Fixed Point” on page 4-765 section.

#### **CustomConvolutionAccumulatorDataType — Word and fraction lengths of convolution accumulator**

`numericType([],32,20)` (default)

Word and fraction lengths of the convolution accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

#### **Dependencies**

This property applies when you set the “ConvolutionAccumulatorDataType” on page 4-0 property to 'Custom'.

#### **StepSizeErrorProductDataType — Step size error product word length and fraction length settings**

`'Same as first input'` (default) | `'Custom'`

Step size error product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the step size error product to be the same as that of the first input.
- 'Custom' -- The data type of the step size error product is specified as a custom numeric type through the “CustomStepSizeErrorProductDataType” on page 4-0 property.

For more information on the step size error product data type this object uses, see the “Fixed Point” on page 4-765 section.

#### **CustomStepSizeErrorProductDataType — Word and fraction lengths of step size error product**

`numericType([],32,20)` (default)

Word and fraction lengths of the step size error product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

#### **Dependencies**

This property applies when you set the “StepSizeErrorProductDataType” on page 4-0 property to 'Custom'.

#### **WeightsUpdateProductDataType — Filter weights update product word length and fraction length settings**

`'Same as first input'` (default) | `'Custom'`

Word and fraction length settings of the filter weights update product, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights update product to be the same as that of the first input.
- 'Custom' -- The data type of the filter weights update product is specified as a custom numeric type through the “CustomWeightsUpdateProductDataType” on page 4-0 property.

For more information on the filter weights update product data type this object uses, see the “Fixed Point” on page 4-765 section.

### **CustomWeightsUpdateProductDataType — Word and fraction lengths of filter weights update product**

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

#### **Dependencies**

This property applies when you set the “WeightsUpdateProductDataType” on page 4-0 property to 'Custom'.

### **QuotientDataType — Quotient word length and fraction length settings**

'Same as first input' (default) | 'Custom'

Quotient word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the quotient data type to be the same as that of the first input.
- 'Custom' -- The quotient data type is specified as a custom numeric type through the “CustomQuotientDataType” on page 4-0 property.

For more information on the quotient data type this object uses, see the “Fixed Point” on page 4-765 section.

#### **Dependencies**

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

### **CustomQuotientDataType — Word and fraction lengths of quotient**

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

#### **Dependencies**

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “QuotientDataType” on page 4-0 property to 'Custom'.

## **Usage**

### **Syntax**

```
[y,err,wts] = lms(x,d)
[y,err] = lms(x,d)
[___] = lms(x,d,mu)
[___] = lms(x,d,a)
[___] = lms(x,d,r)
[y,err,wts] = lms(x,d,mu,a,r)
```

## Description

`[y,err,wts] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y`, the filter error in `err`, and the estimated filter weights in `wts`. The LMS filter object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`[y,err] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err` when the “WeightsOutput” on page 4-0 property is set to 'None'.

`[ ___ ] = lms(x,d,mu)` filters the input signal, `x`, using `d` as the desired signal and `mu` as the step size, when the “StepSizeSource” on page 4-0 property is set to 'Input port'. These inputs can be used with either of the previous sets of outputs.

`[ ___ ] = lms(x,d,a)` filters the input signal, `x`, using `d` as the desired signal and `a` as the adaptation control when the “AdaptInputPort” on page 4-0 property is set to `true`. When `a` is nonzero, the System object continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

`[ ___ ] = lms(x,d,r)` filters the input signal, `x`, using `d` as the desired signal and `r` as a reset signal when the “WeightsResetInputPort” on page 4-0 property is set to `true`. The “WeightsResetCondition” on page 4-0 property can be used to set the reset trigger condition. If a reset event occurs, the System object resets the filter weights to their initial values.

`[y,err,wts] = lms(x,d,mu,a,r)` filters the input signal, `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal, and returns the filtered output in `y`, the filter error in `err`, and the adapted filter weights in `wts`.

## Input Arguments

### **x** — Data input

scalar | column vector

The signal to be filtered by the LMS filter. The input, `x`, and the desired signal, `d` must have the same size, data type, and complexity. If the input is fixed-point, the data type must be signed and must have the same word length as the desired signal.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### **d** — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity. If the desired signal is fixed-point, the data type must be signed and must have the same word length as the data input.

The input, `d` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**mu — Step size**

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. For convergence of the normalized LMS method, the step size should be greater than 0 and less than 2. The data type of the step size input must match the data type of `x` and `d`. If the data type is fixed-point, the data type must be signed.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

**Dependencies**

This input is required when the “StepSizeSource” on page 4-0 property is set to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**a — Adaptation control**

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

**Dependencies**

This input is required when the “AdaptInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

**r — Reset signal**

scalar

Reset signal that resets the filter weights based on the values of the “WeightsResetCondition” on page 4-0 property.

**Dependencies**

This input is required when the “WeightsResetInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

**Output Arguments****y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### **err — Difference between output and desired signal**

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal. For more details on how `err` is computed, see “Algorithms” on page 4-768.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### **wts — Adaptive filter weights**

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in “Length” on page 4-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### **Specific to dsp.LMSFilter**

`maxstep` Maximum step size for LMS adaptive filter convergence  
`msepred` Predicted mean squared error for LMS adaptive filter  
`msestim` Estimated mean squared error for adaptive filters

### **Common to All System Objects**

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## **Examples**

### **Predict Mean Squared Error for LMS Filter**

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the `msepred` and `msestim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

### Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

### LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

### Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

### Plot the Coefficient Trajectories

meanWsim is the mean value of the simulated coefficients given by msesim. meanW is the mean value of the predicted coefficients given by msepred.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}

```

```
PlotTitle = 2x1 cell
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}

```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')

```

In steady state, both the trajectories converge.

### Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

### Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
for k = 1:size(x,2)
    x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
end
mu = 0.1;
LMSFilter = dsp.LMSFilter('Length',32,...
    'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)

mumax = 0.0625
mumaxmse = 0.0536
```

## System Identification of FIR Filter Using LMS Algorithm

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm. In this example, set the `Method` property of `dsp.LMSFilter` to 'LMS' to choose the LMS adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `firband` is the unknown system.
- Appropriate input data to exercise the adaptation process. For the generic LMS model, these are the desired signal  $d(k)$  and the input signal  $x(k)$ .

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter  $y(k)$  and the output of the unknown system (or the system to be identified)  $d(k)$ . Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

### Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;  
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...  
{'w' 'c'});
```

Pass the signal  $x$  to the FIR filter. The desired signal  $d$  is the sum of the output of the unknown system (FIR filter) and an additive noise signal  $n$ .

```
x = 0.1*randn(250,1);  
n = 0.01*randn(250,1);  
d = filt(x) + n;
```

### Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the adaptive LMS filter object to identify the unknown filter.

Preparing the adaptive filter object requires starting values for estimates of the filter coefficients and the LMS step size ( $\mu$ ). You can start with some set of nonzero values as estimates for the filter coefficients. This example uses zeros for the 13 initial filter weights. Set the `InitialConditions` property of `dsp.LMSFilter` to the desired initial values of the filter weights. For the step size, 0.8 is a good compromise between being large enough to converge well within 250 iterations (250 input sample points) and small enough to create an accurate estimate of the unknown filter.

Create a `dsp.LMSFilter` object to represent an adaptive filter that uses the LMS adaptive algorithm. Set the length of the adaptive filter to 13 taps and the step size to 0.8.

```
mu = 0.8;  
lms = dsp.LMSFilter(13,'StepSize',mu)
```

```
lms =  
  dsp.LMSFilter with properties:  
  
          Method: 'LMS'  
         Length: 13  
  StepSizeSource: 'Property'  
         StepSize: 0.8000  
    LeakageFactor: 1  
  InitialConditions: 0  
    AdaptInputPort: false  
  WeightsResetInputPort: false  
        WeightsOutput: 'Last'
```

Show all properties

Pass the primary input signal  $x$  and the desired signal  $d$  to the LMS filter. Run the adaptive filter to determine the unknown system. The output  $y$  of the adaptive filter is the signal converged to the desired signal  $d$  thereby minimizing the error  $e$  between the two signals.

Plot the results. The output signal does not match the desired signal as expected, making the error between the two nontrivial.

```
[y,e,w] = lms(x,d);  
plot(1:250, [d,y,e])  
title('System Identification of an FIR filter')  
legend('Desired','Output','Error')  
xlabel('Time index')  
ylabel('Signal value')
```

### Compare the Weights

The weights vector  $w$  represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

The estimated filter weights do not closely match the actual filter weights, confirming the results seen in the previous signal plot.

```
stem([(filt.Numerator). ' w'])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

### Changing the Step Size

As an experiment, change the step size to 0.2. Repeating the example with  $\mu = 0.2$  results in the following stem plot. The filters do not converge, and the estimated weights are not good approximations of the actual weights.

```
mu = 0.2;
lms = dsp.LMSFilter(13, 'StepSize', mu);
[~,~,w] = lms(x,d);
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

### Increase the Number of Data Samples

Increase the frame size of the desired signal. Even though this increases the computation involved, the LMS algorithm now has more data that can be used for adaptation. With 1000 samples of signal data and a step size of 0.2, the coefficients are aligned closer than before, indicating an improved convergence.

```
release(filt);
x = 0.1*randn(1000,1);
n = 0.01*randn(1000,1);
d = filt(x) + n;
[y,e,w] = lms(x,d);
stem([filt.Numerator.' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
       'Location','NorthEast')
```

Increase the number of data samples further by inputting the data through iterations. Run the algorithm on 4000 samples of data, passed to the LMS algorithm in batches of 1000 samples over 4 iterations.

Compare the filter weights. The weights of the LMS filter match the weights of the FIR filter very closely, indicating a good convergence.

```

release(filt);
n = 0.01*randn(1000,1);
for index = 1:4
    x = 0.1*randn(1000,1);
    d = filt(x) + n;
    [y,e,w] = lms(x,d);
end
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
       'Location','NorthEast')

```

The output signal matches the desired signal very closely, making the error between the two close to zero.

```
plot(1:1000, [d,y,e])  
title('System Identification of an FIR filter')  
legend('Desired', 'Output', 'Error')  
xlabel('Time index')  
ylabel('Signal value')
```

### System Identification of FIR Filter Using Normalized LMS Algorithm

To improve the convergence performance of the LMS algorithm, the normalized variant (NLMS) uses an adaptive step size based on the signal power. As the input signal power changes, the algorithm calculates the input power and adjusts the step size to maintain an appropriate value. The step size changes with time, and as a result, the normalized algorithm converges faster with fewer samples in many cases. For input signals that change slowly over time, the normalized LMS algorithm can be a more efficient LMS approach.

For an example using the LMS approach, see “System Identification of FIR Filter Using LMS Algorithm”.

### Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
```

Pass the signal `x` to the FIR filter. The desired signal `d` is the sum of the output of the unknown system (FIR filter) and an additive noise signal `n`.

```
x = 0.1*randn(1000,1);  
n = 0.001*randn(1000,1);  
d = filt(x) + n;
```

### Adaptive Filter

To use the normalized LMS algorithm variation, set the `Method` property on the `dsp.LMSFilter` to 'Normalized LMS'. Set the length of the adaptive filter to 13 taps and the step size to 0.2.

```
mu = 0.2;  
lms = dsp.LMSFilter(13, 'StepSize', mu, 'Method', ...  
    'Normalized LMS');
```

Pass the primary input signal `x` and the desired signal `d` to the LMS filter.

```
[y,e,w] = lms(x,d);
```

The output `y` of the adaptive filter is the signal converged to the desired signal `d` thereby minimizing the error `e` between the two signals.

```
plot(1:1000, [d,y,e])  
title('System Identification by Normalized LMS Algorithm')  
legend('Desired', 'Output', 'Error')  
xlabel('Time index')  
ylabel('Signal value')
```

### Compare the Adapted Filter to the Unknown System

The weights vector  $w$  represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

```
stem([filt.Numerator.' w])
title('System Identification by Normalized LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

### Compare Convergence Performance Between LMS Algorithm and Normalized LMS Algorithm

An adaptive filter adapts its filter coefficients to match the coefficients of an unknown system. The objective is to minimize the error signal between the output of the unknown system and the output of the adaptive filter. When these two outputs converge and match closely for the same input, the coefficients are said to match closely. The adaptive filter at this state resembles the unknown system. This example compares the rate at which this convergence happens for the normalized LMS (NLMS) algorithm and the LMS algorithm with no normalization.

#### Unknown System

Create a `dsp.FIRFilter` that represents the unknown system. Pass the signal  $x$  as an input to the unknown system. The desired signal  $d$  is the sum of the output of the unknown system (FIR filter) and an additive noise signal  $n$ .

```
filt = dsp.FIRFilter;  
filt.Numerator = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...  
{'w' 'c'});  
x = 0.1*randn(1000,1);  
n = 0.001*randn(1000,1);  
d = filt(x) + n;
```

### Adaptive Filter

Create two `dsp.LMSFilter` objects, with one set to the LMS algorithm, and the other set to the normalized LMS algorithm. Choose an adaptation step size of 0.2 and set the length of the adaptive filter to 13 taps.

```
mu = 0.2;  
lms_nonnormalized = dsp.LMSFilter(13,'StepSize',mu,...  
    'Method','LMS');  
lms_normalized = dsp.LMSFilter(13,'StepSize',mu,...  
    'Method','Normalized LMS');
```

Pass the primary input signal `x` and the desired signal `d` to both the variations of the LMS algorithm. The variables `e1` and `e2` represent the error between the desired signal and the output of the normalized and nonnormalized filters, respectively.

```
[~,e1,~] = lms_normalized(x,d);  
[~,e2,~] = lms_nonnormalized(x,d);
```

Plot the error signals for both variations. The error signal for the NLMS variant converges to zero much faster than the error signal for the LMS variant. The normalized version adapts in far fewer iterations to a result almost as good as the nonnormalized version.

```
plot([e1,e2]);  
title('Comparing the LMS and NLMS Conversion Performance');  
legend('NLMS derived filter weights', ...  
    'LMS derived filter weights','Location','NorthEast');  
xlabel('Time index')  
ylabel('Signal value')
```

### Cancel Noise Using LMS Filter

Cancel additive noise,  $n$ , added to an unknown system using an LMS adaptive filter. The LMS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system represents the error signal,  $e$ . Minimizing this error signal is the objective of the adaptive filter.

The unknown system and the LMS filter process the same input signal,  $x$ , and produce outputs  $d$  and  $y$ , respectively. If the coefficients of the adaptive filter match the coefficients of the unknown system, the error,  $e$ , in effect represents the additive noise.

Create a `dsp.FIRFilter` System object to represent the unknown system. Create a `dsp.LMSFilter` object and set the length to 11 taps and the step size to 0.05. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
scope = timescope('TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*NIter, ...
```

```
'ShowLegend',true,'ChannelNames', ...
{'Noisy signal', 'Error signal'});
```

Create a random input signal,  $x$  and pass the signal to the FIR filter. Add a sine wave to the output of the FIR filter to generate the noisy signal,  $d$ . The signal,  $d$  is the output of the unknown system. Pass the noisy signal and the primary input signal to the LMS filter. View the noisy signal and the error signal in the time scope.

```
for k = 1:NIter
    x = randn(FrameSize,1);
    d = firfilt2(x) + sinewave();
    [y,e,w] = lmsfilt2(x,d);
    scope([d,e])
end
release(scope)
```

The error signal,  $e$ , is the sinusoidal noise added to the unknown system. Minimizing the error signal minimizes the noise added to the system.

### Noise Cancellation Using Sign-Data LMS Algorithm

When the amount of computation required to derive an adaptive filter drives your development process, the sign-data variant of the LMS (SDLMS) algorithm might be a very good choice, as demonstrated in this example.

In the standard and normalized variations of the LMS adaptive filter, coefficients for the adapting filter arise from the mean square error between the desired signal and the output signal from the unknown system. The sign-data algorithm changes the mean square error calculation by using the sign of the input data to change the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size  $\mu$ . If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by  $\mu$  — note the sign change.

When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-data LMS algorithm is:

$$w(k+1) = w(k) + \mu e(k) \text{sgn}(x(k)),$$

where

$$\text{sgn}(x(k)) = \begin{cases} 1, & x(k) > 0 \\ 0, & x(k) = 0 \\ -1, & x(k) < 0 \end{cases}$$

with vector  $w$  containing the weights applied to the filter coefficients and vector  $x$  containing the input data. The vector  $e$  is the error between the desired signal and the filtered signal. The objective of the SDLMS algorithm is to minimize this error. Step size is represented by  $\mu$ .

With a smaller  $\mu$ , the correction to the filter weights gets smaller for each sample, and the SDLMS error falls more slowly. A larger  $\mu$  changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select  $\mu$  within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}},$$

where  $N$  is the number of samples in the signal. Also, define  $\mu$  as a power of two for efficient computing.

**Note:** How you set the initial conditions of the sign-data algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal, the algorithm can become unstable easily.

A series of large input values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-data algorithm to get out of control by choosing a small step size ( $\mu \ll 1$ ) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Data LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal  $d(k)$ . The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is  $x(k)$ . The signal  $x(k)$

is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);  
filt = dsp.FIRFilter;  
filt.Numerator = fir1(11,0.4);  
fnoise = filt(noise);  
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-data algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-data algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.  
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for `dsp.LMSFilter` prepared, construct the LMS filter object, run the adaptation, and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Data LMS',...  
    'StepSize',mu,'InitialConditions',coeffs);  
[~,e] = lms(noise,d);  
L = 200;  
plot(0:L-1,signal(1:L),0:L-1,e(1:L));  
title('Noise Cancellation by the Sign-Data Algorithm');  
legend('Actual signal','Result of noise cancellation',...  
    'Location','NorthEast');  
xlabel('Time index')  
ylabel('Signal values')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-data adaptation requires only multiplication by bit shifting when the step size is a power of two.

Although the performance of the sign-data algorithm as shown in this plot is quite good, the sign-data algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the processed signal is a very good match to the input signal, but the algorithm could very easily grow without bound rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and  $\mu$  (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail.

### Noise Cancellation Using Sign-Error LMS Algorithm

In the standard and normalized variations of the LMS adaptive filter, the coefficients for the adapting filter arise from calculating the mean square error between the desired signal and the output signal from the unknown system, and applying the result to the current filter coefficients. The sign-error LMS (SELMS) algorithm replaces the mean square error calculation by using the sign of the error to modify the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size  $\mu$ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by  $\mu$  — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-error LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k))x(k),$$

where

$$\text{sgn}(e(k)) = \begin{cases} 1, & e(k) > 0 \\ 0, & e(k) = 0 \\ -1, & e(k) < 0 \end{cases}$$

with vector  $w$  containing the weights applied to the filter coefficients and vector  $x$  containing the input data. The vector  $e$  is the error between the desired signal and the filtered signal. The objective of the SELMS algorithm is to minimize this error.

With a smaller  $\mu$ , the correction to the filter weights gets smaller for each sample and the SELMS error falls more slowly. A larger  $\mu$  changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select  $\mu$  within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where  $N$  is the number of samples in the signal. Also, define  $\mu$  as a power of two for efficient computation.

**Note:** How you set the initial conditions of the sign-error algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-error algorithm to become unstable by choosing a small step size ( $\mu \ll 1$ ) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Error LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal  $d(k)$ . The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is  $x(k)$ . The signal  $x(k)$  is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
```

```
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

fnoise is the correlated noise and d is now the desired input to the sign-error algorithm.

To prepare the dsp.LMSFilter object for processing, set the initial conditions of the filter weights (InitialConditions) and mu (StepSize). As noted earlier in this section, the values you set for coeffs and mu determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-error algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (filt.Numerator) and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for dsp.LMSFilter prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Error LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-error LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When the sign-error LMS algorithm runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-error adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-error algorithm as shown in this plot is quite good, the sign-error algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and  $\mu$  (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

### Noise Cancellation Using Sign-Sign LMS Algorithm

The sign-sign LMS algorithm (SSLMS) replaces the mean square error calculation by using the sign of the input data to change the filter coefficients. When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size  $\mu$ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by  $\mu$  — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In essence, the algorithm quantizes both the error and the input by applying the sign operator to them.

In vector form, the sign-sign LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k)) \text{sgn}(x(k)),$$

where

$$\text{sgn}(z(k)) = \begin{cases} 1, & z(k) > 0 \\ 0, & z(k) = 0 \\ -1, & z(k) < 0 \end{cases}$$

$$z(k) = e(k) \text{sgn}(x(k))$$

Vector  $w$  contains the weights applied to the filter coefficients and vector  $x$  contains the input data. The vector  $e$  is the error between the desired signal and the filtered signal. The objective of the SSLMS algorithm is to minimize this error.

With a smaller  $\mu$ , the correction to the filter weights gets smaller for each sample and the SSLMS error falls more slowly. A larger  $\mu$  changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select  $\mu$  within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where  $N$  is the number of samples in the signal. Also, define  $\mu$  as a power of two for efficient computation

**Note:**

How you set the initial conditions of the sign-sign algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal and the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-sign algorithm to become unstable by choosing a small step size ( $\mu \ll 1$ ) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the `Method` property of `dsp.LMSFilter` to 'Sign-Sign LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is the desired signal  $d(k)$ . The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is  $x(k)$ . The signal  $x(k)$  is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-sign algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights (`InitialConditions`) and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path. In “System Identification of FIR Filter Using LMS Algorithm” on page 4-742, you constructed a default filter that sets the filter coefficients to zeros. Usually that approach does not work for the sign-sign algorithm.

The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively. For this example, you start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).' -0.01; % Set the filter initial conditions.
mu = 0.05;
```

With the required input arguments for `dsp.LMSFilter` prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Sign LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-sign LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-sign adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-sign algorithm as shown in this plot is quite good, the sign-sign algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and  $\mu$  (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

### Access Full History of LMS Filter Weights

**Note:** This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights.

Initialize the `dsp.LMSFilter` System object and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

scope = timescope('TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, w.

```
x = randn(FrameSize,1); % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in w is a set of weights estimated for the respective input sample. Each column in w gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
scope([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)])
```

## More About

### Fixed Point

The following diagrams show the data types used within the `dsp.LMSFilter` object for fixed-point signals. The table summarizes the definitions of the variables used in the diagrams:

| Variable                            | Definition  |
|-------------------------------------|---|
| $\mathbf{u}$                        | Input vector  |
| $\mathbf{W}$                        | Vector of filter weights                                    |
| $\mu$                               | Step size   |
| $e$                                 | Error   |
| $Q$                                 | Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$   |
| Product $\mathbf{u}'\mathbf{u}$     | Product data type in Energy calculation diagram             |
| Accumulator $\mathbf{u}'\mathbf{u}$ | Accumulator data type in Energy calculation diagram         |
| Product $\mathbf{W}'\mathbf{u}$     | Product data type in Convolution diagram                    |
| Accumulator $\mathbf{W}'\mathbf{u}$ | Accumulator data type in Convolution diagram                |
| Product $\mu \cdot e$               | Product data type in Product of step size and error diagram |

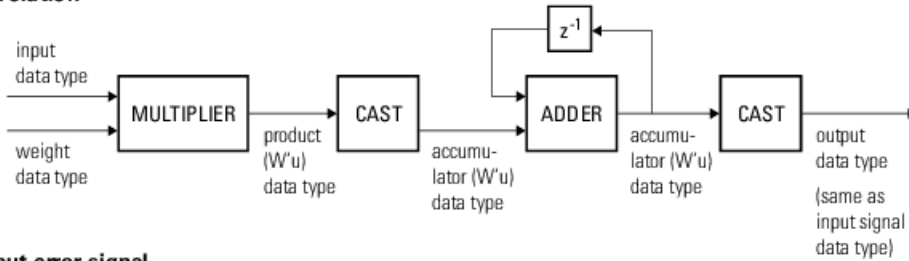

| Variable            | Definition   |
|---------------------|--|
| Product $Q \cdot u$ | Product and accumulator data type in Weight update diagram. <sup>1</sup> |

<sup>1</sup>The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

**Energy calculation (for normalized LMS algorithm only)**

**Convolution**

**Output error signal**

**Product of step size and error (for LMS and Sign-Data LMS algorithms only)****Quotient (for normalized LMS only)****Weight update**

You can set the data type of the properties, weights, products, quotient, and accumulators in the System object properties. Fixed-point inputs, outputs, and System object properties must have the following characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.
- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the  $\mathbf{u}'\mathbf{u}$ ,  $\mathbf{W}'\mathbf{u}$ ,  $\mu \cdot e$ , and  $Q \cdot \mathbf{u}$  operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the  $\mathbf{u}'\mathbf{u}$  and  $\mathbf{W}'\mathbf{u}$  operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

## Algorithms

The LMS filter algorithm is defined by the following equations.

$$\begin{aligned}y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\e(n) &= d(n) - y(n) \\ \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)\end{aligned}$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS -- Solves the Wiener-Hopf equation and finds the filter coefficients for an adaptive filter.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS -- Normalized variation of the LMS algorithm.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant,  $\varepsilon$ , has been added in the denominator. For double-precision floating-point input,  $\varepsilon$  is the output of the `eps` function. For single-precision floating-point input,  $\varepsilon$  is the output of `eps('single')`. For fixed-point input,  $\varepsilon$  is 0.

- Sign-Data LMS -- Correction to the filter weights at each iteration depends on the sign of the input  $\mathbf{u}(n)$ .

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

- Sign-Error LMS -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error,  $e(n)$ .

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n))\mathbf{u}^*(n)$$

- Sign-Sign LMS -- Correction applied to the current filter weights for each successive iteration depends on both the sign of  $\mathbf{u}(n)$  and the sign of  $e(n)$ .

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n))\text{sign}(\mathbf{u}(n))$$

where  $\mathbf{u}(n)$  is real.

The variables are as follows:

| Variable          | Description   |
|-------------------|---|
| $n$               | The current time index  |
| $\mathbf{u}(n)$   | The vector of buffered input samples at step $n$                          |
| $\mathbf{u}^*(n)$ | The complex conjugate of the vector of buffered input samples at step $n$ |
| $\mathbf{w}(n)$   | The vector of filter weight estimates at step $n$                         |
| $y(n)$            | The filtered output at step $n$   |
| $e(n)$            | The estimation error at step $n$  |
| $d(n)$            | The desired response at step $n$  |

| Variable      | Description  |
|---------------|--|
| $\mu$         | The adaptation step size   |
| $\alpha$      | The leakage factor ( $0 < \alpha \leq 1$ )   |
| $\varepsilon$ | A constant that corrects any potential numerical instability that occurs during the update of weights. |

## Version History

Introduced in R2012a

## References

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The dsp.LMSFilter System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Method is set to 'LMS' or 'Normalized LMS'.
- WeightsOutput is set to 'None' or 'Last'.
- Input signal is real-valued.
- Input signal has a data type of single or double.

The SIMD technology significantly improves the performance of the generated code.

# **dsp.LogicAnalyzer**

**Package:** dsp

Visualize, measure, and analyze transitions and states over time

## **Description**

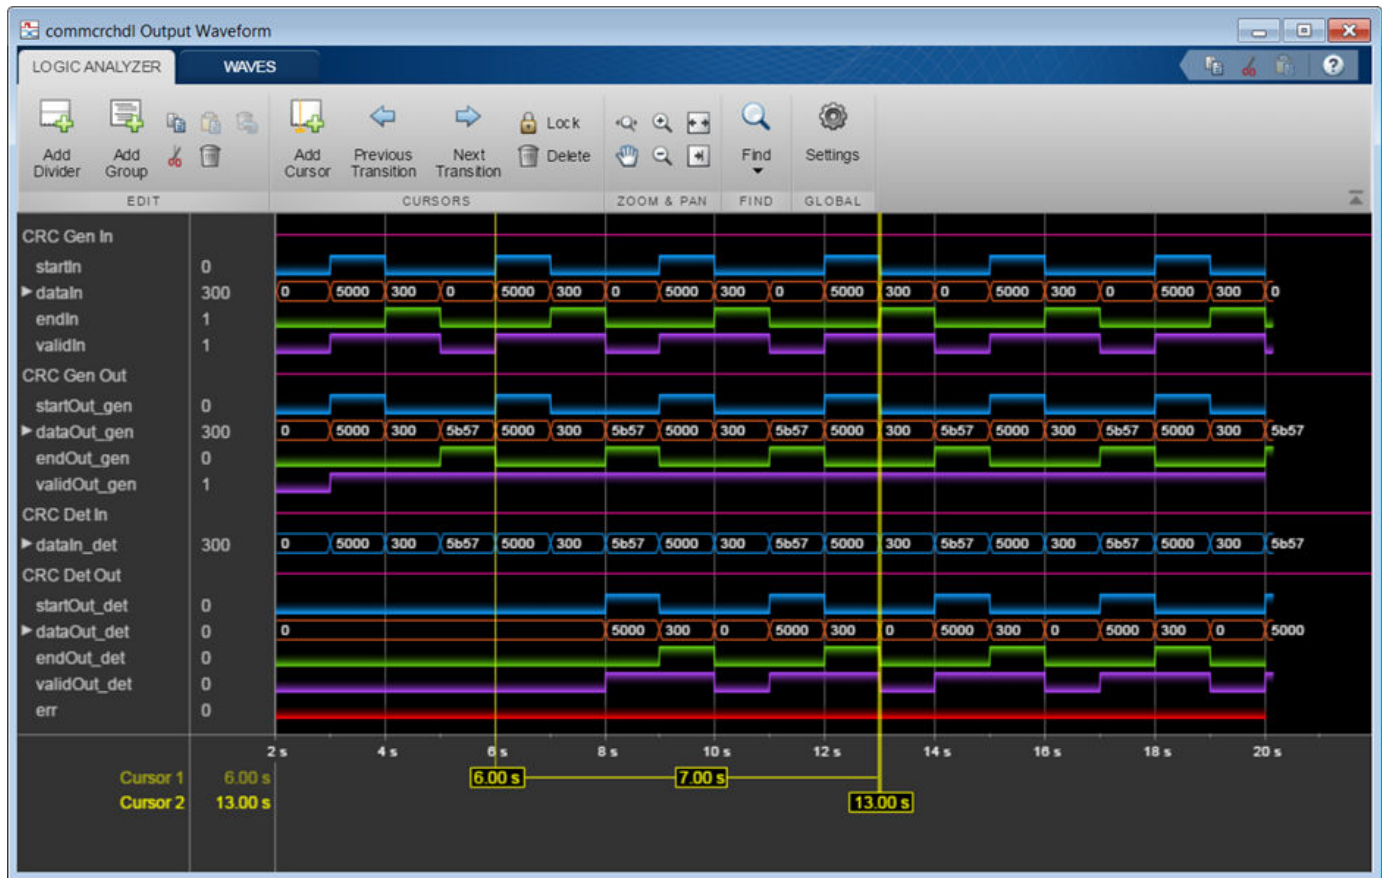

The Logic Analyzer System object displays the transitions in time-domain signals. Using `dsp.LogicAnalyzer`, you can:

- Debug and analyze models
- Trace and correlate 96 signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

To display the transitions of signals in the Logic Analyzer:

- 1** Create the `dsp.LogicAnalyzer` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

For more information about how to configure and customize the Logic Analyzer, see **Logic Analyzer**.

## Creation

### Syntax

```
scope = dsp.LogicAnalyzer
scope = dsp.LogicAnalyzer(Name,Value)
```

### Description

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.LogicAnalyzer('BackgroundColor','White','NumInputPorts',4)`.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **BackgroundColor** — Background color for display

'Black' (default) | 'White'

Background color of the display, specified as 'Black' or 'White'.

**Tunable:** Yes

Data Types: char | string

### **DisplayChannelColor** — Color for channels in display

[0.0588 1 1] (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **DisplayChannelFontSize** — Font size for channels in display

10 (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative integer.

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **DisplayChannelFormat** — Format for channels in display

'Automatic' (default) | 'Analog' | 'Digital'

Format for channels in the display, specified as one of the following:

- 'Automatic' — Displays floating-point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- 'Analog' — Shows values as an analog plot.
- 'Digital' — Shows values as digital transitions.

**Tunable:** Yes

Data Types: char | string

### **DisplayChannelHeight** — Channel height in display

12 (default) | positive real scalar

Channel height in the display, in pixels, specified as a positive real scalar in the range [8, 200].

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**DisplayChannelRadix — Base used to display values**

'Hexadecimal' (default) | 'Binary' | 'Octal' | 'Signed decimal' | 'Unsigned decimal'

This property applies only to fixed-point (fi) values.

**Tunable:** Yes

Data Types: char | string

**DisplayChannelSpacing — Spacing between channels in display (pixels)**

4 (default) | positive integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Name — Caption to display on scope window**

'Logic Analyzer' (default) | character vector | string scalar

Caption to display on the scope window, specified as a character vector or string.

**Tunable:** Yes

Data Types: char | string

**NumInputPorts — Number of input ports**

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

**Position — Scope window position**

[left bottom width height] vector

Position of the scope window on your screen, in pixels, specified as a [left bottom width height] vector. The default position depends on your screen resolution. By default, the scope window appears in the center of your screen, with a width of 800 pixels and height of 600 pixels.

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**SampleTime — Input sample time**

1 (default) | scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**TimeDisplayOffset — Time display offset**

0 (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### **TimeSpan — Time span**

10 | positive scalar

Time span in seconds, specified as a positive scalar. The x-axis limits are calculated as follows:

- Minimum x-axis limit = `min(TimeDisplayOffset)`
- Maximum x-axis limit = `max(TimeDisplayOffset) + TimeSpan`

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

**Tunable:** Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

## **Usage**

### **Syntax**

```
scope(signal)
scope(signal1,signal2,...signalN)
```

### **Description**

`scope(signal)` displays the signal `signal` in the Logic Analyzer scope.

`scope(signal1,signal2,...signalN)` displays multiple signals in the Logic Analyzer when you set the `NumInputPorts` property to `N`. Each signal can have different data types and dimensions.

### **Input Arguments**

#### **signal — Input signal or signals to visualize**

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.LogicAnalyzer`. Signals can have different data types and dimensions.

Integers are supported up to 64 bits and fixed-point signals are supported up to 128 bits.

Example: `scope(signal1,signal2)`

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | struct | table | cell

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.LogicAnalyzer

|                       |   |
|-----------------------|---|
| addCursor             | Add cursor to Logic Analyzer                        |
| addDivider            | Add divider to Logic Analyzer                       |
| addWave               | Add wave to Logic Analyzer                          |
| deleteCursor          | Delete Logic Analyzer cursor                        |
| deleteDisplayChannel  | Delete Logic Analyzer channel                       |
| getCursorInfo         | Return settings for Logic Analyzer cursor           |
| getCursorTags         | Return all Logic Analyzer cursor tags               |
| getDisplayChannelInfo | Return settings for Logic Analyzer display channel  |
| getDisplayChannelTags | Return all Logic Analyzer display channel tags      |
| modifyCursor          | Modify properties of Logic Analyzer cursor          |
| modifyDisplayChannel  | Modify properties of Logic Analyzer display channel |
| moveDisplayChannel    | Move position of Logic Analyzer display channel     |

### Specific to Scopes

|           |                               |
|-----------|-------------------------------|
| show      | Display scope window          |
| hide      | Hide scope window             |
| isVisible | Determine visibility of scope |

### Common to All System Objects

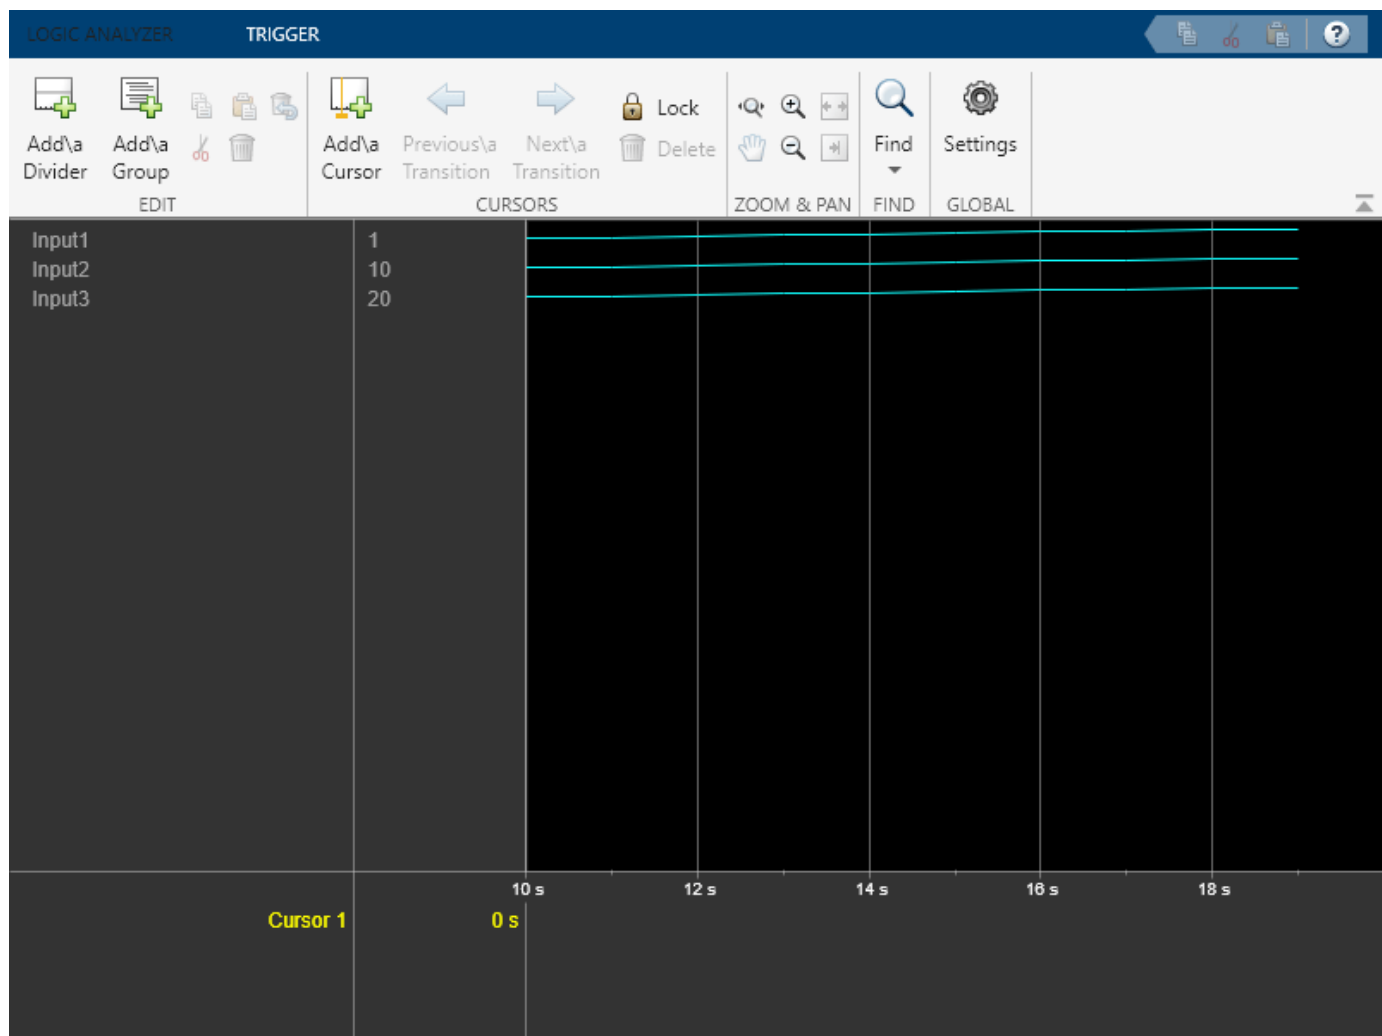

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Display Simple Ramp Signals

Create a dsp.LogicAnalyzer object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

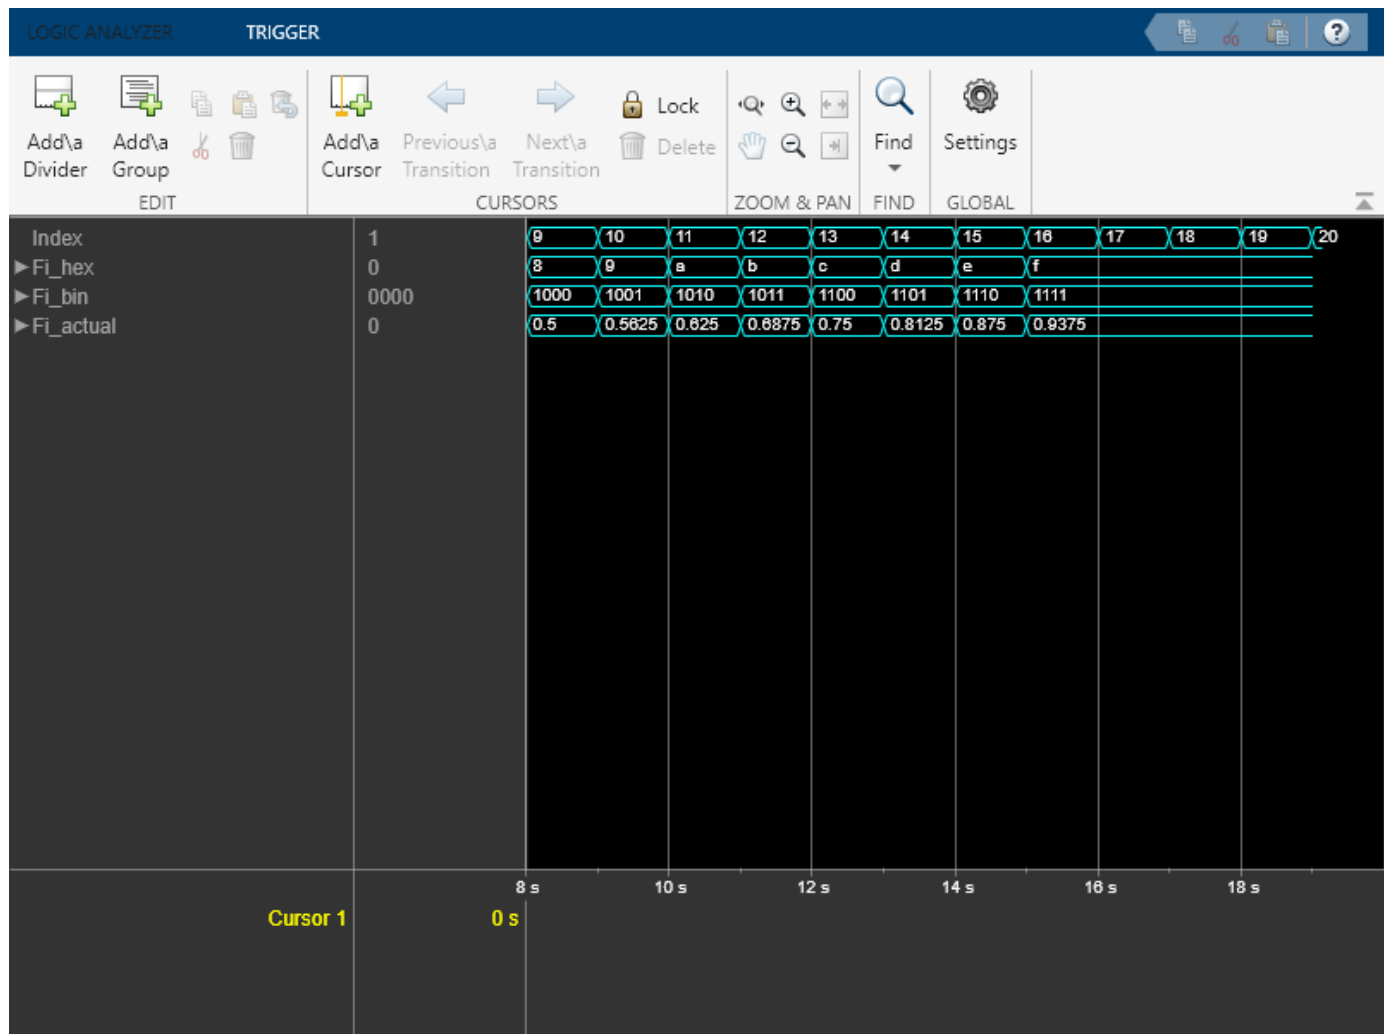

### Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;
```

```
modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');
```

```
for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```

### Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```
classdef WeekDaysInt < int32
    enumeration
        Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
    end
end
```

Create a `dsp.LogicAnalyzer` object and configure the vector, complex, and enumerated data signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',6);
waves = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,waves{1},'InputChannel',1,'Name','Vector Digital');
```

```

modifyDisplayChannel(scope,waves{2}, 'InputChannel',2, 'Name', 'Vector Analog', ...
    'Format', 'Analog', 'Height',80);
modifyDisplayChannel(scope,waves{3}, 'InputChannel',3, 'Name', 'Complex Digital');
modifyDisplayChannel(scope,waves{4}, 'InputChannel',4, 'Name', 'Complex Analog', ...
    'Format', 'Analog', 'Height',80, 'Color', 'Green');
modifyDisplayChannel(scope,waves{5}, 'InputChannel',5, 'Name', 'Enum Digital');
modifyDisplayChannel(scope,waves{6}, 'InputChannel',6, 'Name', 'Enum Analog', ...
    'Format', 'Analog', 'Height',80);

```

Call the scope object in a loop to display the signals.

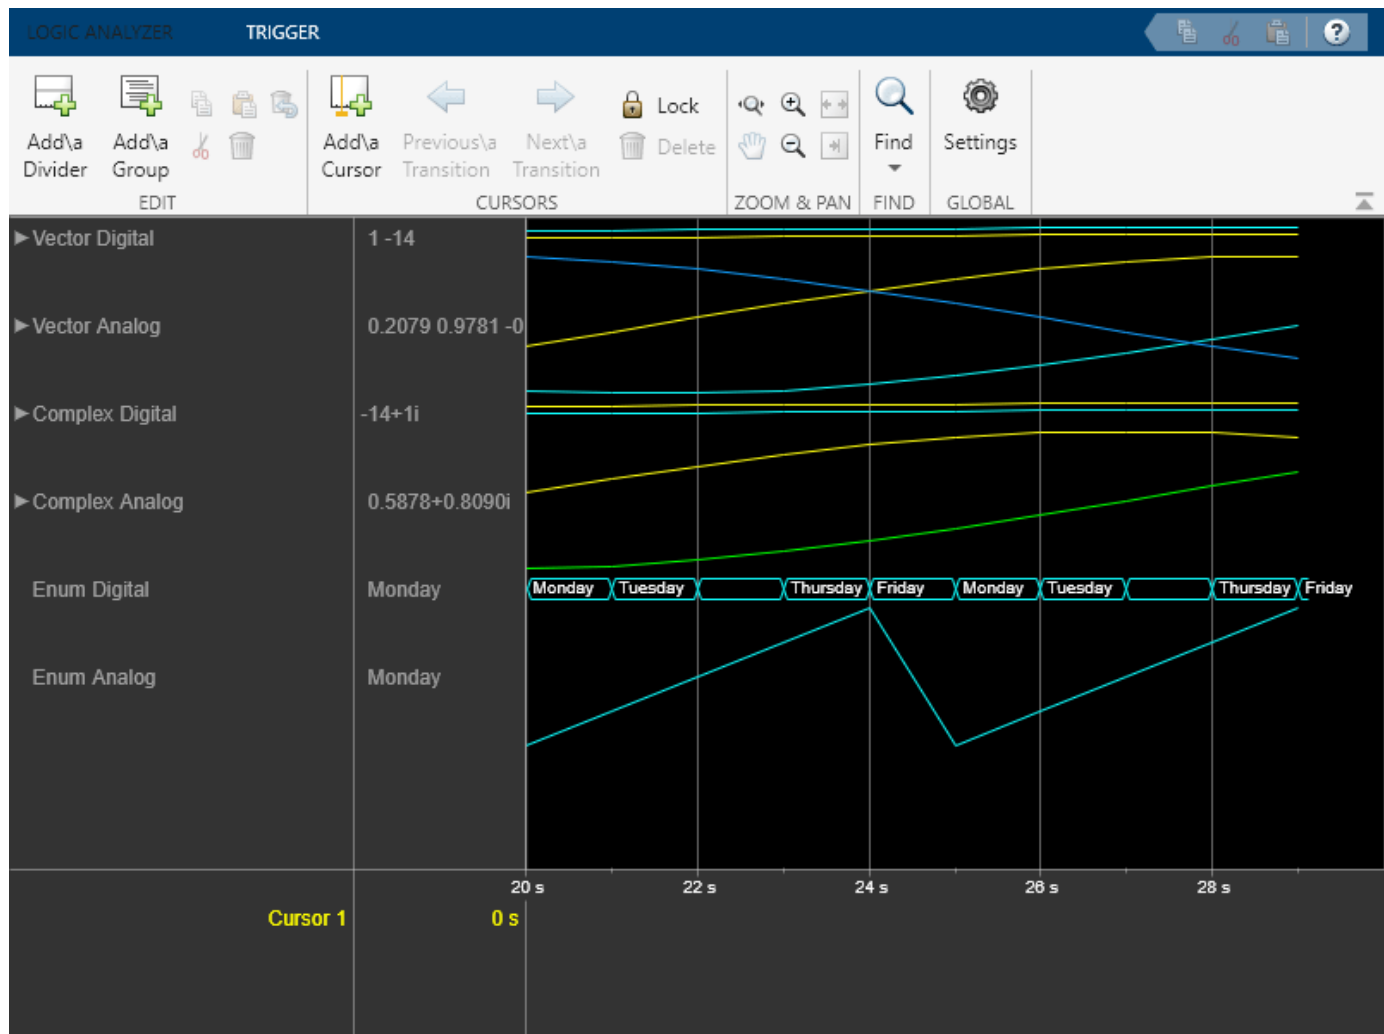

```

stop = 30;
for count = 1:stop
    sinValVec      = sin(count/stop*2*pi);
    cosValVec      = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
    sinValReal     = sin((count+2)/stop*2*pi);
    cosValImag     = cos((count+2)/stop*2*pi);

    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(count-1,5));

    scope(...
        [count (count-(stop/2))],...           % digital vector
        [sinValVec cosValVec cosValVecOffset],... % analog vector
        complex((count-(stop/2)),count),...   % digital complex
        complex(sinValReal, cosValImag),...   % analog complex
        day,...                               % digital enum
        day...                                 % analog enum
    )
end

```

## Tips

To close the logic analyzer window and clear its associated data, use the MATLAB `clear` function.

## dsp.LowerTriangularSolver

**Package:** dsp

(Removed) Solve lower-triangular matrix equation

---

**Note** `dsp.LowerTriangularSolver` has been removed. Use the `mldivide` function or the `\` operator instead. For more information, see “Compatibility Considerations”.

---

### Description

The `LowerTriangularSolver` object solves  $LX = B$  for  $X$  when  $L$  is a square, lower-triangular matrix with the same number of rows as  $B$ .

To solve  $LX = B$  for  $X$ :

- 1 Create the `dsp.LowerTriangularSolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
lowtriang = dsp.LowerTriangularSolver  
lowtriang = dsp.LowerTriangularSolver(Name,Value)
```

#### Description

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system  $LX = B$ , where  $L$  is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver(Name,Value)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **OverwriteDiagonal — Replace diagonal elements of input with ones**

false (default) | true

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input,  $L$ , with ones. This property is useful when matrix  $L$  is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the  $D$  matrix.

### **RealDiagonalElements — Indicate that diagonal of complex input is real**

`false` (default) | `true`

When you set this property to `true`, the linear system solver optimizes computation speed if the input  $L$  is complex, but its diagonal elements are real. Set this property to either `true` or `false`.

#### **Dependencies**

This property applies only when you set the `OverwriteDiagonal` property to `false`.

### **Fixed-Point Properties**

#### **RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

#### **OverflowAction — Overflow action for fixed-point operations**

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

#### **ProductDataType — Data type of product**

`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

#### **CustomProductDataType — Product word and fraction lengths**

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

#### **Dependencies**

This property applies only when you set the `ProductDataType` property to `Custom`.

#### **AccumulatorDataType — Data type of accumulator**

`Full precision` (default) | `Same as first input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`.

#### **CustomAccumulatorDataType — Accumulator word and fraction lengths**

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

#### **Dependencies**

This property applies only when you set the `AccumulatorDataType` property to `Custom`.

**OutputDataType — Data type of output**

Same as first input (default) | Custom

Specify the output data type as Same as first input or Custom.

**CustomOutputDataType — Output word and fraction lengths**

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the OutputDataType property to Custom.

**Usage****Syntax**`X = lowtriang(L,B)`**Description**

`X = lowtriang(L,B)` computes the solution,  $X$ , of the matrix equation  $LX = B$ , where  $L$  is a square, lower-triangular matrix with the same number of rows as the matrix  $B$ .

**Input Arguments****L — Lower-triangular matrix**

matrix

Lower-triangular square matrix of size  $M$ -by- $M$ .

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

**B — Input B**

vector | matrix

Input  $B$  in the equation  $LX = B$ , where  $B$  is an  $M$ -by- $N$  matrix.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

**Output Arguments****X — Solution of the equation**

vector | matrix

Solution of the  $LX = B$  equation, returned as an  $M$ -by- $N$  output matrix. The object uses only the elements in the lower triangle of input  $L$  and ignores the upper elements. When you set `OverwriteDiagonal` to `true`, the object replaces the elements on the diagonal of the input,  $L$ , with ones.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Solve a Lower Triangular Matrix

```
rng(1);
lowtriang = dsp.LowerTriangularSolver;
u = tril(rand(4,4));
b = rand(4,1);
```

Check that result is the solution to the linear equations.

```
x1 = u\b
```

```
x1 = 4×1
```

```
    1.0007
   -1.7557
    1.1148
   -0.3901
```

```
x = lowtriang(u,b)
```

```
x = 4×1
```

```
    1.0007
   -1.7557
    1.1148
   -0.3901
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

## Version History

**Introduced in R2012a**

**R2021b: dsp.LowerTriangularSolver System object will be removed***Warns starting in R2021b*

`dsp.LowerTriangularSolver` System object will be removed in a future release. Use the `mldivide` function or the `\` operator instead.

**R2023a: dsp.LowerTriangularSolver System object has been removed***Errors starting in R2023a*

The `dsp.LowerTriangularSolver` System object has been removed. Use the `mldivide` function or the `\` operator instead.

**Update Code**

This table shows how to update existing code to use the `mldivide` function or the `\` operator.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <pre>rng(1); lowtriang = dsp.LowerTriangularSolver; u = tril(rand(4,4)); b = rand(4,1); x = lowtriang(u,b)  x = 4x1     1.0007    -1.7557     1.1148    -0.3901</pre> | <pre>x1 = u\b  x1 = 4x1     1.0007    -1.7557     1.1148    -0.3901</pre> <p>Alternatively, you can also use the <code>mldivide</code> function.</p> <pre>x1 = mldivide(u,b)  x1 = 4x1     1.0007    -1.7557     1.1148    -0.3901</pre> |

# dsp.LowpassFilter

**Package:** dsp

FIR or IIR lowpass filter

## Description

The `dsp.LowpassFilter` object independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property to 'FIR' or 'IIR' to implement the object as an FIR or an IIR lowpass filter.

When the `FilterType` property is set to 'FIR', using this object is an alternative to using the `firceqrip` and `firgr` functions with `dsp.FIRFilter`. The `dsp.LowpassFilter` object condenses the two-step process into one. You can use `measure` to verify that the design meets the prescribed specifications.

To filter each channel of your input:

- 1 Create the `dsp.LowpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
LPF = dsp.LowpassFilter  
LPF = dsp.LowpassFilter(Name=Value)
```

### Description

`LPF = dsp.LowpassFilter` returns a minimum order FIR lowpass filter with the default filter settings. Calling the object with the default property settings filters the input data with a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

`LPF = dsp.LowpassFilter(Name=Value)` returns a lowpass filter with additional properties specified by one or more `Name-Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. For example, `PassbandFrequency=8000` sets the passband frequency specification of the filter to 8000 Hz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

**FilterType — Type of filter response**

'FIR' (default) | 'IIR'

Type of filter response, specified as one of these options:

- 'FIR' — The object designs an FIR lowpass filter.
- 'IIR' — The object designs an IIR lowpass (biquad) filter.

**DesignForMinimumOrder — Flag to design minimum order filter**

true (default) | false

Flag to design minimum order filter, specified as:

- true -- The object designs the minimum order filter that meets the filter design specifications.
- false -- The object designs the filter with the order that you specify in the `FilterOrder` property.

**FilterOrder — Order of the FIR or IIR filter**

50 (default) | positive integer

Order of the FIR or IIR filter, specified as a positive integer.

**Dependencies**

To enable this property, set `DesignForMinimumOrder` to false.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**PassbandFrequency — Filter passband edge frequency**

8000 (default) | real positive scalar

Filter passband edge frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- false -- The value of the passband edge frequency is in Hz and must be less than the stopband frequency and half the `SampleRate` property value.
- true -- The value of the passband edge frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**StopbandFrequency — Filter stopband edge frequency**

12000 (default) | real positive scalar

Filter stopband edge frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- false -- The value of the stopband edge frequency is in Hz. The value must be greater than the passband edge frequency and less than half the `SampleRate` property value.

- `true` -- The value of the stopband edge frequency is in normalized frequency units. The value must be a positive scalar greater than the passband edge frequency and less than `1.0`.

### Dependencies

To enable this property, set the `DesignForMinimumOrder` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### PassbandRipple — Maximum ripple of filter response in the passband

`0.1` (default) | real positive scalar

Maximum ripple of filter response in the passband, specified as a real positive scalar in dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### StopbandAttenuation — Minimum attenuation in the stopband

`80` (default) | real positive scalar

Minimum attenuation in the stopband, specified as a real positive scalar in dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### NormalizedFrequency — Flag to set frequencies in normalized units

`false` (default) | `true`

Flag to set frequencies in normalized units, specified as one of these values:

- `true` -- The passband edge and stopband edge frequencies must be in the normalized frequency units and less than `1.0`.
- `false` -- The passband edge and stopband edge frequencies are in Hz. You can specify the input sample rate through the `SampleRate` property.

Data Types: `logical`

### SampleRate — Input sample rate

`44100` (default) | real positive scalar

Input sample rate in Hz, specified as a real positive scalar.

### Dependency

To enable this property, set `NormalizedFrequency` to `false`.

Data Types: `single` | `double`

### Fixed-Point Properties

#### RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

#### CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

## Usage

### Syntax

```
y = LPF(x)
```

### Description

`y = LPF(x)` lowpass filters the input signal, `x`. `y` is a lowpass-filtered version of `x`.

### Input Arguments

#### **x** — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.LowpassFilter

|             |   |
|-------------|---|
| freqz       | Frequency response of discrete-time filter System object                      |
| fvtool      | Visualize frequency response of DSP filters                                   |
| impz        | Impulse response of discrete-time filter System object                        |
| info        | Information about filter System object  |
| coeffs      | Returns the filter System object coefficients in a structure                  |
| cost        | Estimate cost of implementing filter System object                            |
| grpdelay    | Group delay response of discrete-time filter System object                    |
| generatehdl | Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder) |
| measure     | Measure frequency response characteristics of filter System object            |

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter(SampleRate=Fs,...
                           FilterType=filtertype,...
                           PassbandFrequency=Fpass,...
                           StopbandFrequency=Fstop,...
                           PassbandRipple=Rp,...
                           StopbandAttenuation=Astop);
```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,Analysis='impulse')
```

Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF,Analysis='impulse')
```

Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,Analysis='freq')
```

Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF,Analysis='freq')
```

Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```

Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```

### Filter White Gaussian Noise Signal With FIR Lowpass Filter

Create a lowpass filter using the `dsp.LowpassFilter` System object™. Setting the `NormalizedFrequency` property to `true` designs the filter with frequency specifications in normalized frequency units.

```
LPF = dsp.LowpassFilter(NormalizedFrequency=true)
```

```
LPF =  
dsp.LowpassFilter with properties:
```

```
    FilterType: 'FIR'  
    DesignForMinimumOrder: true  
    PassbandFrequency: 0.3628  
    StopbandFrequency: 0.5442  
    PassbandRipple: 0.1000  
    StopbandAttenuation: 80  
    NormalizedFrequency: true
```

```
Show all properties
```

Create a `spectrumAnalyzer` object to visualize the input and output signal spectra. With a sample rate of  $44.1 \times 10^3$  Hz, the passband frequency and the stopband frequency of the filter translate to 8000 Hz and 12000 Hz, respectively.

```
SA = spectrumAnalyzer(SampleRate=44.1e3,...
    PlotAsTwoSidedSpectrum=false,ShowLegend=true,...
    YLimits=[-150 30],...
    Title='Input Signal and Output Signal of Lowpass Filter');
SA.ChannelNames = {'Input','Output'};
```

Run the lowpass filter algorithm to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    SA([Input,Output]);
end
```

### Filter White Gaussian Noise with IIR Lowpass Filter

Set up the IIR lowpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 8 kHz, the stopband frequency is 12 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
```

```

Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
LPF = dsp.LowpassFilter(SampleRate=Fs,...
    FilterType=filtertype,...
    PassbandFrequency=Fpass,...
    StopbandFrequency=Fstop,...
    PassbandRipple=Rp,...
    StopbandAttenuation=Astop);

```

View the magnitude response of the lowpass filter.

```
fvtool(LPf)
```

Create a spectrum analyzer object.

```

SA = spectrumAnalyzer(SampleRate=Fs,...
    PlotAsTwoSidedSpectrum=false,...
    ShowLegend=true,YLimits=[-150 30],...
    Title='Input Signal and Output Signal of IIR Lowpass Filter');
SA.ChannelNames = {'Input','Output'};

```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```

for k = 1:100
    Input = randn(1024,1);

```

```

Output = LPF(Input);
SA([Input,Output]);
end

```

### Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter
```

```
LPF =
    dsp.LowpassFilter with properties:
```

```

    FilterType: 'FIR'
    DesignForMinimumOrder: true
    PassbandFrequency: 8000
    StopbandFrequency: 12000
    PassbandRipple: 0.1000
    StopbandAttenuation: 80
    NormalizedFrequency: false
    SampleRate: 44100

```

Show all properties

```
LPFMeas = measure(LPF)
```

```
LPFMeas =
Sample Rate      : 44.1 kHz
Passband Edge    : 8 kHz
3-dB Point       : 9.1311 kHz
6-dB Point       : 9.5723 kHz
Stopband Edge    : 12 kHz
Passband Ripple  : 0.08289 dB
Stopband Atten.  : 81.6141 dB
Transition Width : 4 kHz
```

## Algorithms

### FIR Lowpass Filter

For the minimum order design, the algorithm uses generalized Remez FIR filter design algorithm. For the specified order design, the algorithm uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct` form structure.

### IIR Lowpass Filter

In the IIR configuration, the algorithm uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The algorithm uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the lowpass filter.

## Version History

### Introduced in R2015a

#### R2023a: Support for normalized frequencies

When you set the `NormalizedFrequency` property to `true`, you must specify the passband and stopband frequencies in normalized frequency units (0 to 1).

When you set the `NormalizedFrequency` property to `true` while creating the object, the passband and stopband frequency values are automatically set to normalized frequency units using the default sample rate of 44100 Hz.

```
lpFilter = dsp.LowpassFilter(NormalizedFrequency=true)
```

```
lpFilter =
dsp.LowpassFilter with properties:
    FilterType: 'FIR'
    DesignForMinimumOrder: true
    PassbandFrequency: 0.3628
```

```
StopbandFrequency: 0.5442
PassbandRipple: 0.1000
StopbandAttenuation: 80
NormalizedFrequency: true
```

When you set the `NormalizedFrequency` property to `true` after you create the object, the passband and stopband frequencies must be manually set to the normalized frequency values before you run the object algorithm.

```
lpFilter = dsp.LowpassFilter
```

```
lpFilter =
dsp.LowpassFilter with properties:
```

```
FilterType: 'FIR'
DesignForMinimumOrder: true
PassbandFrequency: 8000
StopbandFrequency: 12000
PassbandRipple: 0.1000
StopbandAttenuation: 80
NormalizedFrequency: false
SampleRate: 44100
```

To specify the normalized frequency values, set `NormalizedFrequency` to `true` and manually convert the frequency values in Hz to normalized values using the input sample rate in Hz. For example, if the input sample rate is 44100 Hz, the corresponding values in normalized units are computed using these equations.

```
lpFilter.NormalizedFrequency = true;
lpFilter.PassbandFrequency = 8000/(44100/2);
lpFilter.StopbandFrequency = 12000/(44100/2)
```

```
lpFilter =
dsp.LowpassFilter with properties:
```

```
FilterType: 'FIR'
DesignForMinimumOrder: true
PassbandFrequency: 0.3628
StopbandFrequency: 0.5442
PassbandRipple: 0.1000
StopbandAttenuation: 80
NormalizedFrequency: true
```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see “Code Generation for ARM Cortex-M and ARM Cortex-A Processors”.

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- `FilterType` is set to `'FIR'`.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

### **HDL Code Generation**

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

## dsp.LPCToLSF

**Package:** dsp

(Removed) Convert linear prediction coefficients to line spectral frequencies

---

**Note** dsp.LPCToLSF has been removed. Use `poly2lsf` from Signal Processing Toolbox™ instead. For more information, see “Compatibility Considerations”.

---

### Description

The LPCToLSF object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

- 1 Define and set up your LPC to LSF converter. See “Construction” on page 4-804.
- 2 Call `step` to convert LPC according to the properties of `dsp.LPCToLSF`. The behavior of `step` is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

---

### Construction

`lpc2lsf = dsp.LPCToLSF` returns a System object, `lpc2lsf`, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

`lpc2lsf = dsp.LPCToLSF('PropertyName', PropertyValue, ...)` returns an LPC to LSF System object, `lpc2lsf`, with each specified property set to the specified value.

### Properties

#### NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, *n*, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (-1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval (-1, 1) into *n* subintervals and looks for roots in each subinterval. If you set *n* too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is 64. This property is tunable.

**NumBisects**

Value of bisection refinement used for finding roots

Specify the root bisection refinement value,  $k$ , used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here  $n$  is the value of the `NumCoarseGridPoints` property, and the object searches a maximum of  $k \cdot (n - 1)$  points for finding the roots. You must set the `NumBisects` property value  $k$ , to a positive scalar integer. The default is 4. This property is tunable.

**ExceptionOutputPort**

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of 1 indicates valid output. A logical value of 0 indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

**OverwriteInvalidOutput**

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

**FirstOutputValuesSource**

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

**FirstOutputValues**

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

## NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action the object takes when the first coefficient of each channel of the LPC input is not 1 as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

## Methods

`reset`    Reset values for overwriting invalid outputs to their initial values  
`step`     Convert LPC coefficients to line spectral frequencies

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>release</code> | Allow System object property value changes |
|----------------------|--|

## Examples

### Convert LPC Coefficients To LSF Coefficients

**Note** This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Convert LPC to LSF coefficients

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsf = dsp.LPCToLSF;
y = lpc2lsf(a);
display(y);
```

$y = 5 \times 1$

```
0.7842
1.5605
1.8776
1.8984
2.3593
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except: There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range  $(0, \infty)$

## Version History

Introduced in R2012a

**R2022b: dsp.LPCToLSF System object has been removed***Errors starting in R2022b*

`dsp.LPCToLSF` System object has been removed. Use `poly2lsf` instead.

**Update Code**

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <pre>a = [1.0000 0.6149 0.9899 0.0000 0.0031]; lpc2lsf = dsp.LPCToLSF lsfObj = lpc2lsf(a)</pre> <p>If you are using a release prior to R2016b, replace <code>lpc2lsf(a)</code> with <code>step(lpc2lsf,a)</code>.</p> | <pre>a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]; lsfFn = poly2lsf(a)</pre> |

**Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

**See Also****Functions**

`poly2lsf`

## **reset**

Reset values for overwriting invalid outputs to their initial values

### **Syntax**

```
reset(lpc2lsf)
```

### **Description**

`reset(lpc2lsf)` resets the values for overwriting the invalid outputs to their initial values.

## step

**System object:** dsp.LPCToLSF

**Package:** dsp

Convert LPC coefficients to line spectral frequencies

### Syntax

```
LSF = step(lpc2lsf,A)
[... , STATUS] = step(lpc2lsf,A)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`LSF = step(lpc2lsf,A)` converts the LPC coefficients, `A`, to line spectral frequencies, `LSF`, in the range  $(0 \pi)$ . The System object operates along the columns of the input `A`.

`[... , STATUS] = step(lpc2lsf,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

## dsp.LUFactor

**Package:** dsp

(Removed) Factor square matrix into lower and upper triangular matrices

---

**Note** dsp.LUFactor has been removed. Use lu instead. For more information, see “Compatibility Considerations”.

---

### Description

The LUFactor object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

- 1 Define and set up your System object. See “Construction” on page 4-810.
- 2 Call step to factor the square matrix according to the properties of dsp.LUFactor. The behavior of step is specific to each object in the toolbox.

---

**Note** Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example,  $y = \text{step}(\text{obj}, x)$  and  $y = \text{obj}(x)$  perform equivalent operations.

---

### Construction

$\text{lu} = \text{dsp.LUFactor}$  returns an LUFactor System object, lu, which factors a row permutation of a square input matrix  $A$  as  $A_p = L \cdot U$ , where  $L$  is the unit-lower triangular matrix, and  $U$  is the upper triangular matrix. The row-pivoted matrix  $A_p$  contains the rows of  $A$  permuted as indicated by the permutation index vector  $P$ . The equivalent MATLAB code is  $A_p = A(P, :)$ .

$\text{lu} = \text{dsp.LUFactor}('PropertyName', PropertyValue, \dots)$  returns an LUFactor object, lu, with each specified property set to the specified value.

### Properties

#### ExceptionOutputPort

Set to true to output singularity of input

Set this property to true to output the singularity of the input as logical data type values of true or false. An output of true indicates that the current input is singular, and an output of false indicates the current input is nonsingular.

#### Fixed-Point Properties

#### RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `|Ceiling|Convergent|Floor|Nearest |Round | Simplest | Zero|`. The default is `Floor`.

### **OverflowAction**

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

### **ProductDataType**

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

### **CustomProductDataType**

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **AccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`.

### **CustomAccumulatorDataType**

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

### **OutputDataType**

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

### **CustomOutputDataType**

Output word and fraction lengths

Specify the output fixed-point type as a scaled numeric type object with a Signedness of Auto. This property applies when you set the "OutputDataType" on page 4-0 property to Custom. The default is `numericType([], 16, 15)`.

## Methods

`step` Decompose matrix into lower and upper triangular matrices

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>release</code> | Allow System object property value changes |
|----------------------|--|

## Examples

### Decompose a Square Matrix

**Note** If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Decompose a square matrix into the lower and upper components.

```
lu = dsp.LUFactor;
x = rand(4)

x = 4x4

    0.8147    0.6324    0.9575    0.9572
    0.9058    0.0975    0.9649    0.4854
    0.1270    0.2785    0.1576    0.8003
    0.9134    0.5469    0.9706    0.1419

[LU, P] = lu(x);
L = tril(LU, -1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U

y = 4x4

    0.9134    0.5469    0.9706    0.1419
    0.9058    0.0975    0.9649    0.4854
    0.8147    0.6324    0.9575    0.9572
    0.1270    0.2785    0.1576    0.8003
```

Check back whether `y` equals the permuted `x`

```
xp = x(P, :)

xp = 4x4
```

|        |        |        |        |
|--------|--------|--------|--------|
| 0.9134 | 0.5469 | 0.9706 | 0.1419 |
| 0.9058 | 0.0975 | 0.9649 | 0.4854 |
| 0.8147 | 0.6324 | 0.9575 | 0.9572 |
| 0.1270 | 0.2785 | 0.1576 | 0.8003 |

## Algorithms

This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

## Version History

### Introduced in R2012a

#### **R2021b: dsp.LUFactor System object will be removed**

*Warns starting in R2021b*

`dsp.LUFactor` System object will be removed in a future release. Use the `lu` function instead.

#### **R2023a: dsp.LUFactor System object has been removed**

*Errors starting in R2023a*

The `dsp.LUFactor` System object has been removed. Use the `lu` function instead.

### Update Code

This table shows how to update existing code to use the `lu` function.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <pre>rng(1) lu = dsp.LUFactor; x = rand(4)  x = 4x4      0.4170    0.1468    0.3968    0.2045     0.7203    0.0923    0.5388    0.8781     0.0001    0.1863    0.4192    0.0274     0.3023    0.3456    0.6852    0.6705  [LU,P] = lu(x)  LU = 4x4     0.7203    0.0923    0.5388    0.8781     0.4197    0.3068    0.4591    0.3019     0.0002    0.6070    0.1404   -0.1560     0.5789    0.3041   -0.3900   -0.4566  P = 4x1      2      4      3      1</pre> | <pre>[LUfn,Pfn] = lu(x)  LUfn = 4x4     0.7203    0.0923    0.5388    0.8781     0.4197    0.3068    0.4591    0.3019     0.0002    0.6070    0.1404   -0.1560     0.5789    0.3041   -0.3900   -0.4566  Pfn = 4x1      2      4      3      1</pre> |

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

### See Also

lu

## step

**System object:** dsp.LUFactor

**Package:** dsp

Decompose matrix into lower and upper triangular matrices

### Syntax

```
[LU,P] = step(lu,A)
[LU,P,S] = step(lu,A)
```

### Description

---

**Note** Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

---

`[LU,P] = step(lu,A)` decomposes the matrix `A` into lower and upper triangular matrices. The output `LU` is a composite matrix with lower triangle elements from `L` and upper triangle elements from `U`. The permutation vector `P` is the second output.

`[LU,P,S] = step(lu,A)` returns an additional output `S` indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

---

**Note** `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

# dsp.MatFileReader

**Package:** dsp

Read MAT file

## Description

The `dsp.MatFileReader` System object reads V7.3 MAT files.

To read V7.3 MAT files:

- 1 Create the `dsp.MatFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mfr = dsp.MatFileReader
mfr = dsp.MatFileReader(fname,vname,framesize)
mfr = dsp.MatFileReader( ___,Name,Value)
```

### Description

`mfr = dsp.MatFileReader` returns a System object, `mfr`, to read a stream of scalar data from a V7.3 MAT file.

`mfr = dsp.MatFileReader(fname,vname,framesize)` reads frames of MAT file data, using the specified file name, variable name, and frame size.

`mfr = dsp.MatFileReader( ___,Name,Value)` reads MAT file data with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Filename — Name of MAT file

'Untitled.mat' (default) | character vector | string scalar

Name of the MAT file from which to read, specified as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path.

**VariableName — Name of variable to read**

'x' (default) | character vector | string scalar

Name of the variable to read from the MAT file, specified as a character vector or a string scalar.

**SamplesPerFrame — Number of samples per output frame**

1 (default) | scalar

Number of samples per output frame to read from the MAT file on each call to the object algorithm, specified as a positive, integer-valued scalar.

## Usage

### Syntax

```
data = mfr()
```

### Description

`data = mfr()` reads data from a specified variable stored in a MAT-file. The variable is assumed to be  $N$ -dimensional and a MATLAB built-in data type. The data is read into MATLAB by reading along the first dimension.

### Output Arguments

**data — Data read from MAT file**

scalar | vector | matrix

Data read from the MAT file, returned as a scalar, vector, or a matrix. The data can be an  $N$ -dimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.MatFileReader

`isDone` End-of-data status

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Read MAT File

Read a MAT file using the `MatFileReader` object.

```
filename = [tempname '.mat']; % Create variable name
originalData = rand(40,2);
save(filename,'originalData','-v7.3'); % Write to MAT file

mfr = dsp.MatFileReader(filename,'VariableName',...
    'originalData','SamplesPerFrame', 4);
while ~isDone(mfr) % Stream data into MATLAB
    finalData = mfr();
end
```

## Version History

Introduced in R2012b

# dsp.MatFileWriter

**Package:** dsp

Write MAT file

## Description

The `dsp.MatFileWriter` System object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

- 1 Create the `dsp.MatFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
mfw = dsp.MatFileWriter  
mfw = dsp.MatFileWriter(fname,vname)  
mfw = dsp.MatFileWriter(Name,Value)
```

### Description

`mfw = dsp.MatFileWriter` returns a MAT file writer System object, `mfw`, that writes data to a V7.3 MAT file.

`mfw = dsp.MatFileWriter(fname,vname)` returns a MAT file writer System object with the `Filename` property set to `fname` and the `VariableName` property set to `vname`.

`mfw = dsp.MatFileWriter(Name,Value)` returns a MAT file writer System object with each specified property set to the specified value. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Filename — Name of MAT file to write

'Untitled.mat' (default) | character vector | string scalar

Specify the name of a MAT file as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path.

**VariableName — Name of variable to write**

'x' (default) | character vector | string scalar

Name of the variable to which to write, returned as a character vector or a string scalar. This variable is stored in the MAT file. You cannot overwrite a variable that is already in an existing MAT file.

## Usage

### Syntax

```
mfw(data)
```

### Description

`mfw(data)` writes one frame of data to the variable stored in the MAT file. The variable is assumed to be  $N$ -dimensional and a MATLAB built-in data type. The data is written to the file by concatenating along the first dimension.

### Input Arguments

**data — Data to be written to MAT file**

scalar | vector | matrix

Data to be written to the MAT file, specified as a scalar, vector, or a matrix. The data can be an  $N$ -dimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Write Data Into a MAT File

First, create a variable name.

```
filename = [tempname '.mat'];
```

Next, write that variable to a MAT-file.

```
mfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData');  
for i = 1:10  
    originalData = rand(4,2);  
    mfw(originalData);  
end  
release(mfw); % This will close the MAT file
```

Finally, load the variable back into MATLAB.

```
data = load(filename, 'originalData');
```

Plot the data.

```
plot(data.originalData);
```

## Version History

Introduced in R2012b

## See Also

### Objects

dsp.MatFileReader

# dsp.MatrixViewer

**Package:** dsp

Visualize matrix data

## Description

The `dsp.MatrixViewer` visualizes matrix data by mapping the matrix elements to a specified range of colors.

To visualize matrix data in the Matrix Viewer:

- 1 Create the `dsp.MatrixViewer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Zoom and Pan

To scale the plot axes, you can use the scroll button on your mouse to zoom in/out of the plot and **CTRL+Click** and drag to pan around the plot. Additionally, you can use the buttons that appear when you hover over the upper right corner of the plot window.

-  — Autoscale the axes to fit the data.
-  — Zoom in to the plot.
-  — Pan around the axes.

## Cursor Measurements

Activate cursor measurements by hovering over the matrix viewer and selecting the cursor button

Two horizontal and two vertical cursors appear on the plot. A dialog box shows the difference between the two intersection points. Hovering over an intersection point shows the value at that intersection point. Move the cursors by clicking and dragging the cursor lines or the intersection points to your desired location. Additionally, you can **Alt+Click** and drag the cursor dialog box to move the cursors while keeping the distance between the cursor lines constant.

## Creation

### Syntax

```
scope = dsp.MatrixViewer
scope = dsp.MatrixViewer(Name, Value)
```

### Description

`scope = dsp.MatrixViewer` creates a Matrix Viewer System object, `scope`.

`scope = dsp.MatrixViewer(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.MatrixViewer("AxisOrigin", "Lower left corner")`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Matrix Information

#### XDataMode — x-axis numbering mode

"Offset and resolution" (default) | "Custom"

Specify the x-axis numbering mode.

- "Offset and resolution" - Compute the x-axis data points from the XResolution and XOffset properties.
- "Custom" - Compute the x-axis data points using the CustomXData property.

Data Types: char | string

#### YDataMode — y-axis numbering mode

"Offset and resolution" (default) | "Span and resolution" | "Custom"

Specify the y-axis numbering mode:

- "Span and resolution" - Compute the y-axis data points from the YSpan and YResolution properties.
- "Offset and resolution" - Compute the y-axis data points from the YResolution and YOffset properties.
- "Custom" - Compute the y-axis data points using the CustomYData property.

Data Types: char | string

#### CustomXData — Custom data values for x-axis

[1 numberOfColumns] (default) | [min max] | monotonically increasing numeric vector

Specify custom values for the x-axis using a two-element numeric vector or a numeric vector with a finite number of elements.

If you specify a two-element vector, the numbers are used as the min and max values of the x-axis. If you specify a vector with more than two elements, the values must be monotonically increasing and the scope uses the first and last values of the vector as the minimum and maximum values, respectively. If you do not specify x-axis data limits, the scope uses the number of input columns as the maximum x-axis value.

Example: [5 156]

**Tunable:** Yes

#### Dependency

To enable this property, you must set XDataMode to "Custom".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CustomYData — Custom data values for y-axis**

[1 numberOfRows] (default) | [min max] | monotonically increasing numeric vector

Specify custom values for the y-axis using a two-element numeric vector or a numeric vector with a finite number of elements.

If you specify a two-element vector, the numbers are used as the min and max values of the y-axis. If you specify a vector with more than two elements, the values must be monotonically increasing and the scope uses the first and last values of the vector as minimum and maximum values, respectively. If you do not specify y-axis data limits, the scope uses the number of input rows as the maximum y-axis value.

Example: [-130 10]

**Tunable:** Yes

#### **Dependency**

To enable this property, you must set `YDataMode` to "Custom".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **XOffset — Display offset of x-axis**

0 (default) | scalar

Specify the offset to display on the x-axis as a scalar.

**Tunable:** Yes

#### **Dependency**

To enable this property, you must set `XDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **XResolution — Spacing of x-axis**

1 (default) | scalar

Specify the spacing of values along the x-axis as a scalar.

**Tunable:** Yes

#### **Dependency**

To enable this property, you must set `XDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YOffset — Display offset of y-axis**

0 (default) | scalar

Specify the offset to display on the y-axis as a scalar.

**Tunable:** No

#### **Dependency**

To enable this property, you must set `YDataMode` to "Offset and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YResolution — Spacing of y-axis**

1 (default) | scalar

Specify the spacing of values along the y-axis as a scalar.

**Tunable:** No

#### **Dependency**

To enable this property, you must set `YDataMode` to "Offset and resolution" or "Span and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **YSpan — Span of y-axis**

100 (default) | positive scalar

Specify the span of values along the y-axis as a scalar.

**Tunable:** No

#### **Dependency**

To enable this property, you must set `YDataMode` to "Span and resolution".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Visualization**

### **Name — Window name**

"Matrix Viewer" (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify the title of plot, use the `Title` property.

Data Types: `char` | `string`

### **AxisOrigin — Starting location of plot**

"Upper left corner" (default) | "Lower left corner"

Specify the starting location of the plot. If you specify "Upper left corner", the plot starts in the top left corner of the axes and continues down.

Data Types: `char` | `string`

### **Position — Scope window position in pixels**

screen center (default) | [`left bottom width height`]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form [`left bottom width height`]. By default, the scope window appears in the center of your screen with a width of 410 pixels and height of 300 pixels. The default values for this property may change depending on your screen resolution.

### **Title — Display title**

"" (default) | character vector | string scalar

Specify the title of the plot as a character vector or string. By default, there is no title.

**Tunable:** Yes

Data Types: char | string

**XLabel — x-axis label**

"" (default) | character vector | string

Specify the text for the scope to display below the x-axis. By default, the axes is unlabeled.

**Tunable:** Yes

Data Types: char | string

**YLabel — y-axis label**

"" (default) | character vector | string

Specify the text for the scope to display to the left of the y-axis. By default, the axes is unlabeled.

**Tunable:** Yes

Data Types: char | string

**ColorBarLabel — Color bar label**

"" (default) | character vector | string

Specify the text for the scope to display next to the color bar. By default, the color bar is unlabeled.

**Tunable:** Yes

Data Types: char | string

**Colormap — Color scheme**

"parula" (default) | colormap name | three-column matrix of RGB triplets

Color scheme for the colormap, specified as a predefined colormap name or a three-column matrix of RGB triplets.

For a list of acceptable colormap names, see `map`.

To use a custom colormap, specify a three-column matrix of RGB triplets. You can create the RGB matrix yourself, or you can call a predefined colormap function, such as `colormap`, to create the matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | string

**ColorLimits — Color bar limits**

minimum and maximum matrix values (default) | two-element numeric vector [min max]

Specify the color bar limits as a two-element numeric vector [min max]. By default, limits are set as the minimum and maximum values of the input matrix.

Example: [1 80]

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ColorBarLocation — Color bar location**

"eastoutside" (default) | "northoutside" | "southoutside" | "westoutside"

Location of the color bar relative to the axes.

**Tunable:** Yes

Data Types: char | string

**ShowColorBar — Color bar visibility**

true (default) | false

Set this property to false to hide the color bar on the plot.

**ShowGrid — Grid visibility**

true (default) | false

Set this property to false to hide grid lines on the plot.

**Tunable:** Yes

**ShowTicks — Axes tick visibility**

true (default) | false

Set this property to false to hide the ticks on the x-axis and y-axis.

**Usage****Syntax**

scope(matrix)

**Description**

scope(matrix) displays the matrix by mapping matrix element values to a range of colors.

**Input Arguments****matrix — Matrix to visualize**

*n*-by-*m* numeric matrix

Specify an *n*-by-*m* numeric matrix to visualize.

Example: scope(rand(3,5))

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

release(obj)

### Specific to `dsp.MatrixViewer`

`setCursorDataLabels` Customize data labels for cursor measurements

### Specific to Scopes

`show` Display scope window  
`hide` Hide scope window  
`isVisible` Determine visibility of scope

### Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Generate Spectrogram with `dsp.MatrixViewer`

This example shows how to create a spectrogram of a quadratic chirp with the `dsp.MatrixViewer` System object.

Set up the sample rate and a chirp signal.

```
Fs = 233e3;  
frameSize = 20e3;  
chirp = dsp.Chirp("SampleRate",Fs,"SamplesPerFrame",frameSize,...  
    "InitialFrequency",11e3,"TargetFrequency",11e3+55e3,...  
    "Type","Quadratic");
```

Create a `dsp.MatrixViewer` scope. Set the axis labels, select a colormap, and set the limits of the colormap.

```
scope = dsp.MatrixViewer(...  
    "ColorBarLabel","Power/Frequency (dB/Hz)",...  
    "XLabel","Frequency (Hz)",...  
    "YLabel","Time (secs)",...  
    "Colormap","hsv",...  
    "ColorLimits",[-100,-30]);
```

Visualize the spectrogram of the chirp signal in the scope.

```
for idx = 1:50  
    y = chirp() + 0.05*randn(frameSize,1);  
    [~,~,~,Ps] = spectrogram(y,128,120,128,1e3);  
    val = 10*log10(abs(Ps)'+eps);  
    scope(val);  
end
```

## Version History

Introduced in R2019a

## See Also

# dsp.MedianFilter

**Package:** dsp

Median filter

## Description

The `dsp.MedianFilter` System object computes the moving median of the input signal along each channel, independently over time. The object uses the sliding window method to compute the moving median. In this method, a window of specified length is moved over each channel, sample by sample, and the object computes the median of the data in the window. For more details, see “Algorithms” on page 4-836.

To compute the moving median of the input:

- 1 Create the `dsp.MedianFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
medFilt = dsp.MedianFilter
medFilt = dsp.MedianFilter(Len)
medFilt = dsp.MedianFilter(Name,Value)
```

### Description

`medFilt = dsp.MedianFilter` returns a median filter object, `medFilt`, using the default properties.

`medFilt = dsp.MedianFilter(Len)` sets the `WindowLength` property to `Len`.

`medFilt = dsp.MedianFilter(Name,Value)` specifies the `WindowLength` property using a `Name,Value` pair.

### Example:

```
movMin = dsp.MedianFilter('WindowLength',5);
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **WindowLength — Length of sliding window**

5 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

## **Usage**

### **Syntax**

```
y = medFilt(x)
```

### **Description**

`y = medFilt(x)` computes the moving median of the input signal, `x`, using the sliding window method.

### **Input Arguments**

#### **x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving median is computed along each channel. The object accepts multichannel inputs, that is,  $m$ -by- $n$  size inputs, where  $m \geq 1$ , and  $n > 1$ .  $m$  is the number of samples in each frame (or channel), and  $n$  is the number of channels.

The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

### **Output Arguments**

#### **y — Filtered signal**

vector | matrix

Filtered signal, returned as a vector or a matrix. The size and data type of the output matches the size and data type of the input.

Data Types: `single` | `double`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

`step`      Run System object algorithm

- release Release resources and allow changes to System object property values and input characteristics
- reset Reset internal states of System object

## Examples

### Remove High-Frequency Noise Using Median Filter

Filter high-frequency noise from a noisy sine wave signal using a median filter. Compare the performance of the median filter with an averaging filter.

#### Initialization

Set up a `dsp.MedianFilter` object, `medFilt`, and a `dsp.MovingAverage` object, `movavgWin`. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```
Fs = 1000;
medFilt = dsp.MedianFilter(7);
movavgWin = dsp.MovingAverage(7);
scope = timescope('SampleRate',Fs,...
    'TimeSpanSource','Property',...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1,'ShowGrid',true,...
    'YLimits',[-3 3],...
    'LayoutDimensions',[3 1],...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Moving Average Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';

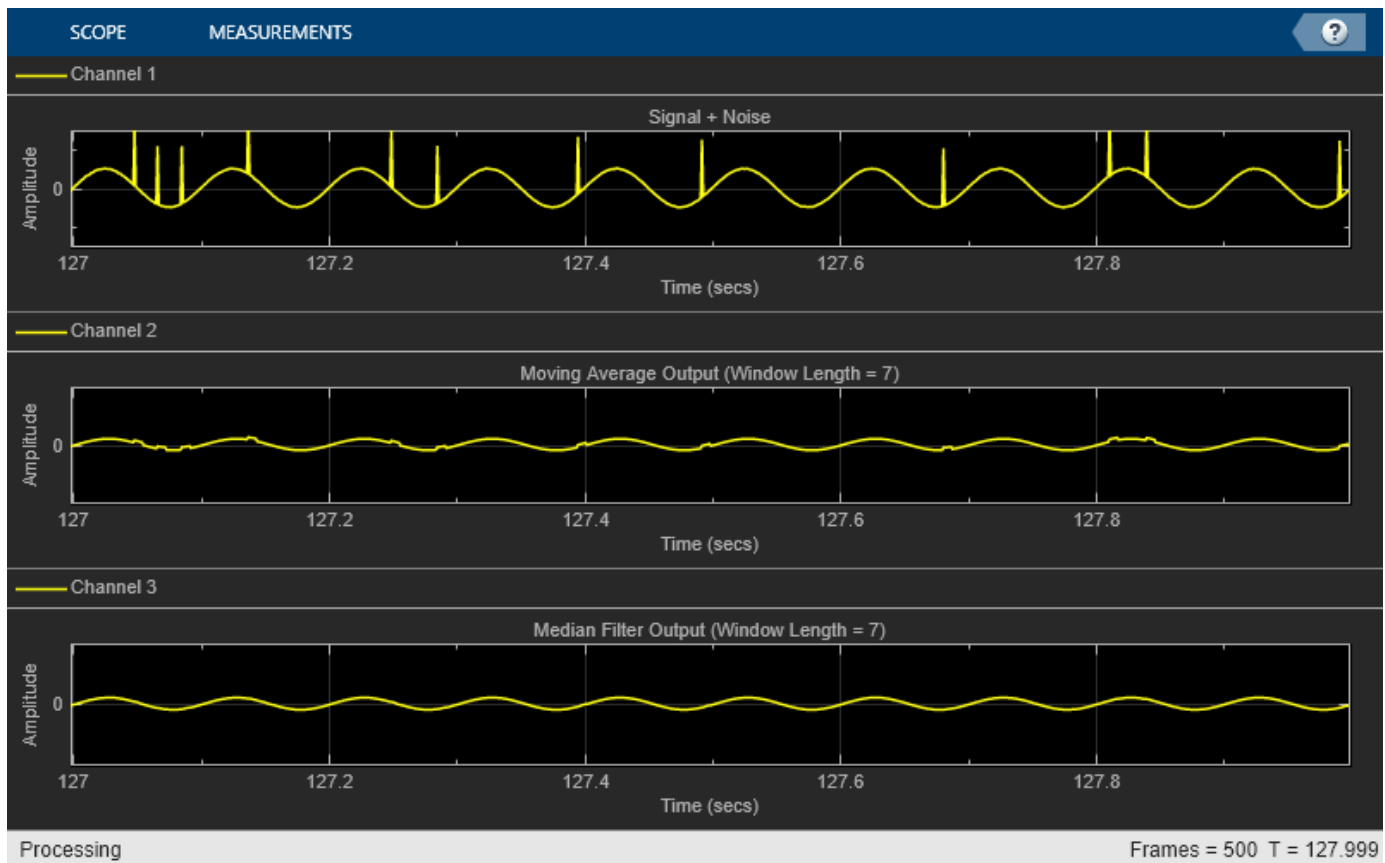

FrameLength = 256;
count = 1;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);
```

#### Filter the Noisy Sine Wave

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the median filter and the moving average object to the signal. View the output on the time scope.

```
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = movavgWin(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

The median filter removes the high-frequency noise more effectively than the moving average object does.

### Remove High-Frequency Noise from Gyroscope Data

This example shows how to remove the high-frequency outliers from a streaming signal using the `dsp.MedianFilter` System object?

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The gyroscope MAT file contains 3 columns of data, with each column containing 7140 samples. The three columns represent the X-axis, Y-axis, and Z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.MedianFilter` System object uses a window length of 10. Create a `timescope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,...
    'Filename','LSM9DS1gyroData73.mat',...
    'VariableName','data');
medFilt = dsp.MedianFilter(10);
scope = timescope('NumInputPorts',1,...
    'SampleRate',119,...
    'YLimits',[-300 300],...
    'ChannelNames',{'Input','Filtered Output'},...
    'TimeSpanSource','Property',...
    'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.MedianFilter` System object. View the filtered Z-axis data in the time scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = medFilt(gyroData);
    scope([gyroData(:,3),filteredData(:,3)]);
end
```

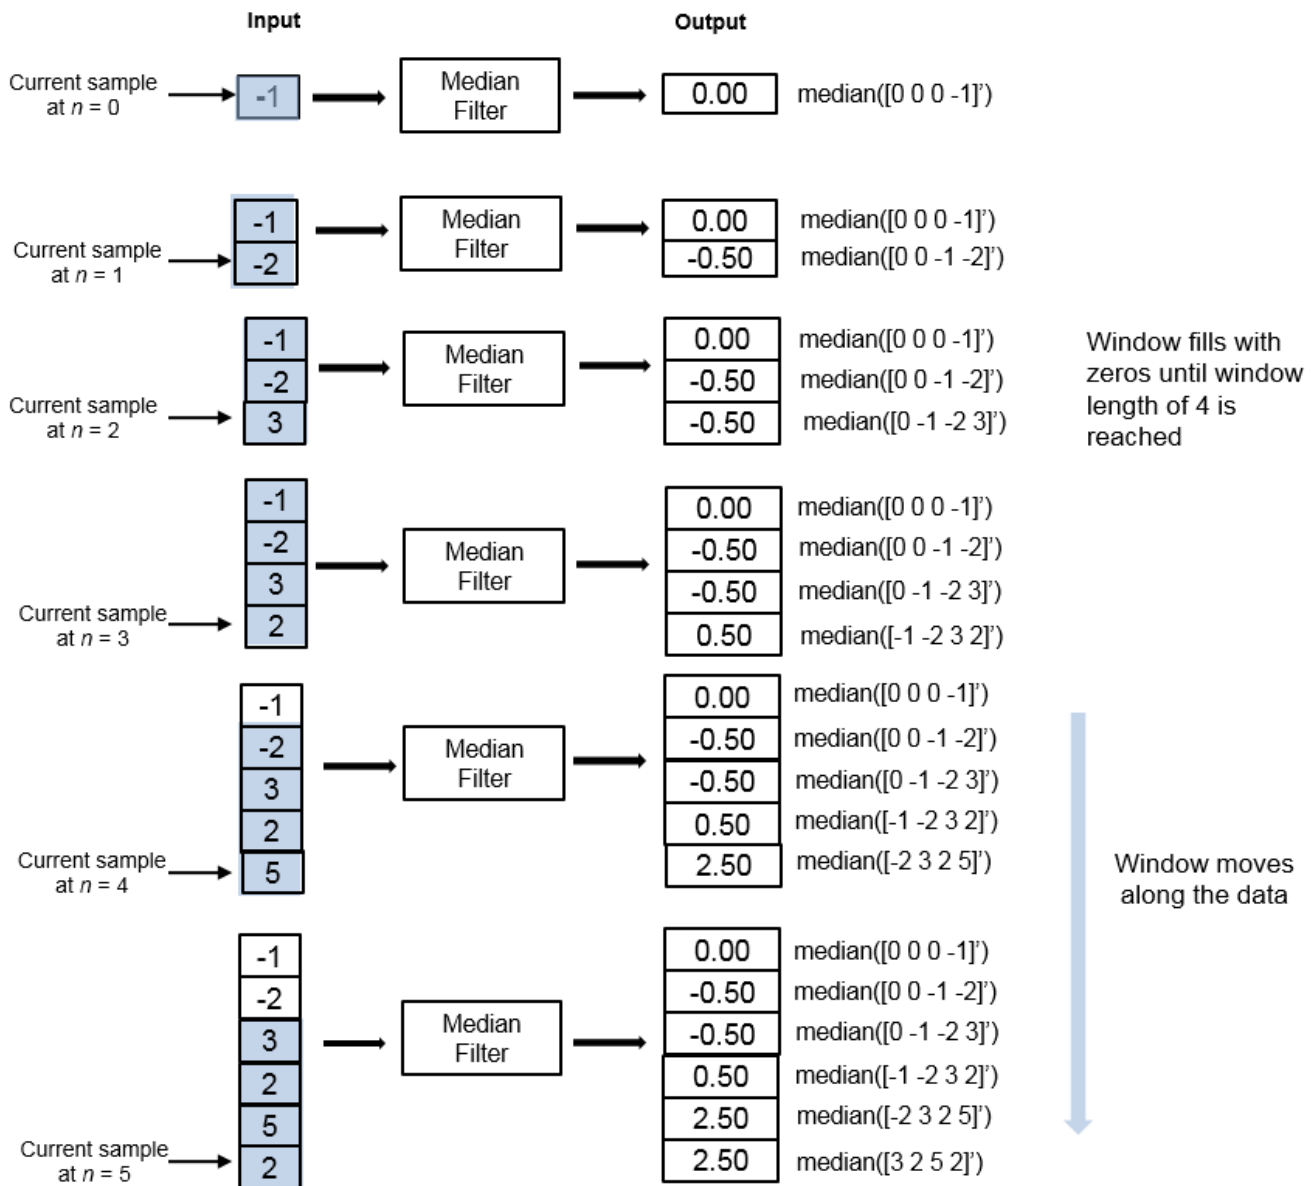

The original data contains several outliers. Zoom in on the data to confirm that the median filter removes all the outliers.

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first  $Len - 1$  outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with  $Len - 2$  zeros. The data vector,  $x$ , is then the two data samples followed by  $Len - 2$  zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

# dsp.MovingAverage

**Package:** dsp

Moving average

## Description

The `dsp.MovingAverage` System object computes the moving average of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the average is computed over the data in the window. In the exponential weighting method, the object multiplies the data samples with a set of weighting factors. The average is computed by summing the weighted data. For more details on these methods, see “Algorithms” on page 4-843.

To compute the moving average of the input:

- 1 Create the `dsp.MovingAverage` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
movAvg = dsp.MovingAverage
movAvg = dsp.MovingAverage(Len)
movAvg = dsp.MovingAverage(Len,Overlap)
movAvg = dsp.MovingAverage(Name,Value)
```

### Description

`movAvg = dsp.MovingAverage` returns a moving average object, `movAvg`, using the default properties.

`movAvg = dsp.MovingAverage(Len)` sets the `WindowLength` property to `Len`.

`movAvg = dsp.MovingAverage(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`movAvg = dsp.MovingAverage(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

```
Example: movAvg = dsp.MovingAverage('Method','Exponential
weighting','ForgettingFactor',0.9);
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Method — Averaging method

'Sliding window' (default) | 'Exponential weighting'

Averaging method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the average over the data in the window.
- 'Exponential weighting' — The object multiplies the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the average, the algorithm sums the weighted data.

For more details on these methods, see “Algorithms” on page 4-843.

### SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the average is computed using the current sample and all the past samples.

### Dependencies

This property applies when you set `Method` to 'Sliding window'.

### WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

### Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range  $[0, \text{WindowLength} - 1]$ . If not specified, the overlap length is `WindowLength - 1`.

**Dependencies**

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ForgettingFactor — Exponential weighting factor**

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

**Tunable:** Yes

**Dependencies**

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

**Usage****Syntax**

$$y = \text{movAve}(x)$$
**Description**

$y = \text{movAve}(x)$  computes the moving average of the input signal,  $x$ , using either the sliding window method or exponential weighting method.

**Input Arguments****x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If  $x$  is a matrix, each column is treated as an independent channel. The moving average is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

**Output Arguments****y — Moving average**

vector | matrix

Moving average of the input signal, returned as a vector or a matrix.

When you input a signal of size  $m$ -by- $n$  to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-845.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step`     Run System object algorithm  
`release`   Release resources and allow changes to System object property values and input characteristics  
`reset`     Reset internal states of System object

## Examples

### Moving Average of Noisy Ramp Signal

Compute the moving average of a noisy ramp signal using the `dsp.MovingAverage` object.

#### Initialization

Set up `movavgWindow`, `movavgWindow_overlap`, and `movavgExp` objects. `movavgWindow` uses the sliding window method with a window length of 50 samples and a default overlap length of 49 samples, which is one sample less than the specified window length. `movavgWindow_overlap` uses a window length of 50 samples and an overlap length of 45 samples. `movavgExp` uses the exponentially weighting method with a forgetting factor of 0.95.

Create a time scope for viewing the output.

```
FrameLength = 1001;
Fs = 1000;
movavgWindow = dsp.MovingAverage(50);
movavgWindow_overlap = dsp.MovingAverage(50,45);
movavgExp = dsp.MovingAverage('Method','Exponential weighting',...
    'ForgettingFactor',0.95);
scope = timescope('SampleRate',[Fs, Fs, Fs/(50-45), Fs],...
    'TimeSpanOvrrunAction','Scroll',...
    'ShowGrid',true,...
    'YLimits',[-0.5 1.5]);
title = 'Moving Average';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...
    'Sliding window of 50 samples with default overlap',...

```

```
'Sliding window of 50 samples with an overlap of 45 samples',...
'Exponential weighting with forgetting factor of 0.95'};
```

### Compute the Average

Generate a ramp signal with an amplitude of 1 and a time span of 2 seconds. Apply the sliding window average and exponentially weighted average to the ramp. View the output in the time scope.

```
for i = 1:500
    t = (0:0.001:1)';
    unitstep = t>=0;
    ramp = t.*unitstep;
    x = ramp + 0.1 * randn(FrameLength,1);
    y1 = movavgWindow(x);
    y2 = movavgWindow_overlap(x);
    y3 = movavgExp(x);
    scope(x,y1,y2,y3);
end
```

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined

as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

### Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$
$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x_N$$

- $\bar{x}_{N,\lambda}$  — Moving average at the current sample
- $x_N$  — Current data input sample
- $\bar{x}_{N-1,\lambda}$  — Moving average at the previous sample
- $\lambda$  — Forgetting factor
- $w_{N,\lambda}$  — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) \bar{x}_{N-1,\lambda}$  — Effect of the previous data on the average

For the first sample, where  $N = 1$ , the algorithm chooses  $w_{N,\lambda} = 1$ . For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

## Version History

### Introduced in R2016b

#### R2022b: Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `Method` property set to 'Sliding window' and the `SpecifyWindowLength` property set to `true`, and if you input a signal with a frame length that is a multiple of the hop size (window length - overlap length), this object generates

a fixed-size output signal in the generated code . For more details, see “Code Generation” on page 4-845.

## References

- [1] Bodenham, Dean. “Adaptive Filtering and Change Detection for Streaming Data.” PH.D. Thesis. Imperial College, London, 2012.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

| Input signal  | Input size   | Output signal   |
|---------------|--------------|---|
| Fixed-size    | $m$ -by- $n$ | When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- $n$ .<br><br>When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- $n$ . |
| Variable-size | $m$ -by- $n$ | Output is a variable-size signal.<br><br>Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- $n$ .  |

# dsp.MovingMaximum

**Package:** dsp

Moving maximum

## Description

The `dsp.MovingMaximum` System object determines the moving maximum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving maximum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the maximum of the data in the window. For more details, see “Algorithms” on page 4-850.

To determine the moving maximum of the input:

- 1 Create the `dsp.MovingMaximum` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
movMax = dsp.MovingMaximum
movMax = dsp.MovingMaximum(Len)
movMax = dsp.MovingMaximum(Name,Value)
```

### Description

`movMax = dsp.MovingMaximum` returns a moving maximum object, `movMax`, using the default properties.

`movMax = dsp.MovingMaximum(Len)` sets the `WindowLength` property to `Len`.

`movMax = dsp.MovingMaximum(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example: `movMax = dsp.MovingMaximum('SpecifyWindowLength',1,'WindowLength',10);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**SpecifyWindowLength — Specify window length**`true (default) | false`

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the maximum of the current sample and all the past samples.

**WindowLength — Length of the sliding window**`4 (default) | positive scalar integer`

Length of the sliding window in samples, specified as a positive scalar integer.

**Dependencies**

This property applies when you set `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Usage****Syntax**

```
y = movMax(x)
```

**Description**

`y = movMax(x)` determines the moving maximum of the input signal, `x`, using the sliding window method.

**Input Arguments****x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving maximum is determined along each channel. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Output Arguments****y — Moving maximum output**`vector | matrix`

Moving maximum of the input signal, returned as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Moving Maximum of Sine Wave Signal

Compute the moving maximum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

#### Initialization

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMaximum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMax = dsp.MovingMaximum(30);
scope = timescope('SampleRate',100,...
    'TimeSpanOvrrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',10,'ShowGrid',true,...
    'YLimits',[-4.5 4.5]);
```

#### Compute the Moving Maximum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMax` object to determine the maximum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmax = movMax(x);
    scope([x,xmax])
end
```

## Algorithms

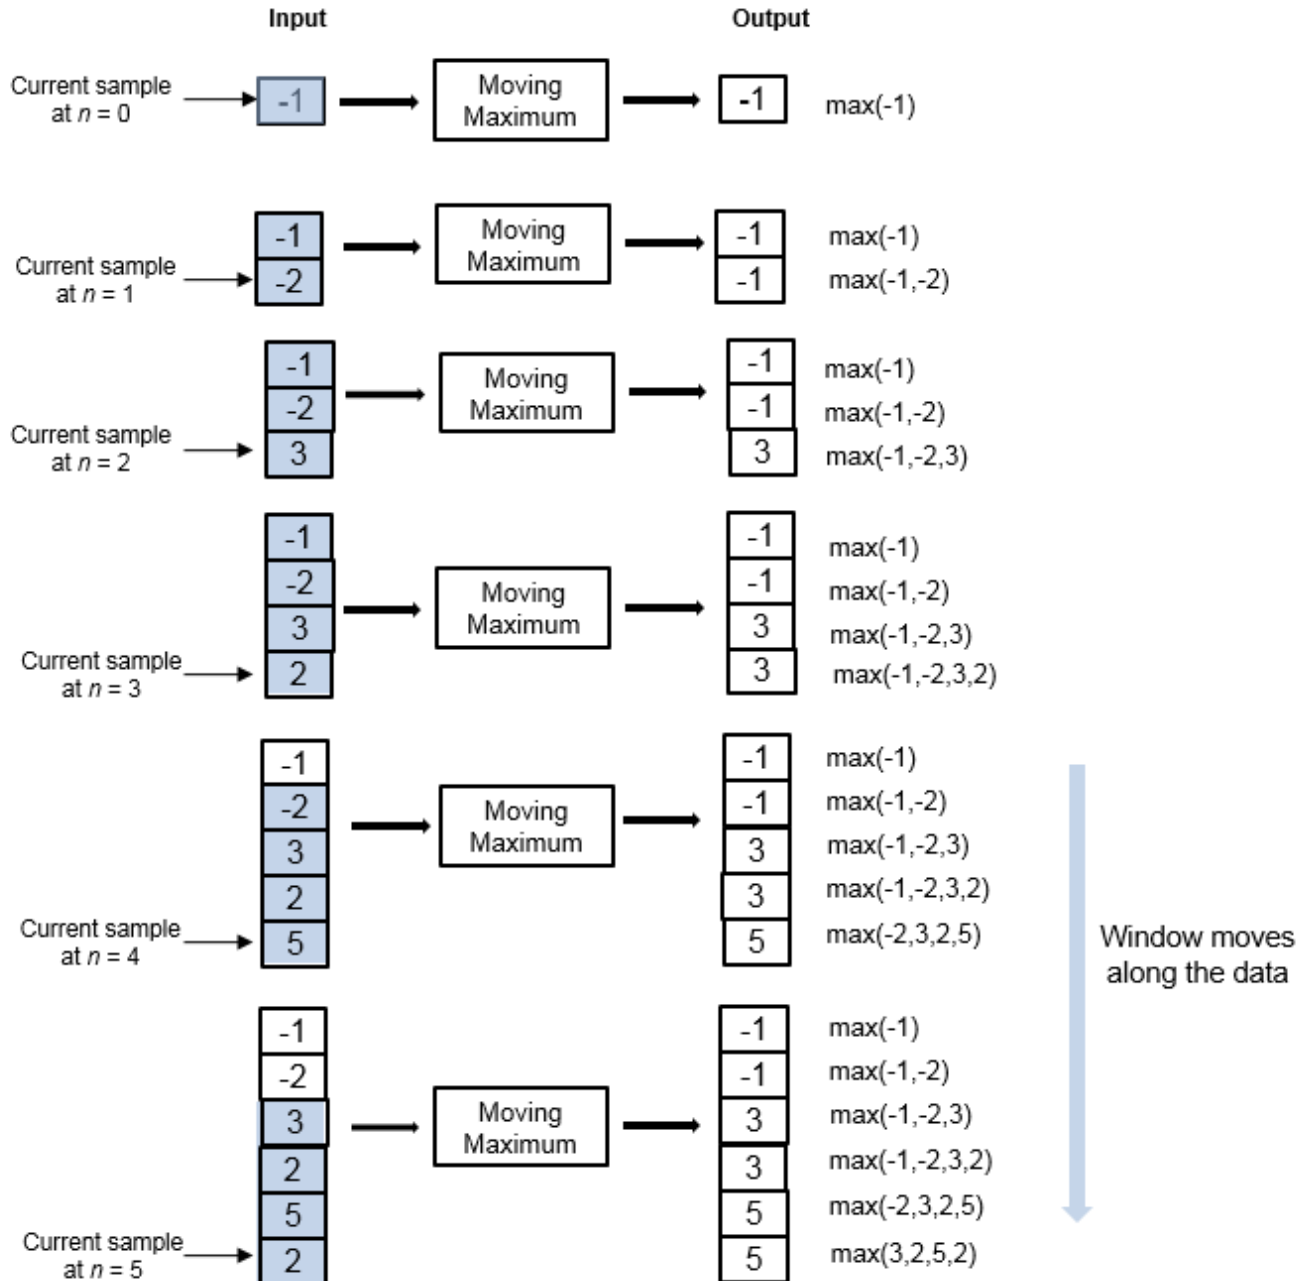

### Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. When the algorithm computes the first  $Len - 1$  outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

**Package:** dsp

Moving minimum

## Description

The `dsp.MovingMinimum` System object determines the moving minimum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving minimum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the minimum of the data in the window. For more details, see “Algorithms” on page 4-856.

To determine the moving minimum of the input:

- 1 Create the `dsp.MovingMinimum` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
movMin = dsp.MovingMinimum
movMin = dsp.MovingMinimum(Len)
movMin = dsp.MovingMinimum(Name,Value)
```

### Description

`movMin = dsp.MovingMinimum` returns a moving minimum object, `movMin`, using the default properties.

`movMin = dsp.MovingMinimum(Len)` sets the `WindowLength` property to `Len`.

`movMin = dsp.MovingMinimum(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

Example: `movMin = dsp.MovingMinimum('SpecifyWindowLength',1,'WindowLength',10);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**SpecifyWindowLength — Specify window length**`true (default) | false`

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the minimum of the current sample and all the past samples.

**WindowLength — Length of the sliding window**`4 (default) | positive scalar integer`

Length of the sliding window in samples, specified as a positive scalar integer.

**Dependencies**

This property applies when you set `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Usage****Syntax**

```
y = movMin(x)
```

**Description**

`y = movMin(x)` determines the moving minimum of the input signal, `x`, using the sliding window method.

**Input Arguments****x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving minimum is determined along each channel. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Output Arguments****y — Moving minimum output**`vector | matrix`

Moving minimum output, returned as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

## Examples

### Moving Minimum of Sine Wave Signal

Compute the moving minimum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

#### Initialization

Set up an input signal that is a sum of three sine waves with frequencies at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMinimum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMin = dsp.MovingMinimum(30);
scope = timescope('SampleRate',100,...
    'TimeSpanSource','property','TimeSpan',10,...
    'TimeSpanOvverrunAction','Scroll',...
    'ShowGrid',true,'YLimits',[-4.5 4.5]);
```

#### Compute the Moving Minimum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMin` object to determine the minimum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmin = movMin(x);
    scope([x,xmin])
end
scope.AxesScaling = 'onceatstop';
```

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the minimum of the current sample and the  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. When the algorithm computes the first  $Len - 1$  outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the minimum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving minimum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Window moves  
along the data

# dsp.MovingRMS

**Package:** dsp

Moving root mean square

## Description

The `dsp.MovingRMS` System object computes the moving root mean square (RMS) of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the RMS is computed over the data in the window. In the exponential weighting method, the object squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The object then computes the RMS by taking the square root of the sum. For more details on these methods, see “Algorithms” on page 4-864.

To compute the moving RMS of the input:

- 1 Create the `dsp.MovingRMS` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
movRMS = dsp.MovingRMS
movRMS = dsp.MovingRMS(Len)
MovRMS = dsp.MovingRMS(Len,Overlap)
movRMS = dsp.MovingRMS(Name,Value)
```

### Description

`movRMS = dsp.MovingRMS` returns a moving RMS object, `movRMS`, using the default properties.

`movRMS = dsp.MovingRMS(Len)` sets the `WindowLength` property to `Len`.

`MovRMS = dsp.MovingRMS(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`movRMS = dsp.MovingRMS(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

```
Example: movRMS = dsp.MovingRMS('Method','Exponential
weighting','ForgettingFactor',0.9);
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### Method — Moving RMS method

'Sliding window' (default) | 'Exponential weighting'

Moving RMS method, specified as 'Sliding window' or 'Exponential weighting'.

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the RMS over the data in the window.
- 'Exponential weighting' — The object multiplies the squares of the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the RMS, the algorithm sums the weighted data, and takes a square root of the sum.

For more details on these methods, see “Algorithms” on page 4-864.

### SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the RMS is computed using the current sample and all past samples.

### Dependencies

This property applies when you set `Method` to 'Sliding window'.

### WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

### Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### OverlapLength — Overlap length between windows

`WindowLength - 1` (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range  $[0, \text{WindowLength} - 1]$ . If not specified, the overlap length is  $\text{WindowLength} - 1$ .

### Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ForgettingFactor — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

**Tunable:** Yes

### Dependencies

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

## Usage

### Syntax

`y = movRMS(x)`

### Description

`y = movRMS(x)` computes the moving RMS of the input signal, `x`, using either the sliding window method or exponential weighting method.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving RMS is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

## Output Arguments

### **y** — Moving RMS

vector | matrix

Moving RMS of the input signal, returned as a vector or a matrix.

When you input a signal of size  $m$ -by- $n$  to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of `ceil(m/hop size)`-by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-867.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Moving RMS of Noisy Square Wave Signal

Compute the moving RMS of a noisy square wave signal with varying amplitude using the `dsp.MovingRMS` object.

#### Initialization

Set up `movrmsWin`, `movrmsWin_overlap`, and `movrmsExp` objects. `movrmsWin` uses the sliding window method with a window length of 20 samples and a default overlap length of 19 samples, which is one sample less than the specified window length. `movrmsWin_overlap` uses a window length of 20 samples and an overlap length of 15 samples. `movrmsExp` uses the exponentially weighting method with a forgetting factor of 0.995.

Create a time scope for viewing the output.

```
FrameLength = 10;  
Fs = 100;  
movrmsWin = dsp.MovingRMS(20);  
movrmsWin_overlap = dsp.MovingRMS(20,15);  
movrmsExp = dsp.MovingRMS('Method','Exponential weighting',...  
    'ForgettingFactor',0.995);
```

```

scope = timescope('SampleRate',[Fs,Fs,Fs/(20-15),Fs],...
    'TimeSpanOvverrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',100,...
    'ShowGrid',true,...
    'YLimits',[-1.0 5.5]);
title = 'Moving RMS';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...
    'Sliding window of 20 samples with default overlap',...
    'Sliding window of 20 samples with an overlap of 15 samples',...
    'Exponential weighting with forgetting factor of 0.995'};

```

### Compute the RMS

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method to this signal. View the output in the time scope.

```

count = 1;
Vect = [1/8 1/2 1 2 3 4];
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:160
        x = V + 0.1 * randn(FrameLength,1);
        y1 = movrmsWin(x);
        y2 = movrmsWin_overlap(x);
        y3 = movrmsExp(x);
        scope(x,y1,y2,y3);
    end
end

```

## Algorithms

### Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and  $Len - 1$  previous samples.  $Len$  is the length of the window in samples. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1$$

$$x_{rmsN,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rmsN-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N^2}$$

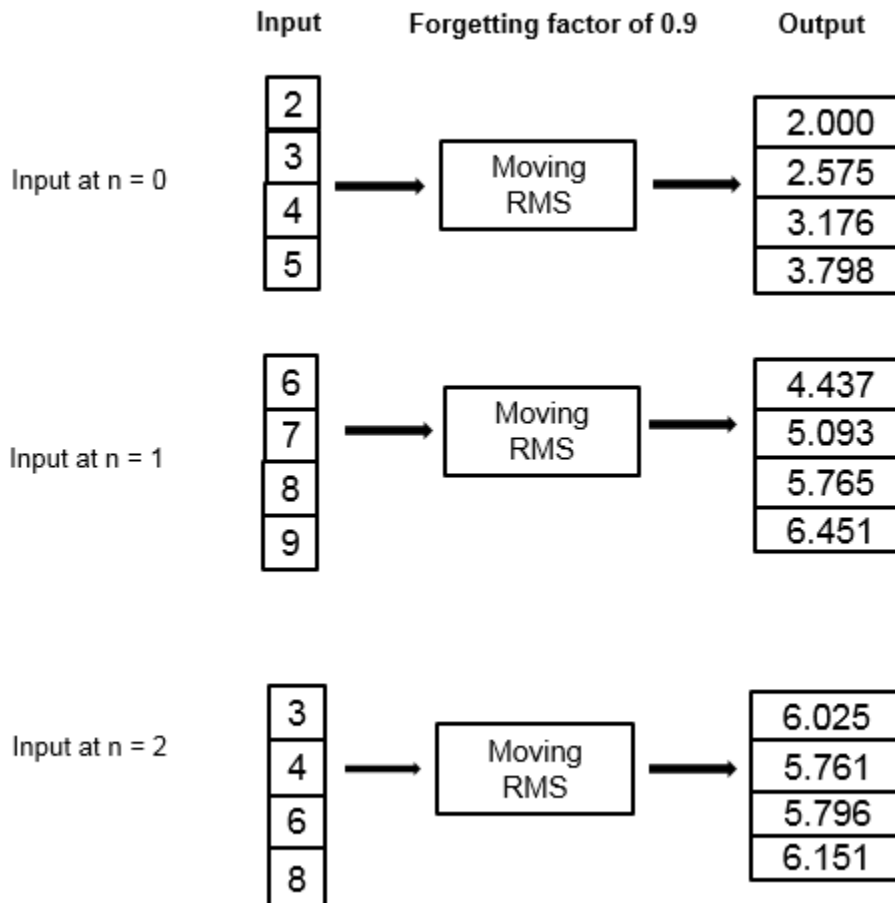

- $x_{rmsN,\lambda}$  – Moving RMS at the current sample
- $x_N^2$  – Square of the current input data sample

- $x_{rms_{N-1,\lambda}}$  — Moving RMS at the previous sample
- $\lambda$  — Forgetting factor
- $w_{N,\lambda}$  — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)x_{rms_{N-1,\lambda}}$  — Effect of the previous data on the RMS

For the first sample, where  $N = 1$ , the algorithm chooses  $w_{N,\lambda} = 1$ . For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

## Version History

Introduced in R2016b

### R2022b: Change in variable-size behavior for output signal in generated code

Starting in R2022b, if you generate code from this object with the `Method` property set to 'Sliding window' and the `SpecifyWindowLength` property set to `true`, and if you input a signal with a frame length that is a multiple of the hop size (window length – overlap length), this object generates a fixed-size output signal in the generated code. For more details, see “Code Generation” on page 4-867.

## References

[1] Bodenham, Dean. “Adaptive Filtering and Change Detection for Streaming Data.” PH.D. Thesis. Imperial College, London, 2012.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, and generate code from this object, the variable-size behavior of the output depends on the input frame length and whether the size of the input signal is fixed or variable.

See this table for more details.

| Input signal  | Input size   | Output signal   |
|---------------|--------------|---|
| Fixed-size    | $m$ -by- $n$ | When the input frame length is a multiple of the hop size, the output signal has a fixed-size of $(m/\text{hop size})$ -by- $n$ .<br><br>When input frame length is not a multiple of the hop size, the output signal is variable-sized and has an upper bound of $\text{ceil}(m/\text{hop size})$ -by- $n$ . |
| Variable-size | $m$ -by- $n$ | Output is a variable-size signal.<br><br>Output has an upper bound size of $\text{ceil}(m/\text{hop size})$ -by- $n$ .  |

**Package:** dsp

Moving standard deviation

## Description

The `dsp.MovingStandardDeviation` System object computes the moving standard deviation of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the object computes the standard deviation over the data in the window. In the exponential weighting method, the object computes the exponentially weighted moving variance, and takes the square root. For more details on these methods, see “Algorithms” on page 4-874.

To compute the moving standard deviation of the input:

- 1 Create the `dsp.MovingStandardDeviation` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
MovStd = dsp.MovingStandardDeviation
MovStd = dsp.MovingStandardDeviation(Len)
MovStd = dsp.MovingStandardDeviation(Len,Overlap)
MovStd = dsp.MovingStandardDeviation(Name,Value)
```

### Description

`MovStd = dsp.MovingStandardDeviation` returns a moving standard deviation object, `MovStd`, using the default properties.

`MovStd = dsp.MovingStandardDeviation(Len)` sets the `WindowLength` property to `Len`.

`MovStd = dsp.MovingStandardDeviation(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`MovStd = dsp.MovingStandardDeviation(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `MovStd = dsp.MovingStandardDeviation('Method','Exponential weighting','ForgettingFactor',0.999);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Method — Moving standard deviation method

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the standard deviation over the data in the window.
- 'Exponential weighting' — The object computes the exponentially weighted moving variance, and takes the square root.

For more details on these methods, see “Algorithms” on page 4-874.

### SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the standard deviation is computed using the current sample and all the past samples.

### Dependencies

This property applies when you set `Method` to 'Sliding window'.

### WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

### Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range  $[0, \text{WindowLength} - 1]$ . If not specified, the overlap length is `WindowLength - 1`.

**Dependencies**

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ForgettingFactor — Exponential weighting factor**

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

Since this property is tunable, you can change its value even when the object is locked.

**Tunable:** Yes

**Dependencies**

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

**Usage****Syntax**

`y = movStd(x)`

**Description**

`y = movStd(x)` computes the moving standard deviation of the input signal, `x`, using either the sliding window method or exponential weighting method.

**Input Arguments****x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving standard deviation is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

**Output Arguments****y — Moving standard deviation**

vector | matrix

Moving standard deviation of the input signal, returned as a vector or a matrix.

When you input a signal of size  $m$ -by- $n$  to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-877.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Moving Standard Deviation of Noisy Square Wave Signal

Compute the moving standard deviation of a noisy square wave signal with varying amplitude using the `dsp.MovingStandardDeviation` object.

#### Initialization

Set up `movstdWindow`, `movstdWindow_overlap`, and `movstdExp` objects. `movstdWindow` uses the sliding window method with a window length of 800 samples and a default overlap length of 799 samples, which is one sample less than the specified window length. `movstdWindow_overlap` uses a window length of 800 samples and an overlap length of 700 samples. `movstdExp` uses the exponentially weighting method with a forgetting factor of 0.999.

Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movstdWindow = dsp.MovingStandardDeviation(800);
movstdWindow_overlap = dsp.MovingStandardDeviation(800,700);
movstdExp = dsp.MovingStandardDeviation(...
    'Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope = timescope('SampleRate',[Fs,Fs,Fs/(800-700),Fs],...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpanSource','Property',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 3e-2]);
title = 'Moving Standard Deviation';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...}
```

```
'Sliding window of 800 samples with default overlap',...
'Sliding window of 800 samples with an overlap of 700 samples',...
'Exponential weighting with forgetting factor of 0.999'}];
```

### Compute the Standard Deviation

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method to this signal. The actual standard deviation is  $\sqrt{np}$ . The object uses this value while adding noise to the data. Compare the actual standard deviation with the computed standard deviation in the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = sqrt(np)*ones(FrameLength,1);
    for i = 1:250
        x = sqrt(np) * randn(FrameLength,1);
        y1 = movstdWindow(x);
        y2 = movstdWindow_overlap(x);
        y3 = movstdExp(x);
        scope(yexp,y1,y2,y3);
    end
end
```

## Algorithms

### Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2}$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

- $s_{N,\lambda}$  — Moving standard deviation of the current data sample with respect to the rest of the data.
- $[x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$  — Weighting factor applied to the sum.
- $\lambda$  — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

## Version History

Moving variance

## Description

The `dsp.MovingVariance` System object computes the moving variance of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the variance is computed over the data in the window. In the exponential weighting method, the object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. For more details on these methods, see “Algorithms” on page 4-884.

To compute the moving variance of the input:

- 1 Create the `dsp.MovingVariance` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
MovVar = dsp.MovingVariance
MovVar = dsp.MovingVariance(Len)
MovVar = dsp.MovingVariance(Len,Overlap)
MovVar = dsp.MovingVariance(Name,Value)
```

### Description

`MovVar = dsp.MovingVariance` returns a moving variance object, `MovVar`, using the default properties.

`MovVar = dsp.MovingVariance(Len)` sets the `WindowLength` property to `Len`.

`MovVar = dsp.MovingVariance(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`MovVar = dsp.MovingVariance(Name,Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

```
Example: MovVar = dsp.MovingVariance('Method','Exponential
weighting','ForgettingFactor',0.9);
```

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Method — Method to compute the variance

'Sliding window' (default) | 'Exponential weighting'

- 'Sliding window' — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the variance over the data in the window.
- 'Exponential weighting' — The object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero.

For more details on these methods, see “Algorithms” on page 4-884.

### SpecifyWindowLength — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- true — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- false — The length of the sliding window is infinite. In this mode, the variance is computed using the current sample and all past samples.

### Dependencies

This property applies when you set `Method` to 'Sliding window'.

### WindowLength — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window in samples, specified as a positive scalar integer.

### Dependencies

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to true.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range  $[0, \text{WindowLength} - 1]$ . If not specified, the overlap length is set to `WindowLength - 1`.

**Dependencies**

This property applies when you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ForgettingFactor — Exponential weighting factor**

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Since this property is tunable, you can change its value even when the object is locked.

**Tunable:** Yes

**Dependencies**

This property applies when you set `Method` to 'Exponential weighting'.

Data Types: `single` | `double`

**Usage****Syntax**

```
y = movVar(x)
```

**Description**

`y = movVar(x)` computes the moving variance of the input signal, `x`, using either the sliding window method or exponential weighting method.

**Input Arguments****x — Data input**

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving variance is computed along each channel.

The object accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

**Output Arguments****y — Moving variance**

vector | matrix

Moving variance of the input signal, returned as a vector or a matrix.

When you input a signal of size  $m$ -by- $n$  to the object, and if you set `Method` to 'Sliding window' and `SpecifyWindowLength` to `true`, the output has an upper bound size of  $\text{ceil}(m/\text{hop size})$ -by- $n$ . Hop size is window length – overlap length. In other cases, the output has a size of  $m$ -by- $n$ .

When you generate code from this object, the variable-size behavior of the output in the generated code depends on the input frame length and whether the size of the input signal is fixed or variable. For more details, see “Code Generation” on page 4-888.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Moving Variance of Noisy Square Wave Signal

Compute the moving variance of a noisy square wave signal with varying amplitude using the `dsp.MovingVariance` object.

#### Initialization

Set up `movvarWindow`, `movvarWindow_overlap`, and `movvarExp` objects. `movvarWindow` uses the sliding window method with a window length of 800 samples and a default overlap length of 799 samples, which is 1 sample less than the specified window length. `movvarWindow_overlap` uses a window length of 800 samples and an overlap length of 700 samples. `movvarExp` uses the exponentially weighting method with a forgetting factor of 0.999.

Create a time scope for viewing the output.

```
FrameLength = 100;  
Fs = 100;  
movvarWindow = dsp.MovingVariance(800);  
movvarWindow_overlap = dsp.MovingVariance(800,700);  
movvarExp = dsp.MovingVariance('Method','Exponential weighting',...  
    'ForgettingFactor',0.999);  
scope = timescope('SampleRate',[Fs,Fs,Fs/(800-700),Fs],...  
    'TimeSpanOverrunAction','Scroll',...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1000,...  
    'ShowGrid',true,...  
    'BufferLength',1e7,...  
    'YLimits',[0 7e-4]);
```

```

title = 'Moving Variance';
scope.Title = title;
scope.ChannelNames = {'Original Signal',...
    'Sliding window of 800 samples with default overlap',...
    'Sliding window of 800 samples with an overlap of 700 samples',...
    'Exponential weighting with forgetting factor of 0.999'};

```

### Compute the Variance

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponentially weighting method on this signal. The actual variance is  $np$ . This value is used while adding noise to the data. Compare the actual variance with the computed variances on the time scope.

```

count = 1;
noisepower = 1e-4 * [1 2 3 4];
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = np*ones(FrameLength,1);
    for i = 1:250
        x = 1 + sqrt(np) * randn(FrameLength,1);
        y1 = movvarWindow(x);
        y2 = movvarWindow_overlap(x);
        y3 = movvarExp(x);
        scope(yexp,y1,y2,y3);
    end
end
end

```

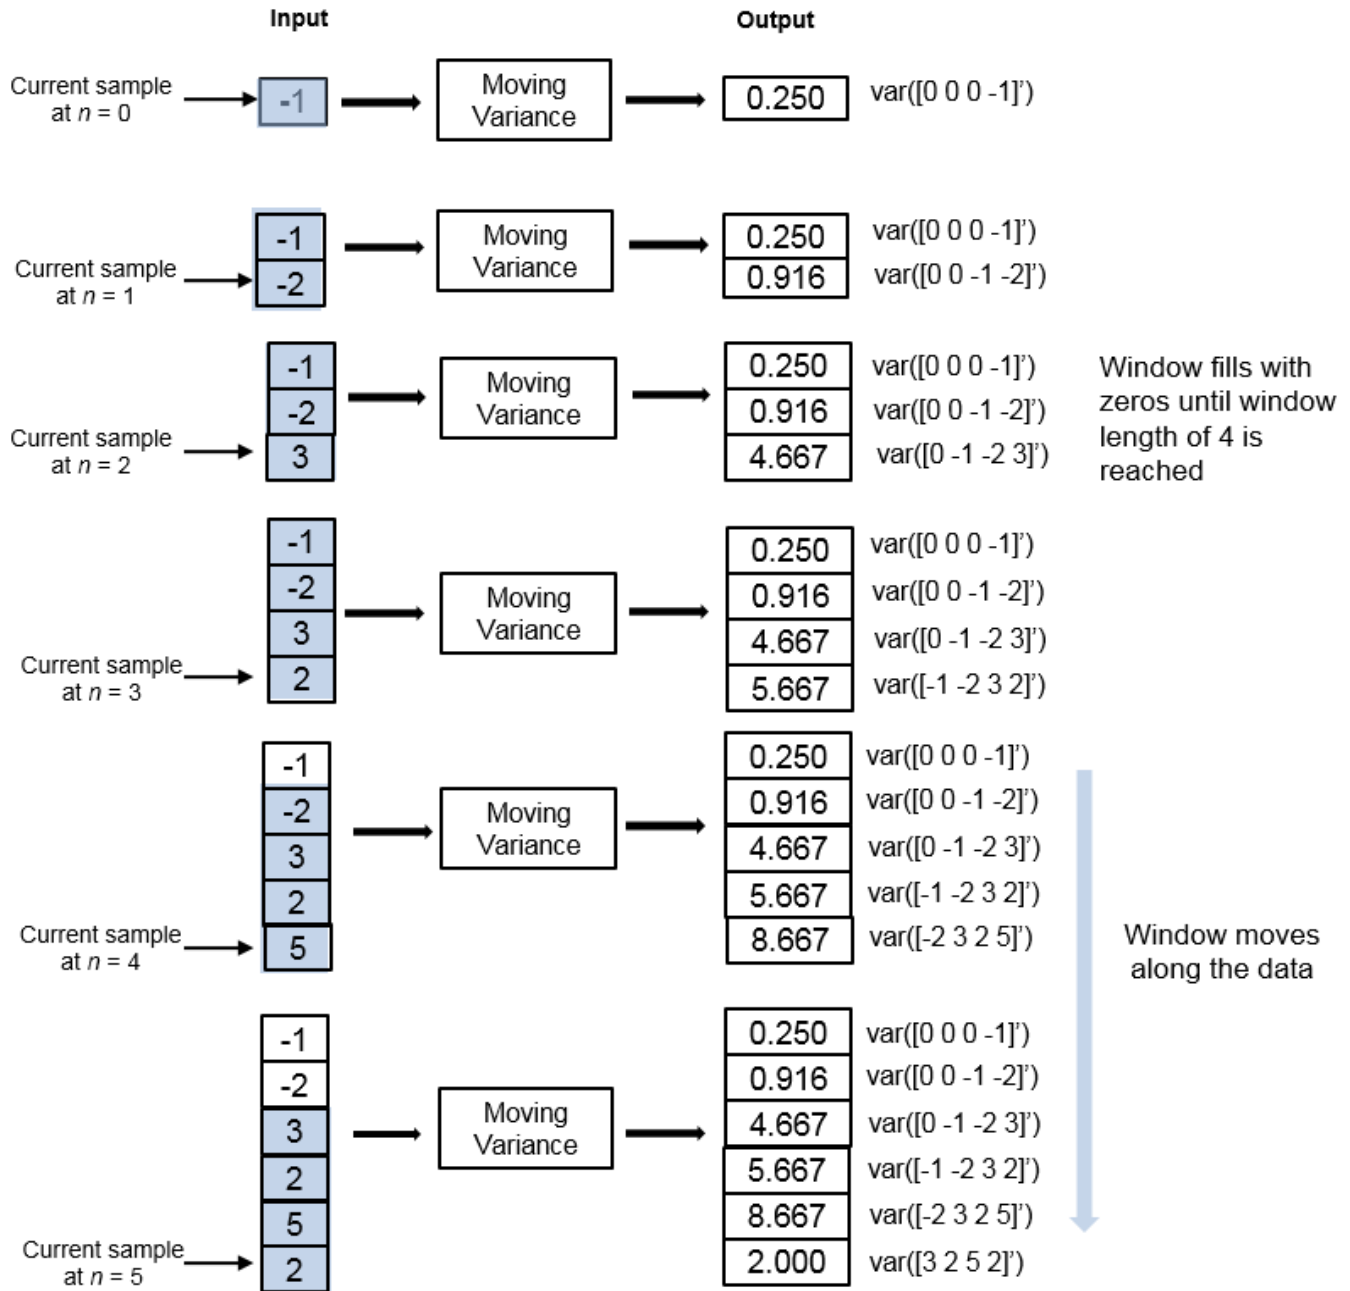

## Algorithms

### Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first output sample, the algorithm waits until it receives the hop size number of input samples. Hop size is defined as window length - overlap length. Remaining samples in the window are considered to be zero. As an example, if the window length is 5 and the overlap length is 2, then the algorithm waits until it receives 3 samples of input to compute the first sample of the output. After generating the first output, it generates the subsequent output samples for every hop size number of input samples.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4 and an overlap length of 3. With each input sample that comes in, the window of length 4 moves along the data.

### Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$$

$$v_{N,\lambda} = \frac{2\lambda(1 - \lambda^{N-1})}{(1 - \lambda)(1 + \lambda)}$$

To compute the moving variance, the algorithm implements these equations recursively.

- $s_{N,\lambda}^2$  — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$  — Moving average at the current sample. For details on computing the moving average, see `dsp.MovingAverage`.
- $[x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^N \lambda^{N-k} [x_k - \bar{x}_{N,\lambda}]^2$  — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$  — Weighting factor applied to the sum.
- $\lambda$  — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

**Package:** dsp

Generate real or complex sinusoidal signals

## Description

The numerically controlled oscillator, or NCO object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

- 1 Create the `dsp.NCO` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
nco = dsp.NCO
nco = dsp.NCO(Name, Value)
```

### Description

`nco = dsp.NCO` returns an NCO System object, `nco`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`nco = dsp.NCO(Name, Value)` returns an NCO System object, `nco`, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### PhaseIncrementSource — Source of phase increment

'Input port' (default) | 'Property'

Specify the source of the phase increment as 'Property' or 'Input port'.

### PhaseIncrement — Phase increment

100 (default) | scalar | vector

Specify the phase increment as an integer-valued scalar or vector.

**Dependencies**

This property applies only when you set the “PhaseIncrementSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**PhaseOffsetSource — Source of phase offset**

'Property' (default) | 'Input port'

Specify the source of the phase offset as 'Property' or 'Input port'.

**PhaseOffset — Phase offset**

0 (default) | scalar | vector

Specify the phase offset as an integer-valued scalar or vector.

**Dependencies**

This property applies only when you set the “PhaseOffsetSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Dither — Enable adding internal dithering to NCO algorithm**

`true` (default) | `false`

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator.

**NumDitherBits — Number of dither bits**

4 (default) | positive integer

Specify the number of dither bits as a positive integer.

**Dependencies**

This property applies only when you set the `Dither` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**PhaseQuantization — Enable quantization of accumulated phase**

`true` (default) | `false`

Set this property to `true` to enable quantization of the accumulated phase.

**NumQuantizerAccumulatorBits — Number of quantizer accumulator bits**

12 (default) | integer

Specify the number of quantizer accumulator bits as an integer scalar greater than 2 and less than the accumulator word length (“CustomAccumulatorDataType” on page 4-0 ). This property determines the number of entries in the lookup table of sine values.

**Dependencies**

This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PhaseQuantizationErrorOutputPort — Enable output of phase quantization error**

`false` (default) | `true`

Set this property to `true` to output the phase quantization error.

#### **Dependencies**

This property applies only when you set the “PhaseQuantization” on page 4-0 property to `true`.

### **Waveform — Type of output signal**

`'Sine'` (default) | `'Cosine'` | `'Complex exponential'` | `'Sine and cosine'`

Specify the type of the output signal.

### **SamplesPerFrame — Number of output samples per frame**

`1` (default) | positive integer

Specify the number of samples per frame of the output signal. When the `PhaseOffsetSource` property is `'Input port'`, and the “PhaseIncrementSource” on page 4-0 property is `'Property'`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the “PhaseOffsetSource” on page 4-0 and “PhaseIncrementSource” on page 4-0 properties to `'Input port'`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

#### **Dependencies**

This property applies only when you set the “PhaseOffsetSource” on page 4-0 property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### **OutputDataType — Output data type**

`'Custom'` (default) | `'double'` | `'single'`

Specify the output data type as `'double'`, `'single'` or `'Custom'`. When you select `'Custom'`, you must also set the “CustomOutputDataType” on page 4-0 property.

## **Fixed-Point Properties**

### **RoundingMethod — Rounding method for fixed-point operations**

`'Floor'` (default)

This constant property has a value `'Floor'`.

### **OverflowAction — Overflow action for fixed-point operations**

`'Wrap'` (default)

This constant property has a value `'Wrap'`.

### **AccumulatorDataType — Accumulator word and fraction lengths**

`'Custom'` (default)

This constant property has a value `'Custom'`.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

numericitytype([],16) (default) | numericitytype

Specify the accumulator fixed-point type as an unscaled numericitytype object with a Signedness of Auto.

**CustomOutputDataType — Output word and fraction lengths**

numericitytype([],16,14) (default) | numericitytype

Specify the output fixed-point type as a scaled numericitytype object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

**Usage****Syntax**

```
Y = nco()  
Y = nco(phInc)  
Y = nco(OFFSET)  
Y = nco(phInc,OFFSET)  
[Y,cosine] = nco(____)  
[Y,qErr] = nco(____)
```

**Description**

`Y = nco()` returns a sinusoidal signal when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both set to 'Property'.

`Y = nco(phInc)` returns a sinusoidal signal, `Y`, generated by the NCO with the specified phase increment, `phInc`.

`Y = nco(OFFSET)` returns a sinusoidal signal, `Y`, with phase offset, `OFFSET`, when the `PhaseOffsetSource` property is set to 'Input port'.

`Y = nco(phInc,OFFSET)` returns a sinusoidal signal, `Y`, with phase increment, `phInc`, and phase offset, `OFFSET`, when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both 'Input port'. `phInc` and `OFFSET` must both be row vectors of the same length, where the length determines the number of channels in the output signal.

`[Y,cosine] = nco(____)` returns a sinusoidal signal, `Y`, and a cosinusoidal signal, `cosine`, when the `Waveform` property is set to 'Sine and cosine'. This syntax can include any of the input arguments in previous syntaxes.

`[Y,qErr] = nco(____)` returns a sinusoidal signal, `Y`, and output quantization error, `qErr`, when the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are both true.

**Input Arguments****phInc — Phase increment**

scalar | row vector

Phase increment, specified as a scalar or a row vector, where each element corresponds to a separate channel.

When both `PhaseIncrementSource` and `PhaseOffsetSource` properties are set to 'Input port', the two inputs, `phInc` and `OFFSET` must have the same number of channels.

#### Dependencies

This property applies only when the `PhaseIncrementSource` property is set to 'Input port'.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

#### OFFSET — Phase offset

row vector | matrix

Phase offset, specified as a row vector or a matrix. The number of rows of `OFFSET` determines the number of samples per frame of the output signal. The number of columns of `OFFSET` determines the number of channels of the output signal.

When both `PhaseIncrementSource` and `PhaseOffsetSource` properties are set to 'Input port', `phInc` and `OFFSET` must have the same number of channels.

#### Dependencies

This property applies only when the `PhaseOffsetSource` property is set to 'Input port'.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

#### Output Arguments

##### Y — NCO output

vector | matrix

NCO output, returned as a vector or a matrix. The number of rows in the output signal is determined by:

- `SamplesPerFrame` property -- When `PhaseOffsetSource` is set to 'Property'
- `OFFSET` input argument -- When `PhaseOffsetSource` is set to 'Input port'

The number of channels in the output signal is determined by the number of channels in the phase offset and the phase increment signals, which must be equal.

The data type of the output is determined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

##### cosine — Cosinusoidal signal

vector | matrix

Cosinusoidal signal, returned as a vector or a matrix. The `cosine` output signal has the same size and data type as the sinusoidal signal, `Y`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

##### qErr — Output quantization error

vector | matrix

Output quantization error, returned as a vector or a matrix. The `qErr` output signal has the same size as the sinusoidal signal, `Y`.

**Dependencies**

This output is only available when both the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are set to `true`.

Data Types: `fi`

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Specific to `dsp.NCO`**

`info` Characteristic information about generated signal

**Common to All System Objects**

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

**Examples****Design NCO Source**

Design an NCO source according to given specifications.

```
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
```

Actual frequency resolution achieved.

```
actdf = 1/(Ts*2^Nacc);
```

Calculate number of quantized accumulator bits required from the SFDR requirement

```
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase offset

```
ph0ffset = 2^Nacc*dphi/(2*pi);
```

Design the NCO source.

```

nco = dsp.NCO('PhaseOffset', phOffset,...
    'NumDitherBits', 4, ...
    'NumQuantizerAccumulatorBits', Nqacc,...
    'SamplesPerFrame', 1/Ts, ...
    'CustomAccumulatorDataType', numerictype([],Nacc));
san = spectrumAnalyzer('SampleRate', 1/Ts,...
    'Method', 'welch', 'AveragingMethod', 'exponential',...
    'ForgettingFactor', 0.3,...
    'PlotAsTwoSidedSpectrum', false);

```

View the output of the NCO source on a spectrum analyzer. Change the output frequency in the middle of the simulation from 510 Hz to 1520 Hz.

```

tic;
while toc < 10
    if toc < 5
        F0 = 510;
    else
        F0 = 1520;
    end
    % Calculate the phase increment
    phIncr = int32(round(F0*Ts*2^Nacc));
    y = nco(phIncr);
    san(y)
end
release(san)

```

### Obtain the Characteristic Information of the NCO Object

The characteristic information of the NCO object is defined by the following fields:

- NumPointsLUT — Number of data points in the lookup table.
- SineLUTSize — Quarter-wave sine lookup table size in bytes.
- TheoreticalSFDR — Theoretical spurious free dynamic range (SFDR) in dBc.
- FrequencyResolution — Frequency resolution of the NCO.

To obtain the above characteristics for a specific NCO object, call the `info` function on the object.

```
nco = dsp.NCO
```

```
nco =  
    dsp.NCO with properties:
```

```
        PhaseIncrementSource: 'Input port'  
        PhaseOffsetSource: 'Property'  
        PhaseOffset: 0  
        Dither: true  
        NumDitherBits: 4  
        PhaseQuantization: true  
        NumQuantizerAccumulatorBits: 12  
        PhaseQuantizationErrorOutputPort: false
```

```

        Waveform: 'Sine'
    SamplesPerFrame: 1
    OutputDataType: 'Custom'

```

Show all properties

```
info(nco)
```

```
ans = struct with fields:
    NumPointsLUT: 1025
    SineLUTSize: 2050
    TheoreticalSFDR: 84
    FrequencyResolution: 1.5259e-05

```

The fields and their corresponding values change depending on the settings of the object. For instance, if the `PhaseQuantization` property is set to `false`, the `TheoreticalSFDR` field does not appear.

```
nco.PhaseQuantization = false;
info(nco)
```

```
ans = struct with fields:
    NumPointsLUT: 16385
    SineLUTSize: 32770
    FrequencyResolution: 1.5259e-05

```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except there is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

## Version History

Introduced in R2012a

## Extended Capabilities

# dsp.NotchPeakFilter

**Package:** dsp

Second-order tunable notching and peaking IIR filter

## Description

The `NotchPeakFilter` object filters each channel of the input using IIR filter implementation.

To filter each channel of the input:

- 1 Create the `dsp.NotchPeakFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
npFilter = dsp.NotchPeakFilter
npFilter = dsp.NotchPeakFilter('Specification','Quality factor and center
frequency')
npFilter = dsp.NotchPeakFilter('Specification','Coefficients')
npFilter = dsp.NotchPeakFilter(Name,Value)
```

### Description

`npFilter = dsp.NotchPeakFilter` returns a second-order notching and peaking IIR filter that independently filters each channel of the input over time, using a specified center frequency and 3 dB bandwidth.

`npFilter = dsp.NotchPeakFilter('Specification','Quality factor and center frequency')` specifies the quality factor (Q factor) of the notch or peak filter instead of the 3 dB bandwidth.

`npFilter = dsp.NotchPeakFilter('Specification','Coefficients')` specifies the coefficient values that affect bandwidth and center frequency directly, rather than specifying the design parameters in Hz. This removes the trigonometry calculations involved when the properties are tuned.

`npFilter = dsp.NotchPeakFilter(Name,Value)` returns a notch filter with each specified property name set to the specified value. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

**Specification — Filter specification**

'Bandwidth and center frequency' (default) | 'Quality factor and center frequency' | 'Coefficients'

Set the specification as 'Bandwidth and center frequency', 'Quality factor and center frequency', or 'Coefficients'.

**Bandwidth — 3 dB bandwidth**

2205 (default) | positive scalar

Specify the filter's 3 dB bandwidth as a finite positive numeric scalar in Hz. The value must be a scalar between 0 and half the sample rate.

**Tunable:** Yes

**Dependencies**

This property is applicable only if Specification is 'Bandwidth and center frequency'.

Data Types: single | double

**CenterFrequency — Notch or peak center frequency**

11025 (default) | positive scalar

Specify the filter's center frequency (for both the notch and the peak) as a finite positive numeric scalar in Hz. The value must be a scalar between 0 and half the sample rate.

**Tunable:** Yes

**Dependencies**

This property is applicable only if Specification is set to 'Bandwidth and center frequency' or 'Quality factor and center frequency'.

Data Types: single | double

**QualityFactor — Quality factor for notch or peak filter**

5 (default) | positive scalar

Specify the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower notch or peak. The Q factor should be a scalar value greater than 0.

**Tunable:** Yes

**Dependencies**

This property is applicable only if Specification is set to 'Quality factor and center frequency'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

**SampleRate — Sample rate of input**

44100 (default) | positive scalar

Specify the sample rate of the input in Hz as a finite numeric scalar.

Data Types: `single` | `double`

**BandwidthCoefficient — Bandwidth coefficient**

0.72654 (default) | real scalar in the range [-1 1]

Specify the value that determines the filter's 3 dB bandwidth as a finite numeric scalar in the range [-1 1]. The value -1 corresponds to the maximum 3 dB bandwidth ( $\text{SampleRate}/4$ ), and 1 corresponds to the minimum 3 dB bandwidth (0 Hz, an allpass filter).

**Tunable:** Yes

**Dependencies**

This property is only applicable if `Specification` is set to `'Coefficients'`.

Data Types: `single` | `double`

**CenterFrequencyCoefficient — Center frequency coefficient**

0 (default) | real scalar in the range [-1 1]

Specify the coefficient that determines the filter's center frequency as a finite numeric scalar in the range [-1 1]. The value -1 corresponds to the minimum center frequency (0 Hz), and 1 corresponds to the maximum center frequency ( $\text{SampleRate}/2$  Hz). The default is 0, which corresponds to  $\text{SampleRate}/4$  Hz.

**Tunable:** Yes

**Dependencies**

This property is only applicable if `Specification` is set to `'Coefficients'`.

Data Types: `single` | `double`

**Usage****Syntax**

```
Y = npFilter(x)
[Yn,Yp] = npFilter(x)
```

**Description**

`Y = npFilter(x)` filters each channel (column) of the input signal, `x`, to produce the notch filter output, `Y`.

`[Yn,Yp] = npFilter(x)` filters each channel of the input signal, `x`, to produce the notch filter output, `Yn`, and peak filter output, `Yp`.

**Input Arguments****x — Input signal**

vector | matrix

Input signal, specified as a vector or a matrix.

Data Types: `single` | `double`

### Output Arguments

#### **Yn — Notch filter output**

vector | matrix

Notch filter output, returned as a vector or a matrix.

Data Types: `single` | `double`

#### **Yp — Peak filter output**

vector | matrix

Peak filter output, returned as a vector or a matrix.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.NotchPeakFilter`

|                                 |                                |
|---------------------------------|--------------------------------|
| <code>getBandwidth</code>       | Get 3 dB bandwidth             |
| <code>getCenterFrequency</code> | Get center frequency           |
| <code>getOctaveBandwidth</code> | Bandwidth in number of octaves |
| <code>getQualityFactor</code>   | Get quality factor             |
| <code>tf</code>                 | Transfer function              |

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Notch Filter

This example shows how to use `dsp.NotchPeakFilter` as a notch filter with center frequency of 5000 Hz and a 3 dB bandwidth of 500 Hz.

```
npFilter = dsp.NotchPeakFilter('CenterFrequency',5000,'Bandwidth',500);
sa = spectrumAnalyzer('SampleRate',44100,'AveragingMethod','exponential',...
    'ForgettingFactor',0.96,'PlotAsTwoSidedSpectrum',false);
for i=1:5000
    y = npFilter(randn(1024,1));
    sa(y);
```

```

if (i==2500)
    % Tune center frequency to 10000
    npFilter.CenterFrequency = 10000;
end
end
release(npFilter)
release(sa)

```

### Get 3 dB Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to 'Quality factor and center frequency'. The default quality factor  $Q$  is 5, and the center frequency  $F_c$  is 11,025 Hz.

```

np = dsp.NotchPeakFilter('Specification',...
    'Quality factor and center frequency')

```

```

np =
    dsp.NotchPeakFilter with properties:

```

```

    Specification: 'Quality factor and center frequency'
    QualityFactor: 5
    CenterFrequency: 11025
    SampleRate: 44100

```

Compute the 3 dB bandwidth of the notch peak filter using the `getBandwidth` function. The bandwidth is computed as the ratio of the center frequency and the quality factor,  $\frac{F_c}{Q}$ .

```
getBandwidth(np)
```

```
ans = 2205
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

### Get Center Frequency of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to `'Coefficients'`.

```
np = dsp.NotchPeakFilter('Specification','Coefficients')
```

```
np =  
  dsp.NotchPeakFilter with properties:  
      Specification: 'Coefficients'  
  BandwidthCoefficient: 0.7265  
  CenterFrequencyCoefficient: 0
```

SampleRate: 44100

Determine the center frequency of the notch peak filter using the `getCenterFrequency` function. When the `Specification` is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

```
getCenterFrequency(np)
```

```
ans = 11025
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

### Get Octave Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration.

```
np = dsp.NotchPeakFilter
```

```
np =  
dsp.NotchPeakFilter with properties:
```

```
Specification: 'Bandwidth and center frequency'
```

```
Bandwidth: 2205  
CenterFrequency: 11025  
SampleRate: 44100
```

Determine the octave bandwidth of the filter using the `getOctaveBandwidth` function.

```
getOctaveBandwidth(np)
```

```
ans = 0.2881
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

### Compute Quality Factor of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration, where the `Specification` property is set to 'Bandwidth and center frequency'.

```
np = dsp.NotchPeakFilter
```

```
np =  
    dsp.NotchPeakFilter with properties:
```

```

Specification: 'Bandwidth and center frequency'
Bandwidth: 2205
CenterFrequency: 11025
SampleRate: 44100

```

Determine the quality factor of the filter using the `getQualityFactor` function. The quality factor is given by the ratio of the center frequency to the bandwidth.

```
getQualityFactor(np)
```

```
ans = 5
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

### Determine Transfer Function of Notch Peak Filter

Create a `dsp.NotchPeakFilter` System object™. Obtain the coefficients of the transfer function corresponding to the notch and peak filters.

```

notchpeak = dsp.NotchPeakFilter;
[Bnotch,Anotch,Bpeak,Apeak] = tf(notchpeak)

```

Bnotch = 1×3

0.8633 -0.0000 0.8633

Anotch = 1×3

1.0000 -0.0000 0.7265

Bpeak = 1×3

0.1367 0 -0.1367

Apeak = 1×3

1.0000 -0.0000 0.7265

Bnotch and Anotch are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the notch filter. Bpeak and Apeak are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the peak filter.

## Algorithms

The design equation for the peak filter is:

$$H(z) = (1 - b) \frac{1 - z^{-2}}{1 - 2b \cos \omega_0 z^{-1} + (2b - 1)z^{-2}}$$

The design equation for the notch filter is:

$$H(z) = b \frac{1 - 2 \cos \omega_0 z^{-1} + z^{-2}}{1 - 2b \cos \omega_0 z^{-1} + (2b - 1)z^{-2}}$$

with

$$b = \frac{1}{1 + \tan(\Delta\omega/2)}$$

where  $\omega_0 = 2\pi f_0/f_s$  is the center frequency in radians/sample ( $f_0$  is the center frequency in Hz and  $f_s$  is the sampling frequency in Hz).  $\Delta\omega = 2\pi\Delta f/f_s$  is the 3 dB bandwidth in radians/sample ( $\Delta f$  is the 3 dB bandwidth in Hz). Note that the two filters are complementary:

$$H_{\text{notch}}(z) + H_{\text{peak}}(z) = 1$$

they can be written as:

$$H_{\text{peak}}(z) = \frac{1}{2}[1 - A(z)]$$

$$H_{\text{notch}}(z) = \frac{1}{2}[1 + A(z)]$$

where  $A(z)$  is a 2<sup>nd</sup> order allpass filter.

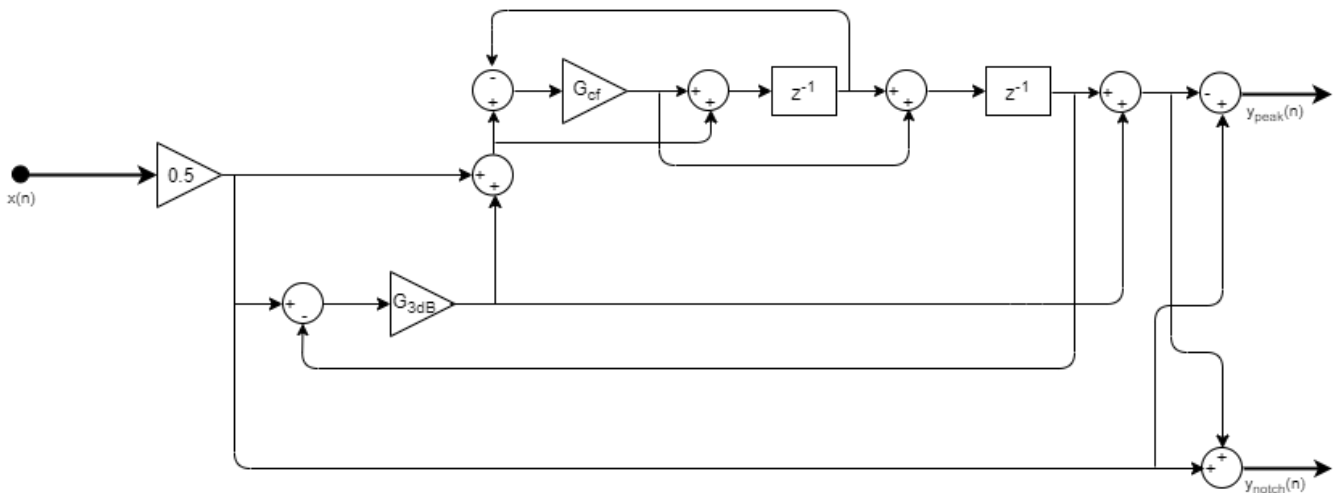

$$A(z) = \frac{a_2 + a_1z^{-1} + z^{-2}}{1 + a_1z^{-1} + a_2z^{-2}}$$

and

$$a_1 = -2b\cos\omega_0$$

$$a_2 = 2b - 1$$

The filter is implemented as follows:

where

$$G_{3\text{dB}} = a_2 = 2b - 1$$

$$G_{\text{cf}} = \frac{a_1 - a_1a_2}{1 - a_2^2} = -\cos\omega_0$$

Notice that  $G_{\text{cf}}$  depends only on the center frequency, and  $G_{3\text{dB}}$  depends only on the 3 dB bandwidth.

# dsp.PeakFinder

**Package:** dsp

(Removed) Identify peak values in input signal

---

**Note** The `dsp.PeakFinder` System object™ has been removed. To determine the local maxima, use the `findpeaks` function. To determine the local minima, use the `islocalmin` function and find the signal values corresponding to the local minima indices that the function determines. For more details, see “Compatibility Considerations”.

---

## Description

The `dsp.PeakFinder` System object counts the number of peak values (maxima, minima, or both) in each column of the real-valued input signal. To qualify as a peak, a point has to be larger (or smaller) than both of its neighboring points. The end points are not considered as peak values. The object can also output the indices and values of the peaks, and a binary array that indicates whether a peak is a maxima or a minima.

To output the peak indices and peak values, set “PeakIndicesOutputPort” on page 4-0 and “PeakValuesOutputPort” on page 4-0 to `true`, respectively. In addition, you can determine which of the peak values is a maxima or a minima using the polarity matrix. The polarity matrix is a logical array in which a 1 indicates a maxima, and a 0 indicates a minima. To view the polarity matrix, set “PeakType” on page 4-0 to 'Maxima and Minima' and access the fourth output.

Use the “MaximumPeakCount” on page 4-0 property to specify how many peak values to look for in each input signal. The object stops searching the input signal once this maximum number of peak values has been found.

If you set “IgnoreSmallPeaks” on page 4-0 to `true`, the object no longer detects low amplitude peaks and ignores noise within a threshold value that you define. In this mode, the current value is a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . The current value is a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ .

To determine the peak values in an input signal:

- 1 Create the `dsp.PeakFinder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
pkFind = dsp.PeakFinder
pkFind = dsp.PeakFinder(Name,Value)
```

## Description

`pkFind = dsp.PeakFinder` creates a peak finder System object that identifies the peak values (maxima, minima, or both) in an input signal.

`pkFind = dsp.PeakFinder(Name, Value)` creates a peak finder System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.PeakFinder('PeakType','Maxima');`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### PeakType — Type of peaks to identify

'Maxima and Minima' (default) | 'Maxima' | 'Minima'

Type of peaks to identify, specified as one of the following:

- 'Maxima' -- If "IgnoreSmallPeaks" on page 4-0 is set to `true`, the current value is identified as a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . Specify *threshold* in "PeakThreshold" on page 4-0 property. If `IgnoreSmallPeaks` is set to `false`, the current value must be larger than both its neighboring points.
- 'Minima' -- If `IgnoreSmallPeaks` is set to `true`, the current value is identified as a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ . If `IgnoreSmallPeaks` is set to `false`, the current value must be smaller than both its neighboring points.
- 'Maxima and Minima' -- The object identifies both the maxima and the minima points.

### PeakIndicesOutputPort — Enable output of peak indices

`false` (default) | `true`

Enable output of the peak indices, specified as either:

- `true` -- The object returns the indices of the input signal peak values.
- `false` -- The object does not return the indices of the input signal peak values.

### PeakValuesOutputPort — Enable output of peak values

`false` (default) | `true`

Enable output of the peak values, specified as either:

- `true` -- The object returns the peak values of the input signal.
- `false` -- The object does not return the peak values of the input signal.

### MaximumPeakCount — Maximum number of peak values to identify

10 (default) | integer greater than or equal to 1

Maximum number of peak values to identify in each input signal, specified as an integer greater than or equal to 1. The object stops searching the input signal for peaks once it identifies the maximum number.

Example: 5

Example: 50

### IgnoreSmallPeaks — Ignore peaks below a threshold

false (default) | true

Ignore peaks below a threshold, specified as either:

- **false** -- The object identifies the current value as a peak, if the current value is larger (or smaller) than both of its neighboring points.
- **true** -- The object identifies the current value as a maximum if  $(current - previous) > threshold$  and  $(current - next) > threshold$ . The object identifies the current value as a minimum if  $(current - previous) < -threshold$  and  $(current - next) < -threshold$ .

### PeakThreshold — Threshold below which peaks are ignored

0 (default) | positive real scalar | vector

Threshold below which peaks are ignored, specified as a real scalar greater than or equal to 0 or a vector with all elements greater than or equal to 0. The length of the vector must be equal to the number of channels.

This property identifies the current input value to be a maximum if  $(current\ input\ value - previous\ input\ value) > threshold$  and  $(current\ input\ value - next\ input\ value) > threshold$ . The current value is a minimum if  $(current\ input\ value - previous\ input\ value) < -threshold$  and  $(current\ input\ value - next\ input\ value) < -threshold$ .

Example: 0.2

Example: [0.3 2.4]

Example: [3; 0.4]

### Dependencies

This property applies only when you set IgnoreSmallPeaks to true.

### Fixed-Point Properties

#### RoundingMethod — Rounding method

'Floor' (default)

Rounding method, specified as 'Floor', which is equivalent to truncation. The setting rounds the result of a calculation to the closest representable number in the direction of negative infinity.

#### OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- **'Wrap'** -- The object wraps the result of its fixed-point operations.
- **'Saturate'** -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

## Usage

### Syntax

```
cnt = pkFind(input)
[cnt,idx] = pkFind(input)
[ ___,val] = pkFind(input)
[ ___,pol] = pkFind(input)
```

### Description

`cnt = pkFind(input)` returns the number of peak values (minima, maxima, or both) in the input signal. Each column of the input is treated as a separate channel.

`[cnt,idx] = pkFind(input)` returns the number of peak values, `cnt`, and peak indices, `idx`, in the input signal.

To access the peak indices output, set the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakIndicesOutputPort',true);
...
[cnt,idx] = pkFind(input);
```

`[ ___,val] = pkFind(input)` returns the peak values `val` in the input signal.

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima', ...
'PeakValuesOutputPort',true);
...
[cnt,idx,val] = pkFind(input);
```

`[ ___,pol] = pkFind(input)` returns the peak value polarity `pol` in input signal. The polarity is 1 for maxima and 0 for minima.

To access the polarity output, set the `PeakType` property to `'Maxima and Minima'`, and the `PeakIndicesOutputPort` property to `true`.

```
pkFind = dsp.PeakFinder('PeakType','Maxima and Minima', ...
'PeakIndicesOutputPort',true);
...
[cnt,idx,val,pol] = pkFind(input);
```

### Input Arguments

#### **input** — Data input

column vector of at least three rows | matrix with at least three rows

Data input whose peak values are detected by the object, specified as a vector or matrix containing at least three rows.

Example: `[9 6 10 3 5 5 0 12; 9 6 1 13 4 1 0 12]'`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### **cnt** — Number of peak values

scalar | row vector

Number of peak values, returned as a scalar or a row vector of length equal to the number of channels in the data input.

Example: [4 3]

Data Types: uint32

### **idx** — Indices of the peak values

column vector | matrix

Indices of the peak values in the input signal, returned as a column vector or matrix. The size of the peak indices output is the same as that of the input. All nonzero elements represent peak indices.

Example: [1 2 3 6 0 0 0 0 0 0; 2 3 6 0 0 0 0 0 0]'

#### Dependencies

To enable this output, set the `PeakIndicesOutputPort` property to `true`.

Data Types: uint32

### **val** — Peak values

column vector | matrix

Peak values in the input signal, returned as a column vector or matrix.

Example: [6 10 3 0 0 0 0 0 0 0; 1 13 0 0 0 0 0 0 0 0]'

#### Dependencies

To access the peak values output, set the `PeakValuesOutputPort` property to `true`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### **pol** — Peak value polarity

column vector | matrix

Peak value polarity in input signal, returned as a column vector or matrix of logical 1s and 0s. The polarity is 1 for maxima and 0 for minima.

Example: [0 1 0 0 0 0 0 0 0 0; 0 1 0 0 0 0 0 0 0 0]'

Data Types: logical

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step     Run System object algorithm  
release   Release resources and allow changes to System object property values and input characteristics  
reset     Reset internal states of System object

## Examples

### Determine Local Maxima and Minima

Determine whether each value of an input signal is a local maximum or minimum.

```
pkFind = dsp.PeakFinder;  
pkFind.PeakIndicesOutputPort = true;  
pkFind.PeakValuesOutputPort = true;
```

```
x1 = [9 6 10 3 4 5 0 12]';
```

Find the peaks of each input [prev; cur; next]: {[9;6;10],[6;10;3],...}

```
[cnt1, idx1, val1, pol1] = pkFind(x1)
```

```
cnt1 = uint32
```

```
5
```

```
idx1 = 10x1 uint32 column vector
```

```

## Version History

### Introduced in R2012a

#### R2021b: dsp.PeakFinder System object has been removed

*Errors starting in R2021b*

The dsp.PeakFinder System object has been removed. To determine the local maxima, use the findpeaks function. To determine the local minima, use the islocalmin function and find the signal values corresponding to the local minima indices that the function determines. For more details, see the **Update Code** section.

#### Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| <p><b>Find Local Maxima</b></p> <pre>x = [9 6 10 3 4 5 0 12]'; pf = dsp.PeakFinder('PeakType','Maxima', ..     'PeakValuesOutputPort', true); [cnt,val] = pf(x)</pre> <p><b>Find Local Minima</b></p> <pre>x = [9 6 10 3 4 5 0 12]'; pf = dsp.PeakFinder('PeakType','Minima', ..     'PeakValuesOutputPort', true); [cnt,val] = pf(x)</pre> <p>If you are using a release prior to R2016b, replace pf(x) with step(pf,x).</p> | <p><b>Find Local Maxima</b></p> <pre>x = [9 6 10 3 4 5 0 12]'; val = findpeaks(x) cnt = numel(val)</pre> <p><b>Find Local Minima</b></p> <pre>x = [9 6 10 3 4 5 0 12]'; tf = islocalmin(x); val = x(tf) cnt = sum(tf)</pre> |

# dsp.PeakToPeak

**Package:** dsp

(Removed) Peak-to-peak value

---

**Note** dsp.PeakToPeak has been removed. Use the peak2peak function instead. For more information, see “Compatibility Considerations”.

---

## Description

The dsp.PeakToPeak System object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

- 1 Create the dsp.PeakToPeak object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

## Creation

### Syntax

```
ptp = dsp.PeakToPeak
ptp = dsp.PeakToPeak(Name, Value)
```

### Description

ptp = dsp.PeakToPeak creates a peak-to-peak System object, ptp, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

ptp = dsp.PeakToPeak(Name, Value) returns a peak-to-peak System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### RunningPeakToPeak — Calculation over successive calls to object algorithm

false (default) | true

Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the algorithm.

**Dimension — Dimension to operate along**

'Column' (default) | 'All' | 'Row' | 'Custom'

Specify the dimension along which to calculate the peak-to-peak ratio as 'All', 'Row', 'Column', or 'Custom'. If you set this property to 'Custom', specify the dimension using the `CustomDimension` property.

**Dependencies**

This property applies when the `RunningPeakToPeak` property is `false`.

**CustomDimension — Dimension to operate along**

1 (default) | positive integer

Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal.

**Dependencies**

This property applies when the `Dimension` property is 'Custom'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ResetInputPort — Enables resetting in running peak-to-peak mode**

`false` (default) | `true`

Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of object algorithm to reset the running peak-to-peak difference.

**Dependencies**

This property applies when the `RunningPeakToPeak` property is `true`.

**ResetCondition — Reset condition for running peak-to-peak mode**

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Specify the event to reset the running peak-to-peak as one of 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'.

**Dependencies**

This property applies when the `ResetInputPort` property is `true`.

## Usage

### Syntax

```
y = ptp(x)
y = ptp(x,r)
```

**Description**

`y = ptp(x)` computes the peak-to-peak value, `y`, of the floating-point input vector `x`.

$y = \text{ptp}(x, r)$  computes the peak-to-peak value of the input elements over successive calls to the object algorithm. The object optionally resets its state based on the reset input signal,  $r$ , and the value of the `ResetCondition` property. To enable reset, set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. If  $x$  is a matrix, each column is treated as an independent channel. The peak-to-peak value is computed along each channel.

Data Types: `single` | `double`

#### **r** — Reset signal

scalar

Reset signal, specified as a scalar value. The reset signal resets the object state based on the reset input signal and the value of the `ResetCondition` property.

### Dependencies

To enable this signal, set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

### Output Arguments

#### **y** — Peak-to-peak value

scalar | vector | matrix

Peak-to-peak value of the input signal, returned as a scalar, vector, or matrix. If `RunningPeakToPeak` is set to:

- `false` -- The object computes the peak-to-peak value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is a 1-by- $N$  vector, where  $N$  is the number of input channels.
- `true` -- The object computes the running peak-to-peak value of the signal. The size of the output signal matches the size of the input signal.

When the `RunningPeakToPeak` property is `true`,  $y$  corresponds to the peak-to-peak value of the input elements over successive calls to the object algorithm.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Peak-to-Peak Value of Vector

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Determine the peak-to-peak value for a vector input.

```
in = (1:10)';  
ptp = dsp.PeakToPeak;  
y = ptp(in)  
  
y = 9
```

## Version History

### Introduced in R2012a

### **R2021b: dsp.PeakToPeak System object will be removed**

*Warns starting in R2021b*

`dsp.PeakToPeak` System object will be removed in a future release. Use the `peak2peak` function instead.

### **R2023a: dsp.PeakToPeak System object has been removed**

*Errors starting in R2023a*

The `dsp.PeakToPeak` System object has been removed. Use the `peak2peak` function instead.

### Update Code

This table shows how to update existing code to use the `peak2peak` function.

| Discouraged Usage  | Recommended Replacement   |
|--|---|
| <p><b>Peak-to-Peak Value of Vector Input</b></p> <pre>in = (1:10)'; ptp = dsp.PeakToPeak; y = ptp(in)</pre> <p><i>y = 1×1</i></p> <p>9</p> <p><b>Peak-to-Peak Value of Matrix Input</b></p> <p>Set the Dimension property of the object to 'All' to compute the peak-to-peak values across both dimensions.</p> <pre>in = magic(4); ptp = dsp.PeakToPeak; ptp.Dimension = 'All'; y = ptp(in)</pre> <p><i>y = 1×1</i></p> <p>15</p> | <p><b>Peak-to-Peak Value of Vector Input</b></p> <pre>yfn = peak2peak(in)</pre> <p><i>yfn = 1×1</i></p> <p>9</p> <p><b>Peak-to-Peak Value of Matrix Input</b></p> <pre>yfn = peak2peak(in, 'all')</pre> <p><i>yfn = 1×1</i></p> <p>15</p> |

dsp.PeakToRMS

# dsp.PeakToRMS

**Package:** dsp

Peak-to-root-mean-square value of vector

## Description

The `dsp.PeakToRMS` System object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

- 1 Create the `dsp.PeakToRMS` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
ptr = dsp.PeakToRMS  
ptr = dsp.PeakToRMS(Name, Value)
```

### Description

`ptr = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `ptr`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`ptr = dsp.PeakToRMS(Name, Value)` returns an peak-to-root-mean-square System object, `ptr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### RunningPeakToRMS — Calculation over successive calls to object algorithm

`false` (default) | `true`

Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the object algorithm.

**Dimension — Dimension to operate along**

'Column' (default) | 'All' | 'Row' | 'Custom'

Specify the dimension along which to calculate the peak-to-RMS ratio as one of 'All', 'Row', 'Column', or 'Custom'. If you set this property to 'Custom', specify the dimension using the CustomDimension property.

**Dependencies**

This property applies when the RunningPeakToRMS property is false.

**CustomDimension — Numerical dimension to operate along**

1 (default) | positive integer

Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal.

**Dependencies**

This property applies when the Dimension property is 'Custom'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**DecibelScaledOutput — Report output in decibels (dB)**

true (default) | false

Set this property to true to enable output in dB. Set this property to false to report output as a ratio.

**ResetInputPort — Enables resetting in running peak-to-RMS mode**

false (default) | true

Set this property to true to enable resetting. When the property is set to true, a reset input must be specified in the call of object algorithm to reset the running peak-to-RMS ratio.

**Dependencies**

This property applies when the RunningPeakToRMS property is true.

**ResetCondition — Reset condition for running peak-to-RMS mode**

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Specify the event to reset the running peak-to-RMS as 'Rising edge', 'Falling edge', 'Either edge', or 'Non-zero'.

**Dependencies**

This property applies when the ResetInputPort property is true.

**Usage****Syntax**

```
y = ptr(x)
y = ptr(x,r)
```

### Description

`y = ptr(x)` computes the peak-to-RMS ratio, `y`, of the floating-point input vector `x`.

`y = ptr(x, r)` computes the peak-to-RMS ratio of the input elements over successive calls to the object algorithm. The object optionally resets its state based on the reset input signal, `r`, and the value of the `ResetCondition` property. To enable reset, set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. If `x` is a matrix, each column is treated as an independent channel. The peak-to-RMS value is computed along each channel.

Data Types: `single` | `double`

#### **r** — Reset signal

scalar

Reset signal, specified as a scalar value. The reset signal resets the object state based on the reset input signal and the value of the `ResetCondition` property.

### Dependencies

To enable this signal, set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

### Output Arguments

#### **y** — Peak-to-RMS value

scalar | vector | matrix

Peak-to-RMS value of the input signal, returned as a scalar, vector, or matrix. If `RunningPeakToRMS` is set to:

- `false` -- The object computes the peak-to-RMS value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is a 1-by- $N$  vector, where  $N$  is the number of input channels.
- `true` -- The object computes the running peak-to-RMS value of the signal. The size of the output signal matches the size of the input signal.

When the `RunningPeakToRMS` property is `true`, `y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the object algorithm.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

```
step      Run System object algorithm
release   Release resources and allow changes to System object property values and input
           characteristics
reset     Reset internal states of System object
```

## Examples

### Peak-to-RMS Ratio of Vector Input

Determine the peak-to-RMS ratio of a vector input.

```
in = (1:10)';
ptr = dsp.PeakToRMS;
y = ptr(in)
```

```
y = 1.6116
```

### Peak-to-RMS Ratio of Matrix Input

Determine the peak-to-RMS ratio of a matrix input.

```
in = magic(4);
ptr = dsp.PeakToRMS;
ptr.Dimension = 'All';
y = ptr(in)
```

```
y = 1.6547
```

## More About

### Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{\|X\|_{\infty}}{\sqrt{\frac{1}{N} \sum_{n=1}^N |X_n|^2}},$$

where the  $l$ -infinity norm and RMS values are computed along the specified dimension.

## Version History

Introduced in R2012a

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.PhaseExtractor

**Package:** dsp

Extract the unwrapped phase of a complex input

## Description

The `dsp.PhaseExtractor` System object extracts the unwrapped phase of a real or a complex input.

To extract the unwrapped phase of a signal input:

- 1 Create the `dsp.PhaseExtractor` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
phase = dsp.PhaseExtractor
phase = dsp.PhaseExtractor(Name, Value)
```

### Description

`phase = dsp.PhaseExtractor` returns a phase extractor System object that extracts the unwrapped phase of an input signal.

`phase = dsp.PhaseExtractor(Name, Value)` returns a phase extractor System object with the specified property name set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **TreatFramesIndependently** — Unwrap phase only within the frame

`false` (default) | `true`

Specify if the phase is to be unwrapped only within the frame, as a logical scalar.

When you set this property to:

- `false` -- The object returns the unwrapped phase while ignoring boundaries between input frames.
- `true` -- The object treats each frame of input data independently, and resets the initial cumulative unwrapped phase value to zero each time a new input frame is received.

### Usage

### Syntax

```
p = phase(input)
```

### Description

`p = phase(input)` extracts the unwrapped phase, `p`, of the input signal. Each column of the input signal is treated as a separate channel. The System object unwraps the phase of each channel of the input signal independently over time.

### Input Arguments

#### **input** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Data Types: `single` | `double`

### Output Arguments

#### **p** — Unwrapped phase

vector | matrix

Unwrapped phase of the input, returned as a vector or a matrix. The size and data type of the unwrapped phase output match the size and data type of the input signal.

Data Types: `single` | `double`

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Plot Unwrapped Phase Of a Sine Wave

Create a `dsp.SineWave` System object™. Specify that the object generates an exponential output with a complex exponent.

```
sine = dsp.SineWave('Frequency',10,...  
    'ComplexOutput',true,'SamplesPerFrame',128);
```

Create a `dsp.PhaseExtractor` System object?. Specify that the object ignores frame boundaries when returning the unwrapped phase.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',false);
```

Extract the unwrapped phase of a sine wave. Plot the phase versus time using a `timescope` System object.

```
timeplot = timescope('PlotType','Line','SampleRate',1000,...  
    'TimeSpanSource','Property','TimeSpan',1.5,'YLimits',[0 80],...  
    'ShowGrid',true,...  
    'YLabel','Unwrapped Phase (rad)');  
for ii = 1:10  
    sineOutput = sine();  
    phaseOutput = phase(sineOutput);  
    timeplot(phaseOutput)  
end
```

### Plot Phase Response of Third-Order IIR Filter

Create a `dsp.TransferFunctionEstimator` System object™.

```
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object must treat each frame of data independently.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',true);
```

Create a `dsp.IIRFilter` System object™. Compute the transfer function of a third-order IIR filter. Use the `butter` function to generate coefficients for the filter.

```
[b,a] = butter(3,.3);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);
```

Extract the phase response of the transfer function. Plot using a `dsp.ArrayPlot` System object™.

```
sampleRate = 1e3;
phaseplot = dsp.ArrayPlot('PlotType','Line','XOffset',-sampleRate/2,...
    'YLimits',[-15 0],...
    'YLabel','Phase Response (rad)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Phase response');
```

```

for ii = 1:100
    % Generate input
    input = 0.05*randn(1000,1);
    % Pass through IIR filter
    filterOutput = iir(input);
    % Estimate transfer function
    transferFunction = tfe(input,filterOutput);
    % Plot transfer function phase
    phaseOutput = phase(transferFunction);
    phaseplot(phaseOutput);
end

```

## Algorithms

Consider an input frame of length  $N$ :

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The object acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here,  $i$  runs from 1 to  $N$ . The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the object treats each frame independently. Therefore, in each frame, the object calculates the phase using the preceding formula where:
  - $\Phi_0$  is 0.
  - $x_0$  is 1.
- If you set `TreatFramesIndependently` to `false`, the object ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - $\Phi_0$  is the last unwrapped phase from the previous frame.
  - $x_0$  is the last sample from the previous frame.

## Version History

Introduced in R2014b

## See Also

### Blocks

Phase Extractor

# dsp.PhaseUnwrapper

**Package:** dsp

Unwrap signal phase

## Description

The `dsp.PhaseUnwrapper` System object unwraps the phase of the input signal specified in radians.

To unwrap the signal phase input:

- 1 Create the `dsp.PhaseUnwrapper` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
phUnwrap = dsp.PhaseUnwrapper
phUnwrap = dsp.PhaseUnwrapper(Name, Value)
```

### Description

`phUnwrap = dsp.PhaseUnwrapper` returns a phase unwrapper System object that adds or subtracts appropriate multiples of  $2\pi$  to each input element to remove phase discontinuities (unwrap).

`phUnwrap = dsp.PhaseUnwrapper(Name, Value)` returns a phase unwrapper System object with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **InterFrameUnwrap — Enable unwrapping of phase discontinuities between successive frames**

true (default) | false

Set this property to `false` to unwrap phase discontinuities only within the frame. Set this property to `true` to also unwrap phase discontinuities between successive frames.

**Tolerance — Jump size as true phase discontinuity**

3.1416 (default) | real scalar

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to  $\pi$  (rather than a smaller value) to avoid altering legitimate signal features. To increase the phase wrapper sensitivity, set the **Tolerance** property to a value slightly less than  $\pi$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Usage****Syntax**

```
output = phUnwrap(input)
```

**Description**

`output = phUnwrap(input)` unwraps the phase of the input signal. This is done by adding or subtracting appropriate multiples of  $2\pi$  to each input element to remove phase discontinuities (unwrap). Each column of the input signal is treated as a separate channel.

**Input Arguments****input — Data input**

vector | matrix

Data input, specified as a vector or a matrix. The phase of the input signal should be in radians.

Data Types: single | double

**Output Arguments****output — Unwrapped phase**

vector | matrix

Unwrapped phase of the input, returned as a vector or a matrix. The size and data type of the unwrapped phase output match the size and data type of the input signal.

Data Types: single | double

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

**Common to All System Objects**

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Unwrap input phase data

```
phUnwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
     4/5 -4/5, -2/5]*pi;
y = phUnwrap(p');
figure,stem(p); hold
```

Current plot held

```
stem(y, 'r');
legend('Input (blue)', 'Unwrapped data (red)');
hold off;
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

# dsp.PulseMetrics

**Package:** dsp

(Removed) Pulse metrics of bilevel waveforms

---

**Note** `dsp.PulseMetrics` has been removed. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `dutycycle`, `midcross`, `pulseperiod`, `pulsesep`, and `pulsewidth` among others. For more information, see “Compatibility Considerations”.

---

## Description

The `dsp.PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

- 1 Create the `dsp.PulseMetrics` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
pm = dsp.PulseMetrics
pm = dsp.PulseMetrics(Name,Value)
```

### Description

`pm = dsp.PulseMetrics` creates a pulse metrics System object, `pm`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`pm = dsp.PulseMetrics(Name,Value)` returns a `PulseMetrics` System object, `pm`, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**CycleOutputPort — Enable cycle metrics**`false` (default) | `true`

If `CycleOutputPort` is `true`, cycle metrics are reported for each pulse period.

**MaximumRecordLength — Maximum samples to preserve**`1000` (default) | positive integer

Maximum samples to preserve between calls to the algorithm. This property requires a positive integer that specifies the maximum number of samples to save between calls to the algorithm. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded.

**Tunable:** Yes

**Dependencies**

This property applies when the `RunningMetrics` property is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**PercentReferenceLevels — Percent reference levels**`[10 50 90]` (default) | three-element row vector

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Data Types: `double`

**PercentStateLevelTolerance — Tolerance of state level**`2` (default) | positive scalar

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Data Types: `double`

**Polarity — Polarity of pulse to extract**`'positive'` (default) | `'negative'`

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are `'positive'` or `'negative'`.

**PostshootOutputPort — Enable posttransition aberration metrics**`false` (default) | `true`

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

**PostshootSeekFactor — Postshoot seek factor**

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

**Tunable:** Yes**Dependencies**

This property is enabled only when the `PostshootOutputPort` property is set to `true`.

Data Types: `double`**PreshootOutputPort — Enable pretransition aberration metrics**`false` (default) | `true`

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

**PreshootSeekFactor — Preshoot seek factor**

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition.

**Tunable:** Yes**Dependencies**

This property is enabled only when the `PreshootOutputPort` property is set to `true`.

Data Types: `double`**RunningMetrics — Enable metrics**`false` (default) | `true`

Enable metrics over all calls to the algorithm. If `RunningMetrics` is set to `false`, metrics are computed for each call to the algorithm independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to the algorithm. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to the algorithm is made with enough data to compute all enabled metrics for that transition.

**SampleRate — Sampling rate**

1 (default) | positive scalar

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero.

**Dependencies**

This property applies when the `TimeInputPort` property is set to `false`.

Data Types: `double`

### **SettlingOutputPort — Enable settling metrics**

`false` (default) | `true`

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time the object algorithm is called if the `RunningMetrics` property is set to `true`.

### **SettlingSeekDuration — Duration of time**

`0.02` (default) | positive scalar

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the object reports `NaN` for all settling metrics.

**Tunable:** Yes

#### **Dependencies**

This property applies only when you set the `SettlingOutputPort` property to `true`.

Data Types: `double`

### **StateLevels — State levels**

`[0 2.3]` (default) | two-element row vector

Low- and high-state levels. This property is a two-element numeric row vector that contains the low- and high-state levels. These state levels correspond to the nominal logic low and high levels of the pulse waveform.

**Tunable:** Yes

Data Types: `double`

### **StateLevelsSource — State-level computation**

`'Property'` (default) | `'Auto'`

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to the object is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

### **TimeInputPort — Specify sample instants**

`false` (default) | `true`

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to the object algorithm to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The

sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

### TransitionOutputPort — Enable transition metrics

`false` (default) | `true`

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

## Usage

### Syntax

```
pulse = pm(x)
[pulse,cycle] = pm(x)
[pulse,transition] = pm(x)
[pulse,preshoot] = pm(x)
[pulse,postshoot] = pm(x)
[pulse,settling] = pm(x)
[pulse,cycle,transition,preshoot,postshoot,settling] = pm(x)
[ ___ ] = pm(x,T)
```

### Description

`pulse = pm(x)` returns a structure array, `pulse`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `x`.

`[pulse,cycle] = pm(x)` returns a structure array, `cycle`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `x`.

`[pulse,transition] = pm(x)` returns a structure array, `transition`, when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns that correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`[pulse,preshoot] = pm(x)` returns a structure array, `preshoot`, when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `postshoot` structure array.

`[pulse,postshoot] = pm(x)` returns a structure, `postshoot`, when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`[pulse,settling] = pm(x)` returns a structure array, `settling`, when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

`[pulse,cycle,transition,preshoot,postshoot,settling] = pm(x)` which returns the `pulse`, `cycle`, `transition`, `preshoot`, `postshoot`, and `settling` structures when the

`CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

[ \_\_\_ ] = `pm`(`x`, `T`) calculates the above metrics with respect to a sampled signal, whose sample values, `x`, and sample instants, `T`, are real-valued column vectors of the same length. The additional input `T` applies only when you set the `TimeInputPort` property to `true`.

### Input Arguments

#### **x** — Input signal

column vector

Input signal, specified as a real-valued column vector.

Data Types: `double`

#### **T** — Sampling instants

column vector

Sampling instants, specified as a real-valued column vector. Set `TimeInputPort` to `true` to enable an additional real input column vector to the object algorithm to specify the sample instants that correspond to the sample values. If `TimeInputPort` is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

### Dependencies

This input is applicable when you set the `TimeInputPort` property to `true`.

Data Types: `double`

### Output Arguments

#### **pu**lse — Complete pulses

structure

Complete pulses, returned as a structure whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `x`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

The `pu`lse output contains the following fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

Data Types: `struct`

### **cycle — Complete pulse periods**

structure

Complete pulse periods, returned as a structure whose fields contain real-valued column vectors. This structure can only be returned when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `x`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `x` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to the algorithm detects the next transition.

The `cycle` output contains the following fields:

- **Period** — Duration between the first transition of the current pulse and the first transition of the next pulse.
- **Frequency** — Reciprocal of the period.
- **Separation** — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse.
- **Width** — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `pulse` structure.
- **DutyCycle** — Ratio of the width to the period for each pulse.

Data Types: `struct`

### **transition — Transition metrics**

structure

Transition metrics, returned as a structure array. This structure can only be returned when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns, which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

The `transition` output contains the following fields:

- **Duration** — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- **SlewRate** — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- **MiddleCross** — Linearly interpolated instant in time where the transition first crosses the mid-reference level
- **LowerCross** — Linearly interpolated instant where the signal crosses the lower-reference level
- **UpperCross** — Linearly interpolated instant where the signal crosses the upper-reference level

Data Types: `struct`

### **preshoot — Preshoot metrics**

structure

Preshoot metrics, returned as a structure array. This structure can only be returned when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `preshoot` output contains the following fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

Data Types: `struct`

### **postshoot — Postshoot metrics**

structure

Postshoot metrics, returned as a structure array. This structure can only be returned when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `postshoot` output contains the following fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

Data Types: `struct`

### **settling — Settling metrics**

structure

Settling metrics for each transition, returned as a structure array. This structure can only be returned when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

The `settling` output contains the following fields:

- `Duration` — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration

- **Instant** — Instant in time where the signal enters and remains within the specified tolerance
- **Level** — Level of the waveform where it enters and remains within the specified tolerance

Data Types: `struct`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.PulseMetrics`

`plot` (To be removed) Plot pulse signal and metrics

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Width, Period, and Duty Cycle

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

```
load('pulseex.mat','x','t');
```

Construct the `dsp.PulseMetrics` object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5 V pulse, set the `StateLevels` property to `[0 5]`.

```
pm = dsp.PulseMetrics('TimeInputPort',true, ...
                    'CycleOutputPort', true, ...
                    'StateLevels',[0 5])
```

```
pm =
  dsp.PulseMetrics with properties:
        Polarity: 'Positive'
  StateLevelsSource: 'Property'
        StateLevels: [0 5]
  PercentStateLevelTolerance: 2
  PercentReferenceLevels: [10 50 90]
        RunningMetrics: false
        TimeInputPort: true
        CycleOutputPort: true
  TransitionOutputPort: false
  PreshootOutputPort: false
  PostshootOutputPort: false
  SettlingOutputPort: false
```

Call the object to compute the cycle metrics and plot the result.

```
[pulse,cycle] = pm(x,t);  
plot(pm)  
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

## Version History

### Introduced in R2012a

#### **R2021b: dsp.PulseMetrics System object will be removed**

*Warns starting in R2021b*

`dsp.PulseMetrics` System object will be removed in a future release. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `dutycycle`, `midcross`, `pulseperiod`, `pulsesep`, and `pulsewidth` among others.

#### **R2023a: dsp.PulseMetrics System object has been removed**

*Errors starting in R2023a*

The `dsp.PulseMetrics` System object has been removed. Use functions from “Pulse and Transition Metrics” instead. This set includes functions such as `dutycycle`, `midcross`, `pulseperiod`, `pulsesep`, and `pulsewidth` among others.

### Update Code

This table shows how to update existing code to use these functions.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <pre>load('clockx.mat','x','t'); pm = dsp.PulseMetrics(SampleRate=4e6,...     TransitionOutputPort=true,...     StateLevelsSource='Auto',... ## **dsp.RLSFilter**

**Package:** dsp

Compute output, error and coefficients using recursive least squares (RLS) algorithm

### **Description**

The `dsp.RLSFilter` System object filters each channel of the input using RLS filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.RLSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### **Creation**

#### **Syntax**

```
rlsFilt = dsp.RLSFilter  
rlsFilt = dsp.RLSFilter(len)  
rlsFilt = dsp.RLSFilter(Name,Value)
```

#### **Description**

`rlsFilt = dsp.RLSFilter` returns an adaptive RLS filter System object, `rlsFilt`. This System object computes the filtered output, filter error, and the filter weights for a given input and desired signal using the RLS algorithm.

`rlsFilt = dsp.RLSFilter(len)` returns an RLS filter System object, `rlsFilt`. This System object has the `Length` property set to `len`.

`rlsFilt = dsp.RLSFilter(Name,Value)` returns an RLS filter System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Method — Method to calculate filter coefficients**

Conventional RLS (default) | Householder RLS | Sliding-window RLS | Householder sliding-window RLS | QR decomposition

You can specify the method used to calculate filter coefficients as Conventional RLS [1] [2], Householder RLS [3] [4], Sliding-window RLS [5][1][2], Householder sliding-window RLS [4], or QR decomposition [1] [2]. This property is nontunable.

**Length — Length of filter coefficients vector**

32 (default) | positive integer

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**SlidingWindowBlockLength — Width of sliding window**

48 (default) | positive integer

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the Length property value. This property is nontunable.

**Dependencies**

This property applies only when the Method property is set to Sliding-window RLS or Householder sliding-window RLS.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**ForgettingFactor — RLS forgetting factor**

1 (default) | positive scalar

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter.

**Tunable:** Yes

Data Types: single | double

**InitialCoefficients — Initial coefficients of filter**

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value.

**Tunable:** Yes

Data Types: single | double

**InitialInverseCovariance — Initial inverse covariance**

1000 (default) | scalar | square matrix

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the Length property value. If you set a scalar value, the InverseCovariance property is initialized to a diagonal matrix with diagonal elements equal to that scalar value.

**Tunable:** Yes

**Dependencies**

This property applies only when the `Method` property is set to `Conventional RLS` or `Sliding-window RLS`.

Data Types: `single` | `double`

**InitialSquareRootInverseCovariance — Initial square root inverse covariance**

`sqrt(1000)` (default) | `scalar` | `square matrix`

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value.

**Tunable:** Yes

**Dependencies**

This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`.

Data Types: `single` | `double`

**InitialSquareRootCovariance — Initial square root covariance**

`sqrt(1/1000)` (default) | `scalar` | `square matrix`

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value.

**Tunable:** Yes

**Dependencies**

This property applies only when the `Method` property is set to `QR-decomposition RLS`.

Data Types: `single` | `double`

**LockCoefficients — Lock coefficient updates**

`false` (default) | `true`

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated).

**Tunable:** Yes

**Usage****Syntax**

```
y = rlsFilt(x,d)  
[y,e] = rlsFilt(x,d)
```

## Description

$y = \text{rlsFilt}(x, d)$  recursively adapts the reference input,  $x$ , to match the desired signal,  $d$ , using the System object, `rlsFilt`. The desired signal,  $d$ , is the signal desired plus some undesired noise.

$[y, e] = \text{rlsFilt}(x, d)$  shows the output of the RLS filter along with the error,  $e$ , between the reference input and the desired signal. The filter adapts its coefficients until the error  $e$  is minimized. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `rlsFilt` filter, call `rlsFilt.Coefficients` after you pass the input and desired signal to the object.

## Input Arguments

### **x** — Data input

scalar | column vector

The signal to be filtered by the RLS filter. The input,  $x$ , and the desired signal,  $d$ , must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`  
Complex Number Support: Yes

### **d** — Desired signal

scalar | column vector

The RLS filter adapts its coefficients to minimize the error,  $e$ , and converge the input signal  $x$  to the desired signal  $d$  as closely as possible.

The input,  $x$ , and the desired signal,  $d$ , must have the same size and data type.

The desired signal,  $d$ , can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`  
Complex Number Support: Yes

## Output Arguments

### **y** — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal  $x$  to match the desired signal  $d$ . The filter outputs the converged signal.

Data Types: `single` | `double`

### **e** — Difference between output and desired signal

scalar | column vector

Difference between the output signal  $y$  and the desired signal  $d$ , returned as a scalar or a column vector. The objective of the RLS filter is to minimize this error. The object adapts its coefficients to

converge toward optimal filter coefficients that produce an output signal that matches closely with the desired signal. For more details on how  $e$  is computed, see “Algorithms” on page 4-964. To access the RLS filter coefficients, call `rlsFilt.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`  
Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.RLSFilter`

`mseSim` Estimated mean squared error for adaptive filters

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### System Identification of FIR Filter Using RLS Filter

Use a recursive least squares (RLS) filter to identify an unknown system modeled with a lowpass FIR filter. Compare the frequency responses of the unknown and estimated systems.

#### Initialization

Create a `dsp.FIRFilter` object that represents the system to be identified. Pass the signal `x` to the FIR filter. The output of the unknown system is the desired signal `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal `n`.

```
filt = dsp.FIRFilter('Numerator',fir1(10,.25));  
x = randn(1000,1);  
n = 0.01*randn(1000,1);  
d = filt(x) + n;
```

#### Adaptive Filter

Create a `dsp.RLSFilter` object to create an RLS filter. Set the length of the filter to 11 taps and the forgetting factor to 0.98. Pass the primary input signal `x` and the desired signal `d` to the RLS filter. The output `y` of the adaptive filter is the signal converged to the desired signal `d` thereby minimizing the error `e` between the two signals.

```
rls = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);  
[y,e] = rls(x,d);  
w = rls.Coefficients;
```

## Plot the results

The output signal matches the desired signal, making the error between the two close to zero.

```
plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index');
ylabel('signal value');
```

## Compare the weights

The weights vector  $w$  represents the coefficients of the RLS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the RLS filter.

The estimated filter weights closely match the actual filter weights, confirming the results seen in the previous signal plot.

```
stem([filt.Numerator; w].');
legend('Actual', 'Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

### Inverse System Identification Using RLS Algorithm

This example demonstrates the RLS adaptive algorithm using the inverse system identification model shown here.

Cascading the adaptive filter with an unknown filter causes the adaptive filter to converge to a solution that is the inverse of the unknown system.

If the transfer function of the unknown system and the adaptive filter are  $H(z)$  and  $G(z)$ , respectively, the error measured between the desired signal and the signal from the cascaded system reaches its

minimum when  $G(z) \times H(z) = 1$ . For this relation to be true,  $G(z)$  must equal  $1/H(z)$ , the inverse of the transfer function of the unknown system.

To demonstrate that this is true, create a signal  $s$  to input to the cascaded filter pair.

```
s = randn(3000,1);
```

In the cascaded filters case, the unknown filter results in a delay in the signal arriving at the summation point after both filters. To prevent the adaptive filter from trying to adapt to a signal it has not yet seen (equivalent to predicting the future), delay the desired signal by 12 samples, which is the order of the unknown system.

Generally, you do not know the order of the system you are trying to identify. In that case, delay the desired signal by number of samples equal to half the order of the adaptive filter. Delaying the input requires prepending 12 zero-value samples to the input  $s$ .

```
delay = zeros(12,1);
d = [delay; s(1:2988)]; % Concatenate the delay and the signal.
```

You have to keep the desired signal vector  $d$  the same length as  $x$ , so adjust the signal element count to allow for the delay samples.

Although not generally the case, for this example you know the order of the unknown filter, so add a delay equal to the order of the unknown filter.

For the unknown system, use a lowpass, 12th-order FIR filter.

```
filt = dsp.FIRFilter;
filt.Numerator = fir1(12,0.55,'low');
```

Filtering  $s$  provides the input data signal for the adaptive algorithm function.

```
x = filt(s);
```

To use the RLS algorithm, create a `dsp.RLSFilter` object and set its `Length`, `ForgettingFactor`, and `InitialInverseCovariance` properties.

For more information about the input conditions to prepare the RLS algorithm object, refer to `dsp.RLSFilter`.

```
p0 = 2 * eye(13);
lambda = 0.99;
rls = dsp.RLSFilter(13,'ForgettingFactor',lambda,...
    'InitialInverseCovariance',p0);
```

This example seeks to develop an inverse solution, you need to be careful about which signal carries the data and which is the desired signal.

Earlier examples of adaptive filters use the filtered noise as the desired signal. In this case, the filtered noise ( $x$ ) carries the unknown system's information. With Gaussian distribution and variance of 1, the unfiltered noise  $d$  is the desired signal. The code to run this adaptive filter is:

```
[y,e] = rls(x,d);
```

where  $y$  returns the filtered output and  $e$  contains the error signal as the filter adapts to find the inverse of the unknown system.

Obtain the estimated coefficients of the RLS filter.

```
b = rls.Coefficients;
```

View the frequency response of the adapted RLS filter (inverse system,  $G(z)$ ) using `freqz`. The inverse system looks like a highpass filter with linear phase.

```
freqz(b,1)
```

View the frequency response of the unknown system,  $H(z)$ . The response is that of a lowpass filter with a cutoff frequency of 0.55.

```
freqz(filt.Numerator,1)
```

The result of the cascade of the unknown system and the adapted filter is a compensated system with an extended cutoff frequency of 0.8.

```
overallCoeffs = conv(filt.Numerator,b);  
freqz(overallCoeffs,1)
```

### Cancel Noise Using RLS Filter

Cancel additive noise  $n$  added to an unknown system using an RLS filter. The RLS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system is the error signal  $e$ , which represents the additive white noise. Minimizing this error signal is the objective of the adaptive filter.

#### Initialization

Create a `dsp.FIRFilter` System object™ to represent the unknown system. Create a `dsp.RLSFilter` object and set the length to 11 taps. Set the method to 'Householder RLS'. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;

rls = dsp.RLSFilter('Length',11,...
    'Method','Householder RLS');
filt = dsp.FIRFilter('Numerator',...
    fir1(10,[.5,.75]));

sinewave = dsp.SineWave('Frequency',0.01,...
```

```
    'SampleRate',1,...
    'SamplesPerFrame',FrameSize);
scope = timescope('LayoutDimensions',[2 1],...
    'NumInputPorts',2, ...
    'TimeUnits','Seconds',...
    'YLimits',[-2.5 2.5], ...
    'BufferLength',2*FrameSize*NIter,...
    'ActiveDisplay',1,...
    'ShowLegend',true,...
    'ChannelNames',{'Noisy signal'},...
    'ActiveDisplay',2,...
    'ShowLegend',true,...
    'ChannelNames',{'Error signal'});

for k = 1:NIter
    x = randn(FrameSize,1);
    d = filt(x) + sinewave();
    [y,e] = rls(x,d);
    w = rls.Coefficients;
    scope(d,e)
end
release(scope)
```

## Algorithms

The `dsp.RLSFilter` System object, when `Conventional` RLS is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as  $\mathbf{P}(n)$  :

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1 + \lambda^{-1}\mathbf{u}^H(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}^*(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^H(n)\mathbf{P}(n-1)$$

where  $\lambda^{-1}$  denotes the reciprocal of the exponential weighting factor. The variables are as follows:

| Variable        | Description                                      |
|-----------------|--|
| $n$             | The current time index                           |
| $\mathbf{u}(n)$ | The vector of buffered input samples at step $n$ |

| Variable          | Description   |
|-------------------|---|
| $\mathbf{P}(n)$   | The conjugate of the inverse correlation matrix at step $n$ |
| $\mathbf{k}(n)$   | The gain vector at step $n$                                 |
| $\mathbf{k}^*(n)$ | Complex conjugate of $\mathbf{k}$                           |
| $\mathbf{w}(n)$   | The vector of filter tap estimates at step $n$              |
| $y(n)$            | The filtered output at step $n$                             |
| $e(n)$            | The estimation error at step $n$                            |
| $d(n)$            | The desired response at step $n$                            |
| $\lambda$         | The forgetting factor                                       |

$\mathbf{u}$ ,  $\mathbf{w}$ , and  $\mathbf{k}$  are all column vectors.

# **dsp.SampleRateConverter**

**Package:** dsp

Multistage sample rate converter

## **Description**

The `SampleRateConverter` System object converts the sample rate of an incoming signal.

To convert the sample rate of a signal:

- 1 Create the `dsp.SampleRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
src = dsp.SampleRateConverter  
src = dsp.SampleRateConverter(Name, Value)
```

### **Description**

`src = dsp.SampleRateConverter` creates a multistage FIR sample rate converter System object, `src`, that converts the sample rate of each channel of an input signal.

`src = dsp.SampleRateConverter(Name, Value)` returns a multistage FIR sample rate converter System object, `src`, with properties and options specified by one or more `Name, Value` pair arguments.

### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **Bandwidth — Two-sided bandwidth of interest**

40000 (default) | positive scalar

Specify the two-sided bandwidth of interest (after rate conversion) as a positive scalar expressed in Hz. This property sets the two-sided bandwidth of the information-carrying portion of the signal that you wish to retain.

**InputSampleRate — Sample rate of input signal**

192000 (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar expressed in Hz. The input sample rate must be greater than the bandwidth of interest.

**OutputRateTolerance — Maximum allowed tolerance for output sample rate**

0 (default) | positive scalar

Specify the maximum allowed tolerance for the sample rate of the output signal as a positive scalar between 0 and 1.

The output rate tolerance allows for a simpler design in many cases. The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range given by `OutputSampleRate ± 1%`.

**OutputSampleRate — Sample rate of output signal**

44100 (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar expressed in Hz. The output sample rate must be greater than the bandwidth of interest.

**StopbandAttenuation — Minimum dB attenuation for aliased components**

80 (default) | positive scalar

Specify the stopband attenuation as a positive scalar expressed in dB. This property is the minimum amount by which any aliasing involved in the process is attenuated.

**Usage****Syntax**

$$y = \text{src}(x)$$
**Description**

`y = src(x)` designs one or more multirate FIR filters and then uses the filters to convert the rate of each channel (column) of the real or complex input signal `x` to the output sampling rate.

**Input Arguments****x — Input signal**

vector | matrix

Input signal, specified as a vector or a matrix of size  $P$ -by- $Q$ . The number of input rows  $P$  can be arbitrary and does not have to be a multiple of the overall decimation factor. You can determine the decimation factor using the `getRateChangeFactors` function. The object treats each column of `x` as a separate channel.

This object supports variable-size input signals, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

Data Types: `single` | `double`

## Output Arguments

### **y** — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

When the input is of size  $P$ -by- $Q$ , the output signal has an upper bound size of  $\text{ceil}(P/R)$ -by- $Q$ , where  $R$  is the ratio of the input sample rate and the output sample rate. The number of channels (columns) does not change.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.SampleRateConverter`

|                                    |  |
|------------------------------------|--|
| <code>getActualOutputRate</code>   | Get actual output rate                           |
| <code>getFilters</code>            | Obtain single-stage filters                      |
| <code>getRateChangeFactors</code>  | Get overall interpolation and decimation factors |
| <code>visualizeFilterStages</code> | Visualize filter stages                          |

## Filter Analysis

|                    |   |
|--------------------|---|
| <code>cost</code>  | Implementation cost of the sample rate converter      |
| <code>freqz</code> | Frequency response of the multirate multistage filter |
| <code>info</code>  | Display information about sample rate converter       |

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Convert Sample Rate of Audio Signal

Convert the sample rate of an audio signal from 44.1 kHz (CD quality) to 96 kHz (DVD quality).

**Note:** The `dsp.AudioFileWriter` System object™ is not supported in MATLAB Online.

```
FsIn = 44.1e3;  
FsOut = 96e3;
```

```
SRC = dsp.SampleRateConverter('Bandwidth',40e3,...  
    'InputSampleRate',FsIn,'OutputSampleRate',FsOut);
```

```
[L,M] = getRateChangeFactors(SRC);
FrameSize = 10*M;
```

```
AR = dsp.AudioFileReader('guitar10min.ogg', ...
    'SamplesPerFrame',FrameSize);
AW = dsp.AudioFileWriter('guitar10min_96k.wav', ...
    'SampleRate',FsOut);
```

Convert 100 frames of audio signal. Release all objects.

```
for n = 1:100
    x = AR();
    y = SRC(x);
    AW(y);
end
```

```
release(AR);
release(AW);
release(SRC);
```

Plot the input and output signals. The latency of the sample rate converter introduces a delay in the output signal.

```
tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
figure
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty,y(:,1),'--')
ylim([-0.25 0.25]);
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty,y(:,2),'--')
ylim([-0.25 0.25]);
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Use the `outputDelay` function to determine this delay value. To account for this delay, shift the output by this delay value.

```
[delay,~,~] = outputDelay(SRC,Fc=0)

delay = 0.0012

tx = (0:length(x)-1)./FsIn;
ty = (0:length(y)-1)./FsOut;
figure
subplot(2,1,1)
plot(tx,x(:,1),'.')
hold on
plot(ty-delay,y(:,1),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),'.')
hold on
plot(ty-delay,y(:,2),'--')
xlim([0 0.005])
xlabel('Time (s)')
legend('Input samples','Output samples','Location','best')
title('Channel 2')
```

Zoom in to see the difference in sample rates.

```
figure
subplot(2,1,1)
plot(tx,x(:,1),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,1),'ro')
plot(ty-delay,y(:,1),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 1')
subplot(2,1,2)
plot(tx,x(:,2),Color=[0.6 0.6 0.6])
hold on
plot(tx,x(:,2),'ro')
plot(ty-delay,y(:,2),'b.')
xlim([0.0105 0.0107])
legend('Interpolated input','Input samples','Output samples')
title('Channel 2')
```

### Convert Sample Rate of Sinusoid

Create a multistage sample rate converter with default properties. The converter converts from 192 kHz to 44.1 kHz in three stages.

```
src = dsp.SampleRateConverter;
```

Use `src` to convert the sample rate of a noisy sinusoid. The sinusoid has a frequency of 20 kHz and is sampled for 0.1 s.

```
f = 20e3;
```

```
FsIn = src.InputSampleRate;  
FsOut = src.OutputSampleRate;
```

```
t1 = (0:1/FsIn:0.1-1/FsIn)';
```

```
sIn = sin(2*pi*f*t1) + randn(size(t1));
```

Estimate the power spectral density of the input.

```
hsa = spectrumAnalyzer('SampleRate',FsIn,...  
    'Method','welch','YLimits',[-40 40]);  
hsa(sIn)  
release(hsa)
```

Convert the sample rate of the signal. Estimate the power spectral density of the output.

```
s0out = src(sIn);
```

```
hsb = spectrumAnalyzer('SampleRate',FsOut,...  
    'Method','welch','YLimits',[-40 40]);
```

```
hsb(s0out)  
release(hsb)
```

### Tolerance Cost in Sample Rate Conversion

A signal output from an A/D converter is sampled at 98.304 MHz. The signal has a bandwidth of 20 MHz. Reduce the sample rate of the signal to 22 MHz, which is the bandwidth of 802.11 channels. Make the conversion exactly and then redo it with an output rate tolerance of 1%.

```
SRC1 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0);
SRC2 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0.01);
```

Use the `cost` method to determine the cost of each sample rate conversion. The zero-tolerance process requires more than 500 times as many coefficients as the 1% process.

```
c1 = cost(SRC1)

c1 = struct with fields:
    NumCoefficients: 84779
    NumStates: 133
    MultiplicationsPerInputSample: 27.0422
    AdditionsPerInputSample: 26.0684
```

```

c2 = cost(SRC2)
c2 = struct with fields:
    NumCoefficients: 150
    NumStates: 127
    MultiplicationsPerInputSample: 22.6667
    AdditionsPerInputSample: 22.1111

```

Find the integer upsampling and downsampling factors used in each conversion.

```

[L1,M1] = getRateChangeFactors(SRC1)
L1 = 1375
M1 = 6144
[L2,M2] = getRateChangeFactors(SRC2)
L2 = 2
M2 = 9

```

Compute the actual sample rate of the output signal when the sample rate conversion has a tolerance of 1%.

```

getActualOutputRate(SRC2)
ans = 2.1845e+07

```

### Reset a Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Determine its overall decimation and interpolation factors.

```

src = dsp.SampleRateConverter;
[L,M] = getRateChangeFactors(src);

```

Create a two-channel random signal. Specify a number of samples equal to the decimation factor. Call the object twice on the signal.

```

x = randn(M,2);
y1 = src(x);
y2 = src(x);
no = all(y2==y1)
no = 1x2 logical array
    0    0

```

The output is different because the internal states of `src` have changed. Use `reset` to reset the converter and call the converter again. Verify that the output is unchanged.

```
reset(src)
y3 = src(x);
yes = all(y3==y1)
yes = 1x2 logical array
     1     1
```

### Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;
[H,f] = freqz(src);
plot(f,20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;
[H,f] = freqz(src,f);
plot(f,20*log10(abs(H)))
```

### Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;

[h,w] = freqz(m);
plot(w/pi,20*log10(abs(h)))
xlabel('\omega / \pi')
ylabel('Magnitude (dB)')
```

### Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz.

```
src = dsp.SampleRateConverter
```

```
src =  
  dsp.SampleRateConverter with properties:
```

```
    InputSampleRate: 192000  
    OutputSampleRate: 44100  
    OutputRateTolerance: 0  
    Bandwidth: 40000  
    StopbandAttenuation: 80
```

Display information about the design.

```
info(src)
```

```
ans =  
  'Overall Interpolation Factor    : 147  
  Overall Decimation Factor      : 640  
  Number of Filters              : 3
```

```

Multiplications per Input Sample: 27.667188
Number of Coefficients           : 8631
Filters:
  Filter 1:
    dsp.FIRDecimator      - Decimation Factor   : 2
  Filter 2:
    dsp.FIRDecimator      - Decimation Factor   : 2
  Filter 3:
    dsp.FIRRateConverter  - Interpolation Factor: 147
                        - Decimation Factor    : 160

```

### Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```

src = dsp.SampleRateConverter;
src.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(src)

```

```

FsOut = 4.4308e+04

```

### Default Resampling Factors

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```

src = dsp.SampleRateConverter;
[L,M] = getRateChangeFactors(src)

```

```

L = 147

```

```

M = 640

```

### Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

```

src = dsp.SampleRateConverter;
visualizeFilterStages(src)

```

## Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation. Actual designs include at most two of these steps.
- The procedure automatically determines the optimal number of decimation or interpolation stages. In special cases, the algorithm can perform a decimation or interpolation in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step ensures that the intermediate sample rate does not go below the bandwidth of interest and that the block does not filter out any information.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.
- The algorithm allows transition-band aliasing because it decreases the implementation cost. It keeps the signal within the bandwidth of interest alias free up to the value specified by the `StopbandAttenuation` property.

## Version History

Introduced in R2014b

**R2023a: Support for arbitrary input frame length**

This object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the decimation factor.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The `getRateChangeFactors` function supports C and C++ code generation.
- This object supports SIMD code generation using Intel AVX2 technology under these conditions:
  - For upsampling, the ratio of output sample rate to input sample rate must be an integer.
  - For downsampling, the ratio of input sample rate to output sample rate must be an integer.
  - Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

- In the code you generate from this object, the resampled signal output is a fixed-size signal if the input signal is fixed size and is a multiple of the decimation factor. If the input is not a multiple of the decimation factor or if the input is a variable-size signal, then the resampled signal output is of variable-size.

## dsp.ScalarQuantizerDecoder

**Package:** dsp

(Removed) Convert each index value into quantized output value

---

**Note** `dsp.ScalarQuantizerDecoder` has been removed.

---

### Description

The `dsp.ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater  $N - 1$  are set to  $N - 1$ .  $N$  is the length of the codebook vector.

To convert an index value into a quantized output value:

- 1 Create the `dsp.ScalarQuantizerDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
sqdec = dsp.ScalarQuantizerDecoder  
sqdec = dsp.ScalarQuantizerDecoder(Name,Value)
```

#### Description

`sqdec = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `sqdec`, that transforms zero-based input index values into quantized output values.

`sqdec = dsp.ScalarQuantizerDecoder(Name,Value)` returns a scalar quantizer decoder object, `sqdec`, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### CodebookSource — How to specify codebook values

'Property' (default) | 'Input port'

Specify how to determine the codebook values as 'Property' or 'Input port'.

### Codebook — Codebook

1:10 (default) | vector

Specify the codebook as a vector of quantized output values that correspond to each index value.

**Tunable:** Yes

### Dependencies

This property applies when you set CodebookSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### OutputDataType — Data type of codebook and quantized output

'double' | 'single' | 'Custom' | 'Same as input'

Specify the data type of the codebook and quantized output values as 'Same as input', 'double', 'single', or 'Custom'.

### Dependencies

This property applies when you set CodebookSource to 'Property'.

### Fixed-Point Properties

#### CustomOutputDataType — Output word and fraction lengths

numerictype(true,16) (default) | numerictype

Specify the output fixed-point type as a signed or unsigned numerictype object.

### Dependencies

This property applies only when you set the OutputDataType property to Custom.

## Usage

### Syntax

```
Q = sqdec(I)
Q = sqdec(I,C)
```

### Description

$Q = \text{sqdec}(I)$  returns the quantized output values  $Q$  corresponding to the input indices  $I$ .

$Q = \text{sqdec}(I,C)$  uses input  $C$  as the codebook values when you set the CodebookSource property to Input port. The data type of  $C$  can be double, single, or fixed-point. The output  $Q$  has the same data type as the codebook input  $C$ .

### Input Arguments

#### I — Input indices

vector | matrix

Input indices, specified as a vector or a matrix.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### **C — Codebook values**

vector

Codebook, specified as a vector of quantized output values that correspond to each index value.

#### **Dependencies**

This property applies when you set `CodebookSource` to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Output Arguments**

#### **Q — Quantized output values**

vector | matrix

Quantized output values, returned as a vector or a matrix of the same size as the input, `I`. When codebook is specified as a property, the output data type is determined by the `OutputDataType` property. When the codebook is specified as an input, the output data type is same as the data type of the codebook input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## **Common to All System Objects**

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## **Examples**

### **Quantize Signal**

Given a codebook and index values as inputs, determine the corresponding output quantized values.

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...  
    0.7844 1.3610 2.1599]);  
indices = uint8([1 3 5 7 6 4 2 0]);  
sqdec = dsp.ScalarQuantizerDecoder;  
sqdec.CodebookSource = 'Input port';  
qout = sqdec(indices,codebook)
```

*qout = 1x8 single row vector*

-1.3238 -0.2249 0.7844 2.1599 1.3610 0.2726 -0.7365 -2.1655

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except there is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N - 1$ .

## Version History

### Introduced in R2012a

### **R2021b: dsp.ScalarQuantizerDecoder System object will be removed**

*Warns starting in R2021b*

`dsp.ScalarQuantizerDecoder` System object will be removed in a future release.

### **R2023a: dsp.ScalarQuantizerDecoder System object has been removed**

*Errors starting in R2023a*

The `dsp.ScalarQuantizerDecoder` System object has been removed.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.ScalarQuantizerEncoder

**Package:** dsp

(Removed) Associate input value with index value of quantization region

---

**Note** dsp.ScalarQuantizerEncoder has been removed.

---

## Description

The dsp.ScalarQuantizerEncoder object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

- 1 Create the dsp.ScalarQuantizerEncoder object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
sqenc = dsp.ScalarQuantizerEncoder  
sqenc = dsp.ScalarQuantizerEncoder(Name,Value)
```

### Description

sqenc = dsp.ScalarQuantizerEncoder returns a scalar quantizer encoder System object, sqenc. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

sqenc = dsp.ScalarQuantizerEncoder(Name,Value) returns a scalar quantizer encoder object, sqenc, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### BoundaryPointsSource — Source of boundary points

'Property' (default) | 'Input port'

Specify how to determine the boundary points and codebook values as 'Property' or 'Input port'.

### Partitioning — Quantizer is bounded or unbounded

'Bounded' (default) | 'Unbounded'

Specify the quantizer as 'Bounded' or 'Unbounded'.

### BoundaryPoints — Boundary points of quantizer regions

1:10 (default) | vector

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$  denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify  $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ . If the quantizer is unbounded, the object uses this property to specify  $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$  and sets  $p_0 = -\text{Inf}$  and  $p_N = +\text{Inf}$ .

**Tunable:** Yes

### Dependencies

This property applies when you set the BoundaryPointsSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### SearchMethod — Find quantizer index by linear or binary search

'Linear' (default) | 'Binary'

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of 'Linear' or 'Binary'. The computational cost of the linear search method is of the order  $P$  and the computational cost of the binary search method is of the order

$$\log_2(P)$$

where  $P$  is the number of boundary points.

### TiebreakerRule — Behavior when input equals boundary point

'Choose the lower index' (default) | 'Choose the higher index'

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting 'Choose the lower index' or 'Choose the higher index'.

### CodewordOutputPort — Enable output of codeword value

false (default) | true

Set this property to true to output the codeword values that correspond to each index value.

### QuantizationErrorOutputPort — Enable output of quantization error

false (default) | true

Set this property to true to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value.

### Codebook — Codebook

1.5:9.5 (default) | vector

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is 'Bounded' and the boundary points vector has length `N`, you must set this property to a vector of length `N-1`. If the `Partitioning` property is 'Unbounded' and the boundary points vector has length `N`, you must set this property to a vector of length `N+1`.

**Tunable:** Yes

**Dependencies**

This property applies when you set the `BoundaryPointsSource` property to 'Property' and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ClippingStatusOutputPort — Enable output of clipping status**

`false` (default) | `true`

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0.

**Dependencies**

This property applies when you set the `Partitioning` property to 'Bounded'.

**OutputIndexDataType — Data type of the index output**

`int32` (default) | `int8` | `int16` | `uint8` | `uint16` | `uint32`

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`.

**Fixed-Point Properties**

**RoundingMethod — Rounding method for fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding method.

**OverflowAction — Overflow action for fixed-point operations**

'Wrap' (default) | 'Saturate'

Specify the overflow action.

## Usage

### Syntax

```
index = sqenc(input)
[index] = sqenc(input,bpoints)
[index] = sqenc(input,bpoints,cBook)
[index,codeword] = sqenc(____)
[____,qerr] = sqenc(____)
[____,cStatus] = sqenc(____)
```

## Description

`index = sqenc(input)` returns the index of the quantization region to which the `input` belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[index] = sqenc(input,bpoints)` uses input `bpoints` as the boundary points when the `BoundaryPointsSource` property is `Input port`.

`[index] = sqenc(input,bpoints,cBook)` uses input `bpoints` as the boundary points and input `cBook` as the codebook when the `BoundaryPointsSource` property is `'Input port'` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`.

`[index,codeword] = sqenc( ___ )` outputs the codeword values that corresponds to each index value when the `CodewordOutputPort` property is `true`.

`[ ___ ,qerr] = sqenc( ___ )` outputs the quantization error `qerr` for each input value when the `QuantizationErrorOutputPort` property is `true`.

`[ ___ ,cStatus] = sqenc( ___ )` also returns output `cStatus` as the clipping status output port for each input value when the `Partitioning` property is `'Bounded'` and the `ClippingStatusOutputPort` property is `true`. If an input value is outside the range defined by the `BoundaryPoints` property, `cStatus` is `true`. If an input value is inside the range, `cStatus` is `false`.

## Input Arguments

### **input** — Input data

vector | matrix

Input data, specified as a vector or a matrix. If the input is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### **bpoints** — Boundary points

vector

Boundary points of the quantizer regions, specified as a vector. The vector values must be in ascending order. Let `[p0 p1 p2 p3 ... pN]` denote the boundary points in the quantizer. If the quantizer is bounded, the object uses this input to specify `[p0 p1 p2 p3 ... pN]`. If the quantizer is unbounded, the object uses this input to specify `[p1 p2 p3 ... p(N-1)]` and sets `p0 = -Inf` and `pN = +Inf`.

## Dependencies

This input applies when you set the `BoundaryPointsSource` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **cBook** — Code book

vector

Codebook, specified as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `'Bounded'` and the boundary points vector has length  $N$ , this input must be a vector of length  $N-1$ . If the `Partitioning` property is `'Unbounded'` and the boundary points vector has length  $N$ , this input must be a vector of length  $N+1$ .

### Dependencies

This input applies when you set the `BoundaryPointsSource` property is 'Input port' and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Output Arguments

#### **index** — Index of quantization region

vector | matrix

Index of the quantization region to which the input belongs, returned as a vector or a matrix of the same size as the input.

Data Types: `int32`

#### **codeword** — Codeword values

vector | matrix

Codeword values that correspond to each index value, returned as a vector or a matrix of the same size as the input.

### Dependencies

This output is available when the `CodewordOutputPort` property is set to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

#### **qerr** — Quantization error

vector | matrix

Quantization error for each input value, returned as a vector or a matrix of the same size as the input.

### Dependencies

This output is available when the `QuantizationErrorOutputPort` property is set to true.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

#### **cStatus** — Clipping status

vector | matrix

Clipping status for each input value, returned as a vector or a matrix. If an input value is outside the range defined by the `BoundaryPoints` property, `cStatus` is true. If an input value is inside the range, `cStatus` is false.

### Dependencies

This output is available when the `Partitioning` property is 'Bounded' and the `ClippingStatusOutputPort` property is set to true.

Data Types: `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Quantize Varying Fractional Inputs

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results.

```
sqenc = dsp.ScalarQuantizerEncoder;
sqenc.BoundaryPoints = [-.001 .499 1.499 ...
    2.499 3.499 4.499 5.001];
sqenc.CodewordOutputPort = true;
sqenc.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = sqenc(input);
plot(1:length(input), [input quantizedValue]);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## Version History

**Introduced in R2012a**

**R2021b: dsp.ScalarQuantizerEncoder System object will be removed**

*Warns starting in R2021b*

dsp.ScalarQuantizerEncoder System object will be removed in a future release.

**R2023a: dsp.ScalarQuantizerEncoder System object has been removed**

*Errors starting in R2023a*

The dsp.ScalarQuantizerEncoder System object has been removed.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## dsp.SignalSink

**Package:** dsp

Log simulation data in buffer

### Description

The `dsp.SignalSink` System object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

- 1 Create the `dsp.SignalSink` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
ss = dsp.SignalSink  
ss = dsp.SignalSink(Name,Value)
```

#### Description

`ss = dsp.SignalSink` returns a signal sink, `ss`, that logs 2-D input data in the object.

`ss = dsp.SignalSink(Name,Value)` returns a signal sink, `ss`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **BufferLength — Maximum number of input frames to log**

`inf` (default) | positive integer

Specify the maximum number of frames to log. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

### **Decimation — Decimation factor**

1 (default) | positive integer

Setting this property to any positive integer  $d$  causes the signal sink to write data at every  $d$ th sample.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FrameHandlingMode — Output dimensionality for frame-based inputs**

2-D array (concatenate) (default) | 3-D array (separate)

Set the dimension of the output array for frame-based inputs as 2-D array (concatenate) or 3-D array (separate). Concatenation occurs along the first dimension for 2-D array (concatenate).

### **Buffer — Logged data (read only)**

matrix

This property is read-only.

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## **Usage**

### **Syntax**

`ss(x)`

### **Description**

`ss(x)` buffers the signal  $x$ . The buffer may be accessed at any time from the `Buffer` property of `ss`.

### **Input Arguments**

#### **x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

## Common to All System Objects

step     Run System object algorithm  
release   Release resources and allow changes to System object property values and input characteristics  
reset     Reset internal states of System object

## Examples

### Log Input Data

```
hlog = dsp.SignalSink;  
for i=1:10  
    y = sin(i);  
    hlog(y);  
end  
log = hlog.Buffer;  
display(log)
```

```
log = 10×1
```

```
    0.8415  
    0.9093  
    0.1411  
   -0.7568  
   -0.9589  
   -0.2794  
    0.6570  
    0.9894  
    0.4121  
   -0.5440
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the To Workspace block reference page. The object properties correspond to the block properties, except the object always generates fixed-point output for fixed-point input.

## Version History

Introduced in R2012b

### Objects

dsp.SignalSource

# dsp.SignalSource

**Package:** dsp

Import variable from workspace

## Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

- 1 Create the `dsp.SignalSource` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
src = dsp.SignalSource
src = dsp.SignalSource(signal,spf)
src = dsp.SignalSource(Name,Value)
```

### Description

`src = dsp.SignalSource` returns a signal source System object, `src`, that outputs the variable, specified by the `Signal` property, one sample or frame at a time.

`src = dsp.SignalSource(signal,spf)` returns a signal source object, `src`, with the `Signal` property set to `signal` and the “SamplesPerFrame” on page 4-0 property set to `spf`.

`src = dsp.SignalSource(Name,Value)` returns a signal source object, `src`, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Signal — Variable or expression containing the signal

[1:10]' (default) | vector | matrix

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

### **SamplesPerFrame — Number of samples per output frame**

1 (default) | positive scalar

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the `Signal` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **SignalEndAction — Action after final signal values are generated**

'Set to zero' (default) | 'Hold final value' | 'Cyclic repetition'

Specify the output after all of the specified signal samples have been generated as one of 'Set to zero', 'Hold final value', or 'Cyclic repetition'.

## **Usage**

### **Syntax**

```
Y = src()
```

### **Description**

`Y = src()` outputs one sample or frame of data from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object, `src`.

### **Output Arguments**

#### **Y — Output data**

scalar | vector | matrix

One sample or one frame of data from each column of the imported signal, returned as a scalar, vector, or matrix. The number of columns in the output signal matches the number of columns in the imported signal, `Signal`. The number of rows in the output signal matches the value specified in the `SamplesPerFrame` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to dsp.SignalSource

isDone End-of-file status for signal reader object

## Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

## Examples

### Create Signal Source

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;
src1.Signal = randn(1024,1);
y1 = zeros(1024,1);
idx = 1;
while(~isDone(src1))
    y1(idx) = src1();
    idx = idx + 1;
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024,1),128);
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except the System object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

dsp.SignalSink

# dsp.SineWave

**Package:** dsp

Generate discrete sine wave

## Description

The `dsp.SineWave` System object generates a real or complex, multichannel sinusoidal signal with independent amplitude, frequency, and phase in each output channel.

For both real and complex sinusoids, the “Amplitude” on page 4-0 , “Frequency” on page 4-0 , and “PhaseOffset” on page 4-0 properties can be scalars or length- $N$  vectors, where  $N$  is the number of channels in the output. When you specify at least one of these properties as a length- $N$  vector, scalar values specified for the other properties are applied to each of the  $N$  channels.

To generate a discrete-time sinusoidal signal:

- 1 Create the `dsp.SineWave` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
sine = dsp.SineWave
sine = dsp.SineWave(Name,Value)
sine = dsp.SineWave(amp,freq,phase,Name,Value)
```

### Description

`sine = dsp.SineWave` creates a sine wave object that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object generates only one sample.

`sine = dsp.SineWave(Name,Value)` creates a sine wave object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `sine = dsp.SineWave('Amplitude',2);`

`sine = dsp.SineWave(amp,freq,phase,Name,Value)` creates a sine wave object with the “Amplitude” on page 4-0 property set to `amp`, “Frequency” on page 4-0 property set to `freq`, “PhaseOffset” on page 4-0 property set to `phase`, and any other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Amplitude — Amplitude of sine wave

1 (default) | scalar | vector

Amplitude of the sine wave, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- $N$  vector contains the amplitudes of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Frequency” on page 4-0 and “PhaseOffset” on page 4-0 properties.

**Tunable:** Yes

### Dependencies

This property is tunable only when you set “Method” on page 4-0 to either 'Trigonometric function' or 'Differential'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Frequency — Frequency of sine wave

100 (default) | scalar | vector

Frequency of the sine wave in Hz, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- $N$  vector contains the frequencies of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “PhaseOffset” on page 4-0 properties.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### PhaseOffset — Phase offset of sine wave

0 (default) | scalar | vector

Phase offset of the sine wave in radians, specified as one of the following:

- scalar -- A scalar applies to all channels.
- vector -- A length- $N$  vector contains the phase offsets of the sine waves in each of the  $N$  output channels. The vector length must be the same as that specified for the “Amplitude” on page 4-0 and “Frequency” on page 4-0 properties.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### ComplexOutput — Flag that indicates whether waveform is real or complex

false (default) | true

Flag that indicates whether the waveform is real or complex, specified as either:

- `false` -- The waveform output is real.
- `true` -- The waveform output is complex.

#### Method — Method used to generate sinusoids

'Trigonometric function' (default) | 'Table lookup' | 'Differential'

Method used to generate sinusoids, specified as one of the following:

- 'Trigonometric function' -- The object computes the sinusoid by sampling the continuous-time function.
- 'Table lookup' -- The object precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed.
- 'Differential' -- The object uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms.

#### TableOptimization — Optimize table of sine values for speed or memory

'Speed' (default) | 'Memory'

Optimize table of sine values for speed or memory, specified as either:

- 'Speed' -- The table contains  $k$  elements, where  $k$  is the number of input samples in one full period of the sine wave. The period of each sinusoid must be an integer multiple of  $1/F_s$ , where  $F_s$  is the value of the "SampleRate" on page 4-0 property value. That is, each element of the "Frequency" on page 4-0 property must be of the form  $F_s/m$ , where  $m$  is an integer greater than 1.
- 'Memory' -- The table contains  $k/4$  elements.

#### Dependencies

This property applies only when you set the Method property to 'Table lookup'.

#### SampleRate — Sample rate of output signal

1000 (default) | positive scalar

Sample rate of output signal in Hz, specified as a positive scalar.

Example: 44100

Example: 22050

#### SamplesPerFrame — Number of samples per frame

1 (default) | positive integer

Number of consecutive samples from each sinusoid to buffer into the output frame, specified as a positive integer.

Example: 1000

Example: 5000

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### OutputDataType — Data type of the sine wave output

'double' (default) | 'single' | 'Custom'

Data type of the sine wave output, specified as 'double', 'single', or 'Custom'.

### Fixed-Point Properties

#### CustomOutputDataType — Output word and fraction lengths

`numericType([],16)` (default) | `numericType([],32,30)`

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16.

Example: `numericType([],32,30)`

Example: `numericType([],16,15)`

### Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'Table lookup' and the “OutputDataType” on page 4-0 property to 'Custom'.

## Usage

### Syntax

```
sineOut = sine()
```

### Description

`sineOut = sine()` creates the sine wave output, `sineOut`.

### Output Arguments

#### sineOut — Sine wave output

vector | matrix

Sine wave output, returned as a vector or matrix. The “SamplesPerFrame” on page 4-0 property determines the number of rows in the output matrix. If the “Frequency” on page 4-0 or the “PhaseOffset” on page 4-0 property is a vector, the length of the vector determines the number of columns (channels) in the output matrix. If the Frequency or the PhaseOffset properties is a scalar, then the number of channels in the output matrix is 1.

The “OutputDataType” on page 4-0 property sets the data type of the output.

Data Types: `single` | `double` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

reset     Reset internal states of System object

## Examples

### Generate a Sine Wave Signal

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and an initial phase of 0.

```
sine1 = dsp.SineWave(2,10);  
sine1.SamplesPerFrame = 1000;  
y = sine1();  
plot(y)
```

Generate two sine waves offset by a phase of  $\pi/2$  radians.

```
sine2 = dsp.SineWave;  
sine2.Frequency = 10;  
sine2.PhaseOffset = [0 pi/2];  
sine2.SamplesPerFrame = 1000;  
y = sine2();  
plot(y)
```

### Filter Frames of a Noisy Sine Wave Signal in MATLAB

This example shows how to lowpass filter a noisy signal in MATLAB® and visualize the original and filtered signals using a spectrum analyzer. For a Simulink® version of this example, see “Filter Frames of a Noisy Sine Wave Signal in Simulink”.

#### Specify Signal Source

The input signal is the sum of two sine waves with frequencies of 1 kHz and 10 kHz. The sampling frequency is 44.1 kHz.

```
Sine1 = dsp.SineWave('Frequency',1e3,'SampleRate',44.1e3);  
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',44.1e3);
```

#### Create Lowpass Filter

The lowpass FIR filter, `dsp.LowpassFilter`, designs a minimum-order FIR lowpass filter using the generalized Remez FIR filter design algorithm. Set the passband frequency to 5000 Hz and the stopband frequency to 8000 Hz. The passband ripple is 0.1 dB and the stopband attenuation is 80 dB.

```
FIRLowPass = dsp.LowpassFilter('PassbandFrequency',5000,...  
    'StopbandFrequency',8000);
```

## Create Spectrum Analyzer

Set up the spectrum analyzer to compare the power spectra of the original and filtered signals. The spectrum units are dBm.

```
SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum',false,...
    'SampleRate',Sine1.SampleRate,...
    'ShowLegend',true, ...
    'YLimits',[-145,45]);

SpecAna.ChannelNames = {'Original noisy signal',...
    'Lowpass filtered signal'};
```

## Specify Samples per Frame

This example uses frame-based processing, where data is processed one frame at a time. Each frame of data contains sequential samples from an independent channel. Frame-based processing is advantageous for many signal processing applications because you can process multiple samples at once. By buffering your data into frames and processing multisample frames of data, you can improve the computational time of your signal processing algorithms. Set the number of samples per frame to 4000.

```
Sine1.SamplesPerFrame = 4000;
Sine2.SamplesPerFrame = 4000;
```

## Filter the Noisy Sine Wave Signal

Add zero-mean white Gaussian noise with a standard deviation of 0.1 to the sum of sine waves. Filter the result using the FIR filter. While running the simulation, the spectrum analyzer shows that frequencies above 8000 Hz in the source signal are attenuated. The resulting signal maintains the peak at 1 kHz because it falls in the passband of the lowpass filter.

```
for i = 1 : 1000
    x = Sine1()+Sine2()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = FIRLowPass(x);
    SpecAna(x,y);
end
release(SpecAna)
```

### Bandpass Filtering of Sinusoids

Bandpass filter a discrete-time sine wave signal which consists of three sinusoids at frequencies, 1 kHz, 10 kHz, and 15 kHz.

Design an FIR Equiripple bandpass filter by first creating a bandpass filter design specifications object, and then designing a filter using these specifications.

#### Design Bandpass Filter

Create a bandpass filter design specifications object using `fdesign.bandpass`.

```
bandpassSpecs = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2', ...
    1/4,3/8,5/8,6/8,60,1,60);
```

List the available design methods for this object.

```
designmethods(bandpassSpecs)
```

Design Methods for class `fdesign.bandpass (Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2)`:

```
butter
cheby1
cheby2
```

```

ellip
equiripple
kaiserwin

```

To design an Equiripple filter, pick 'equiripple'.

```
bpFilter = design(bandpassSpecs, 'equiripple', 'Systemobject', true)
```

```

bpFilter =
  dsp.FIRFilter with properties:
    Structure: 'Direct form'
    NumeratorSource: 'Property'
    Numerator: [-0.0043 -3.0812e-15 0.0136 3.7820e-15 -0.0180 -4.2321e-15 7.1634e-04 4.09e-04]
    InitialConditions: 0

```

Show all properties

Visualize the frequency response of the designed filter.

```
fvtool(bpFilter, 'Fs', 44100)
```

### Create Sinusoidal Signal

Create a signal that is a sum of three sinusoids with frequencies at 1 kHz, 10 kHz, and 15 kHz. Initialize Spectrum Analyzer to view the original signal and the filtered signal.

```
Sine1 = dsp.SineWave('Frequency',1e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);

SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'ShowLegend',true, ...
    'YLimits',[-240,45]);

SpecAna.ChannelNames = {'Original noisy signal','Bandpass filtered signal'};
```

### **Filter Sinusoidal Signal**

Filter the sinusoidal signal using the bandpass filter that has been designed. View the original signal and the filtered signal in the Spectrum Analyzer. The tone at 1 kHz is filtered out and attenuated. The tone at 10 kHz is unaffected, and the tone at 15 kHz is mildly attenuated because it appears in the transition band of the filter.

```
for i = 1 : 1000
    x = Sine1()+Sine2()+Sine3();
    y = bpFilter(x);
    SpecAna(x,y);
end
release(SpecAna)
```

## More About

### Sinusoid

A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A \sin(2\pi f n + \phi)$$

where  $A$  is the amplitude,  $f$  is the frequency in Hz, and  $\phi$  is the initial phase, or phase offset, in radians.

A complex sinusoid is defined as:

$$y(n) = A e^{j(2\pi f n + \phi)}$$

## Algorithms

### Trigonometric Function

The trigonometric function method computes the sinusoid in the  $i$ th channel,  $y_i$ , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \text{ (real)}$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \text{ (complex)}$$

with a period of  $T_s$ , where you specify  $T_s$  in the sample time.

At each sample time, the algorithm evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the algorithm avoids the imprecision of computing the sine of very large numbers. This constraint also eliminates the possibility of discontinuity during extended operations, when an absolute time variable might overflow. This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

### Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is,  $1/(f_i T_s) = k_i$  must be an integer value for every channel  $i = 1, 2, \dots, N$ .

When the algorithm optimizes the table of sine values for **Speed**, the table constructed for each channel contains  $k_i$  elements. When the optimization is for **Memory**, the table constructed for each channel contains  $k_i/4$  elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods. However, the method can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, which need to be optimized for execution speed.

---

**Note** The lookup table for this object is constructed from double-precision floating-point values. When you use the **Table Lookup** computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the output data type to values greater than 53 bits does not improve the precision of your output.

---

### Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by making use of the following identities.

$$\sin(t + T_s) = \sin(t)\cos(T_s) + \cos(t)\sin(T_s)$$

$$\cos(t + T_s) = \cos(t)\cos(T_s) - \sin(t)\sin(T_s)$$

The update equations for the sinusoid in the  $i$ th channel,  $y_i$ , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify  $T_s$  in the sample time. Since  $T_s$  is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of  $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$  is then

computed from the values of  $\sin(2\pi f_i t + \phi_i)$  and  $\cos(2\pi f_i t + \phi_i)$  by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations, when an absolute time variable might overflow.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# **dsp.SOSFilter**

**Package:** dsp

Second-order section biquadratic IIR filter structures

## **Description**

The `dsp.SOSFilter` System object implements an IIR filter structure using second-order sections (SOS).

To implement an IIR filter structure using SOS:

- 1 Create the `dsp.SOSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
sos = dsp.SOSFilter
sos = dsp.SOSFilter(num,den)
sos = dsp.SOSFilter(Name,Value)
```

### **Description**

`sos = dsp.SOSFilter` returns a biquadratic IIR filter System object, `sos`, which independently filters each channel (column) of the input over time using a specified biquadratic structure.

`sos = dsp.SOSFilter(num,den)` returns a biquadratic filter object with the `Numerator` property set to `num` and the `Denominator` property set to `den`.

`sos = dsp.SOSFilter(Name,Value)` returns a biquadratic filter object with each property set to the specified value. Enclose each property name in single quotes.

Example: `sos = dsp.SOSFilter('CoefficientSource','Input port')`

### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**Structure – Filter structure**

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

Filter structure, specified as one of 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

**CoefficientSource – Source of filter coefficients**

'Property' (default) | 'Input port'

Source of the filter coefficients, specified as one of the following:

- 'Property' -- The filter coefficients are specified through the Numerator, Denominator, and ScaleValues properties.
- 'Input port' -- The numerator coefficients, denominator coefficients, and the scale values are specified as inputs to the object while running the algorithm. For more details, see “Usage” on page 4-1016.

**Numerator – Numerator coefficients of filter**

[0.0975 0.195 0.0975] (default) |  $N$ -by-3 matrix

Numerator coefficients of the filter, specified as an  $N$ -by-3 matrix, where  $N$  is the number of biquadratic sections.

The size of this property cannot be modified once you have run the System object algorithm. However, the coefficient values can change as the property is tunable.

**Tunable:** Yes

**Dependencies**

To enable this property, set the CoefficientSource property to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Denominator – Denominator coefficients of filter**

[1 -0.9428 0.3333] (default) |  $N$ -by-3 matrix

Denominator coefficients of the filter, specified as an  $N$ -by-3 matrix, where  $N$  is the number of biquadratic sections.

The leading denominator coefficient is always assumed to be 1. If any other value is specified in the first column, the object ignores this value and treats it as 1.

The size of this property cannot be modified once you step through the algorithm. However, the denominator values can be modified as the property is tunable.

**Tunable:** Yes

**Dependencies**

To enable this property, set CoefficientSource property to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**HasScaleValues – Specify if filter has scale values for each section**

false (default) | true

Specify if the filter has scale values for each section. When set to `true`, using the `ScaleValues` property, you can specify the scale values to be applied before and after each section of the biquadratic filter.

**ScaleValues — Scale values for each biquad second-order section**

[1 1] (default) | vector

Scale values to apply before and after each section of a biquadratic filter, specified as a vector. The length of the `ScaleValues` vector must be  $N + 1$ , where  $N$  is the number of biquadratic sections. If you set this property to a scalar value, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of  $N + 1$  values, each value is used for a separate section of the filter.

**Tunable:** Yes

**Dependencies**

This property applies only when you set the `CoefficientSource` property to `'Property'` and `HasScaleValues` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations, specified as one of the following:

- 'Floor'
- 'Ceiling'
- 'Convergent'
- 'Nearest'
- 'Round'
- 'Simplest'
- 'Zero'

For more details, see Rounding Modes.

**OverflowAction — Overflow action for fixed-point operations**

Wrap (default) | Saturate

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see Overflow Handling for fixed-point operations.

**SectionInputDataType — Section input word- and fraction-length designations**

'Same as input' (default) | `numericType` object

Section input word- and fraction-length designations, specified as either `'Same as input'` or a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

#### **Dependencies**

This property applies only when you set the `HasScaleValues` property to `true`.

#### **SectionOutputDataType — Section output word- and fraction-length designations**

'Same as section input' (default) | `numericType` object

Section output word- and fraction-length designations, specified as either 'Same as section input' or a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

#### **Dependencies**

This property applies only when you set the `HasScaleValues` property to `true`.

#### **NumeratorDataType — Numerator coefficients word- and fraction-length designations**

'Same word length as input' (default) | `numericType` object

Numerator coefficients word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the numerator coefficient values to give the best possible precision.

#### **Dependencies**

This property applies only when you set the `CoefficientSource` property to 'Property'.

#### **DenominatorDataType — Denominator coefficients word- and fraction-length designations**

'Same word length as input' (default) | `numericType` object

Denominator coefficients word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the denominator coefficient values to give the best possible precision.

#### **Dependencies**

This property applies only when you set the `CoefficientSource` property to 'Property'.

#### **ScaleValuesDataType — Scale values word- and fraction-length designations**

'Same word length as input' (default) | `numericType` object

Scale values word- and fraction-length designations, specified as either 'Same word length as input' or as a `numericType` object.

When specified as a `numericType` object, the data type must be signed fixed point with a power-of-two slope and zero bias. If not specified, the fraction length is determined based on the scale values to give the best possible precision.

**Dependencies**

This property applies only when you set the `CoefficientSource` property to 'Property' and `HasScaleValues` property to `true`.

**MultiplicandDataType — Multiplicand word- and fraction-length designations**

'Same as output' (default) | `numerictype` object

Multiplicand word- and fraction-length designations, specified as either 'Same as output' or as a `numerictype` object.

When specified as a `numerictype` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

**Dependencies**

This property applies only when you set the `Structure` property to 'Direct form I transposed'.

**StateDataType — State word- and fraction-length designations**

'Full precision' (default) | `numerictype` object

State word- and fraction-length designations, specified as either 'Full precision' or as a `numerictype` object.

When specified as a `numerictype` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

**Dependencies**

This property applies only when you set the `Structure` property to 'Direct form II'.

**DenominatorAccumulatorDataType — Denominator accumulator word- and fraction-length designations**

`numerictype(1,64,48)` (default) | `numerictype` object

Denominator accumulator word- and fraction-length designations, specified as a `numerictype` object.

**OutputDataType — Output word- and fraction-length designations**

'Full precision' (default) | `numerictype` object

Output word- and fraction-length designations, specified as either 'Full precision' or as a `numerictype` object.

When specified as a `numerictype` object, the data type must be signed fixed point with a power-of-two slope and zero bias.

**Usage****Syntax**

```
y = sos(x)
y = sos(x, num, den)
y = sos(x, num, den, g)
```

## Description

$y = \text{sos}(x)$  filters the input signal  $x$  and outputs the filtered values  $y$ . The sos filter object filters each channel (column) of the input signal independently over successive calls to the algorithm.

This syntax is valid only when the `CoefficientSource` property is set to 'Property'.

$y = \text{sos}(x, \text{num}, \text{den})$  filters the input using `num` as the numerator coefficients and `den` as the denominator coefficients of the sos filter.

This syntax is valid only when the `CoefficientSource` property is set to 'Input port' and `HasScaleValues` property is set to `false`.

$y = \text{sos}(x, \text{num}, \text{den}, g)$  specifies the scale values `g` of the sos filter.

This syntax is valid only when the `CoefficientSource` property is set to 'Input port' and `HasScaleValues` property is set to `true`.

## Input Arguments

### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix.

This object also accepts variable-size inputs. Once you have run the System object algorithm, you can change the size of each input channel, but you cannot change the number of channels.

If the input is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the input data to give the best possible precision.

The data type of all inputs must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### **num** — Numerator coefficients

$N$ -by-3 matrix

Numerator coefficients, specified as an  $N$ -by-3 matrix, where  $N$  is the number of biquadratic sections.

Once you step through the algorithm, the size of this input cannot be modified. However, the numerator coefficient values can be modified as the input is tunable.

If `num` is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the numerator coefficient values to give the best possible precision.

The data type of all inputs must be the same.

The size and complexity of the `num` and `den` inputs must be the same.

**Tunable:** Yes

### Dependencies

This input applies only when you set the `CoefficientSource` property to 'Input port'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**den — Denominator coefficients**

*N*-by-3 matrix

Denominator coefficients of the filter, specified as an *N*-by-3 matrix, where *N* is the number of biquadratic sections.

The leading denominator coefficient is always assumed to be 1. If any other value is specified in the first column, the object ignores this value and treats it as 1.

The size of this input cannot be modified once you step through the algorithm. However, the denominator values can be modified as the input is tunable.

If **den** is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the denominator coefficient values to give the best possible precision.

The data type of all inputs must be the same.

The size and complexity of the **num** and **den** inputs must be the same.

**Tunable:** Yes

**Dependencies**

This input applies only when you set the `CoefficientSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**g — Scale values for each biquad second-order section**

1-by-(*N* + 1) vector

Scale values of the biquadratic filter, specified as a 1-by-(*N*+1) vector, where *N* is the number of biquadratic filter sections.

If **g** is fixed-point, it must be signed fixed point with a power-of-two slope and zero bias. When the fraction length is not specified, the object determines the fraction length based on the scale values to give the best possible precision.

The data type of all inputs must be the same.

**Tunable:** Yes

**Dependencies**

This input applies only when you set the `CoefficientSource` property to `'Input port'` and `HasScaleValues` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**Output Arguments****y — Filtered output**

vector | matrix

Filtered output, returned as a vector or a matrix. The size and complexity of the output signal matches that of the input signal.

The data type of the output is determined based on the value of the `OutputDataType` property. If set to `'Full precision'`, the output data type is computed based on the signal flow diagrams shown in the Fixed-Point Conversion on page 4-1024 section. If set to a custom numeric type, the output data type is cast to the specified numeric type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`  
 Complex Number Support: Yes

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.SOSFilter`

|                         |   |
|-------------------------|---|
| <code>freqz</code>      | Frequency response of discrete-time filter System object          |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Remove High-Frequency Noise Using Biquad SOS Filter

Lowpass filter a noisy sinusoidal signal using the `dsp.SOSFilter` System object. Visualize the original and filtered signals using a spectrum analyzer.

#### Input Signal

The input signal is a sinusoidal signal with two tones, one at 1 kHz and the other at 3 kHz. The sampling frequency is 8 kHz.

```
f1 = 1000;  
f2 = 3000;  
Fs = 8000;  
sine = dsp.SineWave('Frequency', [f1, f2], ...
```

```
'SampleRate',Fs,...  
'SamplesPerFrame',1024);
```

### Create Biquad SOS Filter

Design a 10th-order lowpass Butterworth IIR filter with a cutoff frequency of 2 kHz. The numerator and denominator coefficients are extracted from the designed SOS matrix.

```
Fcutoff = 2000;  
[z,p,k] = butter(10,Fcutoff/(Fs/2));  
[s, g] = zp2sos(z,p,k);  
num = s(:,1:3);  
den = s(:,4:6);
```

```
sosFilter = dsp.SOSFilter(num,den,...  
    'HasScaleValues',true,...  
    'ScaleValues',g)
```

```
sosFilter =  
dsp.SOSFilter with properties:  
  
    Structure: 'Direct form II transposed'  
CoefficientSource: 'Property'  
    Numerator: [5x3 double]  
    Denominator: [5x3 double]  
HasScaleValues: true  
    ScaleValues: [0.0029 1 1 1 1 1]
```

```
Show all properties
```

Visualize the frequency response of the designed SOS filter.

```
fvtool(sosFilter,'Fs',8000)
```

## Streaming

Add zero-mean white Gaussian noise with a standard deviation of 0.1 to the sum of sine waves. Filter the noisy sinusoidal signal with the designed SOS filter.

While running the simulation, the spectrum analyzer shows that the high-frequency tone above 2 kHz in the source signal is attenuated. The resulting signal maintains the peak at 1 kHz because it falls in the passband of the lowpass filter.

```
SA = spectrumAnalyzer(...
    'PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Fs, ...
    'ShowLegend',true,...
    'YLimits',[-200 100],...
    'ChannelNames',{'Input signal','Filtered signal'});

% Stream processing loop
for k = 1:100
    input = sum(sine(),2) + 0.1.*randn(sine.SamplesPerFrame,1);
    filteredOutput = sosFilter(input);
    SA(input,filteredOutput);
end
```

### Design a Time-Varying Lowpass IIR Filter

Design a lowpass biquadratic SOS filter with time-varying coefficients. Visualize the magnitude response of the filter using a dynamic filter visualizer.

```
dfv = dsp.DynamicFilterVisualizer('YLimits', [-120 10])
```

```
dfv =  
    dsp.DynamicFilterVisualizer with properties:
```

```
        FFTLength: 2048  
    NormalizedFrequency: 0  
        SampleRate: 44100  
    FrequencyRange: [0 22050]  
        XScale: 'Linear'  
    MagnitudeDisplay: 'Magnitude (dB)'  
    PlotAsMagnitudePhase: 0  
        PlotType: 'Line'  
    AxesScaling: 'Manual'
```

Show all properties

Create a `dsp.SOSFilter` object.

```
sosfilt = dsp.SOSFilter
```

```

sosfilt =
  dsp.SOSFilter with properties:

    Structure: 'Direct form II transposed'
    CoefficientSource: 'Property'
    Numerator: [0.0975 0.1950 0.0975]
    Denominator: [1 -0.9428 0.3333]
    HasScaleValues: false

  Show all properties

```

Use the `maxflat` function to design a lowpass maximally flat filter. Set the numerator and denominator order of the filter to 2 since the SOS filter is biquadratic. Vary the cutoff frequency in 0.001 increments and design the filter for each increment. Pass the computed coefficients to the SOS filter. Visualize the time-varying magnitude response of the SOS filter using the `dfv` object.

```

for Wn = 0.1:0.001:0.6
    [b,a] = maxflat(2,2,Wn);
    sosfilt.Numerator = b;
    sosfilt.Denominator = a;
    dfv(sosfilt)
end

```

## More About

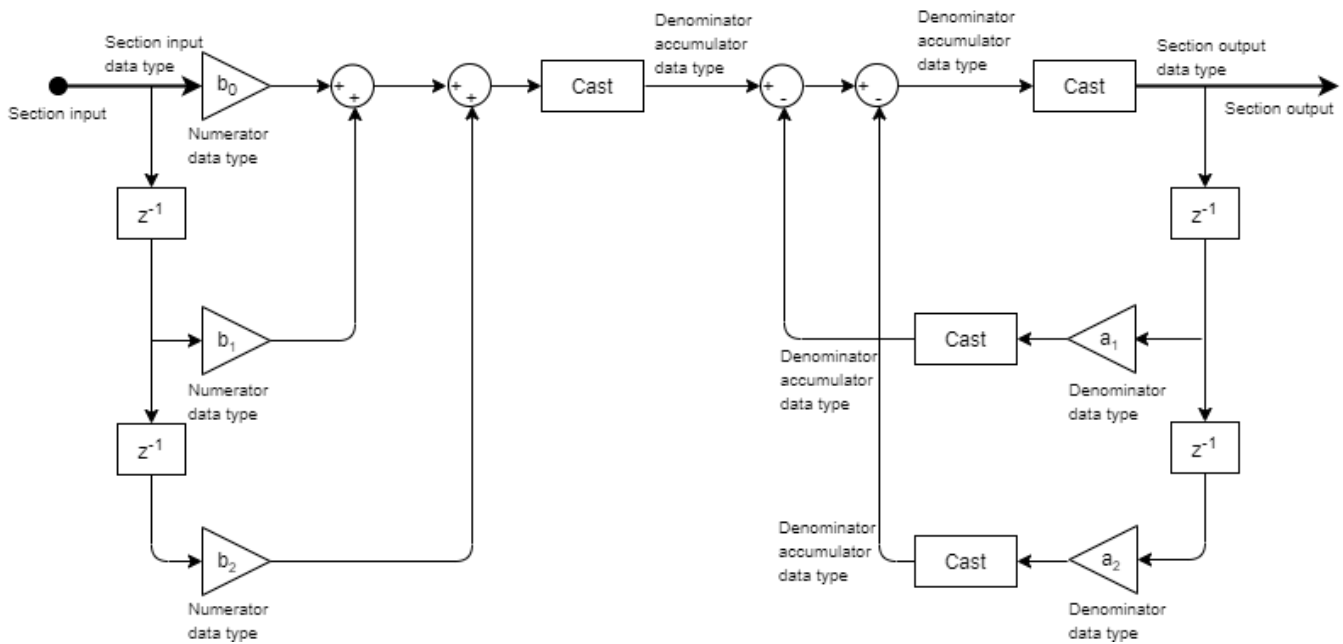

### Fixed Point

These diagrams show the data types used in the `dsp.SOSFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

#### Direct Form I

This diagram shows the data types for one section of the filter for fixed-point signals. The gain operations  $b_0$ ,  $b_1$ ,  $b_2$ ,  $a_1$ , and  $a_2$  operate in full precision.

These diagrams show the fixed-point data types between filter sections.

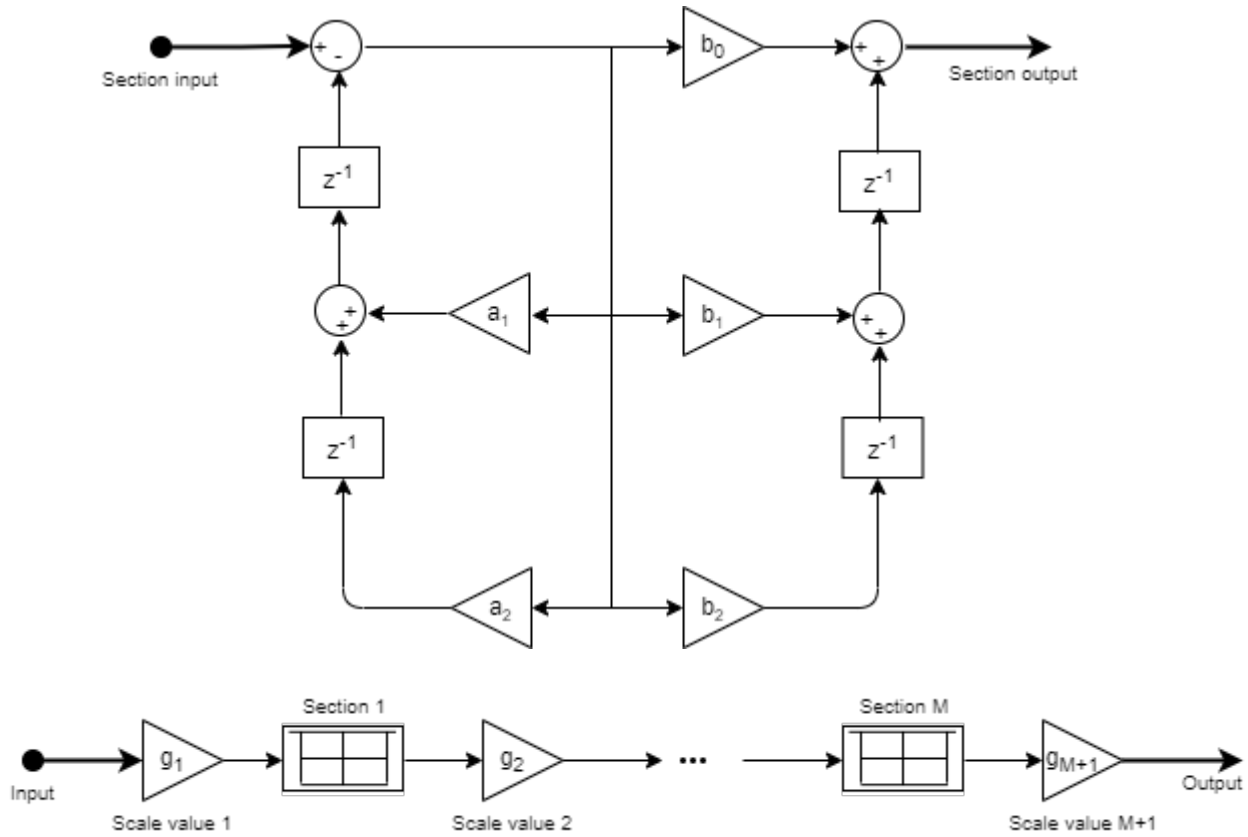

When the data is not optimized:

When you specify scale values to 1:

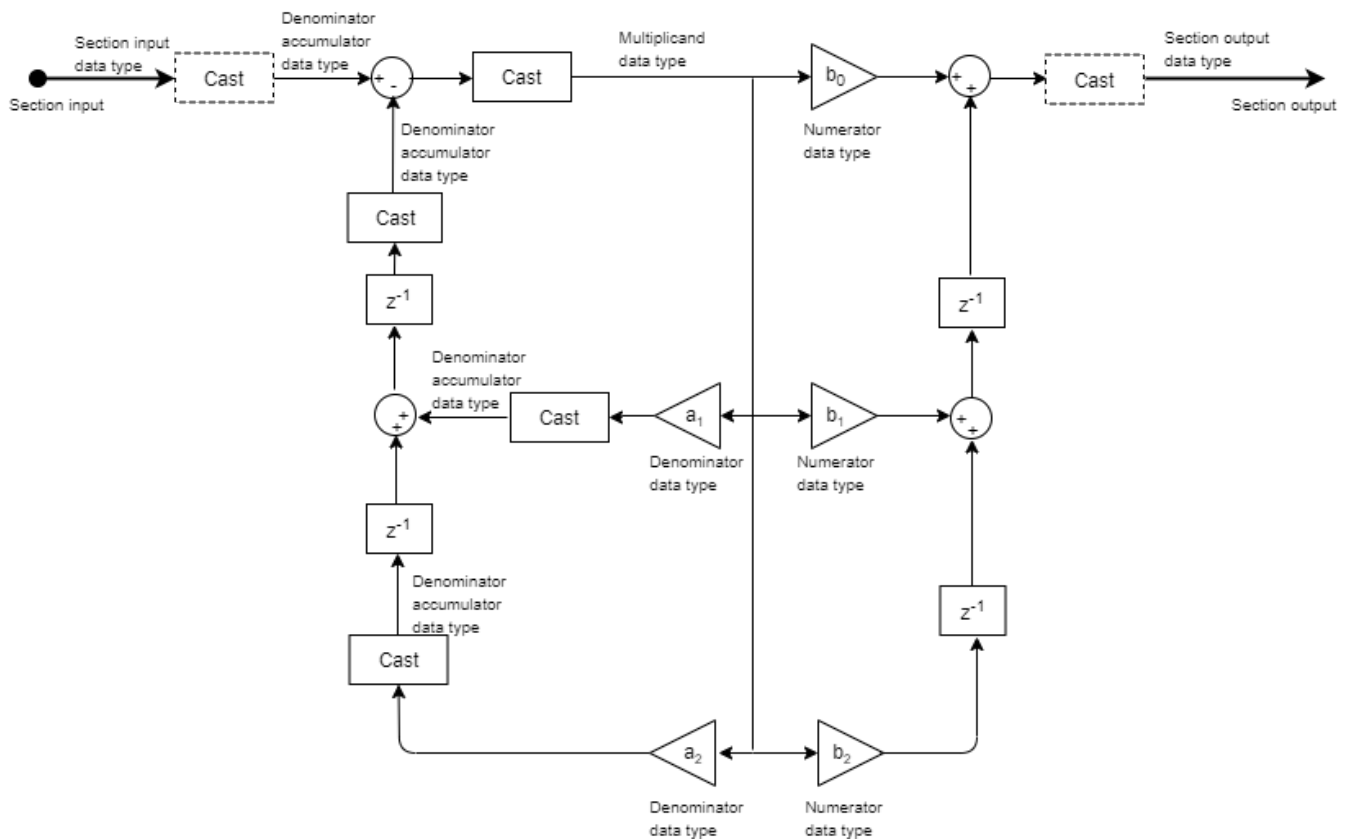

**Direct Form I Transposed**

This diagram shows the data types for one section of the filter for fixed-point signals. The dashed casts are omitted when you set `HasScaleValues` to `false`. The gain operations  $b_0$ ,  $b_1$ ,  $b_2$ ,  $a_1$ , and  $a_2$  operate in full precision.

These diagrams show the fixed-point data types between filter sections.

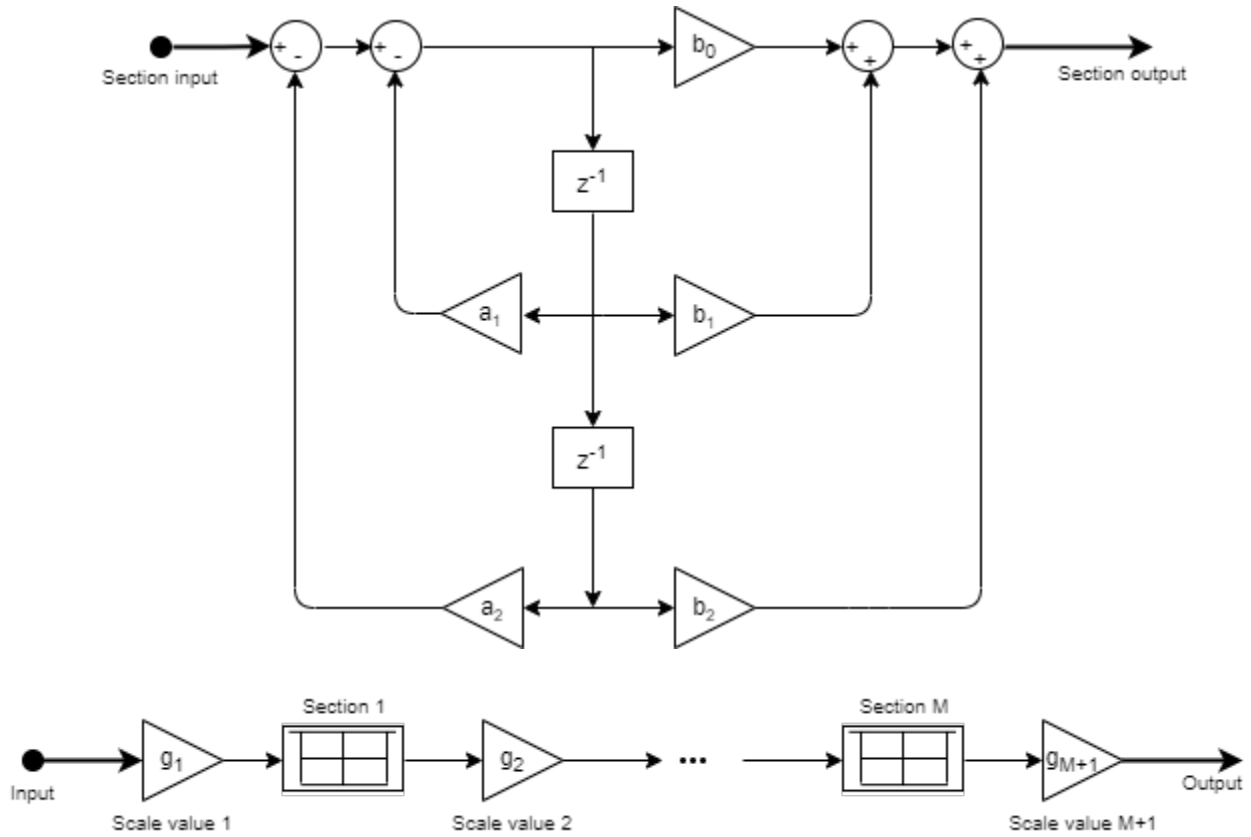

When the data is not optimized:

When you specify scale values to 1:

**Direct Form II**

This diagram shows the data types for one section of the filter for fixed-point signals. The dashed casts are omitted when you set `HasScaleValues` to `false`. The gain operations  $b_0$ ,  $b_1$ ,  $b_2$ ,  $a_1$ , and  $a_2$  operate in full precision.

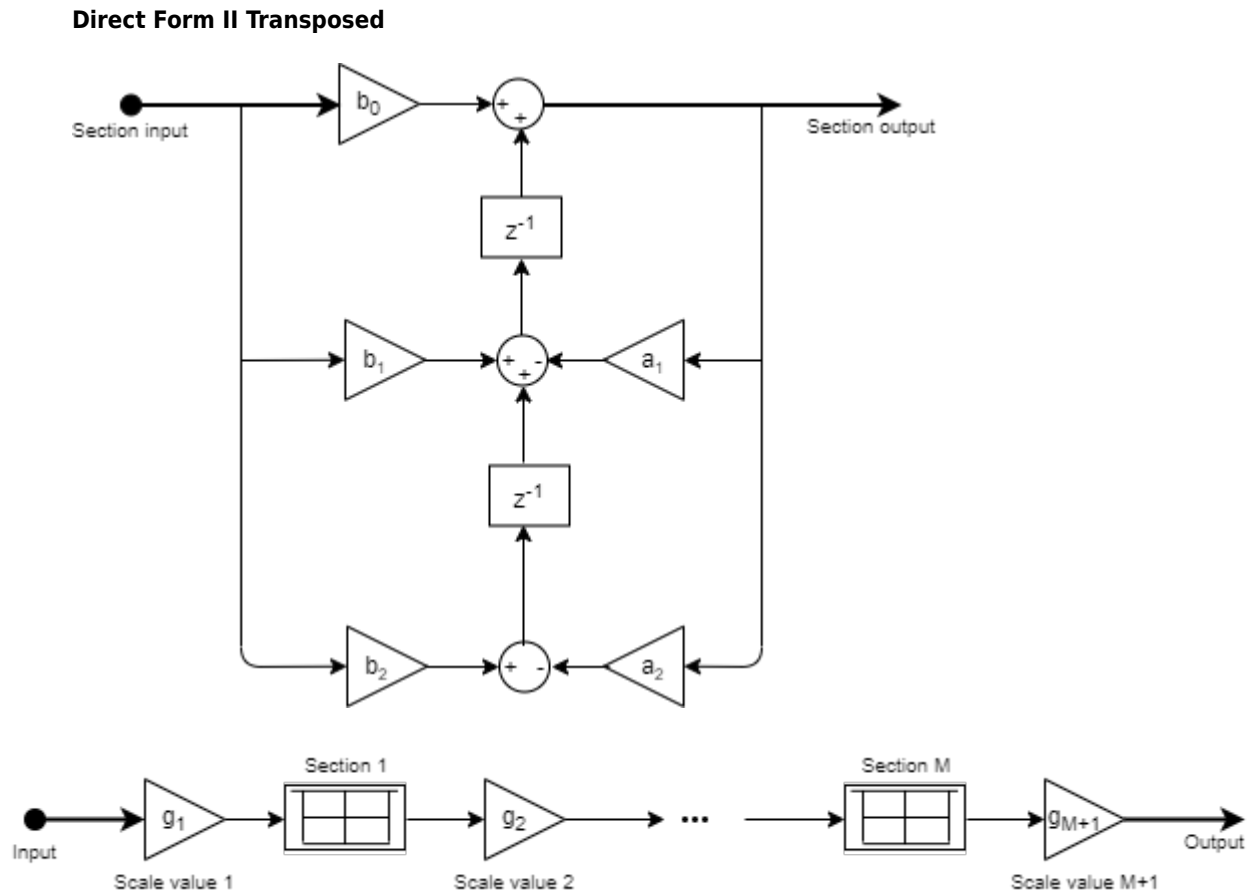

These diagrams show the fixed-point data types between filter sections.

When the data is not optimized:

When you set scale values to 1:

This diagram shows the data types for one section of the filter for fixed-point signals. The gain operations  $b_0$ ,  $b_1$ ,  $b_2$ ,  $a_1$ , and  $a_2$  operate in full precision. When you set `HasScaleValues` to `false`, the data type at the section output is automatically determined by the object algorithm and is not controlled by the value of the `SectionOutputDataType` property.

These diagrams show the fixed-point data types between filter sections.

When the data is not optimized:

When you specify scale values to 1:

## Version History

Introduced in R2020a

### **R2022b: Optimized C code generation for `dsp.SOSFilter` object on ARM Cortex-M processors**

In R2022b, you can generate optimized C code for the `dsp.SOSFilter` object on ARM Cortex-M processors under certain conditions. For more details, see “Code Generation” on page 4-1032.

### **Extended Capabilities**

#### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.SOSFilter` System object supports optimized C code generation on ARM Cortex-M processors under these conditions:

- Input is a single-channel real-valued signal.
- When you set `CoefficientSource` to 'Property' or 'Input port'.
- Data type of the input is `single`.
- When you set `Structure` to 'Direct form I' or 'Direct form II transposed'.
- When you set `HasScaleValues` to `false` after setting `CoefficientSource` to 'Input port'.

# spectrumAnalyzer

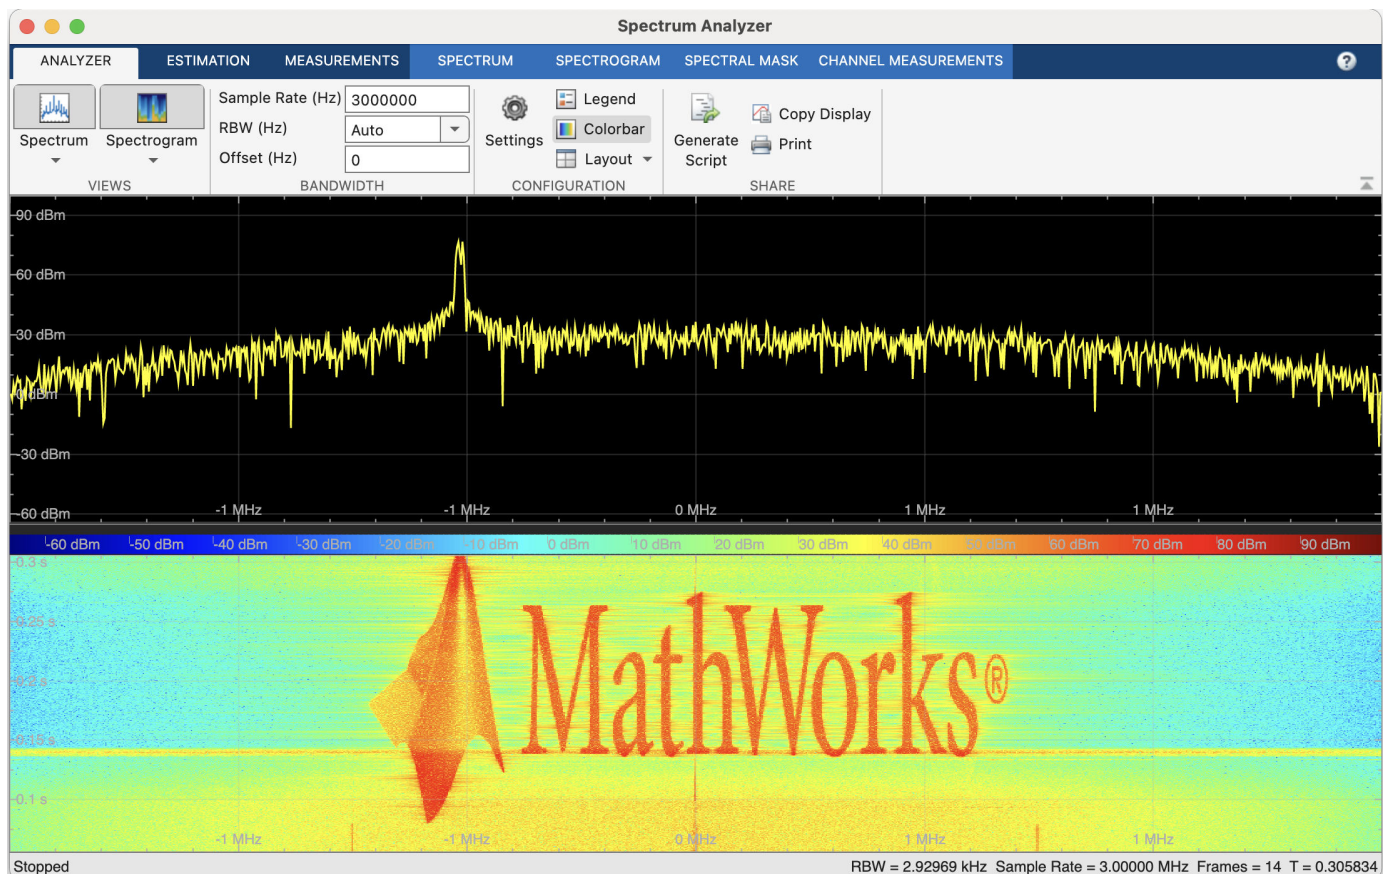

Display frequency spectrum of time-domain signals

## Description

The `spectrumAnalyzer` object displays frequency-domain signals and the frequency spectrum of time-domain signals. The scope shows the spectrum view and the spectrogram view. The object performs spectral estimation using the filter bank method and Welch's method of averaged modified periodograms. You can customize the spectrum analyzer display to show the data and the measurement information that you need. For more details, see “Algorithms” on page 4-1077. The spectrum analyzer can display the power spectrum of the signal in three units, Watts, dBm, and dBW. For more information on how to convert the power within these three units, see “Convert the Power Between Units” on page 4-1070.

To display the spectra of signals in the Spectrum Analyzer:

- 1 Create the `spectrumAnalyzer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

## Creation

### Syntax

```
scope = spectrumAnalyzer  
scope = spectrumAnalyzer(Name=Value)
```

### Description

`scope = spectrumAnalyzer` creates a `spectrumAnalyzer` object that displays the frequency spectrum of real or complex signals.

`scope = spectrumAnalyzer(Name=Value)` specifies nondefault properties for `scope` using one or more name-value arguments. For example, to display both spectrum and spectrogram, set `ViewType` to "spectrum-and-spectrogram".

## Properties

### Frequently Used

#### InputDomain — Domain of input signal

"time" (default) | "frequency"

The domain of the input signal you want to visualize, specified as "time" or "frequency". If you want to visualize time-domain signals, the Spectrum Analyzer transforms the signal to the frequency spectrum based on the algorithm you specify in the `Method` property.

#### Scope Window Use

In the **Estimation** tab on the Spectrum Analyzer toolstrip, set **Input Domain** to Time or Frequency.

Data Types: char | string

#### SpectrumType — Type of spectrum to display

"power" (default) | "power-density" | "rms"

The type of spectrum to display, specified as one of the following:

- "power" — Power spectrum.
- "power-density" — Power spectral density. The power spectral density is the squared magnitude of the spectrum normalized to a bandwidth of 1 hertz.
- "rms" — Root mean square. The root-mean-square shows the square root of the mean square. Use this option to view the frequency of voltage or current signals.

**Tunable:** Yes

#### Dependency

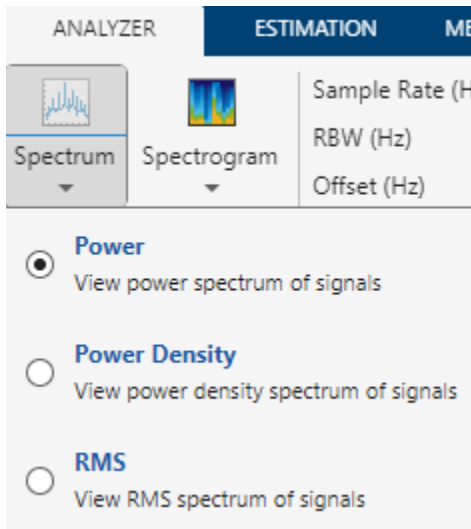

To enable this property, set `InputDomain` to "time".

#### Scope Window Use

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, click the drop down arrow of **Spectrum** to select Power, Power Density, or RMS.

To enable these options, set the **Input Domain** on the **Estimation** tab to Time.

Data Types: char | string

#### ViewType — View to display

"spectrum" (default) | "spectrogram" | "spectrum-and-spectrogram"

View to display, specified as one of the following:

- "spectrum" — Display frequency spectrum of signals.
- "spectrogram" — Display spectrogram of signals. Spectrogram shows the frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the top to the bottom of the display. The most recent spectrogram update is at the top of the display.
- "spectrum-and-spectrogram" — Display both spectrum and spectrogram.

To learn more about how the Spectrum Analyzer computes spectrum and spectrogram, see the "Algorithms" on page 4-1077 section.

**Tunable:** Yes

#### Scope Window Use

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, select **Spectrum**, **Spectrogram**, or both.

Data Types: char | string

#### SampleRate — Sample rate of input

10000 (default) | positive scalar

The sample rate of the input in Hz, specified as a positive scalar.

**Tunable:** Yes

#### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, specify **Sample Rate (Hz)** to a finite scalar.

The Spectrum Analyzer shows the sample rate in the status bar at the bottom of the display.

Data Types: double

#### **Method — Spectrum estimation method**

"filter-bank" (default) | "welch"

Spectrum estimation method, specified as one of the following:

- "filter-bank" -- Use an analysis filter bank to estimate the power spectrum. Compared to Welch's method, this method has a lower noise floor, better frequency resolution, and lower spectral leakage and requires fewer samples per update.
- "welch" -- Use Welch's method of averaged modified periodograms.

For more details on these methods, see "Algorithms" on page 4-1077.

**Tunable:** Yes

#### **Dependency**

To enable this property, set InputDomain to "time".

#### **Scope Window Use**

In the **Estimation** tab of the Spectrum Analyzer toolstrip, set **Method** to Filter bank or Welch.

To enable this parameter, set **Input Domain** to Time in the **Estimation** tab.

Data Types: char | string

#### **PlotAsTwoSidedSpectrum — Option to plot a two-sided spectrum**

true (default) | false

Option to plot a two-sided spectrum, specified as one of the following:

- true — Compute and plot two-sided spectral estimates. When the input signal is complex valued, you must set this property to true.
- false — Compute and plot one-sided spectral estimates. If you set this property to false, then the input signal must be real valued.

When you set this property to false, the Spectrum Analyzer uses power-folding. The y-axis values are twice the amplitude that they would be if you were to set this property to true, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

**Tunable:** Yes

**Scope Window Use**

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) of the Spectrum Analyzer toolstrip. In the **Trace Options** section, select **Two-Sided Spectrum** to compute and plot two-sided spectral estimates.

Data Types: logical

**FrequencyScale — Scale to display frequency**

"linear" (default) | "log"

Scale to display frequency, specified as one of the following:

- "linear" — Use a linear scale to display frequencies on the x-axis.
- "log" — Use a logarithmic scale to display frequencies on the x-axis.

**Tunable:** Yes

**Dependency**

To set this property to "log", set the `PlotAsTwoSidedSpectrum` property to false.

**Scope Window Use**

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) of the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Frequency Scale** to Linear or Log.

To set the **Frequency Scale** to Log, clear the **Two-Sided Spectrum** check box in the **Trace Options** section in the **Spectrum** or the **Spectrogram** tab (if enabled). If you select the **Two-Sided Spectrum** check box, then you must set the **Frequency Scale** to Linear.

Data Types: char | string

**PlotType — Plot type for normal traces**

"line" (default) | "stem"

Type of plot to use for displaying normal traces, specified as "line" or "stem". Normal traces are traces that display free-running spectral estimates.

**Tunable:** Yes

**Dependencies**

To enable this property, set:

- `ViewType` to "spectrum" or "spectrum-and-spectrogram".
- `PlotNormalTrace` to true.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip, navigate to the **Configuration** section and click **Settings**. In the Spectrum Analyzer Settings window that opens, under **Display and Labels**, set **Plot Type** to Line or Stem.

To enable the **Plot Type**, you must:

- Select **Spectrum** in the **Views** section of the **Analyzer** tab.

- Enable the **Normal Trace** check box in the **Trace Options** section of the **Spectrum** tab.

Data Types: char | string

### **AxesScaling** — Axes scaling mode

"auto" (default) | "manual" | "onceatstop" | "updates"

Axes scaling mode, specified as one of the following:

- "auto" — The scope scales the axes to fit the data, both during and after simulation.
- "manual" — The scope does not scale the axes automatically.
- "onceatstop" — The scope scales the axes when the simulation stops and you call the release function.
- "updates" — The scope scales the axes after a specific number of visual updates. It determines the number of updates using the AxesScalingNumUpdates property.

**Tunable:** Yes

Data Types: char | string

### **AxesScalingNumUpdates** — Number of updates before scaling

100 (default) | positive integer

Number of updates before scaling, specified as a positive integer.

**Tunable:** Yes

#### **Dependency**

To enable this property, set AxesScaling to "updates".

Data Types: double

#### **Advanced**

### **RBWSource** — Source of resolution bandwidth value

"auto" (default) | "property"

The source of the resolution bandwidth (RBW), specified as "auto" or "property".

- "auto" — The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- "property" — Specify the resolution bandwidth directly using the RBW property.

**Tunable:** Yes

#### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **RBW (Hz)** to either **Auto** or a positive scalar.

Data Types: char | string

### **RBW** — Resolution bandwidth

9.76 (default) | positive scalar

Resolution bandwidth (RBW) in Hz, specified as a positive scalar. Specify the value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW satisfies this condition:

$$\frac{\text{span}}{\text{RBW}} > 2$$

Specify the overall span based on how you set the `FrequencySpan` property.

RBW controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that can be resolved. A smaller value gives a higher spectral resolution and lowers the noise floor. That is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

**Tunable:** Yes

**Dependency**

To enable this property, set `RBWSource` to "property".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **RBW (Hz)** to a positive scalar.

The Spectrum Analyzer shows the value of RBW in the status bar at the bottom of the display.

Data Types: double

**FilterSharpness — Sharpness of lowpass filter**

0.3 (default) | nonnegative scalar in the range [0,1]

Sharpness of the prototype lowpass filter, specified as a real nonnegative scalar in the range [0,1].

Increasing the filter sharpness decreases the spectral leakage and gives a more accurate power reading.

**Tunable:** Yes

**Dependencies**

To enable this property, set `Method` to "filter-bank".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Resolution** section, move the **Sharpness** slider.

To enable this parameter, set **Input Domain** to Time in the **Estimation** tab.

Data Types: double

**FrequencyVectorSource — Source of frequency vector**

"auto" (default) | "property"

Source of the frequency vector, specified as one of the following:

- "auto" — The Spectrum Analyzer computes the frequency vector based on the frame size of the input signal and the specified sample rate.

- "property" — Enter a custom vector in the FrequencyVector property.

**Tunable:** Yes

**Dependency**

To enable this property, set InputDomain to "frequency".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Frequency (Hz)** to either Auto or a monotonically increasing vector of length equal to the input signal frame size.

To enable the **Frequency (Hz)**, set **Input Domain** to Frequency.

Data Types: char | string

**FrequencyVector — Custom frequency vector**

[-5000 5000] (default) | monotonically increasing vector

Custom frequency vector, specified as a monotonically increasing vector. This vector determines the x-axis of the display. The vector must be monotonically increasing and must have the same length as the input signal frame size.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "frequency".
- FrequencyVectorSource to "property".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Frequency (Hz)** to either Auto or a monotonically increasing vector of length equal to the input signal frame size.

To enable the **Frequency (Hz)**, set **Input Domain** to Frequency.

Data Types: double

**FrequencySpan — Frequency span mode**

"full" (default) | "span-and-center-frequency" | "start-and-stop-frequencies"

Frequency span mode, specified as one of the following:

- "full" -- The Spectrum Analyzer computes and plots the spectrum over the entire "Nyquist Frequency Interval" on page 4-1082.
- "span-and-center-frequency" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- "start-and-stop-frequencies" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

**Tunable:** Yes

**Dependency**

To enable this property, set `InputDomain` to "time".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Full, Span and Center Frequency, or Start and Stop Frequencies.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

**Span — Frequency span to compute spectrum**

10e3 (default) | real positive scalar

Frequency span over which the Spectrum Analyzer computes and plots the spectrum, specified as a positive scalar in Hz. The overall span, defined by this property and the `CenterFrequency` property, must fall within the "Nyquist Frequency Interval" on page 4-1082.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- `InputDomain` to "time"
- `FrequencySpan` to "span-and-center-frequency"

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Span and Center Frequency and **Span (Hz)** to a positive scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: double

**CenterFrequency — Center of frequency span**

0 (default) | real scalar

Center of frequency span over which the Spectrum Analyzer computes and plots the spectrum, specified as a real scalar in Hz. The overall frequency span, defined by `Span` and this property, must fall within the "Nyquist Frequency Interval" on page 4-1082.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- `InputDomain` to "time"
- `FrequencySpan` to "span-and-center-frequency"

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Span and Center Frequency and **Center Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: double

### **StartFrequency — Starting frequency in frequency interval**

-5e3 (default) | real scalar

Starting frequency in the frequency interval over which the Spectrum Analyzer computes and plots the spectrum, specified as a real scalar in Hz. The overall span, which is defined by this property and **StopFrequency**, must fall within the “Nyquist Frequency Interval” on page 4-1082.

**Tunable:** Yes

#### **Dependency**

To enable this property, set:

- **InputDomain** to "time"
- **FrequencySpan** to "start-and-stop-frequencies"

#### **Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Start Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: double

### **StopFrequency — Ending frequency in frequency interval**

5e3 (default) | real scalar

Ending frequency in the frequency interval over which the Spectrum Analyzer computes and plots the spectrum, specified as a real scalar in Hz. The overall span, which is defined by this property and the **StartFrequency** property, must fall within the “Nyquist Frequency Interval” on page 4-1082.

**Tunable:** Yes

#### **Dependency**

To enable this property, set:

- **InputDomain** to "time"
- **FrequencySpan** to "start-and-stop-frequencies"

#### **Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Stop Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: double

### **OverlapPercent — Percentage of overlap**

0 (default) | scalar in the range [0 100)

Percentage of overlap between the previous and current buffered data segments, specified as a scalar in the range [0 100). The overlap creates a window segment that the object uses to compute a spectral estimate.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "time"
- Method to "welch"

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Overlap (%)**.

To enable the **Overlap (%)**, set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: double

**Window — Window function**

"hann" (default) | "blackman-harris" | "chebyshev" | "custom" | "flat-top" | "hamming" | "kaiser" | "rectangular"

Window function, specified as one of the following preset windows. For more information on a window option, click the link to the corresponding function.

| Window Option     | Corresponding Signal Processing Toolbox Function |
|-------------------|--|
| "hann"            | hann   |
| "blackman-harris" | blackmanharris                                   |
| "chebyshev"       | chebwin  |
| "flat-top"        | flattopwin                                       |
| "hamming"         | hamming  |
| "kaiser"          | kaiser   |
| "rectangular"     | rectwin  |

To use your own spectral estimation window, set this property to "custom" and specify a custom window function in the CustomWindow property.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "time"
- Method to "welch"

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Window**.

To enable the **Window**, set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: char | string

**CustomWindow — Name of custom window function**

"hann" (default) | character array | string scalar

Name of custom window function, specified as a character array or string scalar. The custom window function name must be on the MATLAB path. Use this property to customize a window function using additional properties available with the Signal Processing Toolbox.

**Tunable:** Yes

**Example:**

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, "periodic")
end

scope.Window = "custom";
scope.CustomWindow = "my_hann"
```

**Dependency**

To use this property, set Window to "custom".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, for the **Window**, enter a custom window function name.

Data Types: char | string

**SidelobeAttenuation — Sidelobe attenuation of window**

60 (default) | scalar greater than or equal to 45

Sidelobe attenuation of the window in decibels (dB), specified as a positive scalar greater than or equal to 45.

**Tunable:** Yes

**Dependency**

To enable this property, set Window to "chebyshev" or "kaiser".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Attenuation (dB)**.

To enable the **Attenuation (dB)**, set:

- **Input Domain** to Time
- **Method** to Welch
- **Window** to either Chebyshev or Kaiser in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: double

### **AveragingMethod — Averaging method**

"vbw" (default) | "exponential"

Averaging method, specified as one of the following:

- "vbw" — Video bandwidth method. The object uses a lowpass filter to smooth the trace and decrease noise. Use the VBWSource and VBW properties to specify the VBW value.
- "exponential" — Weighted average of samples. The object computes the average over samples weighted by an exponentially decaying forgetting factor. Use the ForgettingFactor property to specify the weighted forgetting factor.

For more information on averaging methods, see "Averaging Method" on page 4-1085.

**Tunable:** Yes

#### **Dependency**

To enable this property, set InputDomain to "time".

#### **Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **Averaging Method** to VBW or Exponential.

To enable the **Averaging Method**, set **Input Domain** to Time.

Data Types: char | string

### **ForgettingFactor — Forgetting factor of weighted average method**

0.9 (default) | scalar in the range [0,1]

Forgetting factor of the exponential weighted averaging method, specified as a scalar in the range [0,1].

**Tunable:** Yes

#### **Dependency**

To enable this property, set:

- InputDomain to "time".
- AveragingMethod to "exponential"

#### **Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, adjust the slider for **Forgetting Factor**.

To enable the **Forgetting Factor**, set **Input Domain** to Time and **Averaging Method** to Exponential.

Data Types: double

**VBWSource — Source of video bandwidth**

"auto" (default) | "property"

Source of the video bandwidth (VBW), specified as either "auto" or "property".

- "auto" — The Spectrum Analyzer adjusts the VBW such that the equivalent forgetting factor is 0.9.
- "property" — The Spectrum Analyzer adjusts the VBW using the value specified in the VBW property.

For more details on the video bandwidth method, see "Averaging Method" on page 4-1085.

**Tunable:** Yes

**Dependency**

To enable this property, set `InputDomain` to "time" and `AveragingMethod` to "vbw".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **VBW (Hz)** to either Auto or a positive real scalar less than or equal to **Sample Rate (Hz)/2**.

To enable the **VBW (Hz)**, set **Input Domain** to Time and **Averaging Method** to VBW.

Data Types: char | string

**VBW — Video bandwidth**

10 (default) | positive scalar

Video bandwidth, specified as a positive scalar less than or equal to `SampleRate/2`. For more details on the video bandwidth method, see "Averaging Method" on page 4-1085.

The Spectrum Analyzer shows the value of VBW in the status bar at the bottom of the display.

**Tunable:** Yes

**Dependency**

To enable this property, set `VBWSource` to "property".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **VBW (Hz)** to either Auto or enter a positive real scalar that is less than or equal to **Sample Rate (Hz)/2**.

To enable the **VBW (Hz)**, set **Input Domain** to Time and **Averaging Method** to VBW.

Data Types: double

**InputUnits — Units of frequency input**

"dBm" (default) | "dBV" | "dBW" | "Vrms" | "Watts" | "none"

Units of the frequency-domain input, specified as "dBm", "dBV", "dBW", "Vrms", "Watts", or "none". The Spectrum Analyzer scales frequency data according to the specified display unit.

**Tunable:** Yes

**Dependency**

To enable this property, set `InputDomain` to "frequency".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Input Unit**.

To enable the **Input Unit**, set **Input Domain** to Frequency.

Data Types: char | string

**SpectrumUnits — Units of the spectrum**

"dBm" (default) | "dBFS" | "dBV" | "dBW" | "Vrms" | "Watts" | "dBm/Hz" | "dBW/Hz" | "dBFS/Hz" | "Watts/Hz" | "auto"

Units in which the Spectrum Analyzer displays power values, specified as one of the following:

- "dBm"
- "dBFS"
- "dBV"
- "dBW"
- "Vrms"
- "Watts"
- "dBm/Hz"
- "dBW/Hz"
- "dBFS/Hz"
- "Watts/Hz"
- "auto"

**Tunable:** Yes

**Dependency**

The spectrum units available depend on the value you specify in the `SpectrumType` property.

| InputDomain | SpectrumType    | Allowed SpectrumUnits                        |
|-------------|-----------------|--|
| "time"      | "power"         | "dBm", "dBW", "dBFS", "Watts"                |
|             | "power-density" | "dBm/Hz", "dBW/Hz", "dBFS/Hz", "Watts/Hz"    |
|             | "rms"           | "dBV", "Vrms"                                |
| "frequency" | —               | "auto", "dBm", "dBV", "dBW", "Vrms", "Watts" |

If you set the `InputDomain` property to "frequency" and the `SpectrumUnits` property to "auto", the Spectrum Analyzer assumes the spectrum units to be equal to input units specified in the `InputUnits` property. If you set `InputDomain` to "time" and `SpectrumUnits` to any option other than "auto", the Spectrum Analyzer converts the units specified in `InputUnits` to the units specified in `SpectrumUnits`.

### Scope Window Use

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set **Spectrum Unit**.

Data Types: char | string

### FullScaleSource — Source of full-scale value

"auto" (default) | "property"

Source of the dBFS scaling factor, specified as either "auto" or "property".

- "auto" -- The Spectrum Analyzer adjusts the scaling factor based on the input data.
- "property" -- Specify the full-scale scaling factor using the FullScale property.

**Tunable:** Yes

### Dependency

To enable this property, set:

- InputDomain to "time"
- SpectrumType to "power" or "power-density"
- SpectrumUnits to "dBFS" or "dBFS/Hz"

### Scope Window Use

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Full Scale** to either Auto or a positive scalar.

To enable the **Full Scale**:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

Data Types: char | string

### FullScale — dBFS full scale

1 (default) | positive scalar

dBFS full scale, specified a positive scalar.

**Tunable:** Yes

### Dependency

To enable this property, set:

- 1 InputDomain to "time"
- 2 SpectrumType to "power" or "power-density"
- 3 SpectrumUnits to "dBFS" or "dBFS/Hz"
- 4 FullScaleSource to "property"

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Full Scale** to either **Auto** or enter a positive scalar.

To enable the **Full Scale**:

- In the **Analyzer** tab, set the spectrum type to **Power** or **Power Density**.
- In the **Estimation** tab, set **Input Domain** to **Time**.
- In the **Spectrum** tab, set **Spectrum Unit** to **dBFS** or **dBFS/Hz** (when spectrum type is set to **Power Density**).

Data Types: double

**ReferenceLoad — Reference load to compute power levels**

1 (default) | positive scalar

Load that the scope uses as a reference to compute power levels, specified as a positive scalar in Ohms.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- **SpectrumType** to "power" or "power-density".
- **SpectrumUnits** to any option other than "dBFS" or "dBFS/Hz".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set **Reference Load ( $\Omega$ )**.

Data Types: double

**FrequencyOffset — Offset to apply to frequency axis**

0 (default) | scalar | vector

Offset to apply to the frequency axis (x-axis) in units of Hz, specified as one of the following:

- **Scalar** — Apply the same frequency offset to all channels.
- **Vector** — Apply a specific frequency offset for each channel. The vector length must be equal to the number of input channels.

The overall span must fall within the "Nyquist Frequency Interval" on page 4-1082. You can control the overall span in different ways based on how you set the **FrequencySpan** property.

**Tunable:** Yes

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **Offset (Hz)**.

Data Types: double

## Spectrogram

### **SpectrogramChannel** — Channel for which spectrogram is plotted

1 (default) | positive integer

Channel for which the spectrogram is plotted, specified as a positive integer in the range [1  $N$ ], where  $N$  is the number of input channels.

**Tunable:** Yes

#### **Dependency**

To enable this property, set `ViewType` to "spectrogram" or "spectrum-and-spectrogram".

#### **Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Channel** section, select a **Channel**.

Data Types: double

### **TimeResolutionSource** — Source of the time resolution

"auto" (default) | "property"

Source of the time resolution of each spectrogram line, specified as either "auto" or "property".

When you set `RBWSource` and `TimeResolutionSource` to "auto", then RBW is set such that there are 1024 RBW intervals in one frequency span. The time resolution is set to 1/RBW.

When `RBWSource` is set to "auto" and `TimeResolutionSource` is set to "property", then time resolution becomes the main control and RBW is set to 1/`TimeResolution` Hz.

When `RBWSource` is set to "property" and `TimeResolutionSource` is set to "auto", then RBW becomes the main control and the time resolution is set 1/RBW s.

When both `RBWSource` and `TimeResolutionSource` are set to "property", then the specified time resolution value must be equal to or larger than the minimum attainable time resolution which is defined by 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution.

**Tunable:** Yes

#### **Dependency**

To enable this property, set `ViewType` to "spectrogram" or "spectrum-and-spectrogram".

#### **Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Resolution (s)** to Auto or enter a positive scalar.

To enable the **Time Resolution (s)**, select **Spectrogram** in the **Analyzer** tab.

Data Types: char | string

### **TimeResolution** — Time resolution of each spectrogram line

0.001 (default) | positive scalar

Time resolution of each spectrogram line in seconds, specified as a positive scalar.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to "spectrogram" or "spectrum-and-spectrogram"
- TimeResolutionSource to "property".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Resolution (s)** to Auto or enter a positive scalar.

To enable the **Time Resolution (s)**, select **Spectrogram** in the **Analyzer** tab.

Data Types: double

**TimeSpanSource — Source of time span value**

"auto" (default) | "property"

Source for the time span of the spectrogram, specified as either one of these:

- "auto" -- The spectrogram displays 100 spectrogram lines at any given time.
- "property" -- The spectrogram uses the time duration you specify in seconds in the TimeSpan property.

The time span that you specify must be at least two times larger than the duration of the number of samples required for a spectral update.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "spectrogram" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Span (s)** to Auto or enter a positive scalar.

Data Types: char | string

**TimeSpan — Time span of spectrogram**

0.1 (default) | positive scalar

Time span of the spectrogram display in seconds, specified as a positive scalar. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to "spectrogram" or "spectrum-and-spectrogram".
- TimeSpanSource to "property".

### Scope Window Use

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Span (s)** to Auto or enter a positive scalar.

Data Types: double

### Measurements

#### MeasurementChannel — Channel for which to obtain measurements

1 (default) | positive integer

The channel for which you need to obtain measurements, specified as a positive integer in the range [1  $N$ ], where  $N$  is the number of input channels.

**Tunable:** Yes

### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel** section, select a **Channel**.

Data Types: double

#### ChannelMeasurements — Channel measurements

ChannelMeasurementsConfiguration object

Channel measurements, specified as a ChannelMeasurementsConfiguration object. Enable channel measurements to compute and display the occupied bandwidth or adjacent channel power ratio. All ChannelMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

### Dependency

To enable this property, set ViewType to either "spectrum" or "spectrum-and-spectrogram".

### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip and modify the measurement settings.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

#### CursorMeasurements — Cursor measurements

CursorMeasurementsConfiguration object

Cursor measurements, specified as a CursorMeasurementsConfiguration object. Enable cursor measurements to display waveform cursors. All CursorMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

**Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the cursor measurements in the **Cursors** section.

**DistortionMeasurements — Distortion measurements**

`DistortionMeasurementsConfiguration` object

Distortion measurements, specified as a `DistortionMeasurementsConfiguration` object. Enable distortion measurements to compute and display the harmonic distortion and intermodulation distortion. All `DistortionMeasurementsConfiguration` properties are tunable. For more details, see “Distortion Measurements” on page 4-1083 and “Harmonic Measurements” on page 4-1084.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to either "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the distortion measurements in the **Distortion** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

**PeakFinder — Peak finder measurement**

`PeakFinderConfiguration` object

Peak finder measurement, specified as a `PeakFinderConfiguration` object. Enable peak finder to compute and display the largest calculated peak values. All `PeakFinderConfiguration` properties are tunable.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to either "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the peak finder measurements in the **Peaks** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

**SpectralMask — Spectral mask configuration**

`SpectralMaskConfiguration` object

Spectral mask configuration, specified as a `SpectralMaskConfiguration` object. Use the spectral mask configuration to draw upper and lower or upper or lower mask lines in the power and power-density plots. All `SpectralMaskConfiguration` properties are tunable.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to either "spectrum" or "spectrum-and-spectrogram".
- SpectrumType to either "power" or "power-density".

**Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip and modify the settings.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose either Power or Power Density.

**Visualization****Name — Caption to display in spectrum Analyzer window**

"Spectrum Analyzer" (default) | character vector | string scalar

Caption to display in the scope window, specified as a character vector or string scalar.

**Tunable:** Yes

Data Types: char | string

**Position — Spectrum Analyzer window position in pixels**

[left bottom 800 500] (default) |[left bottom width height]

Spectrum Analyzer window position in pixels, specified as a four-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values of this property.

By default, the window appears at the center of your screen with a width of 800 pixels and height of 500 pixels. The exact center coordinates depend on your screen resolution.

**Tunable:** Yes

**MaximizeAxes — Maximize axes control**

"auto" (default) | "on" | "off"

Maximize axes control, specified as one of the following:

- "auto" -- The Spectrum Analyzer maximizes axes only if the display does not contain any labels or title annotations.
- "on" -- The Spectrum Analyzer maximizes axes in all displays.
- "off" -- The Spectrum Analyzer does not maximize axes in any display.

**Tunable:** Yes

Data Types: char | string

**PlotNormalTrace — Option to plot normal trace**

true (default) | false

To remove normal traces from the display, set this property to false. These traces display the free-running spectral estimates. The Spectrum Analyzer continues its spectral computations even when you set this property to false.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Normal Trace** check box in the **Trace Options** section.

To enable the **Normal Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**PlotMaxHoldTrace — Option to plot max-hold trace**

`false` (default) | `true`

Option to plot max-hold trace, specified as `true` or `false`. To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The Spectrum Analyzer computes the maximum-hold spectrum at each frequency bin by keeping the maximum value of all the power spectrum estimates. When you change the value of this property, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Max-Hold Trace** check box in the **Trace Options** section.

To enable the **Max-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**PlotMinHoldTrace — Option to plot min-hold trace**

`false` (default) | `true`

Option to plot min-hold trace, specified as `true` or `false`. To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The Spectrum Analyzer computes the minimum-hold spectrum at each frequency bin by keeping the minimum value of all the power spectrum estimates. When you change the value of this property, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Min-Hold Trace** check box in the **Trace Options** section.

To enable the **Min-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

### **Title – Display title**

' ' (default) | character vector | string scalar

Display title, specified as a character vector or a string scalar.

**Tunable:** Yes

### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Title**.

Data Types: `char` | `string`

### **YLabel – y-axis label**

' ' (default) | character vector | string scalar

y-axis label, specified as a character vector or a string scalar. The Spectrum Analyzer displays the label to the left of the y-axis.

Regardless of this property, Spectrum Analyzer always displays power units as one of the `SpectrumUnits` values.

**Tunable:** Yes

### **Dependency**

To enable this property, set `ViewType` to "spectrum" or "spectrum-and-spectrogram".

### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Y-Label**.

To enable the **Y-Label**, select **Spectrum** in the **Analyzer** tab.

Data Types: `char` | `string`

### **YLimits – y-axis limits**

[-80, 20] (default) | [ymin ymax]

y-axis limits, specified as a two-element numeric vector of the form [ymin ymax]. The units of the y-axis limits depend on the `SpectrumUnits` property.

Example: `scope.YLimits = [-10,20]`

**Tunable:** Yes

### **Dependencies**

To enable this property, set the `ViewType` property to "spectrum" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Y-Axis Limits**.

To enable the **Y-Axis Limits**, select **Spectrum** in the **Analyzer** tab.

**ColorLimits — Color limits of spectrogram**

`[-80, 20]` (default) | `[colorMin colorMax]`

Color limits of the spectrogram, specified as a two-element numeric vector of the form `[colorMin colorMax]`. The units of the color limits directly depend upon the `SpectrumUnits` property.

Example: `scope.ColorLimits = [-10,20]`

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ViewType` property to "spectrogram" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Color Limits**.

To enable the **Color Limits**, select **Spectrogram** in the **Analyzer** tab.

**Colormap — Color look-up table**

"jet" (default) | "bone" | "cool" | "copper" | "gray" | "hot" | "parula" | three-column matrix

Color look-up table, specified as a valid colormap name or a three-column matrix with values in the range `[0,1]` defining RGB triplets.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ViewType` property to "spectrogram" or "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Color Map**.

To enable the **Color Map**, select **Spectrogram** in the **Analyzer** tab.

Data Types: `double` | `char` | `string`

**ShowGrid — Flag to show grid**

`true` (default) | `false`

Flag to show the grid, specified as `true` or `false`. Set this property to `true` to show grid lines in the plot.

**Tunable:** Yes

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that appears, under **Display and Labels**, select **Show Grid**.

Data Types: `logical`

### ShowLegend — Show or hide legend

`false` (default) | `true`

Show or hide the legend, specified as `true` or `false`. To show a legend with the input names, set this property to `true`.

Use the legend to control which signals are visible. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

### Dependencies

To enable this property, set the `ViewType` property to `"spectrum"` or `"spectrum-and-spectrogram"`.

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

### ShowColorbar — Show or hide color bar

`true` (default) | `false`

Show or hide color bar, specified as `true` or `false`.

**Tunable:** Yes

### Dependencies

To enable this property, set the `ViewType` property to `"spectrogram"` or `"spectrum-and-spectrogram"`.

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the color bar, click **Colorbar** in the **Configuration** section.

To enable the **Colorbar**, select **Spectrogram** in the **Analyzer** tab.

Data Types: `logical`

**ChannelNames — Channel names**

empty cell (default) | cell array of character vectors | array of strings

Channel names in the input data, specified as a cell array of character vectors or an array of strings. The names you specify in this property appear in the following locations:

- Legend
- **Spectrum Analyzer Settings > Color and styling** section
- **Measurements** and **Channel Measurements** tabs

If you do not specify channel names, the Spectrum Analyzer names the channels as Channel 1, Channel 2, and so on.

**Tunable:** Yes

**Dependency**

To see the channel names, set ShowLegend to true.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolbar. To see the legend, click **Legend** in the **Configuration** section.

Data Types: char

**AxesLayout — Layout of axes**

"vertical" (default) | "horizontal"

Layout of the axes, specified as one of "vertical" or "horizontal". A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "spectrum-and-spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolbar. Select **Spectrum** and **Spectrogram**. In the **Configuration** section, select and update **Layout**.

Data Types: char | string

**Usage****Syntax**

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

## Description

`scope(signal)` displays the frequency spectrum of the time-domain signal in the Spectrum Analyzer. If `signal` is a frequency-domain signal, the signal is displayed directly in the Spectrum Analyzer.

`scope(signal1,signal2,...,signalN)` displays the frequency spectrum of multiple signals in the Spectrum Analyzer. The number of channels in each signal can be different but the frame size of each signal should be the same.

## Input Arguments

### **signal** — Input signal or signals to visualize

scalar | vector | matrix

Input signal or signals to visualize, specified as a scalar, vector, or a matrix. The number of channels in each signal can be different but the frame size of each signal should be the same.

This scope supports variable-size input signals. That is, the frame size (number of rows) of the input signals can change during simulation, but the number of channels (number of columns) cannot change.

When you set the `InputDomain` property to "time", the input signals can be real or complex. When you set the `InputDomain` property to "frequency", the input signals must be real.

Example: `scope(signal1,signal2)`

## Scope Window Use

To change the appearance of signals in the Spectrum Analyzer, click the **Analyzer** tab and then click **Settings**. In the Spectrum Analyzer Settings window, under **Color and styling**, select a signal and modify its style, width, color, and marker type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Object Functions

### Specific to spectrumAnalyzer

|                                    |   |
|------------------------------------|---|
| <code>generateScript</code>        | Generate MATLAB script to create scope with current settings        |
| <code>getMeasurementsData</code>   | Get the current measurement data displayed on the spectrum analyzer |
| <code>getSpectralMaskStatus</code> | Get test results of current spectral mask                           |
| <code>getSpectrumData</code>       | Save spectrum data shown in spectrum analyzer                       |
| <code>isNewDataReady</code>        | Check spectrum analyzer for new data                                |

### Specific to Scopes

|                        |                               |
|------------------------|-------------------------------|
| <code>show</code>      | Display scope window          |
| <code>hide</code>      | Hide scope window             |
| <code>isVisible</code> | Determine visibility of scope |

### Common to All System Objects

|                   |                             |
|-------------------|-----------------------------|
| <code>step</code> | Run System object algorithm |
|-------------------|-----------------------------|

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

---

**Note** If you want to restart the simulation from the beginning, call `reset` to clear the scope window display. Do not call `reset` after calling `release`.

---

## Examples

### Spectrum Analyzer for One-Sided Power Spectrum

View a one-sided power spectrum made from the sum of fixed real sine waves with different amplitudes and frequencies.

```

Fs = 100e6; % Sample rate
fSz = 5000; % Frame size

sin1 = dsp.SineWave(1e0,5e6,0,SamplesPerFrame=fSz,SampleRate=Fs);
sin2 = dsp.SineWave(1e-1,15e6,0,SamplesPerFrame=fSz,SampleRate=Fs);
sin3 = dsp.SineWave(1e-2,25e6,0,SamplesPerFrame=fSz,SampleRate=Fs);
sin4 = dsp.SineWave(1e-3,35e6,0,SamplesPerFrame=fSz,SampleRate=Fs);
sin5 = dsp.SineWave(1e-4,45e6,0,SamplesPerFrame=fSz,SampleRate=Fs);

scope = spectrumAnalyzer(SampleRate=Fs,AveragingMethod="exponential",...
    PlotAsTwoSidedSpectrum=false,...
    RBWSource="auto",SpectrumUnits="dBW");

for idx = 1:250
    y1 = sin1();
    y2 = sin2();
    y3 = sin3();
    y4 = sin4();
    y5 = sin5();
    scope(y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end

```

Call the `release` function to let property values and input characteristics change. The scope automatically scales the axes.

```
release(scope)
```

Run the `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

### Spectrum Analyzer For Two-Sided Power Spectrum

View a two-sided power spectrum of a noisy sine wave on the Spectrum Analyzer.

```
sin = dsp.SinWave(Frequency=100,SampleRate=1000,...
    SamplesPerFrame=1000);
scope = spectrumAnalyzer(SampleRate=sin.SampleRate);
for ii = 1:250
    x = sin() + 0.05*randn(1000,1);
    scope(x);
end
```

Call the `release` function to change property values and input characteristics. The scope automatically scales the axes and updates the display one more time if the internal buffer contains any more data.

```
release(scope);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

### Spectrogram of Chirp Signal

Plot the spectrogram for a chirp signal with added random noise.

```
Fs = 233e3;
frameSize = 20e3;
chirp = dsp.Chirp(SampleRate=Fs, SamplesPerFrame=frameSize, ...
    InitialFrequency=11e3, TargetFrequency=11e3+55e3);

scope = spectrumAnalyzer(SampleRate=Fs, ...
    AveragingMethod="exponential", ...
    ForgettingFactor=0.3, ViewType="spectrogram", ...
    RBWSource="property", RBW=500, ...
    TimeSpanSource="property", TimeSpan=2);

scope.PlotAsTwoSidedSpectrum = false;

for idx = 1:50
    y = chirp()+0.05*randn(frameSize,1);
    scope(y);
end
```

```
end
release(scope)
```

### Display Frequency Input from Spectral Estimation

Use the Spectrum Analyzer to display frequency input from spectral estimates of sinusoids embedded in white Gaussian noise.

#### Initialization

Create two `dsp.SpectrumEstimator` objects. Set one object to use the Welch-based spectral estimation technique with a Hann window. Set the other object to use the filter bank estimation. Specify a noisy sine wave input signal with four sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles per sample. View the spectral estimate using the `spectrumAnalyzer` object.

```
FrameSize = 420;
Fs = 1;
Frequency = [0.16 0.2 0.205 0.25];
singen = dsp.SineWave(SampleRate=Fs, SamplesPerFrame=FrameSize, ...
    Frequency=Frequency, Amplitude=[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAvg = 8;

hannEstimator = dsp.SpectrumEstimator(PowerUnits="dBm", ...
```

```

Window="Hann",FrequencyRange="onesided",...
SpectralAverages=numAvgs,SampleRate=Fs);

filterBankEstimator = dsp.SpectrumEstimator(PowerUnits="dBm",...
Method="Filter bank",FrequencyRange="onesided",...
SpectralAverages=numAvgs,SampleRate=Fs);

spectrumPlotter = spectrumAnalyzer(InputDomain="frequency",...
SampleRate=Fs,SpectrumUnits="dBm",...
YLimits=[-120,40],PlotAsTwoSidedSpectrum=false,...
ChannelNames={'Hann window','Filter bank'},ShowLegend=true);

```

### Streaming

Stream the input. Compare the spectral estimates in the spectrum analyzer.

```

for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb])
end

```

### Obtain Measurements Data Programmatically for spectrumAnalyzer object

Compute and display the power spectrum of a noisy sinusoidal input signal using the spectrumAnalyzer MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- PeakFinder
- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements

#### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two dsp.SinWave System objects to generate these two frequencies. Create a spectrumAnalyzer object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SinWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SinWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
    PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...
    YLimits=[-120 40],ShowLegend=true);
```

#### Enable Measurements Data

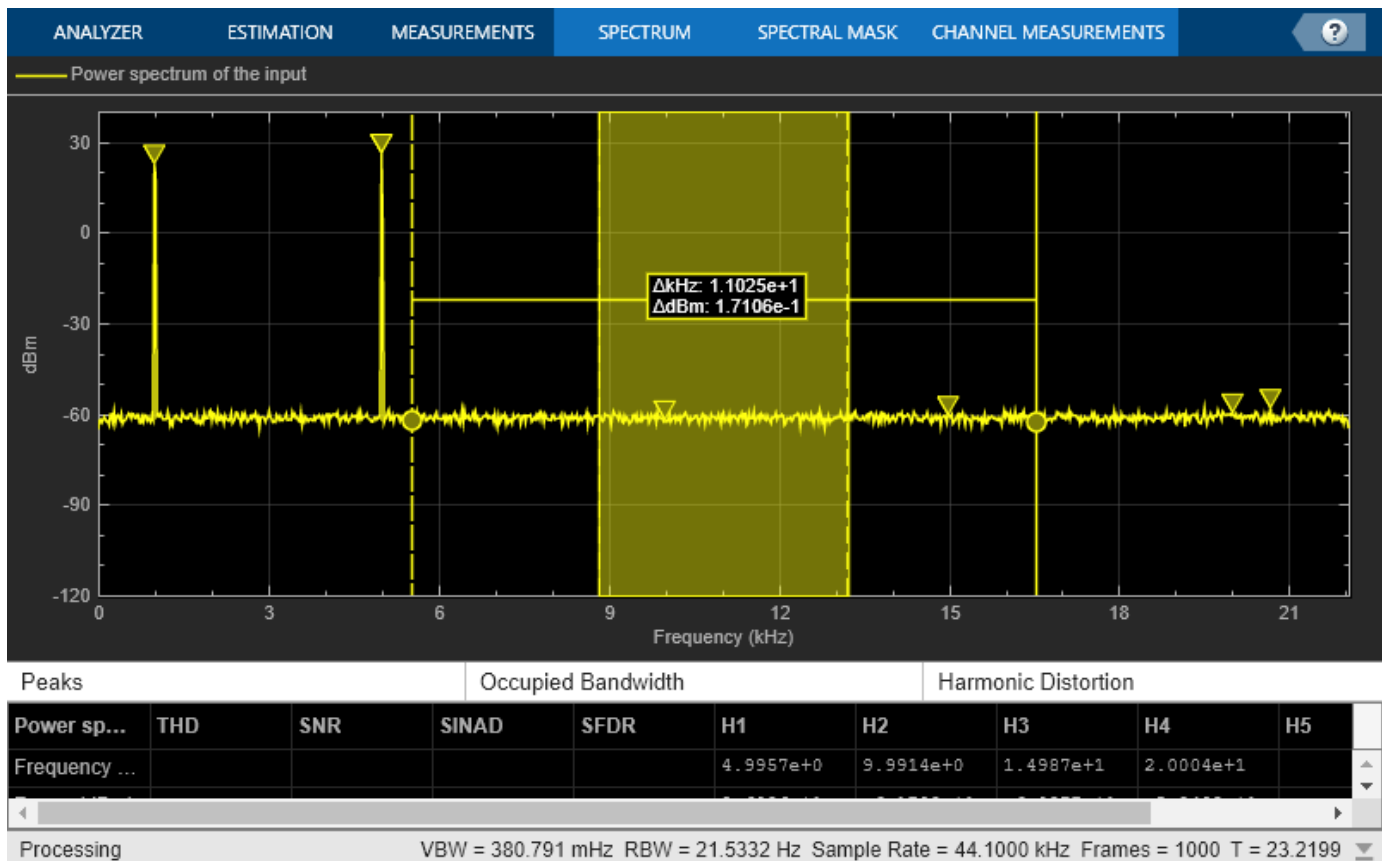

To obtain the measurements, set the Enabled property to true.

```
SA.CursorMeasurements.Enabled = true;
SA.ChannelMeasurements.Enabled = true;
SA.PeakFinder.Enabled = true;
SA.DistortionMeasurements.Enabled = true;
```

#### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrumAnalyzer object. Measure the characteristics of the spectrum. Use the getMeasurementsData function to obtain these measurements programmatically. The isNewDataReady function returns true when there is new spectrum data. Store the measured data in the variable data.

```
data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    NoisyInput = Input + 0.001*randn(1024,1);
    SA(NoisyInput);
    if SA.isNewDataReady
        data = [data;getMeasurementsData(SA)];
    end
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

Use the `PeakFinder` property to obtain peak values. Verify that the peak values in the last time step of `data` match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3x1
```

```
26.3957
22.7830
-57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3x1
```

```
4.9957
0.9905
```

20.6719

## More About

### Convert the Power Between Units

Conversion of power between units on the Spectrum Analyzer window.

The Spectrum Analyzer provides three units to specify the power spectral density: **Watts/Hz**, **dBm/Hz**, and **dBW/Hz**. Corresponding units of power are **Watts**, **dBm**, and **dBW**. For electrical engineering applications, you can also view the RMS of your signal in **Vrms** or **dBV**. The default spectrum type is **Power** in **dBm**.

### Convert the Power in Watts to dBW and dBm

Power in **dBW** is given by:

$$P_{\text{dBW}} = 10\log_{10}(\text{power in watt}/1 \text{ watt})$$

Power in **dBm** is given by:

$$P_{\text{dBm}} = 10\log_{10}(\text{power in watt}/1 \text{ milliwatt})$$

For a sine wave signal with an amplitude of 1 V, the power of a one-sided spectrum in **Watts** is given by:

$$P_{\text{Watts}} = A^2/2$$

$$P_{\text{Watts}} = 1/2$$

Corresponding power in **dBm** is given by this equation.

$$P_{\text{dBm}} = 10\log_{10}(\text{power in watt}/1 \text{ milliwatt})$$

$$P_{\text{dBm}} = 10\log_{10}(0.5/10^{-3})$$

$$P_{\text{dBm}} = 26.9897 \text{ dBm}$$

For a white noise signal, the spectrum is flat for all frequencies. Consider a white noise signal with a variance of  $1e-4$ . The power per unit bandwidth therefore ( $P_{\text{unitbandwidth}}$ ) is  $1e-4$ . For a one-sided spectrum in the range  $[0, Fs/2]$ , the total power of white noise in **Watts** is given by this equation.

$$P_{\text{whitenoise}} = P_{\text{unitbandwidth}} \cdot \text{number of frequency bins},$$

$$P_{\text{whitenoise}} = (10^{-4}) \cdot \left( \frac{Fs/2}{RBW} \right)$$

$F_s$  is the input sample rate. The number of frequency bins is the ratio of total bandwidth to RBW. For a one-sided spectrum, the total bandwidth is half the sample rate. Consider a sample rate of 44100 Hz and a RBW of 21.53 Hz. With these values, the total power of white noise in **Watts** is 0.1024 W.

$$P_{\text{whitenoise}} = 10\log_{10}(0.1024/10^{-3})$$

$$P_{\text{whitenoise}} = 20.103 \text{ dBm}$$

In **dBm**, the power of white noise can be calculated using  $10 \cdot \log_{10}(0.1024/10^{-3})$ , which equals 20.103 **dBm**.

### Convert Power in Watts to dBFS

If you set the spectral units to dBFS and set the full scale (FullScaleSource) to "auto", power in dBFS is computed as:

$$P_{\text{dBFS}} = 20 \cdot \log_{10}(\sqrt{P_{\text{watts}}}/\text{Full\_Scale})$$

where:

- $P_{\text{watts}}$  is the power in watts
- For double and float signals, *Full\_Scale* is the maximum value of the input signal.
- For fixed point or integer signals, *Full\_Scale* is the maximum value that can be represented.

If you specify a manual full scale (set FullScaleSource to "property"), power in dBFS is given by:

$$P_{\text{FS}} = 20 \cdot \log_{10}(\sqrt{P_{\text{watts}}}/\text{FS})$$

Where FS is the full-scaling factor specified in the FullScale property.

For a sine wave signal with an amplitude of 1 V, the power of a one-sided spectrum in Watts is given by:

$$P_{\text{Watts}} = A^2/2$$

$$P_{\text{Watts}} = 1/2$$

The corresponding power in dBFS is given by:

$$P_{\text{FS}} = 20 \cdot \log_{10}(\sqrt{1/2}/1)$$

$$P_{\text{FS}} = -3.0103 \text{ dBFS}$$

To confirm the power value in the spectrum analyzer, run these commands:

```
Fs = 1000; % Sampling frequency
sinef = dsp.SineWave(SampleRate=Fs, SamplesPerFrame=100);
scope = spectrumAnalyzer(SampleRate=Fs, ...
    SpectrumUnits="dBFS", PlotAsTwoSidedSpectrum=false)
```

```
for ii = 1:100000
xsine = sinef();
scope(xsine)
end
```

Enable **Peak Finder** in the **Measurements** tab of the spectrum analyzer toolstrip.

### Convert the Power in dBm to RMS in Vrms

Power in dBm is given by:

$$P_{\text{dBm}} = 10 \log_{10}(\text{power in watt}/1 \text{ milliwatt})$$

Voltage in RMS is given by:

$$V_{\text{rms}} = 10^{P_{\text{dBm}}/20} \sqrt{10^{-3}}$$

From the previous example,  $P_{\text{dBm}}$  equals 26.9897 dBm. The  $V_{\text{rms}}$  is calculated as

$$V_{\text{rms}} = 10^{26.9897/20} \sqrt{0.001}$$

which equals 0.7071.

To confirm this value using the peak finder:

- 1 In the **Analyzer** Tab of the Spectrum Analyzer toolstrip, select **Spectrum > RMS**.
- 2 Enable **Peak Finder** in the **Measurements** tab.

### Cursor Measurements

Measure signal values using vertical waveform cursors that track along the signal.

When you click the **Data Cursors** button in the **Measurements** tab of the Spectrum Analyzer, the spectrum display shows vertical cursors on each signal. Each cursor tracks a vertical line along the signal. The scope displays the difference between  $x$ - and  $y$ -values of the signal at the two cursors in the box between the cursors.

To enable cursor measurements, click the **Data Cursors** button in the **Measurements** tab. The cursors appear only when the Spectrum Analyzer has at least one signal in its display.

You can use the mouse to move the vertical cursors left and right.

In the **Measurements** tab, click the **Data Cursors** drop-down arrow to select one of these options:

- **Snap to Data** — To position the cursors on the signal data points.
- **Lock Cursor Spacing** — To lock the frequency difference between the two cursors.

For modifying the cursor measurements programmatically, see the `CursorMeasurementsConfiguration` object.

### Peak Finder Measurements

Compute and display peak values in the scope display.

When you click on the **Peak Finder** button in the **Measurements** tab of the Spectrum Analyzer, an arrow appears on the plot at each maxima and a **Peaks** panel appears at the bottom of the scope window. The Spectrum Analyzer computes peaks from the portion of the input signal that is currently on display in the scope, and the **Peaks** panel shows the peak values and the frequencies at which they occur.

The **Peaks** section in the **Measurements** tab allows you to specify the number of peaks you want the scope to display, the minimum height above which you want the scope to detect peaks, the minimum distance between peaks, and label the peaks.

The Spectrum Analyzer algorithm defines a peak as a local maximum with lower values present on either side of the peak. It does not consider end points as peaks. For more information on the algorithm, see the `findpeaks` function.

The peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

For modifying the peak finder measurements programmatically, see the `PeakFinderConfiguration` object. For more information on these settings in the UI, see “Peaks” on page 2-0 .

## Distortion Measurements

Measure harmonic distortion and intermodulation distortion.

When you click the **Distortion** button in the **Distortion** section of the **Measurements** tab, a distortion panel opens at the bottom of the Spectrum Analyzer window. This panel shows the harmonic and distortion measurement values for the input signal currently on display in the scope. The **Distortion** section in the **Measurements** tab allows you to specify the distortion type, number of harmonics, and even label the harmonics.

---

**Note** For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the Spectrum Analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious noise content. In general, you should set the RBW value such that there is at least a 10 dB separation between the peaks of the sinusoids and the noise floor. You also might need to select a different spectral window to obtain a valid measurement.

---

You can set the **Distortion Type** parameter to one of these values:

- **Harmonic** -- Select **Harmonic** if your input is a single sinusoid.
- **Intermodulation** -- Select **Intermodulation** if your input is two equal-amplitude sinusoids. Intermodulation can help you determine distortion when the scope uses only a small portion of the available bandwidth.

See “Distortion Measurements” on page 2-1341 for information on how distortion measurements are calculated.

### Harmonic Distortion

When you set the **Distortion Type** to **Harmonic**, these fields appear in the **Harmonic Distortion** panel at the bottom of the Spectrum Analyzer window.

- **H1** — Fundamental frequency in Hz and its power in decibels of the measured power referenced to 1 milliwatt (dBm).
- **H2, H3, ...** — Harmonics frequencies in Hz and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — Total harmonic distortion. This value represents the ratio of the power in the harmonics  $D$  to the power in the fundamental frequency  $S$ . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of the power in the fundamental frequency  $S$  to the power of all nonharmonic content  $N$ , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total nonharmonic content of your signal is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion ratio. This value represents the ratio of the power in the fundamental frequency  $S$  to all other content (including noise  $N$  and harmonic distortion  $D$ ) in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N + D}\right)$$

- **SFDR** — Spurious-free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency  $S$  to power of the largest spurious signal  $R$  regardless of where it falls in the frequency spectrum. The worst spurious signal might or might not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal and ignores any DC component. The measurement does not include any harmonics that are outside the Spectrum Analyzer frequency span. Adjust your frequency span so that it includes all the desired harmonics.

**Note** To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. The noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

### Intermodulation Distortion

When you set the **Distortion Type** to **Intermodulation**, the following fields appear in the **Intermodulation Distortion** panel at the bottom of the Spectrum Analyzer window.

- **F1** — Lower fundamental first-order frequency.
- **F2** — Upper fundamental first-order frequency.
- **2F1 - F2** — Lower intermodulation product from third-order harmonics.

- **2F2 - F1** — Upper intermodulation product from third-order harmonics.
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

The intermodulation distortion measurement automatically locates the fundamental and the first-order frequencies ( $F1$  and  $F2$ ). It then computes the frequencies of the third-order intermodulation products ( $2F1 - F2$  and  $2F2 - F1$ ).

For modifying the distortion measurements programmatically, see the `DistortionMeasurementsConfiguration` object. For more information on these settings in the UI, see “Distortion” on page 2-0 .

### Channel Measurements

Measure the occupied bandwidth or adjacent channel power ratio (ACPR).

When you click the **Channel Measurements** button in the **Channel Measurements** tab, a channel measurements panel opens at the bottom of the Spectrum Analyzer window. This panel displays the occupied bandwidth or the adjacent channel power ratio measurements. In the **Channel Measurements** tab, you can specify the occupied bandwidth or the ACPR settings, frequency span, center frequency, and start and stop frequencies.

You can select the channel measurements **Type** to:

- **Occupied BW** -- Occupied bandwidth
- **ACPR** -- Ratio of the power of the main channel to the power of the adjacent channel

For more details on how the Spectrum Analyzer calculates the occupied bandwidth, see “Occupied BW” on page 2-1341.

### Occupied Bandwidth

When you set the **Type** of channel measurement to compute and display to **Occupied BW**, these fields appear in the measurements panel at the bottom of the scope window.

- **Channel Power** — Total power in the channel
- **Occupied BW** — Bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum.
- **Frequency Error** — Difference between the center of the occupied band and the center frequency (**Center Frequency (Hz)**) of the channel

### ACPR

When you set the **Type** of channel measurement to compute and display to ACPR, these fields appear in the measurements panel at the bottom of the scope window.

- **Lower (Rel Power (dBc))** — Ratio of the power of the lower sideband to the power of the main channel
- **Upper (Rel Power (dBc))** — Ratio of the power of the upper sideband to the power of the main channel

To modify the channel measurements programmatically, see the `ChannelMeasurementsConfiguration` object. For more information on these settings in the UI, see “Channel Measurements” on page 2-0 .

### Spectral Mask

Visualize spectrum limits and compare spectrum values to specification values.

Add upper and lower masks to the Spectrum Analyzer to visualize spectrum limits and compare spectrum values to specification values. To enable the **Spectral Mask** tab, select **Spectrum** in the **Analyzer** tab. When you click the **Upper Mask** and **Lower Mask** buttons in the **Spectral Mask** tab, a **Spectral Mask** panel opens at the bottom of the Spectrum Analyzer window. This panel provides information on pass-fail statistics of masks, names of masks currently failing or passing, and names of channels causing the failure.

You can modify the mask settings in the **Spectral Mask** tab. For more information on these settings in the UI, see Spectral Mask on page 2-1322. For modifying the channel measurements programmatically, see the `SpectralMaskConfiguration` object.

### Check Spectral Masks

You can check the status of the spectral mask using the `getSpectralMaskStatus` function. This function gives details on the number of times a mask succeeded or failed, names of channels causing mask failure, and so on.

You can even use the `MaskTestFailed` event to perform an action every time the mask fails. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger it. For more details about using events, see “Events”.

### Customize Visualization

Set configuration and style settings in the Spectrum Analyzer.

To control the settings of the display and labels, color and styling, click on **Settings** () in the **Analyzer** tab of the Spectrum Analyzer toolbar.

In the dialog box that opens, you can customize the font size, plot type, y-axis properties of the spectrum plot, and color map properties of the spectrogram plot. You can change the color of the spectrum plot, background, axes, and labels and also change the line properties.

When you view the spectrum or the spectrogram, you see only the relevant options. For more details about these options, see Configuration > Spectrum Settings on page 2-0 .

### Display Controls

Zoom and pan axes using display controls.

To scale the plot axes, use the mouse to pan around the axes and the scroll button on your mouse to zoom in and out of the plot. Additionally, you can use the buttons that appear when you hover over the plot window.

-  — Maximize the axes, hide all labels and inset the axes values.

-  — Zoom in on the plot.
-  — Pan the plot.
-  — Autoscale the axes to fit the shown data.

## Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a Spectrum Analyzer.

## Algorithms

### Spectrum Estimation — Filter Bank

When you choose the `Filter Bank` method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal  $x(n)$ , of sample rate  $fs$ , into multiple narrow band signals  $y_0(m)$ ,  $y_1(m)$ , ...,  $y_{M-1}(m)$ , of sample rate  $fs/M$ .

The variable  $M$  represents the number of frequency bands in the filter bank. In the Spectrum Analyzer,  $M$  is equal to the number of data points needed to achieve the specified RBW value or 1024, whichever is larger. For more information on the analysis filter bank and its implementation, see the “More About” on page 4-198 and the “Algorithm” on page 4-200 sections in the `dsp.Channelizer` object.

After the Spectrum Analyzer splits the broadband input signal into multiple narrow bands, it computes the power in each narrow frequency band using the following equation. Each  $Z_i$  value is the power estimate over that narrow frequency band.

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

$L$  is length of the narrowband signal  $y_i(m)$  and  $i = 1, 2, \dots, M-1$ .

The power values in all the narrow frequency bands (denoted by  $Z_i$ ) form the  $Z$  vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The Spectrum Analyzer averages the current  $Z$  vector with the previous  $Z$  vectors using one of the two moving average methods: video bandwidth or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 4-1085.

The Spectrum Analyzer uses the value you specify in the **RBW (Hz)** parameter to determine the input frame length. To view the **RBW (Hz)** parameter in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth property **RBW (Hz)**.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to Auto, the Spectrum Analyzer calculates RBW using this equation.

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- The Spectrum Analyzer calculates the number of samples  $N_{samples}$  using this equation.

$$N_{samples} = \frac{F_s}{RBW}$$

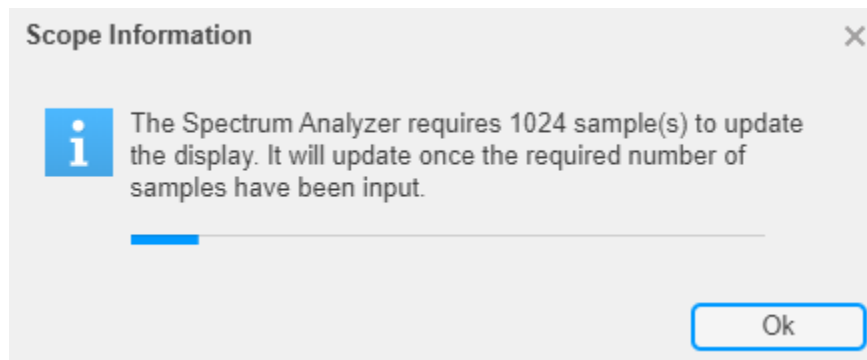

$F_s$  is the sample rate of the input signal as specified in the **Sample Rate (Hz)** property. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you specify a resolution bandwidth using the **RBW (Hz)** parameter, you must specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two.

$$\frac{span}{RBW} > 2$$

$span$  is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Frequency Options** section. To enable this property, set **Frequency Span** to Span and Center Frequency.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

### Spectrum Estimation – Welch's Method

When you select the Welch method, the power spectrum estimate is the averaged modified periodograms.

The algorithm in the Spectrum Analyzer consists of these steps:

- 1 The block buffers the input into  $N$ -point data segments. Each data segment is split into  $P$  overlapping data segments, each of length  $M$ , overlapping by  $D$  points. The data segments can be represented as:

$$x_i(n) = x(n + iD), \quad n = 0, 1, \dots, M - 1$$

$$i = 0, 1, \dots, P - 1$$

- If  $D = M/2$ , the overlap is 50%.
- If  $D = 0$ , the overlap is 0%.

- 2 Apply a window to each of the  $P$  overlapping data segments in the time domain.

The Spectrum Analyzer uses **RBW (Hz)** in the **Analyzer** tab to determine the data window length  $N_{window}$  internally. Then, it partitions the input signal into a number of windowed data segments.

Most window functions afford more influence to the data at the center of the set than to the data at the edges, which represents a loss of information. To mitigate that loss, the individual data sets are commonly overlapped in time. For each windowed segment, compute the periodogram by computing the discrete Fourier transform. Then compute the squared magnitude of the result and divide the result by  $M$ .

$$P_{xx}^i(f) = \frac{1}{MU} \left| \sum_{n=0}^{M-1} x_i(n)w(n)e^{-j2\pi fn} \right|^2, \quad i = 0, 1, \dots, P - 1$$

where  $U$  is the normalization factor for the power in the window function and is given by

$$U = \frac{1}{M} \sum_{n=0}^{M-1} w^2(n)$$

You can specify the window using the **Window** parameter in the **Estimation** tab of the Spectrum Analyzer toolstrip.

- 3 The Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS using the modified Periodogram estimator. For more information about the Periodogram method, see **periodogram**.

To determine the power spectrum estimate for Welch's method, the Spectrum Analyzer averages the result of the periodograms for the last  $P$  data segments. The averaging reduces the variance, compared to the original  $N$ -point data segment. For more details on the averaging, see "Averaging Method" on page 4-1085.

$$\text{PSD}(f) = \frac{1}{P} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 4 The Spectrum Analyzer computes the power spectral density using:

$$\text{PSD}(f) = \frac{1}{P * F_s} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 5 The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by this equation.

$$P_{\text{spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times \text{NENBW}}{N_{\text{window}}}$$

- 6 The Spectrum Analyzer plots the power as a spectrogram in the **Spectrogram** mode. Each line of the spectrogram is one periodogram. The time resolution of each line is  $1/\text{RBW}$ , which is the minimum attainable resolution. Achieving the resolution you want might require combining several periodograms. You then use interpolation to calculate noninteger values of  $1/\text{RBW}$ . In the spectrogram display, time scrolls from top to bottom, so the most recent data appears at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

The Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth (RBW).

$$N_{\text{samples}} = \frac{\left(1 - \frac{O_p}{100}\right) \times \text{NENBW} \times F_s}{\text{RBW}}$$

where  $O_p$  on page 4-1080 is the overlap percentage, NENBW on page 4-1081 is the normalized effective noise bandwidth,  $F_s$  on page 4-1081 is the input sample rate, and RBW on page 4-1081 is the resolution bandwidth.

The Spectrum Analyzer shows the number of samples per update in the Spectrum Analyzer status bar.

You can enable **Samples/Update** in the status bar only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Overlap Percentage ( $O_p$ )

The overlap percentage  $O_p$  is the value you specify in the **Overlap %** property. To view the **Overlap %** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Window Options** section.

When you increase the overlap percentage, the Spectrum Analyzer needs fewer new input samples to compute a new spectral update.

| $O_p$ | $N_{samples}$ |
|-------|---------------|
| 0%    | 100           |
| 50%   | 50            |
| 80%   | 20            |

### Normalized Effective Noise Bandwidth (NENBW)

The normalized effective noise bandwidth  $NENBW$  is a window parameter that measures the noise performance of the window.  $NENBW$  is determined using the window length and the window coefficients, and is given by the following equation:

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[ \sum_{n=1}^{N_{window}} w(n) \right]^2}$$

$w(n)$  denotes the vector of window coefficients (calculated internally).  $N_{window}$  is the window length the Spectrum Analyzer needs to compute one spectral update, and is directly related to the resolution bandwidth and normalized effective noise bandwidth.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

The rectangular window has the smallest  $NENBW$ , with a value of 1. All other windows have a larger  $NENBW$  value. For example, the Hann window has an  $NENBW$  value of approximately 1.5.

The Spectrum Analyzer shows the value of  $NENBW$  in the Spectrum Analyzer status bar.

You can enable  $NENBW$  only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Input Sample Rate ( $F_s$ )

$F_s$  is the sample rate of the input signal. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section. You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **Sample Rate**.

### Resolution Bandwidth (RBW)

Resolution bandwidth controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that the scope can resolve. A smaller value gives a higher spectral resolution and lowers the noise floor, that is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

You can set the resolution bandwidth through the **RBW (Hz)** property. To view **RBW (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to **Auto**, the Spectrum Analyzer calculates using this equation.

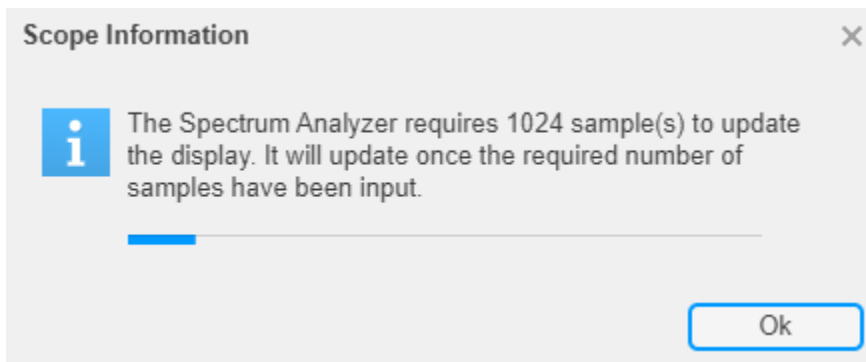

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- Specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

*span* is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. Spectrum Analyzer shows the span through the **Span (Hz)** property. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip, navigate to the **Frequency Options** section, and set **Frequency Span** to **Span and Center Frequency**.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **RBW**.

### Nyquist Frequency Interval

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the Nyquist frequency interval is

$$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

When you clear the **Two-Sided Spectrum**, the Nyquist frequency interval is

$$\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

## Frequency Vector

When you set **Frequency (Hz)** to Auto, the software calculates the frequency vector for the frequency-domain input.

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the frequency vector is:

$$\left[ -\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right]$$

When you clear the **Two-Sided Spectrum**, the frequency vector is:

$$\left[ 0, \frac{\text{SampleRate}}{2} \right]$$

## Occupied BW

The Spectrum Analyzer calculates *Occupied BW* using these steps.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, sum the power distributed in each frequency until the result is

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, sum the power distributed in each frequency until the result reaches

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

## Distortion Measurements

The Spectrum Analyzer calculates Distortion Measurements using these steps.

- 1 Estimate spectral content by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values by treating all these values as if they belong to the peak. Using this method, the algorithm removes all spectral content centered at DC (0 Hz) from the spectrum and records the amount of bandwidth cleared ( $W_0$ ).
- 2 Determine the fundamental power ( $P_1$ ) from the remaining maximum value of the displayed spectrum. Create a local estimate ( $Fe_1$ ) of the fundamental frequency by computing the central moment of the power near the peak. Record the bandwidth of the fundamental power content ( $W_1$ ). Then remove the power from the fundamental as in step 1.
- 3 Determine the power and width of the higher-order harmonics ( $P_2, W_2, P_3, W_3$ , etc.) in succession by examining the frequencies closest to the appropriate multiple of the local estimate ( $Fe_1$ ).

Remove any spectral content that decreases monotonically about the harmonic frequency from the spectrum before proceeding to the next harmonic.

- 4 After removing the DC, fundamental, and harmonic content from the spectrum, examine the power of the remaining spectrum for its sum ( $P_{remaining}$ ), peak value ( $P_{maxspur}$ ), and median value ( $P_{estnoise}$ ).
- 5 Compute the sum of all the removed bandwidth as  $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$ .

Compute the sum of powers of the second and higher-order harmonics as  $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$ .

- 6 Estimate the sum of the noise power as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum})/RBW$$

Where  $dF$  is the absolute difference between frequency bins, and  $RBW$  is the resolution bandwidth of the window.

- 7 Then compute the metrics for SNR, THD, SINAD, and SFDR from the estimates.

$$THD = 10 \cdot \log_{10} \left( \frac{P_{harmonic}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left( \frac{P_1}{P_{harmonic} + P_{noise}} \right)$$

$$SNR = 10 \cdot \log_{10} \left( \frac{P_1}{P_{noise}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left( \frac{P_1}{\max(P_{maxspur}, \max(P_2, P_3, \dots, P_n))} \right)$$

### Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer might exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 Ignore the DC component.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, the Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4  $N^{\text{th}}$  order intermodulation products occur at  $A \cdot F1 + B \cdot F2$ ,

where  $F1$  and  $F2$  are the sinusoid input frequencies and  $|A| + |B| = N$ .  $A$  and  $B$  are integer values.

- 5 For intermodulation measurements, compute the third-order intercept (TOI) point as follows.

- $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = (TOI_{lower} + TOI_{upper})/2$

Where  $P$  is power in decibels of the measured power referenced to 1 milliwatt (dBm).

### Averaging Method

The Spectrum Analyzer can calculate the moving average using two methods:

- Video bandwidth — The Spectrum Analyzer uses a time-domain lowpass filter to smooth the noise in the signal. The video bandwidth (VBW) filter smooths the trace and decreases noise, and the Spectrum Analyzer applies the filter to the data before displaying it.

Video bandwidth is the bandwidth of the lowpass filter that Spectrum Analyzer uses to average or smooth the noise in the signal before displaying it in the scope. The Spectrum Analyzer computes the video bandwidth using this equation:

$$VBW = \frac{(1 - \lambda)RBW}{2\pi\lambda NENBW}$$

where,

- $\lambda$  is the forgetting factor.
- RBW on page 4-1081 is the resolution bandwidth.
- NENBW on page 4-1081 is the normalized effective noise bandwidth.

Video bandwidth does not affect the level of the noise (noise floor), but only increases the signal-to-noise ratio and smooths the trace of the noise. When you decrease the value of VBW, the signal-to-noise ratio improves.

The cutoff frequency of the video bandwidth filter is given by:

$$\omega_c = \frac{2\pi VBW}{F_s/NFFT}$$

where  $F_s$  is the input sample rate and NFFT is the number of FFT points.

The Spectrum Analyzer shows the values of sample rate, VBW, and NFFT in the status bar at the bottom of the display. To enable, right-click the status bar and select **Sample Rate**, **VBW**, and **NFFT**.

- Exponential — The moving average algorithm uses the exponential weighting method to update the weights and compute the moving average recursively for each  $Z$  vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- $\lambda$  — Forgetting factor
- $w_N$  — Weighting factor applied to the current  $Z$  vector
- $z_N$  — Current  $Z$  vector

- $\bar{z}_{N-1}$  — Moving average until the previous  $Z$  vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$  — Effect of the previous  $Z$  vectors on the average
- $\bar{z}_N$  — Moving average including the current  $Z$  vector

## Version History

### Introduced in R2022a

#### R2022b: Channel names support array of strings

Starting in R2022b, you can specify the `ChannelNames` property of the `spectrumAnalyzer` object as an array of strings.

```
sa = spectrumAnalyzer(ChannelNames=["Input", "Output"]);
```

#### R2022b: New FilterSharpness property

When the object uses the filter bank spectral estimation method, you can now increase the sharpness of the filter bank in the `spectrumAnalyzer` object. Increasing the filter sharpness decreases the spectral leakage and gives a more accurate power reading.

#### R2022b: New fields on Spectrum Analyzer status bar

Starting in R2022b, the Spectrum Analyzer displays these fields on the status bar:

- **Updates** -- This field shows when you select **Spectrum updates processed** in the Customize Status Bar window.
- **Channel number** -- This field shows when you select **Spectrogram channel** in the Customize Status Bar window.

The **Spectrogram channel** field is enabled only when the display shows spectrogram.

To enable these fields, right-click the status bar and select the properties in the Customize Status Bar window.

For more details, see "Configure Spectrum Analyzer".

#### R2022b: Support for waveform cursors in spectrogram mode

Starting in R2022b, the Spectrum Analyzer supports data cursors even when the scope shows only the spectrogram display.

In the command line, you can edit the `CursorMeasurementsConfiguration` object when you set the `ViewType` to "spectrogram".

#### R2022b: Enhancements to Data Cursor Measurements

Starting in R2022b, the `CursorMeasurementsConfiguration` object has the new `LockSpacing` property. Using this property, you can lock the spacing between waveform cursors in the scope window.

In the **Measurements** tab of the scope UI window, these data cursor settings are new:

- **Lock cursor spacing** -- This setting corresponds to the `LockSpacing` property in the `CursorMeasurementsConfiguration` object.
- **X location** -- These fields are enabled and correspond to the `XLocation` property in the `CursorMeasurementsConfiguration` object.

### **R2023a: SampleRate and PlotAsTwoSidedSpectrum properties are tunable**

Starting in R2023a, the `SampleRate` and `PlotAsTwoSidedSpectrum` properties are tunable, so you can change the values of these properties even when the object is locked.

## **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `spectrumAnalyzer` object supports MEX code generation by treating the calls to the object as extrinsic.
- The object does not support code generation for standalone applications.

## **dsp.SpectrumAnalyzer**

**Package:** dsp

(To be removed) Display frequency spectrum of time-domain signals

---

### **Note**

- The `dsp.SpectrumAnalyzer` object will be removed in a future release. Use the `spectrumAnalyzer` MATLAB® object instead.
- The `CCDFMeasurements` property of the `dsp.SpectrumAnalyzer` object will be removed in a future release. Use the `powermeter` object instead to compute and visualize CCDF measurements.

For more information on how to replace your existing code, see [“Compatibility Considerations”](#).

---

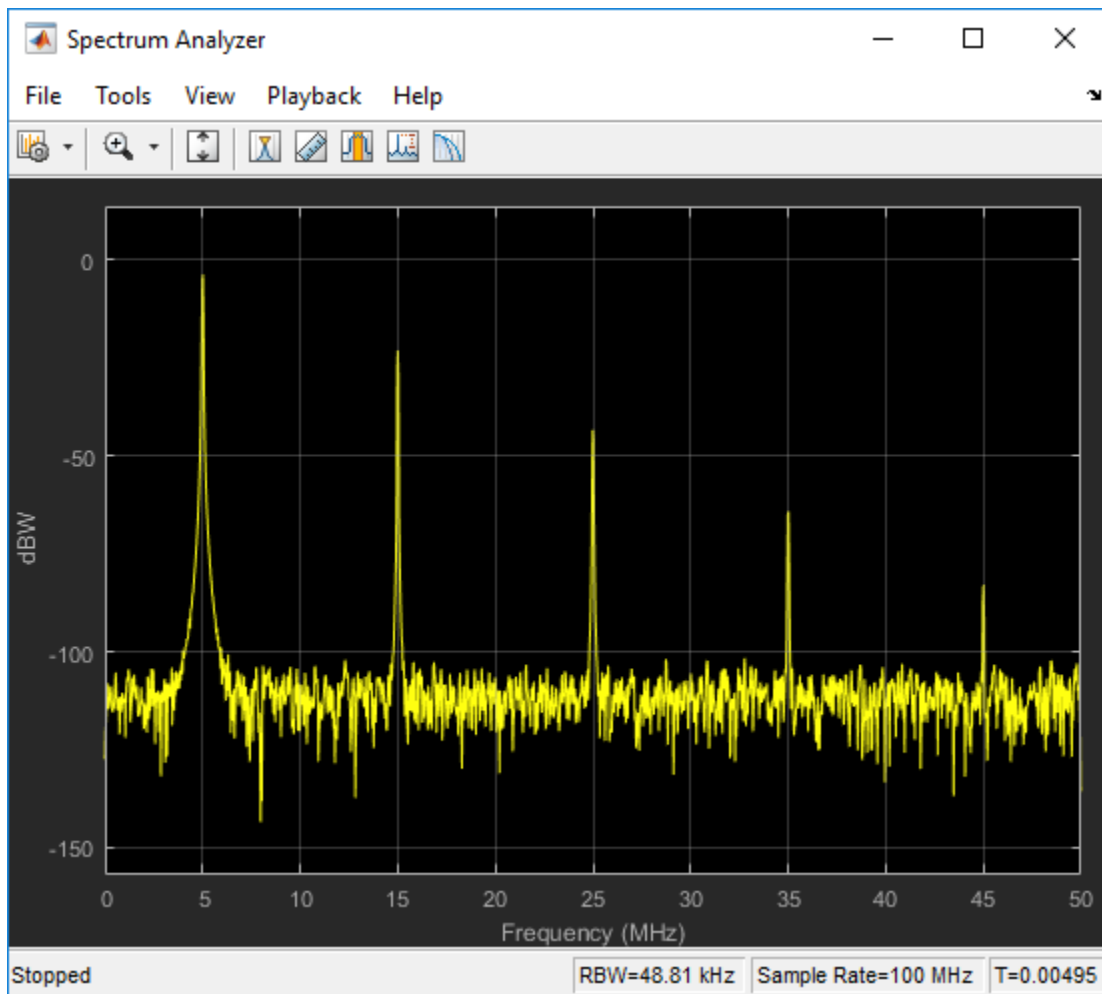

### **Description**

The Spectrum Analyzer System object displays the frequency spectrum of time-domain signals. This scope supports variable-size input, which allows the input frame size to change. Frame size is the first dimension of the input vector. The number of input channels must remain constant.

To display the spectra of signals in the Spectrum Analyzer:

- 1** Create the `dsp.SpectrumAnalyzer` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
scope = dsp.SpectrumAnalyzer
scope = dsp.SpectrumAnalyzer(ports)
scope = dsp.SpectrumAnalyzer(Name,Value)
```

### Description

`scope = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`scope = dsp.SpectrumAnalyzer(ports)` creates a Spectrum Analyzer object and sets the `NumInputPorts` property to the value of `ports`.

`scope = dsp.SpectrumAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### Frequently Used

#### **NumInputPorts** — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

#### **InputDomain** — Domain of input signal

"Time" (default) | "Frequency"

The domain of the input signal you want to visualize, specified as "Time" or "Frequency". If you visualize time-domain signals, the Spectrum Analyzer transforms the signal to the frequency spectrum based on the algorithm specified in the `Method` property.

#### **Scope Window Use**

In the **Estimation** tab on the Spectrum Analyzer toolstrip, set **Input Domain** to Time or Frequency.

Data Types: char | string

#### **SpectrumType** — Spectrum type

"Power" (default) | "Power density" | "RMS"

Spectrum type, specified as one of these:

"Power" — Power spectrum

"Power density" — Power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 Hz.

"RMS" — Root mean square. The root mean square shows the square root of the mean square. Use this option to view the frequency of voltage or current signals.

**Tunable:** Yes

#### **Dependency**

To enable this property, set `InputDomain` to "Time".

#### **Scope Window Use**

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, select **Spectrum**. Click **Spectrum** to select Power, Power Density, or RMS.

To enable these options, set the **Input Domain** on the **Estimation** tab to Time.

Data Types: char | string

### ViewType – Viewer type

"Spectrum" (default) | "Spectrogram" | "Spectrum and spectrogram"

Specify the spectrum type as one of "Spectrum", "Spectrogram", or "Spectrum and spectrogram".

- "Spectrum" — Shows the power spectrum.
- "Spectrogram" — Shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- "Spectrum and Spectrogram" — Shows a dual view of a spectrum and spectrogram.

**Tunable:** Yes

### Scope Window Use

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, select **Spectrum**, **Spectrogram**, or both.

Data Types: char | string

### SampleRate – Sample rate of input

10000 (default) | finite scalar

Specify the sample rate, in hertz, of the input signals as a finite numeric scalar.

### Scope Window Use

Open the **Spectrum Settings**. In the **Main options** section, set **Sample rate (Hz)**.

### Method – Spectrum estimation method

"Filter Bank" (default) | "Welch"

Spectrum estimation method, specified as one of the following:

- "Filter bank" -- Use an analysis filter bank to estimate the power spectrum. Compared to Welch's method, this method has a lower noise floor, better frequency resolution, and lower spectral leakage and requires fewer samples per update.
- "Welch" -- Use Welch's method of averaged modified periodograms.

For more details on these methods, see "Algorithms" on page 2-1335.

**Tunable:** Yes

### Dependency

To enable this property, set InputDomain to "Time".

### Scope Window Use

In the **Estimation** tab of the Spectrum Analyzer toolstrip, set **Method** to Filter bank or Welch.

To enable this parameter, set **Input Domain** to Time in the **Estimation** tab.

Data Types: char | string

**PlotAsTwoSidedSpectrum — Option to plot a two-sided spectrum**`true (default) | false`

Option to plot a two-sided spectrum, specified as one of the following:

- `true` — Compute and plot two-sided spectral estimates. When the input signal is complex valued, you must set this property to `true`.
- `false` — Compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued.

When you set this property to `false`, the Spectrum Analyzer uses power-folding. The y-axis values are twice the amplitude that they would be if you were to set this property to `true`, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

**Tunable:** Yes

**Scope Window Use**

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) of the Spectrum Analyzer toolstrip. In the **Trace Options** section, select **Two-Sided Spectrum** to compute and plot two-sided spectral estimates.

Data Types: `logical`

**FrequencyScale — Frequency scale**`"Linear" (default) | "Log"`

Scale to display frequency, specified as one of the following:

- `"Linear"` — Use a linear scale to display frequencies on the x-axis. To use the `"Linear"` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `true`.
- `"Log"` — Use a logarithmic scale to display frequencies on the x-axis. To use the `"Log"` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`.

**Tunable:** Yes

**Scope Window Use**

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) of the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Frequency Scale** to `Linear` or `Log`.

To set the **Frequency Scale** to `Log`, clear the **Two-Sided Spectrum** check box in the **Trace Options** section in the **Spectrum** or the **Spectrogram** tab (if enabled). If you select the **Two-Sided Spectrum** check box, then you must set the **Frequency Scale** to `Linear`.

Data Types: `char` | `string`

**Advanced****FrequencySpan — Frequency span mode**`"Full" (default) | "Span and center frequency" | "Start and stop frequencies"`

Frequency span mode, specified as one of the following:

- "Full" -- The Spectrum Analyzer computes and plots the spectrum over the entire "Nyquist Frequency Interval" on page 4-1124.
- "Span and center frequency" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- "Start and stop frequencies" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

**Tunable:** Yes

**Dependency**

To enable this property, set InputDomain to "Time".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Full, Span and Center Frequency, or Start and Stop Frequencies.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

**Span — Frequency span to compute spectrum**

10e3 (default) | real positive scalar

Specify the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. The overall span, defined by this property and the CenterFrequency property, must fall within the "Nyquist Frequency Interval" on page 4-1124.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to "Span and center frequency".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** check box and set Span.

**StartFrequency — Start frequency to compute spectrum**

-5e3 (default) | real scalar

Start of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and StopFrequency, must fall within the "Nyquist Frequency Interval" on page 4-1124.

**Tunable:** Yes

**Dependency**

To enable this property, set FrequencySpan to "Start and stop frequencies".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStart (Hz)**.

### StopFrequency — Stop frequency to compute spectrum

5e3 (default) | real scalar

End of the frequency interval over which spectrum is computed, specified in hertz as a real scalar. The overall span, which is defined by this property and the StartFrequency property, must fall within the “Nyquist Frequency Interval” on page 4-1124.

**Tunable:** Yes

#### Dependency

To enable this property, set FrequencySpan to "Start and stop frequencies".

#### Scope Window Use

Open the **Spectrum Settings**. In the **Main options** section, clear the **Full frequency span** and change Span to FStart. Set **FStop (Hz)**.

### CenterFrequency — Center of frequency span

0 (default) | real scalar

Specify in hertz the center frequency of the span over which the Spectrum Analyzer computes and plots the spectrum. The overall frequency span, defined by the Span and this property, must fall within the “Nyquist Frequency Interval” on page 4-1124.

**Tunable:** Yes

#### Dependency

To enable this property, set FrequencySpan to "Span and center frequency".

#### Scope Window Use

Open the **Spectrum Settings**. In the **Main**, clear **Full frequency span** and set **CF (Hz)**.

### FrequencyResolutionMethod — Frequency resolution method

"RBW" (default) | "WindowLength" | "NumFrequencyBands"

Specify the frequency resolution method of the Spectrum Analyzer.

- "RBW" - The RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. The FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.
- "WindowLength" - Applies only when the Method property is set to "Welch". The WindowLength property controls the frequency resolution. You can control the number of FFT points only when the FrequencyResolutionMethod property is "WindowLength".
- "NumFrequencyBands" - Applies only when the Method property is set to "Filter Bank". The FFTLengthSource and FFTLength properties control the frequency resolution.

**Tunable:** Yes

#### Dependency

To enable this property, set InputDomain to "Time".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, set the frequency resolution method by selecting the **RBW (Hz)** dropdown.

Data Types: char | string

**RBWSource — Source of resolution bandwidth value**

"Auto" (default) | "Property"

Specify the source of the resolution bandwidth (RBW) as either "Auto" or "Property".

- "Auto" — The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- "Property" — Specify the resolution bandwidth directly using the RBW property.

**Tunable:** Yes

**Dependency**

To enable this property, set either:

- InputDomain to "Time" and FrequencyResolutionMethod to "RBW".
- InputDomain to "Frequency".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

Data Types: char | string

**RBW — Resolution bandwidth**

9.76 (default) | real positive scalar

RBW controls the spectral resolution of Spectrum Analyzer. Specify the resolution bandwidth in hertz as a real positive scalar. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two:

$$\frac{\text{span}}{\text{RBW}} > 2$$

You can specify the overall span in different ways based on how you set the FrequencySpan property.

**Dependency**

To enable, set:

- RBWSource to "Property"

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, set **RBW (Hz)**.

**WindowLength — Window length**

1024 (default) | integer greater than 2

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2.

**Tunable:** Yes

### Dependencies

To enable this property, set:

- FrequencyResolutionMethod to "WindowLength", which controls the frequency resolution based on your window length setting
- Method to "Welch"

### Scope Window Use

Open the **Spectrum Settings**. Change the **RBW (Hz)** dropdown to Window length.

### FFTLengthSource — Source of the FFT length

"Auto" (default) | "Property"

- "Auto" - sets the FFT length to the window length specified in the WindowLength property or 1024, whichever is larger.
- "Property" - number of FFT points using the FFTLength property. FFTLength must be greater than WindowLength.

**Tunable:** Yes

### Dependency

To enable this property, set FrequencyResolutionMethod to "WindowLength".

### Scope Window Use

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

Data Types: char | string

### FFTLength — Length of FFT

1024 (default) | positive integer

Specify the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates.

If FrequencyResolutionMethod is "RBW", the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

**Tunable:** Yes

### Dependencies

To use this property, the following must be true:

- FrequencyResolutionMethod is set to "WindowLength" or "NumFrequencyBands"
- FFTLength is greater than or equal to the WindowLength.
- FFTLengthSource is set to "Property".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, next to the **RBW (Hz)** option, enter a number or select Auto.

**NumTapsPerBand — Number of filter taps per frequency band**

12 (default) | positive even scalar

Specify the number of filter taps or coefficients for each frequency band. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to NumTapsPerBand + FFTLength.

**Dependency**

To enable this property, set Method to "Filter Bank"

**Scope Window Use**

Open the **Spectrum Settings**. In the **Main options** section, set **Taps per band**.

**FrequencyVectorSource — Source of frequency vector**

"Auto" (default) | "Property"

- "Auto" — The frequency vector is calculated from the length of the input. See "Frequency Vector" on page 4-1124.
- "Property" — Enter a custom vector as the frequency vector.

**Dependency**

To enable this property, set InputDomain to "Frequency".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Frequency (Hz)**.

Data Types: char | string

**FrequencyVector — Custom frequency vector**

[-5000 5000] (default) | monotonically increasing vector

Custom frequency vector, specified as a monotonically increasing vector. This vector determines the x-axis of the display. The vector must be monotonically increasing and must have the same length as the input signal frame size.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "Frequency".
- FrequencyVectorSource to "Property".

to .

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Frequency (Hz)** to a monotonically increasing vector of length equal to the input signal frame size.

To enable the **Frequency (Hz)**, set **Input Domain** to Frequency.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OverlapPercent – Overlap percentage**

0 (default) | real, scalar value

The percentage overlap between the previous and current buffered data segments, specified as a real, scalar value. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

**Tunable:** Yes

**Scope Window Use**

Open the **Spectrum Settings**. In the **Window options** section, set **Overlap (%)**.

**Window – Window function**

"Hann" (default) | "Rectangular" | "Chebyshev" | "Flat Top" | "Hamming" | "Kaiser" | "Blackman-Harris" | "Custom"

Specify a window function for the spectral estimator. The following table shows preset windows. For more information, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

| Window Option     | Corresponding Signal Processing Toolbox Function |
|-------------------|--|
| "Rectangular"     | rectwin  |
| "Chebyshev"       | chebwin  |
| "Flat Top"        | flattopwin                                       |
| "Hamming"         | hamming  |
| "Hann"            | hann   |
| "Kaiser"          | kaiser   |
| "Blackman-Harris" | blackmanharris                                   |

To set your own spectral estimation window, set this property to "Custom" and specify a custom window function in the CustomWindow property.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "Time".
- Method to "Welch"

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Window**.

To enable the **Window**, set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: char | string

**CustomWindow — Name of custom window function**

"hann" (default) | character vector | string scalar

Name of the custom window function, specified as a character vector or string scalar. The name of the custom window function must be on the MATLAB path. Use this property if you want to customize the window using additional properties available with the Signal Processing Toolbox version of the window function.

**Tunable:** Yes

**Example**

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, 'periodic')
end

scope.Window = 'Custom';
scope.CustomWindow = 'my_hann'
```

**Dependency**

To use this property, set Window to "Custom".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, for the **Window**, enter the name of the custom window function.

Data Types: char | string

**SidelobeAttenuation — Sidelobe attenuation of window**

60 (default) | real positive scalar

The window sidelobe attenuation, in decibels (dB). The value must be greater than or equal to 45.

**Tunable:** Yes

**Dependency**

To enable this property, set Window to "Chebyshev" or "Kaiser".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Window options** section, set **Attenuation (dB)**.

**InputUnits — Units of frequency input**

"dBm" (default) | "dBV" | "dBW" | "Vrms" | "Watts"

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the SpectrumUnits property.

#### Dependency

This option is only available when InputDomain is set to Frequency.

#### Scope Window Use

Open the **Spectrum Settings**. In the **Frequency input options** section, set **Input units**.

Data Types: char | string

#### SpectrumUnits — Units of the spectrum

"dBm" (default) | "dBFS" | "dBV" | "dBW" | "Vrms" | "Watts" | "dBm/Hz" | "dBW/Hz" | "dBFS/Hz" | "Watts/Hz" | "Auto"

Specify the units in which the Spectrum Analyzer displays power values.

**Tunable:** Yes

#### Dependency

The spectrum units available depend on the value you specify in the SpectrumType property.

| InputDomain | SpectrumType    | Allowed SpectrumUnits                        |
|-------------|-----------------|--|
| "Time"      | "Power"         | "dBm", "dBW", "dBFS", "Watts"                |
|             | "Power density" | "dBm/Hz", "dBW/Hz", "dBFS/Hz", "Watts/Hz"    |
|             | "RMS"           | "dBV", "Vrms"                                |
| "Frequency" | —               | "Auto", "dBm", "dBV", "dBW", "Vrms", "Watts" |

If you set the InputDomain property to "Frequency" and the SpectrumUnits property to "Auto", the Spectrum Analyzer assumes the spectrum units to be equal to input units specified in the InputUnits property. If you set InputDomain to "Time" and SpectrumUnits to any option other than "Auto", then the Spectrum Analyzer converts the units specified in InputUnits to the units specified in SpectrumUnits.

#### Scope Window Use

Click the **Spectrum** tab on the Spectrum Analyzer toolbar. In the **Scale** section, set **Spectrum Unit**.

Data Types: char | string

#### FullScaleSource — Source of full scale

"Auto" (default) | "Property"

Specify the source of the dBFS scaling factor as either "Auto" or "Property".

- "Auto" -- The Spectrum Analyzer adjusts the scaling factor based on the input data.
- "Property" -- Specify the full-scale scaling factor using the FullScale property.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "Time"
- SpectrumType to "Power" or "Power density"
- SpectrumUnits to "dBFS" or "dBFS/Hz" (when spectrum type is set to "Power density")

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Full Scale** to either Auto or a positive scalar.

To enable the **Full Scale**:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

Data Types: char | string

**FullScale — Full scale**

1 (default) | positive scalar

Specify a real positive scalar for the dBFS full scale.

**Tunable:** Yes

**Dependency**

To enable this option set:

- SpectrumUnits to "dBFS"
- FullScaleSource to "Property"

**Scope Window Use**

Open the **Spectrum Settings**. In the **Trace options** section, set **Full scale** to Auto or enter a number.

**AveragingMethod — Smoothing method**

"VBW" (default) | "Exponential"

Averaging method, specified as one of the following:

- "VBW" — Video bandwidth method. The object uses a lowpass filter to smooth the trace and decrease noise. Use the VBWSource and VBW properties to specify the VBW value.
- "Exponential" — Weighted average of samples. The object computes the average over samples weighted by an exponentially decaying forgetting factor. Use the ForgettingFactor property to specify the weighted forgetting factor.

For more information, see "Averaging Method" on page 2-1343.

**Tunable:** Yes

### Dependency

To enable this property, set `InputDomain` to "Time".

### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **Averaging Method** to VBW or Exponential.

To enable the **Averaging Method**, set **Input Domain** to Time.

Data Types: char | string

### SpectralAverages — Number of spectral averages

1 (default) | positive integer

The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last  $N$  power spectrum estimates. This property defines  $N$ .

**Tunable:** Yes

### Dependency

To enable this property, set `ViewType` to "Spectrum".

### Dependency

This property applies only when the `AveragingMethod` is "Running".

### Scope Window Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Averages**.

### ForgettingFactor — Weighting forgetting factor

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting as a scalar value greater than 0 and less than or equal to 1.

### Dependency

This property applies only when the `AveragingMethod` is "Exponential".

### Scope Window Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Forgetting factor**.

### ReferenceLoad — Reference load

1 (default) | real positive scalar

The load the scope uses as a reference to compute power levels.

**Tunable:** Yes

### Scope Window Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Ref. load (Ohms)**.

### FrequencyOffset — Frequency offset

0 (default) | scalar | vector

- **Scalar** — Apply the same frequency offset to all channels, specified in hertz as a character vector.
- **Vector** — apply a specific frequency offset for each channel, specify a vector of frequencies. The vector length must be equal to number of input channels.

The frequency-axis values are offset by the values specified in this property. The overall span must fall within the “Nyquist Frequency Interval” on page 4-1124. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

**Tunable:** Yes

#### Scope Window Use

Open the **Spectrum Settings**. In the **Trace options** section, set **Offset (Hz)**.

### Spectrogram

#### **SpectrogramChannel** — Channel for which spectrogram is plotted

1 (default) | positive scalar integer

Specify the channel for which the spectrogram is plotted, as a real, positive scalar integer in the range [1  $N$ ], where  $N$  is the number of input channels.

**Tunable:** Yes

#### Dependency

To enable this property, set `ViewType` to "Spectrogram" or "Spectrum and spectrogram".

#### Scope Window Use

Open the **Spectrum Settings**. In the **Spectrogram options** section, select a **Channel**.

#### **TimeResolutionSource** — Source of the time resolution value

"Auto" (default) | "Property"

Specify the source for the time resolution of each spectrogram line as either "Auto" or "Property". The `TimeResolution` property shows the time resolution for the different frequency resolution methods and time resolution properties.

**Tunable:** Yes

#### Dependency

To enable this property, set `ViewType` to "Spectrogram" or "Spectrum and spectrogram".

#### Scope Window Use

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Resolution (s)** to Auto or enter a positive scalar.

To enable the **Time Resolution (s)**, select **Spectrogram** in the **Analyzer** tab.

Data Types: char | string

#### **TimeResolution** — Time resolution

0.001 (default) | positive scalar

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds.

The Spectrum Analyzer determines the time resolution value based on the frequency resolution method, RBW, and time resolution properties.

| Method               | RBW              | Time Resolution  | Resulting Time Resolution in Seconds  |
|----------------------|------------------|------------------|---|
| Welch or Filter Bank | Auto             | Auto             | 1/RBW   |
| Welch or Filter Bank | Auto             | Manually entered | 1/Time Resolution Hz  |
| Welch or Filter Bank | Manually entered | Auto             | 1/RBW seconds   |
| Welch or Filter Bank | Manually entered | Manually entered | Equal to or greater than the minimum attainable time resolution 1/RBW. The Spectrum Analyzer combines several spectral estimates into one spectrogram line to obtain the desired time resolution. It uses interpolation to obtain time resolution values that are not integer multiples of 1/RBW. |

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to "Spectrogram" or "Spectrum and spectrogram"
- TimeResolutionSource to "Property".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time res (s)** box, enter a number.

**TimeSpanSource — Source of time span value**

"Auto" (default) | "Property"

Source for the time span of the spectrogram, specified as either "Auto" or "Property". If you set this property to "Auto", the spectrogram displays 100 spectrogram lines at any given time. If you set this property to "Property", the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolbar. In the **Time Options** section, set the **Time Span (s)** to Auto or enter a positive scalar.

Data Types: char | string

**TimeSpan — Time span**

0.1 (default) | positive scalar

Specify the time span of the spectrogram display in seconds. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

**Tunable:** Yes**Dependency**

To enable this property, set:

- ViewType to "Spectrogram" or "Spectrum and spectrogram".
- TimeSpanSource to "Property".

**Scope Window Use**

Open the **Spectrum Settings**. In the **Spectrogram options** section, in the **Time span (s)** box, enter a number.

**Measurements****MeasurementChannel — Channel for which measurements are obtained**

1 (default) | positive integer

Channel for which the measurements are obtained, specified as a real, positive integer greater than 0 and less than or equal to 100. The maximum number you can specify is the number of channels (columns) in the input signal.

**Tunable:** Yes**Scope Window Use**

Click on **Tools > Measurements** and open the **Trace Selection** settings.

Data Types: double

**SpectralMask — Spectral mask lines**

SpectralMaskSpecification object

Specify whether to display upper and lower spectral mask lines on a spectrum plot. This property uses properties from a SpectralMaskSpecification object to enable and configure the spectral masks.

**Tunable:** Yes**Scope Window Use**

Open the **Spectral Mask** pane and modify the **Settings** options.

**PeakFinder — Peak finder measurement**

PeakFinderConfiguration object

Peak finder measurement, specified as a PeakFinderConfiguration object. Enable peak finder to compute and display the largest calculated peak values. All PeakFinderConfiguration properties are tunable.

**Tunable:** Yes

### Dependency

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the peak finder measurements in the **Peaks** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### CursorMeasurements — Cursor measurements

`CursorMeasurementsConfiguration` object

Cursor measurements, specified as a `CursorMeasurementsConfiguration` object. Enable cursor measurements to display waveform cursors. All `CursorMeasurementsConfiguration` properties are tunable.

**Tunable:** Yes

### Dependency

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the cursor measurements in the **Cursors** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### ChannelMeasurements — Channel measurements

`ChannelMeasurementsSpecification` object

Enable channel measurements to compute and display the occupied bandwidth or adjacent channel power ratio. The `ChannelMeasurements` property uses the `ChannelMeasurementsSpecification` properties.

The `ChannelMeasurementsSpecification` properties are:

- `Algorithm` -- Type of measurement data to display, specified as either "Occupied BW" or "ACPR".  
Default: "Occupied BW"
- `FrequencySpan` -- Frequency span mode, specified as either "Span and center frequency" or "Start and stop frequencies"  
Default: "Span and center frequency"
- `Span` -- Frequency span over which the channel measurements are computed, specified as a real, positive scalar in Hz. This property applies when you set the `FrequencySpan` property to "Span and center frequency".  
Default: 2000 Hz
- `CenterFrequency` -- Center frequency of the span over which the channel measurements are computed, specified as a real scalar in Hz. This property applies when you set the `FrequencySpan` property to "Span and center frequency".

Default: 0 Hz

- **StartFrequency** -- Start frequency over which the channel measurements are computed, specified as a real scalar in Hz. This property applies when you set the **FrequencySpan** property to "Start and stop frequencies".

Default: -1000 Hz

- **StopFrequency** -- Stop frequency over which the channel measurements are computed, specified as a real scalar in Hz. This property applies when you set the **FrequencySpan** property to "Start and stop frequencies".

Default: 1000 Hz

- **PercentOccupiedBW** -- Percent of power over which to compute the occupied bandwidth, specified as a positive real scalar. This property applies when you set the **Algorithm** property to "Occupied BW".

Default: 99

- **NumOffsets** -- Number of adjacent channel pairs, specified as a real, positive integer. This property applies when you set the **Algorithm** property to "ACPR".

Default: 2

- **AdjacentBW** -- Adjacent channel bandwidth, specified as a real, positive scalar. This property applies when you set the **Algorithm** property to "ACPR".

Default: 1000

- **FilterShape** -- Filter shape for both main and adjacent channels, specified as "None", "Gaussian", or "RRC". This property applies when you set the **Algorithm** property to "ACPR".

Default: "None"

- **FilterCoeff** -- Channel filter coefficient, specified as a real scalar between 0 and 1. This property applies when you set the **Algorithm** property to "ACPR" and the **FilterShape** property to either "Gaussian" or "RRC".

Default: 0.5

- **ACPROffsets** -- Frequency of the adjacent channel relative to the center frequency of the main channel, specified as a real vector of length equal to the number of offset pairs specified in **NumOffsets**. This property applies when you set the **Algorithm** property to "ACPR".

Default: [2000 3500]

- **Enable** -- Set this property to **true** to enable channel measurements. Valid values are **true** or **false**.

Default: false

All **ChannelMeasurementsSpecification** properties are tunable.

### Scope Window Use

Open the **Channel Measurements** pane () and modify the **Measurement** and **Channel Settings** options.

### DistortionMeasurements — Distortion measurements

*DistortionMeasurementsConfiguration* object

Distortion measurements, specified as a `DistortionMeasurementsConfiguration` object. Enable distortion measurements to compute and display the harmonic distortion and intermodulation distortion. All `DistortionMeasurementsConfiguration` properties are tunable.

**Tunable:** Yes

### Dependency

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the distortion measurements in the **Distortion** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### Visualization

#### Name — Caption to display in spectrum Analyzer window

"Spectrum Analyzer" (default) | character vector | string scalar

Caption to display in the scope window, specified as a character vector or string scalar.

**Tunable:** Yes

Data Types: char | string

#### Position — Window position

screen center (default) | [left bottom width height]

Spectrum Analyzer window position in pixels, specified by the size and location of the scope window as a four-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The exact center coordinates depend on your screen resolution.

**Tunable:** Yes

#### PlotType — Plot type to display normal traces

"Line" (default) | "Stem"

Plot type to display normal traces, specified as "Line" or "Stem". Normal traces are traces that display free-running spectral estimates.

**Tunable:** Yes

### Dependencies

To enable this property, set:

- `ViewType` to "Spectrum" or "Spectrum and spectrogram".
- `PlotNormalTrace` to true.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip, navigate to the **Configuration** section and click **Settings**. In the Spectrum Analyzer Settings window, under **Display and Labels**, set **Plot Type** to Line or Stem.

To enable the **Plot Type**, you must:

- Select **Spectrum** in the **Views** section of the **Analyzer** tab.
- Enable the **Normal Trace** check box in the **Trace Options** section of the **Spectrum** tab.

Data Types: char | string

**PlotNormalTrace — Normal trace flag**

true (default) | false

To remove normal traces from the display, set this property to `false`. These traces display the free-running spectral estimates. The Spectrum Analyzer continues its spectral computations even when you set this property to `false`.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Normal Trace** check box in the **Trace Options** section.

To enable the **Normal Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: logical

**PlotMaxHoldTrace — Max-hold trace flag**

false (default) | true

To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Max-Hold Trace** check box in the **Trace Options** section.

To enable the **Max-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: logical

**PlotMinHoldTrace — Min-hold trace flag**`false (default) | true`

To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Min-Hold Trace** check box in the **Trace Options** section.

To enable the **Min-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**Title — Display title**`'' (default) | character vector | string scalar`

Display title, specified as a character vector or a string scalar.

**Tunable:** Yes

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Title**.

Data Types: `char | string`

**YLabel — Y-axis label**`'' (default) | character vector | string scalar`

y-axis label, specified as a character vector or a string scalar. The Spectrum Analyzer displays the label to the left of the y-axis.

Regardless of the value of this property, Spectrum Analyzer always displays power units as one of the `SpectrumUnits` values.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Y-Label**.

To enable the **Y-Label**, select **Spectrum** in the **Analyzer** tab.

Data Types: char | string

### ShowLegend — Flag to show legend

false (default) | true

Flag to show the legend, specified as true or false. To show a legend with the input names, set this property to true.

Use the legend to control which signals are visible. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

### Dependencies

To enable this property, set the ViewType property to "Spectrum" or "Spectrum and spectrogram".

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

Data Types: logical

### ChannelNames — Channel names

empty cell (default) | cell array of character vectors | array of strings

Channel names in the input data, specified as a cell array of character vectors or an array of strings. The names you specify in this property appear in the following locations:

- Legend
- **Spectrum Analyzer Settings > Color and styling** section
- **Measurements** and **Channel Measurements** tabs

If you do not specify channel names, the Spectrum Analyzer names the channels as Channel 1, Channel 2, and so on.

**Tunable:** Yes

### Dependency

To see the channel names, set ShowLegend to true.

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

Data Types: char

### ShowGrid — Flag to show grid

true (default) | false

Flag to show the grid, specified as `true` or `false`. Set this property to `true` to show grid lines in the plot.

**Tunable:** Yes

#### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that appears, under **Display and Labels**, select **Show Grid**.

Data Types: `logical`

#### **YLimits — Y-axis limits**

`[-80, 20]` (default) | `[ymin ymax]`

y-axis limits, specified as a two-element numeric vector of the form `[ymin ymax]`. The units of the y-axis limits depend on the `SpectrumUnits` property.

Example: `scope.YLimits = [-10,20]`

**Tunable:** Yes

#### **Dependencies**

- To enable this property, set the `ViewType` property to "Spectrum" or "Spectrum and spectrogram".
- The units directly depend upon the `SpectrumUnits` property.

#### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Y-Axis Limits**.

To enable the **Y-Axis Limits**, select **Spectrum** in the **Analyzer** tab.

#### **ColorLimits — Scale spectrogram color limits**

`[-80, 20]` (default) | `[colorMin colorMax]`

Color limits of the spectrogram, specified as a two-element numeric vector of the form `[colorMin colorMax]`. The units of the color limits directly depend upon the `SpectrumUnits` property.

Example: `scope.ColorLimits = [-10,20]`

**Tunable:** Yes

#### **Dependencies**

- To enable this property, set the `ViewType` property to "Spectrogram" or "Spectrum and spectrogram".
- The units directly depend upon the `SpectrumUnits` property.

#### **Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Color Limits**.

To enable the **Color Limits**, select **Spectrogram** in the **Analyzer** tab.

### AxesScaling — Axes scaling mode

"Auto" (default) | "Manual" | "OnceAtStop" | "Updates"

Axes scaling mode, specified as one of these:

- "Auto" — The scope scales the axes to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes after a specific number of visual updates. It determines the number of updates using the `AxesScalingNumUpdates` property.

**Tunable:** Yes

Data Types: char | string

### AxesLayout — Orientation of the spectrum and spectrogram

"Vertical" (default) | "Horizontal"

Layout of the axes, specified as one of "Vertical" or "Horizontal". A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side.

**Tunable:** Yes

#### Dependency

To enable this property, set `ViewType` to "Spectrum and spectrogram".

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. Select **Spectrum** and **Spectrogram**. In the **Configuration** section, select and update **Layout**.

Data Types: char | string

## Usage

### Syntax

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

### Description

`scope(signal)` updates the spectrum of the signal in the spectrum analyzer.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the spectrum analyzer. The signals must have the same frame length, but can vary in number of channels. You must set the `NumInputPorts` property to enable multiple input signals.

### Input Arguments

#### signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.SpectrumAnalyzer`. Signals can have a different number of channels, but must have the same frame length.

Example: `scope(signal1, signal2)`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.SpectrumAnalyzer`

|                                    |   |
|------------------------------------|---|
| <code>generateScript</code>        | Generate MATLAB script to create scope with current settings        |
| <code>getMeasurementsData</code>   | Get the current measurement data displayed on the spectrum analyzer |
| <code>getSpectralMaskStatus</code> | Get test results of current spectral mask                           |
| <code>getSpectrumData</code>       | Save spectrum data shown in spectrum analyzer                       |
| <code>isNewDataReady</code>        | Check spectrum analyzer for new data                                |

### Specific to Scopes

|                        |                               |
|------------------------|-------------------------------|
| <code>show</code>      | Display scope window          |
| <code>hide</code>      | Hide scope window             |
| <code>isVisible</code> | Determine visibility of scope |

### Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

## Examples

### Spectrum Analyzer for One-Sided Power Spectrum

View a one-sided power spectrum made from the sum of fixed real sine waves with different amplitudes and frequencies.

```
Fs = 100e6; % Sampling frequency  
fSz = 5000; % Frame size
```

```
sin1 = dsp.SineWave(1e0, 5e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);  
sin2 = dsp.SineWave(1e-1,15e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);  
sin3 = dsp.SineWave(1e-2,25e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);  
sin4 = dsp.SineWave(1e-3,35e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);  
sin5 = dsp.SineWave(1e-4,45e6,0,'SamplesPerFrame',fSz,'SampleRate',Fs);
```

```

scope = dsp.SpectrumAnalyzer;
scope.SampleRate = Fs;
scope.SpectralAverages = 1;
scope.PlotAsTwoSidedSpectrum = false;
scope.RBWSource = 'Auto';
scope.PowerUnits = 'dBW';
for idx = 1:1e2
    y1 = sin1();
    y2 = sin2();
    y3 = sin3();
    y4 = sin4();
    y5 = sin5();
    scope(y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end

```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(scope)
```

Run the `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

### Spectrum Analyzer For Two-Sided Power Spectrum

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```

sin = dsp.SineWave('Frequency',100,'SampleRate',1000);
sin.SamplesPerFrame = 1000;
scope = dsp.SpectrumAnalyzer('SampleRate',sin.SampleRate);
for ii = 1:250
    x = sin() + 0.05*randn(1000,1);
    scope(x);
end

```

Run the `release` method to change property values and input characteristics. The scope automatically scales the axes. It updates the display one more time if any data is in the internal buffer.

```
release(scope);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('scope');
```

### Spectrogram of Chirp Signal

This example shows the spectrogram for a chirp signal with added random noise.

```

Fs = 233e3;
frameSize = 20e3;
chirp = dsp.Chirp('SampleRate',Fs,...

```

```
'SamplesPerFrame',frameSize,...
'InitialFrequency',11e3,...
'TargetFrequency',11e3+55e3);

scope = dsp.SpectrumAnalyzer('SampleRate',Fs);
scope.ViewType = 'Spectrogram';
scope.RBWSource = 'Property';
scope.RBW = 500;
scope.TimeSpanSource = 'Property';
scope.TimeSpan = 2;
scope.PlotAsTwoSidedSpectrum = false;

for idx = 1:50
    y = chirp()+ 0.05*randn(frameSize,1);
    scope(y);
end

release(scope)
```

### Display Frequency Input from Spectral Estimation

Use the Spectrum Analyzer to display frequency input from spectral estimates of sinusoids embedded in white Gaussian noise.

#### Initialization

Initialize two `dsp.SpectrumEstimator` objects to display. Set one object to use the Welch-based spectral estimation technique with a Hann window, set the other object use a filter bank estimation. Specify a noisy sine wave input signal with four sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles/sample. View the spectral estimate using a third object, a spectrum analyzer, set to process frequency input.

```
FrameSize = 420;
Fs = 1;
Frequency = [0.16 0.2 0.205 0.25];
sinegen = dsp.SineWave('SampleRate',Fs,'SamplesPerFrame',FrameSize,...
    'Frequency',Frequency,'Amplitude',[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAvg = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAvg,'SampleRate',Fs);

spectrumPlotter = dsp.SpectrumAnalyzer('InputDomain','Frequency',...
    'SampleRate',Fs,...
    'SpectrumUnits','dBm','YLimits',[-120,40],...
    'PlotAsTwoSidedSpectrum',false,...
    'ChannelNames',{'Hann window','Filter bank'},'ShowLegend',true);
```

#### Streaming

Stream the input. Compare the spectral estimates in the spectrum analyzer.

```

for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb])
end

```

### Obtain Measurement Data Programmatically for dsp.SpectrumAnalyzer System object

Compute and display the power spectrum of a noisy sinusoidal input signal using the `dsp.SpectrumAnalyzer` System object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion in the spectrum by enabling the following properties:

- PeakFinder
- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements

#### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two `dsp.SineWave` System objects to generate these two frequencies. Create a `dsp.SpectrumAnalyzer` System object to compute and display the power spectrum.

```

Fs = 44100;
Sineobject1 = dsp.SineWave('SamplesPerFrame',1024,...
    'PhaseOffset',10,...
    'SampleRate',Fs,'Frequency',1000);
Sineobject2 = dsp.SineWave('SamplesPerFrame',1024,...
    'SampleRate',Fs,'Frequency',5000);
SA = dsp.SpectrumAnalyzer('SampleRate',Fs,'Method','Filter bank',...
    'SpectrumType','Power','PlotAsTwoSidedSpectrum',false,...
    'ChannelNames',{'Power spectrum of the input'},...
    'YLimits',[-120 40],'ShowLegend',true);

```

#### Enable Measurements Data

To obtain the measurements, set the `Enable` property of the measurements to `true`.

```

SA.CursorMeasurements.Enable = true;
SA.ChannelMeasurements.Enable = true;
SA.PeakFinder.Enable = true;
SA.DistortionMeasurements.Enable = true;

```

#### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrum analyzer. Measure the characteristics of the spectrum. Use the `getMeasurementsData` function to obtain these measurements programmatically. The `isNewDataReady` function indicates when there is new spectrum data. The measured data is stored in the variable `data`.

```

data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();

```

```
Sinewave2 = Sineobject2();  
Input = Sinewave1 + Sinewave2;  
NoisyInput = Input + 0.001*randn(1024,1);  
SA(NoisyInput);  
    if SA.isNewDataReady  
        data = [data;getMeasurementsData(SA)];  
    end  
end
```

The right side of the spectrum analyzer shows the enabled measurement panes. The values shown in these panes match with the values shown in the last time step of the `data` variable. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

Peak values are obtained by the `PeakFinder` property. Verify that the peak values obtained in the last time step of `data` match the values shown on the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3×1
```

```
    26.9851  
    24.1735  
   -51.1973
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3×1
```

```
    4.9957  
    0.9905  
    0.2369
```

## Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a Spectrum Analyzer.

You cannot open Spectrum Analyzer configuration dialog boxes if you have more than one compiled component in your application.

## Algorithms

### Spectrum Estimation — Filter Bank

When you choose the `Filter Bank` method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal  $x(n)$ , of sample rate  $f_s$ , into multiple narrow band signals  $y_0(m)$ ,  $y_1(m)$ , ...,  $y_{M-1}(m)$ , of sample rate  $f_s/M$ .

The variable  $M$  represents the number of frequency bands in the filter bank. In the Spectrum Analyzer,  $M$  is equal to the number of data points needed to achieve the specified RBW value or 1024, whichever is larger. For more information on the analysis filter bank and its implementation, see the “More About” on page 4-198 and the “Algorithm” on page 4-200 sections in the `dsp.Channelizer` object.

After the Spectrum Analyzer splits the broadband input signal into multiple narrow bands, it computes the power in each narrow frequency band using the following equation. Each  $Z_i$  value is the power estimate over that narrow frequency band.

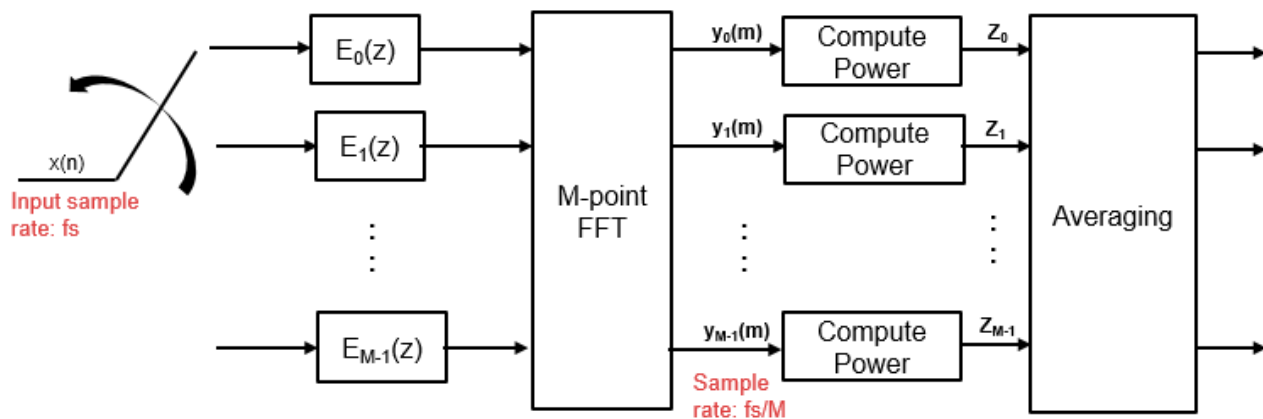

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

$L$  is length of the narrowband signal  $y_i(m)$  and  $i = 1, 2, \dots, M-1$ .

The power values in all the narrow frequency bands (denoted by  $Z_i$ ) form the  $Z$  vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The Spectrum Analyzer averages the current  $Z$  vector with the previous  $Z$  vectors using one of the two moving average methods: video bandwidth or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 4-1126.

The Spectrum Analyzer uses the value you specify in the **RBW (Hz)** parameter to determine the input frame length. To view the **RBW (Hz)** parameter in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth property **RBW (Hz)**.

When you set **RBW (Hz)** to:

- Auto -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW

intervals over the specified frequency span. When you set **RBW (Hz)** to Auto, the Spectrum Analyzer calculates RBW using this equation.

$$RBW_{auto} = \frac{span}{1024}$$

- scalar value -- The Spectrum Analyzer calculates the number of samples  $N_{samples}$  using this equation.

$$N_{samples} = \frac{F_s}{RBW}$$

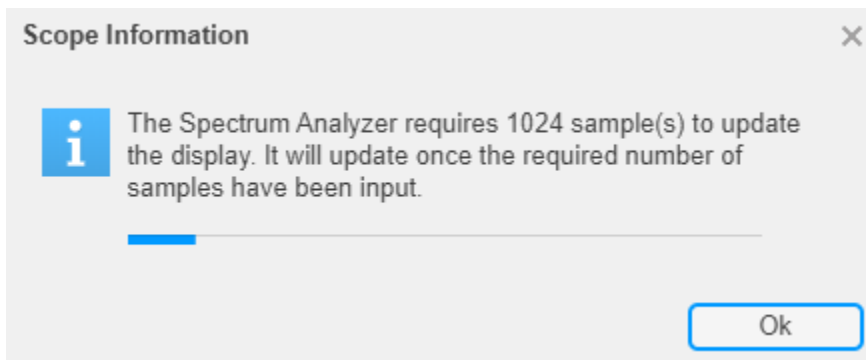

$F_s$  is the sample rate of the input signal as specified in the **Sample Rate (Hz)** property. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you specify a resolution bandwidth using the **RBW (Hz)** parameter, you must specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two.

$$\frac{span}{RBW} > 2$$

$span$  is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Frequency Options** section. To enable this property, set **Frequency Span** to Span and Center Frequency.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

### Spectrum Estimation — Welch's Method

When you select the Welch method, the power spectrum estimate is the averaged modified periodograms.

The algorithm in the Spectrum Analyzer consists of these steps:

- 1 The block buffers the input into  $N$ -point data segments. Each data segment is split into  $P$  overlapping data segments, each of length  $M$ , overlapping by  $D$  points. The data segments can be represented as:

$$x_i(n) = x(n + iD), \quad n = 0, 1, \dots, M - 1$$

$$i = 0, 1, \dots, P - 1$$

- If  $D = M/2$ , the overlap is 50%.
  - If  $D = 0$ , the overlap is 0%.
- 2 Apply a window to each of the  $P$  overlapping data segments in the time domain.

The Spectrum Analyzer uses **RBW (Hz)** in the **Analyzer** tab to determine the data window length  $N_{window}$  internally. Then, it partitions the input signal into a number of windowed data segments.

Most window functions afford more influence to the data at the center of the set than to the data at the edges, which represents a loss of information. To mitigate that loss, the individual data sets are commonly overlapped in time. For each windowed segment, compute the periodogram by computing the discrete Fourier transform. Then compute the squared magnitude of the result and divide the result by  $M$ .

$$P_{xx}^i(f) = \frac{1}{MU} \left| \sum_{n=0}^{M-1} x_i(n)w(n)e^{-j2\pi fn} \right|^2, \quad i = 0, 1, \dots, P - 1$$

where  $U$  is the normalization factor for the power in the window function and is given by

$$U = \frac{1}{M} \sum_{n=0}^{M-1} w^2(n)$$

You can specify the window using the **Window** parameter in the **Estimation** tab of the Spectrum Analyzer toolstrip.

- 3 The Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS using the modified Periodogram estimator. For more information about the Periodogram method, see [periodogram](#).

To determine the power spectrum estimate for Welch's method, the Spectrum Analyzer averages the result of the periodograms for the last  $P$  data segments. The averaging reduces the variance, compared to the original  $N$ -point data segment. For more details on the averaging, see "Averaging Method" on page 4-1126.

$$\text{PSD}(f) = \frac{1}{P} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 4 The Spectrum Analyzer computes the power spectral density using:

$$\text{PSD}(f) = \frac{1}{P * F_s} \sum_{i=0}^{P-1} P_{xx}^i(f)$$

- 5 The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by this equation.

$$P_{\text{spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times NENBW}{N_{\text{window}}}$$

- 6 The Spectrum Analyzer plots the power as a spectrogram in the **Spectrogram** mode. Each line of the spectrogram is one periodogram. The time resolution of each line is  $1/RBW$ , which is the minimum attainable resolution. Achieving the resolution you want might require combining several periodograms. You then use interpolation to calculate noninteger values of  $1/RBW$ . In the spectrogram display, time scrolls from top to bottom, so the most recent data appears at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

The Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This value is directly related to the resolution bandwidth (RBW).

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

where  $O_p$  on page 4-1122 is the overlap percentage,  $NENBW$  on page 4-1122 is the normalized effective noise bandwidth,  $F_s$  on page 4-1123 is the input sample rate, and  $RBW$  on page 4-1123 is the resolution bandwidth.

The Spectrum Analyzer shows the number of samples per update in the Spectrum Analyzer status bar.

You can enable **Samples/Update** in the status bar only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Overlap Percentage ( $O_p$ )

The overlap percentage  $O_p$  is the value you specify in the **Overlap %** property. To view the **Overlap %** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip and navigate to the **Window Options** section.

When you increase the overlap percentage, the Spectrum Analyzer needs fewer new input samples to compute a new spectral update.

| $O_p$ | $N_{samples}$ |
|-------|---------------|
| 0%    | 100           |
| 50%   | 50            |
| 80%   | 20            |

### Normalized Effective Noise Bandwidth (NENBW)

The normalized effective noise bandwidth  $NENBW$  is a window parameter that measures the noise performance of the window.  $NENBW$  is determined using the window length and the window coefficients, and is given by the following equation:

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

$w(n)$  denotes the vector of window coefficients (calculated internally).  $N_{window}$  is the window length the Spectrum Analyzer needs to compute one spectral update, and is directly related to the resolution bandwidth and normalized effective noise bandwidth.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

The Spectrum Analyzer shows the value of *NENBW* in the Spectrum Analyzer status bar.

You can enable NENBW only when you set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

### Input Sample Rate ( $F_s$ )

$F_s$  is the sample rate of the input signal. To view the **Sample Rate (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section. You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select **Sample Rate**.

### Resolution Bandwidth (RBW)

Resolution bandwidth controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that the scope can resolve. A smaller value gives a higher spectral resolution and lowers the noise floor; that is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

You can set the resolution bandwidth through the **RBW (Hz)** property. To view **RBW (Hz)** in the scope, click the **Analyzer** tab on the Spectrum Analyzer toolstrip and navigate to the **Bandwidth** section.

When you set **RBW (Hz)** to:

- **Auto** -- The Spectrum Analyzer requires 1024 samples to update the display. The Spectrum Analyzer determines the appropriate resolution bandwidth to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to **Auto**, the Spectrum Analyzer calculates using this equation.

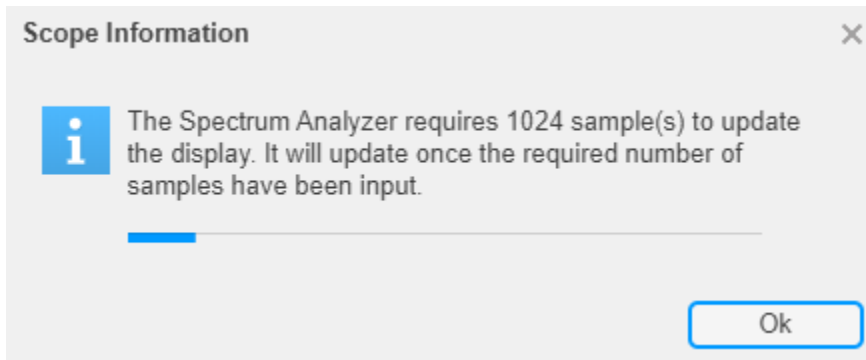

$$RBW_{auto} = \frac{span}{1024}$$

- **scalar value** -- Specify a value such that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

*span* is the frequency span over which the Spectrum Analyzer computes and plots the spectrum. Spectrum Analyzer shows the span through the **Span (Hz)** property. To view the **Span (Hz)** in the scope, click the **Estimation** tab on the Spectrum Analyzer toolstrip, navigate to the **Frequency Options** section, and set **Frequency Span** to **Span and Center Frequency**.

When the number of input samples is not sufficient to achieve the specified resolution bandwidth, the Spectrum Analyzer displays a message similar to this one.

The Spectrum Analyzer removes this message and displays a spectral estimate once you provide enough input samples.

You can enable this property in the status bar at the bottom of the Spectrum Analyzer window. Right-click the status bar and select RBW.

### Nyquist Frequency Interval

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the Nyquist frequency interval is

$$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

When you clear the **Two-Sided Spectrum**, the Nyquist frequency interval is

$$\left[ 0, \frac{SampleRate}{2} \right] + FrequencyOffset \text{ Hz.}$$

### Frequency Vector

When you set **Frequency (Hz)** to Auto, the software calculates the frequency vector for the frequency-domain input.

When you plot the two-sided spectrum by selecting **Two-Sided Spectrum** in the **Spectrum** or **Spectrogram** tab, the frequency vector is:

$$\left[ -\frac{SampleRate}{2}, \frac{SampleRate}{2} \right]$$

When you clear the **Two-Sided Spectrum**, the frequency vector is:

$$\left[ 0, \frac{SampleRate}{2} \right]$$

### Occupied BW

The Spectrum Analyzer calculates *Occupied BW* using these steps.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, sum the power distributed in each frequency until the result is

$$\frac{100 - OccupiedBW\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, sum the power distributed in each frequency until the result reaches

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

### Distortion Measurements

The Spectrum Analyzer calculates Distortion Measurements using these steps.

- 1 Estimate spectral content by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values by treating all these values as if they belong to the peak. Using this method, the algorithm removes all spectral content centered at DC (0 Hz) from the spectrum and records the amount of bandwidth cleared ( $W_0$ ).
- 2 Determine the fundamental power ( $P_1$ ) from the remaining maximum value of the displayed spectrum. Create a local estimate ( $Fe_1$ ) of the fundamental frequency by computing the central moment of the power near the peak. Record the bandwidth of the fundamental power content ( $W_1$ ). Then remove the power from the fundamental as in step 1.
- 3 Determine the power and width of the higher-order harmonics ( $P_2, W_2, P_3, W_3$ , etc.) in succession by examining the frequencies closest to the appropriate multiple of the local estimate ( $Fe_1$ ). Remove any spectral content that decreases monotonically about the harmonic frequency from the spectrum before proceeding to the next harmonic.
- 4 After removing the DC, fundamental, and harmonic content from the spectrum, examine the power of the remaining spectrum for its sum ( $P_{remaining}$ ), peak value ( $P_{maxspur}$ ), and median value ( $P_{estnoise}$ ).
- 5 Compute the sum of all the removed bandwidth as  $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$ .

Compute the sum of powers of the second and higher-order harmonics as  $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$ .

- 6 Estimate the sum of the noise power as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum})/RBW$$

Where  $dF$  is the absolute difference between frequency bins, and  $RBW$  is the resolution bandwidth of the window.

- 7 Then compute the metrics for SNR, THD, SINAD, and SFDR from the estimates.

$$THD = 10 \cdot \log_{10} \left( \frac{P_{\text{harmonic}}}{P_1} \right)$$

$$SINAD = 10 \cdot \log_{10} \left( \frac{P_1}{P_{\text{harmonic}} + P_{\text{noise}}} \right)$$

$$SNR = 10 \cdot \log_{10} \left( \frac{P_1}{P_{\text{noise}}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left( \frac{P_1}{\max(P_{\text{maxspur}}, \max(P_2, P_3, \dots, P_n))} \right)$$

### Harmonic Measurements

- 1 The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer might exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

- 2 Ignore the DC component.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, the Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4  $N^{\text{th}}$  order intermodulation products occur at  $A \cdot F1 + B \cdot F2$ ,

where  $F1$  and  $F2$  are the sinusoid input frequencies and  $|A| + |B| = N$ .  $A$  and  $B$  are integer values.

- 5 For intermodulation measurements, compute the third-order intercept (TOI) point as follows.

- $TOI_{\text{lower}} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{\text{upper}} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = + (TOI_{\text{lower}} + TOI_{\text{upper}})/2$

Where  $P$  is power in decibels of the measured power referenced to 1 milliwatt (dBm).

### Averaging Method

The Spectrum Analyzer can calculate the moving average using two methods:

- Video bandwidth — The Spectrum Analyzer uses a time-domain lowpass filter to smooth the noise in the signal. The video bandwidth (VBW) filter smoothes the trace and decreases noise, and the Spectrum Analyzer applies the filter to the data before displaying it.

Video bandwidth is the bandwidth of the lowpass filter that Spectrum Analyzer uses to average or smooth the noise in the signal before displaying it in the scope. The Spectrum Analyzer computes the video bandwidth using this equation:

$$VBW = \frac{(1 - \lambda)RBW}{2\pi\lambda NENBW}$$

where,

- $\lambda$  is the forgetting factor.
- RBW on page 4-1123 is the resolution bandwidth.
- NENBW on page 4-1122 is the normalized effective noise bandwidth.

Video bandwidth does not affect the level of the noise (noise floor), but only increases the signal-to-noise ratio and smoothes the trace of the noise. When you decrease the value of VBW, the signal-to-noise ratio improves.

The cutoff frequency of the video bandwidth filter is given by:

$$\omega_c = \frac{2\pi VBW}{F_s/NFFT}$$

where  $F_s$  is the input sample rate and NFFT is the number of FFT points.

The Spectrum Analyzer shows the values of sample rate, VBW, and NFFT in the status bar at the bottom of the display. To enable, right-click the status bar and select **Sample Rate, VBW, and NFFT**.

- **Exponential** — The moving average algorithm uses the exponential weighting method to update the weights and compute the moving average recursively for each  $Z$  vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- $\lambda$  — Forgetting factor
- $w_N$  — Weighting factor applied to the current  $Z$  vector
- $z_N$  — Current  $Z$  vector
- $\bar{z}_{N-1}$  — Moving average until the previous  $Z$  vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$  — Effect of the previous  $Z$  vectors on the average
- $\bar{z}_N$  — Moving average including the current  $Z$  vector

## Version History

**Introduced in R2012b**

**R2022a: dsp.SpectrumAnalyzer System object will be removed**

*Not recommended starting in R2022a*

The dsp.SpectrumAnalyzer System object will be removed in a future release. Use the spectrumAnalyzer object instead.

**Update Code**

The `spectrumAnalyzer` object has the same properties as the `dsp.SpectrumAnalyzer` object. However, the default value of the `Method` property has changed to `'filter-bank'`, and the default value of the `AveragingMethod` property has changed to `'vbw'`, which is video bandwidth.

No updates to your code are required except for:

- Replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.
- Updating the values of `Method` and `AveragingMethod` properties, if required.

This table shows how the System object is typically used and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <p><b>Using the default version of <code>dsp.SpectrumAnalyzer</code> object</b></p> <pre>sa = dsp.SpectrumAnalyzer  dsp.SpectrumAnalyzer with properties:      NumInputPorts: 1     InputDomain: 'Time'     SpectrumType: 'Power'     ViewType: 'Spectrum'     SampleRate: 10000     Method: 'Welch'     PlotAsTwoSidedSpectrum: 1     FrequencyScale: 'Linear'  Advanced     FrequencySpan: 'Full'     FrequencyResolutionMethod: 'RBW'     RBWSource: 'Auto'     OverlapPercent: 0     Window: 'Hann'     SpectrumUnits: 'dBm'     AveragingMethod: 'Running'     SpectralAverages: 1     ReferenceLoad: 1     FrequencyOffset: 0</pre> | <p><b>Replacing with the <code>spectrumAnalyzer</code> object</b></p> <p>The <code>spectrumAnalyzer</code> object uses "filter-bank" as the default spectral estimation method. The filter bank method has a lower noise floor, better frequency resolution, and also requires fewer samples per update compared to the Welch method.</p> <p>To retain the same default behavior as the <code>dsp.SpectrumAnalyzer</code> System object, change the <code>Method</code> property to "welch" and the <code>AveragingMethod</code> property to "exponential". **R2022a: CCDF measurements will be removed from the `dsp.SpectrumAnalyzer` object**  
*Warns starting in R2022a*

The `CCDFMeasurements` property will be removed from the `dsp.SpectrumAnalyzer` object. If you try to edit these measurements from the command line or from the user interface (UI), the object throws a warning message.

Use the `powermeter` object instead to plot and visualize the CCDF measurements.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# **dsp.SpectrumEstimator**

**Package:** dsp

Estimate power spectrum or power density spectrum

## **Description**

The `dsp.SpectrumEstimator` System object computes the power spectrum or the power density spectrum of a signal using the Welch algorithm or the filter bank approach.

When you choose the Welch method, the object computes the averaged modified periodograms to compute the spectral estimate. When you choose the filter bank approach, an analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band. For signals with relatively small FFT lengths, the filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and peaks more precise than the Welch method, with low or no spectral leakage. These advantages come at the expense of increased computation and slower tracking.

The spectrum can be expressed in watts or in decibels. This object can also estimate the max-hold and min-hold spectra of the signal.

To estimate the power density spectrum:

- 1 Create the `dsp.SpectrumEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## **Creation**

### **Syntax**

```
SE = dsp.SpectrumEstimator  
SE = dsp.SpectrumEstimator(Name,Value)
```

### **Description**

`SE = dsp.SpectrumEstimator` returns a System object, `SE`, that computes the frequency power spectrum or the power density spectrum of real or complex signals. This System object uses the Welch's averaged modified periodogram method or the filter bank-based spectral estimation method.

`SE = dsp.SpectrumEstimator(Name,Value)` returns a `dsp.SpectrumEstimator` System object with each specified property name set to the specified value. Unspecified properties have default values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### SpectrumType — Spectrum type

'Power' (default) | 'Power density'

Spectrum type, specified as either 'Power' or 'Power density'. When the spectrum type is 'Power', the power density spectrum is scaled by the equivalent noise bandwidth of the window (in Hz).

**Tunable:** Yes

### FFTLengthSource — Source of FFT length value

'Auto' (default) | 'Property'

Source of the FFT length value, specified as either 'Auto' or 'Property'. If you set this property to 'Auto', the spectrum estimator sets the FFT length to the input frame size. If you set this property to 'Property', then you specify the number of FFT points using the `FFTLength` property.

### FFTLength — FFT length

128 (default) | positive integer

Specify the length of the FFT that the spectrum estimator uses to compute spectral estimates as a positive integer.

### Dependencies

This property applies when you set the `FFTLengthSource` property to 'Property'.

Data Types: `double`

### Method — Welch or filter bank

'Welch' (default) | 'Filter bank'

Specify the spectral estimation method:

- 'Welch' — The object uses Welch's averaged modified periodograms method.
- 'Filter bank' — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The object computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.

### Window — Window function

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser'

Specify a window function for the spectral estimator as one of 'Rectangular', 'Chebyshev', 'Flat Top', 'Hamming', 'Hann', or 'Kaiser'.

**Dependencies**

This property applies when you set `Method` to `'Welch'`.

**NumTapsPerBand — Number of filter taps per frequency band**

12 (default) | positive integer

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is given by `NumTapsPerBand × FFTLength`.

**Dependencies**

This property applies when you set `Method` to `'Filter bank'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**FrequencyRange — Frequency range of the spectrum estimate**

`'twosided'` (default) | `'onesided'` | `'centered'`

Specify the frequency range of the spectrum estimator as one of `'twosided'`, `'onesided'`, or `'centered'`.

If you set the `FrequencyRange` to `'onesided'`, then the spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length  $(NFFT/2) + 1$  and is computed over the frequency range  $[0, \text{SampleRate}/2]$ , where `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length  $(NFFT + 1)/2$  and is computed over the frequency range  $[0, \text{SampleRate}/2)$ .

If you set the `FrequencyRange` to `'twosided'`, then the spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $[0, \text{SampleRate})$ , where `SampleRate` is the sample rate of the input signal.

If you set the `FrequencyRange` to `'centered'`, then the spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range  $(-\text{SampleRate}/2, \text{SampleRate}/2]$  when the FFT length is even and  $(-\text{SampleRate}/2, \text{SampleRate}/2)$  when the FFT length is odd.

**PowerUnits — Power units**

`'Watts'` (default) | `'dBW'` | `'dBm'`

Specify the units used to measure power as one of `'Watts'`, `'dBW'`, or `'dBm'`.

**AveragingMethod — Averaging method**

`'Running'` (default) | `'Exponential'`

Specify the averaging method as `'Running'` or `'Exponential'`. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

**SpectralAverages — Number of spectral averages**

8 (default) | positive integer

Number of spectral averages, specified as a positive integer. The spectrum estimator computes the current power spectrum or power density spectrum estimate by averaging the last  $N$  estimates.  $N$  is the number of spectral averages defined in the `SpectralAverages` property.

**Dependencies**

This property applies when you set `AveragingMethod` to 'Running'.

Data Types: double

**ForgettingFactor — Forgetting factor**

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

**Tunable:** Yes

**Dependencies**

This property applies when you set `AveragingMethod` to 'Exponential'.

Data Types: single | double

**ReferenceLoad — Reference load**

1 (default) | positive scalar

Specify the load that the spectrum estimator uses as a reference to compute power values as a real, positive scalar in ohms.

Data Types: single | double

**SidelobeAttenuation — Side lobe attenuation of window**

60 dB (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

**Dependencies**

This property applies when you set `Method` to 'Welch' and `Window` to 'Chebyshev' or 'Kaiser'.

Data Types: double

**OutputMaxHoldSpectrum — Output max-hold spectrum**

false (default) | true

Set this property to `true` so that the spectrum estimator computes and outputs the max-hold spectrum of each input channel. The max-hold spectrum is computed by keeping, at each frequency bin, the maximum value of all the power spectrum estimates.

**OutputMinHoldSpectrum — Output min-hold spectrum**

false (default) | true

Set this property to `true` so that the spectrum estimator computes and outputs the min-hold spectrum of each input channel. The min-hold spectrum is computed by keeping, at each frequency bin, the minimum value of all the power spectrum estimates.

**SampleRate — Sample rate of input**

1 (default) | scalar

Sample rate of the input in Hz, specified as a finite numeric scalar. The sample rate is the rate at which the signal is sampled in time.

Data Types: `single` | `double`

## Usage

## Syntax

```
pxx = SE(x)
[pxx, pmax] = SE(x)
[pxx, pmin] = SE(x)
[pxx, pmax, pmin] = SE(x)
```

## Description

`pxx = SE(x)` computes the power spectrum or power-density spectrum, `pxx`, of the input signal, `x`. The System object treats the columns of `x` as independent channels.

`[pxx, pmax] = SE(x)` also computes the max-hold frequency spectrum, `pmax`, of `x`. To determine the max-hold spectrum, the method keeps the maximum of all the power spectrum estimates computed at each frequency bin. Set `OutputMaxHoldSpectrum` to `true` to obtain the max-hold spectrum.

`[pxx, pmin] = SE(x)` also computes the min-hold frequency spectrum, `pmin`, of `x`. To determine the min-hold spectrum, the method keeps the minimum of all the power spectrum estimates computed at each frequency bin. Set `OutputMinHoldSpectrum` to `true` to obtain the min-hold spectrum.

`[pxx, pmax, pmin] = SE(x)` computes the power spectrum or power-density spectrum, the max-hold spectrum, and the min-hold spectrum of `x`. Set `OutputMaxHoldSpectrum` and `OutputMinHoldSpectrum` to `true` to obtain the max-hold and min-hold spectra.

## Input Arguments

### **x** — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` is the frame size or channel length. Each column of `x` is treated as a separate channel. The column length of `x` is the number of channels.

Data Types: `single` | `double`

## Output Arguments

### **pxx** — Power or power-density spectrum estimate

vector | matrix

Power or power-density spectrum estimate, returned as a vector or matrix of the same data type and complexity as the input signal, `x`.

When `FFTLengthSource` is set to:

- `'Auto'` -- The size of `pxx` is same as the size of the input signal, `x`.

- 'Property' -- The size of pxx is the same as the specified FFT length.

By default, the unit of pxx is 'Watts'. You can also specify the spectrum to be in 'dBm' or 'dBW' through the PowerUnits property.

Data Types: single | double

#### **pmax — Max-hold spectrum estimate**

vector | matrix

Max-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the output signal, pxx.

Data Types: single | double

#### **pmin — Min-hold spectrum estimate**

vector | matrix

Min-hold spectrum estimate, returned as a vector or matrix of the same size, data type, and complexity as the output signal, pxx.

Data Types: single | double

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

### **Specific to dsp.SpectrumEstimator**

getFrequencyVector    Vector of frequencies at which estimation is done

getRBW                Resolution bandwidth of spectrum

### **Common to All System Objects**

step                Run System object algorithm

release            Release resources and allow changes to System object property values and input characteristics

reset              Reset internal states of System object

## **Examples**

### **Power Spectrum of Multichannel Sinusoidal Signal**

Compute the power spectrum of a multichannel sinusoidal signal using the dsp.SpectrumEstimator System object™. You can get the vector of frequencies at which the spectrum is estimated using the getFrequencyVector function. To compute the resolution bandwidth of the estimate (RBW), use the getRBW function.

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by  $\pi/2$  and  $\pi/4$ , respectively.

```
sineSignal = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the `dsp.SpectrumEstimator` object for the computation and the `dsp.ArrayPlot` for the plotting.

```
estimator = dsp.SpectrumEstimator('FrequencyRange','onesided');
plotter = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = sineSignal();
pxx = estimator(y);
plotter(pxx)
```

Get the vector of frequencies at which the spectrum is estimated in Hz, using the `getFrequencyVector` function.

```
f = getFrequencyVector(estimator);
```

Compute the resolution bandwidth (RBW) of the estimate using the `getRBW` function.

```
rbw = getRBW(estimator)
```

```
rbw =
```

```
0.0015
```

The resolution bandwidth of the signal power spectrum is 0.0015 Hz. This frequency is the smallest frequency that can be resolved on the spectrum.

## Spectral Estimation Using Filter Bank

Compare spectral estimates of sinusoids embedded in white Gaussian noise using a Hann window-based Welch method and filter bank method.

### Initialization

Initialize two `dsp.SpectrumEstimator` objects. Specify one estimator to use the Welch-based spectral estimation technique with a Hann window. Specify the other estimator to use an analysis filter bank to perform the spectral estimation. Specify a noisy sine wave input signal with 4 sinusoids at 0.16, 0.2, 0.205, and 0.25 cycles/sample. View the spectral estimate using an array plot.

```
FrameSize = 420;
Fs = 1;
sinegen = dsp.SineWave('SampleRate',Fs,...
    'SamplesPerFrame',FrameSize,...
    'Frequency',[0.16 0.2 0.205 0.25],...
    'Amplitude',[2e-5 1 0.05 0.5]);
NoiseVar = 1e-10;
numAvgs = 8;

hannEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Window','Hann','FrequencyRange','onesided',...
    'SpectralAverages',numAvgs,'SampleRate',Fs);

filterBankEstimator = dsp.SpectrumEstimator('PowerUnits','dBm',...
    'Method','Filter bank','FrequencyRange','onesided',...
    'SpectralAverages',numAvgs,'SampleRate',Fs);

spectrumPlotter = dsp.ArrayPlot(...
    'PlotType','Line','SampleIncrement',Fs/FrameSize,...
    'YLimits',[-250,50],'YLabel','dBm',...
    'ShowLegend',true,'ChannelNames',{'Hann window','Filter bank'});
```

### Streaming

Stream the input. Compare the spectral estimates computed using the Hann window and the analysis filter bank

```
for i = 1:1000
    x = sum(sinegen(),2) + sqrt(NoiseVar)*randn(FrameSize,1);
    Pse_hann = hannEstimator(x);
    Pfb = filterBankEstimator(x);
    spectrumPlotter([Pse_hann,Pfb])
end
```

The Hann window misses the peak at 0.205 cycles/sample. In addition, the window has a significant spectral leakage that makes the peak at 0.16 cycles/sample hard to distinguish, and the noise floor is not correct.

The filter bank estimate has a very good resolution with no spectral leakage.

### Power and Max-Hold Spectra of Noisy Sine Wave

Generate a sine wave.

```
sineWave = dsp.SineWave('Frequency',100,...
    'SampleRate',1000, ...
    'SamplesPerFrame',1000);
```

Use the spectrum estimator to compute the power spectrum and the max-hold spectrum of the sine wave. Use the Array Plot to display the spectra.

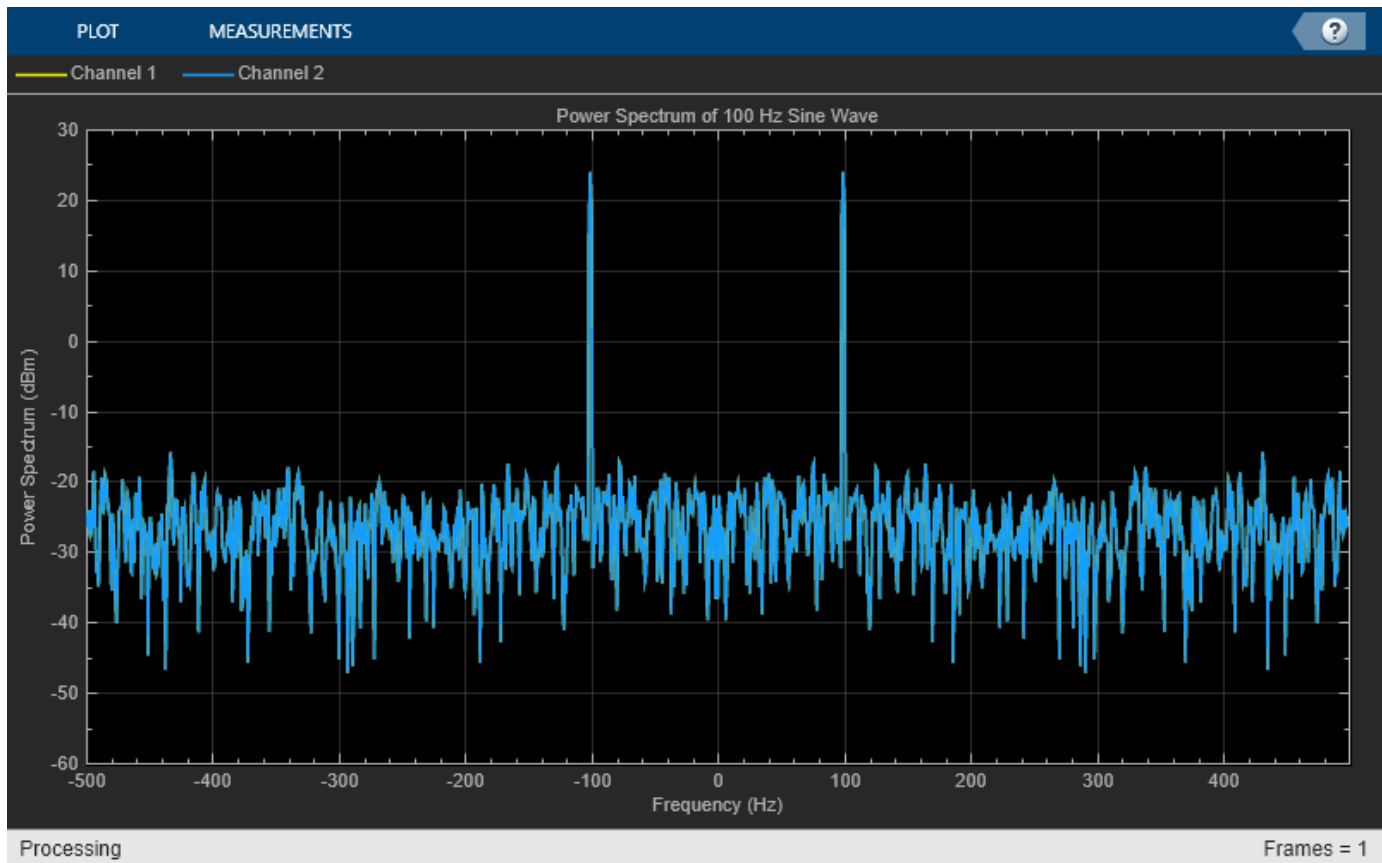

```
SE = dsp.SpectrumEstimator(...
    'SampleRate',sineWave.SampleRate,...
    'SpectrumType','Power','PowerUnits','dBm', ...
    'FrequencyRange','centered',...
    'OutputMaxHoldSpectrum',true);
plotter = dsp.ArrayPlot('PlotType','Line',...
    'Xoffset',-500, ...
    'YLimits',[-60 30],...
    'Yoffset',-500);
```

```
'Title','Power Spectrum of 100 Hz Sine Wave', ...
'YLabel','Power Spectrum (dBm)',...
'XLabel','Frequency (Hz)');
```

Add random noise to the sine wave. Stream in the data, and plot the power spectrum of the signal.

```
for ii = 1:10
    x = sineWave() + 0.05*randn(1000,1);
    [Pxx,Pmax] = SE(x);
    plotter([Pxx Pmax])
end
```

## Algorithms

### Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input,  $x$ :

- 1 Multiply  $x$  by the window and scale the result by the window power.
- 2 Compute the FFT of the signal,  $Y$ , and take the square magnitude using  $Z = Y \cdot \text{conj}(Y)$ .

- 3 Compute the current power spectrum estimate by taking the moving average of the last  $N$  number of  $Z$ 's, and scaling the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 4-1141.

### Filter Bank

The filter-bank-based spectrum estimator uses an analysis filter bank to estimate the power spectrum. The filter bank splits a broadband input signal,  $x(n)$ , of sample rate  $f_s$  into multiple narrow band signals,  $y_0(m)$ ,  $y_1(m)$ , ...,  $y_{M-1}(m)$ , of sample rate  $f_s/M$ .

The variable  $M$  represents the number of frequency bands in the filter bank. When you specify FFT length,  $M$  equals the FFT length. When you do not specify FFT length,  $M$  is equal to the number of rows in the input signal. The number of taps per frequency band sets the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands  $M$ . For more information on the analysis filter bank and how it is implemented, see the "More About" on page 4-198 and the "Algorithm" on page 4-200 sections in `dsp.Channelizer`.

After the broadband input signal is split into multiple narrow bands, the spectrum estimator computes the power in each narrow band using the following equation. Each  $Z_i$  value becomes the estimate of the power over that narrow frequency band.

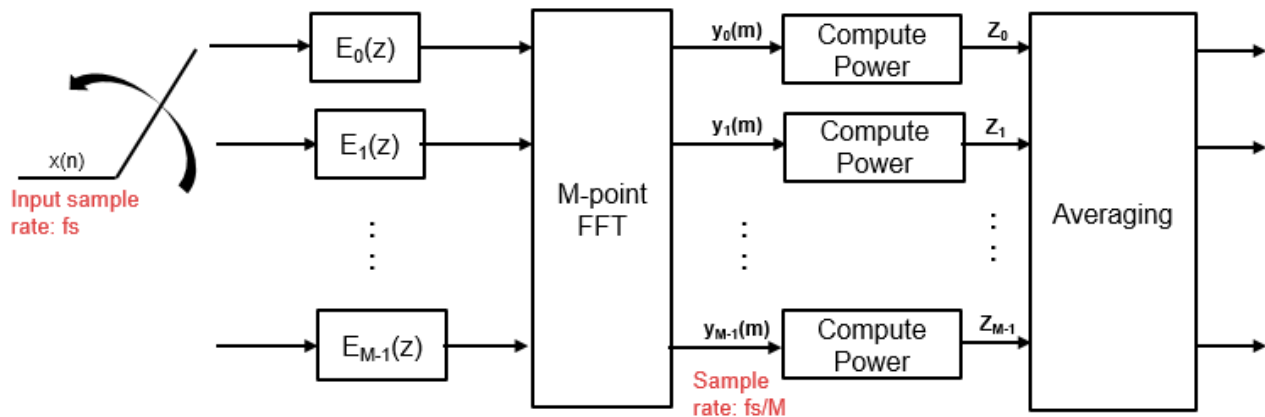

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

$L$  is length of the narrow band signal  $y_i(m)$ , where  $i = 1, 2, \dots, M-1$ .

The power values in all the narrow bands (denoted by  $Z_i$ ) form the  $Z$  vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The filter bank estimator algorithm averages the current  $Z$  vector with the previous  $Z$  vectors using one of the two moving average methods: running or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see "Averaging Method" on page 4-1141.

## Averaging Method

The moving average is calculated using one of the two methods:

- **Running** — For each frame of input, average the last  $N$ -scaled  $Z$  vectors, which are computed by the algorithm. The variable  $N$  is the value you specify for the number of spectral averages. If the algorithm does not have enough  $Z$  vectors, the algorithm uses zeros to fill the empty elements.

|                                 |                                    |       |       |     |     |     |     |     |   |
|---------------------------------|------------------------------------|-------|-------|-----|-----|-----|-----|-----|---|
| Input frame size:<br>[1000 1]   | Number of spectral averages (N): 6 |       |       |     |     |     |     |     |   |
|                                 | ← 1000 elements →                  |       |       |     |     |     |     |     |   |
| Z vector →                      | $Z_1$                              | 3     | 4     | 5   | ... | ... | ... | ... | 4 |
|                                 | $Z_2$                              | 5     | 6     | 7   | ... | ... | ... | ... | 8 |
|                                 | $Z_3$                              | 8     | 4     | 2   | ... | ... | ... | ... | 9 |
|                                 | $Z_4$                              | 3     | 2     | 7   | ... | ... | ... | ... | 3 |
|                                 | $Z_5$                              | 0     | 0     | 0   | ... | ... | ... | ... | 0 |
|                                 | $Z_6$                              | 0     | 0     | 0   | ... | ... | ... | ... | 0 |
| Output: $(Z_1+Z_2+\dots+Z_6)/6$ |                                    | 3.167 | 2.667 | 3.5 | ... | ... | ... | ... | 4 |

- **Exponential** — The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each  $Z$  vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- $\lambda$  — Forgetting factor
- $w_N$  — Weighting factor applied to the current  $Z$  vector
- $z_N$  — Current  $Z$  vector
- $\bar{z}_{N-1}$  — Moving average until the previous  $Z$  vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$  — Effect of the previous  $Z$  vectors on the average
- $\bar{z}_N$  — Moving average including the current  $Z$  vector

# dsp.StateLevels

**Package:** dsp

(Removed) State-level estimation for bilevel rectangular waveform

---

**Note** `dsp.StateLevels` has been removed. Use `statelevels` instead. For more information, see “Compatibility Considerations”.

---

## Description

The `dsp.StateLevels` object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

- 1 Create the `dsp.StateLevels` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
sl = dsp.StateLevels  
sl = dsp.StateLevels(Name,Value)
```

### Description

`sl = dsp.StateLevels` creates a state-level estimation System object, `sl`, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

`sl = dsp.StateLevels(Name,Value)` returns a `StateLevels` System object, `sl`, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **HistogramBounds — Minimum and maximum levels of histogram**

[0 5] (default) | two-element row vector

Minimum and maximum levels of the histogram. Specify the range of the histogram as a two-element real-valued row vector. Signal values outside the range defined by this property are ignored.

**Dependencies**

This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and either `RunningStateLevels` is `true`, or the `HistogramBoundsSource` property is set to `'Property'`.

Data Types: `double`

**HistogramBoundsSource — Source of histogram bounds**

`'Auto'` (default) | `'Property'`

Source of histogram bounds. Specify how to determine the histogram bounds as one of `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the histogram bounds are determined by the minimum and maximum input values. When you set this property to `'Property'`, the histogram bounds are determined by the value of the `HistogramBounds` property.

**Dependencies**

This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and the `RunningStateLevels` property is `false`.

**HistogramNumBins — Number of bins in histogram**

`100` (default) | positive integer

Number of bins in the histogram. Specify the number of bins in the histogram.

**Dependencies**

This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**HistogramOutputPort — Enable histogram output**

`false` (default) | `true`

Enable histogram output. Set this property to `true` to output the histogram used in the computation of the state levels.

**Dependencies**

This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

**Method — Algorithm used to compute state levels**

`'Histogram mode'` (default) | `'Histogram mean'` | `'Peak to peak'`

Algorithm used to compute state levels. Specify the method used to compute state levels as one of `'Histogram mean'`, `'Histogram mode'`, or `'Peak to peak'`.

**RunningStateLevels — Calculation over successive calls**

`false` (default) | `true`

Calculation over successive calls to the algorithm. Set this property to `true` to enable computation of the state levels over successive calls to the algorithm. Otherwise, the object computes the state levels

of only the current input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

## Usage

### Syntax

```
levels = sl(x)
[levels,histogram] = sl(x)
```

### Description

`levels = sl(x)` returns a two-element row vector, `levels`, containing the estimated state levels for the input, `x`.

`[levels,histogram] = sl(x)` returns a double-precision column vector, `histogram`, containing the histogram of the sample values in `x`. You can obtain this output only when you set the `Method` property to either `'Histogram mean'` or `'Histogram mode'`, and you set the `HistogramOutputPort` property to `true`.

### Input Arguments

#### **x** — Input

column vector

Input data, specified as a real-valued column vector.

Data Types: `double`

### Output Arguments

#### **levels** — State levels

two-element row vector

State levels, returned as a two-element row vector.

Data Types: `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to `dsp.StateLevels`

`plot` (To be removed) Plot signal, state levels, and histogram

## Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics  
reset Reset internal states of System object

## Examples

### State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock. Load the clock data in the variable, `x`, and the sampling instants in the variable `t`.

```
load('clockex.mat','x','t');
```

Estimate the state levels.

```
sl = dsp.StateLevels;  
levels = sl(x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(sl)
```

## More About

### State

A state is a particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

### State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state. To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the  $\alpha\%$  tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where  $S_1$  is the low-state level and  $S_2$  is the high-state level. Replace the first term in the equation with  $S_2$  to obtain the  $\alpha\%$  tolerance region for the high state.

This figure shows the lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

## Algorithms

The `dsp.StateLevels` System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

- 1 Determine the maximum and minimum amplitudes and amplitude range of the data.
- 2 For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
- 3 Sort the data values into the histogram bins.
- 4 Identify the lowest-indexed histogram bin,  $i_{low}$ , and highest-indexed histogram bin,  $i_{high}$ , with nonzero counts.
- 5 Divide the histogram into two subhistograms. The lower-histogram bins are  $i_{low} \leq i \leq 1/2(i_{high} - i_{low})$ .

The upper-histogram bins are  $i_{low} + 1/2(i_{high} - i_{low}) \leq i \leq i_{high}$ .

- 6 Compute the state levels by determining the mode or mean of the lower and upper histograms.

## Version History

**Introduced in R2012a**

**R2021b: `dsp.StateLevels` System object will be removed**

*Warns starting in R2021b*

`dsp.StateLevels` System object will be removed in a future release. Use the `statelevels` function instead.

**R2023a: `dsp.StateLevels` System object has been removed**

*Errors starting in R2023a*

The `dsp.StateLevels` System object has been removed. Use the `statelevels` function instead.

### Update Code

This table shows how to update existing code to use the `statelevels` function.

| Discouraged Usage  | Recommended Replacement  |
|--|--|

# dsp.SubbandAnalysisFilter

**Package:** dsp

Decompose signal into high-frequency and low-frequency subbands

## Description

The `dsp.SubbandAnalysisFilter` object decomposes a signal into high-frequency and low-frequency subbands, each with half the bandwidth of the input.

To decompose a signal into high-frequency and low-frequency subbands:

- 1 Create the `dsp.SubbandAnalysisFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
subAna = dsp.SubbandAnalysisFilter
subAna = dsp.SubbandAnalysisFilter(lpc,hpc)
subAna = dsp.SubbandAnalysisFilter(Name,Value)
```

### Description

`subAna = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `subAna`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`subAna = dsp.SubbandAnalysisFilter(lpc,hpc)` returns a two-channel subband analysis filter, `subAna`, with the “LowpassCoefficients” on page 4-0 property set to `lpc` and the `HighpassCoefficients` property set to `lpc`.

`subAna = dsp.SubbandAnalysisFilter(Name,Value)` returns a two-channel subband analysis filter, `subAna`, with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**LowpassCoefficients — Lowpass FIR filter coefficients**`[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**HighpassCoefficients — Highpass FIR filter coefficient**`[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the “LowpassCoefficients” on page 4-0 property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Fixed-Point Properties****FullPrecisionOverride — Full precision override for fixed-point arithmetic**`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

Data Types: `logical`

**RoundingMethod — Rounding method for fixed-point operations**`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

**Dependencies**

This property applies only if the object is not in full precision mode.

**OverflowAction — Action to take when integer input is out of range**`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

**Dependencies**

This property applies only if the object is not in full precision mode.

**CoefficientsDataType — Data type of the coefficients**`Same word length as input` (default) | `Custom`

Specify the FIR filter coefficients fixed-point data type as Same word length as input or Custom.

#### **CustomCoefficientsDataType — Coefficients word and fraction lengths**

`numericType([],16,15)` (default) | `numericType`

Specify the FIR filter coefficients fixed-point type as a `numericType` object with a Signedness of Auto.

#### **Dependencies**

This property applies only when you set the `CoefficientsDataType` property to Custom.

#### **ProductDataType — Data type of product**

`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as one of `Full precision` | `Same as input` | `Custom`.

#### **CustomProductDataType — Product word and fraction lengths**

`numericType([],32,30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a Signedness of Auto.

#### **Dependencies**

This property applies only when you set the `ProductDataType` property to Custom.

#### **AccumulatorDataType — Data type of accumulator**

`Full precision` (default) | `Same as input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

#### **CustomAccumulatorDataType — Accumulator word and fraction lengths**

`numericType([],32,30)` (default) | `numericType`

Specify the accumulator fixed-point type as a scaled `numericType` object with a Signedness of Auto.

#### **Dependencies**

This property applies only when you set the `AccumulatorDataType` property to Custom.

#### **OutputDataType — Data type of output**

`Same as accumulator` (default) | `Same as product` | `Same as input` | `Custom`

Specify the output data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`.

#### **CustomOutputDataType — Output word and fraction lengths**

`numericType([],16,14)` (default) | `numericType`

Specify the output fixed-point type as a scaled `numericType` object with a Signedness of Auto.

#### **Dependencies**

This property applies only when you set the “`OutputDataType`” on page 4-0 property to Custom.

## Usage

### Syntax

```
[hi,lo] = subAna(x)
```

### Description

`[hi,lo] = subAna(x)` decomposes the input signal, `x`, into a high-frequency subband, `hi`, and a low-frequency subband, `lo`.

### Input Arguments

#### **x** — Data input

column vector | matrix

Data input, specified as a column vector or a matrix size  $P$ -by- $Q$ . The number of input rows  $P$  can be arbitrary and does not have to be even.

This object supports variable-size input signals, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

### Output Arguments

#### **hi** — High-frequency subband

column vector | matrix

High-frequency subband, returned as a column vector or a matrix.

When the input is of size  $P$ -by- $Q$ , and  $P$  is not even, the high-frequency subband output has an upper bound size of  $\text{ceil}(P/2)$ -by- $Q$ . If  $P$  is even, then the output is of size  $(P/2)$ -by- $Q$ . The number of channels (columns) does not change.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

#### **lo** — Low-frequency subband

column vector | matrix

Low-frequency subband, returned as a column vector or a matrix.

When the input is of size  $P$ -by- $Q$ , and  $P$  is not even, the low-frequency subband output has an upper bound size of  $\text{ceil}(P/2)$ -by- $Q$ . If  $P$  is even, then the output is of size  $(P/2)$ -by- $Q$ . The number of channels (columns) does not change.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

step     Run System object algorithm  
 release   Release resources and allow changes to System object property values and input characteristics  
 reset     Reset internal states of System object

## Examples

### Decompose and Reconstruct a Signal

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);
```

```
[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

## Version History

**Introduced in R2012a**

### **R2023a: Support for arbitrary input frame length**

This object supports an input signal with an arbitrary frame length, so the input frame length does not have to be even.

### **R2023a: Support for variable-size input signal**

The input signal to this object can be a variable-size signal, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

In the code you generate from this object, the low-frequency and high-frequency subband outputs are fixed-size signals if the input signal is even and is of fixed size. If the input is not even or if the input is a variable-size signal, then the frequency subband outputs are of variable-size.

# dsp.SubbandSynthesisFilter

**Package:** dsp

Reconstruct signal from high-frequency and low-frequency subbands

## Description

The `dsp.SubbandSynthesisFilter` System object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

- 1 Create the `dsp.SubbandSynthesisFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
subSyn = dsp.SubbandSynthesisFilter
subSyn = dsp.SubbandSynthesisFilter(lpc,hpc)
subSyn = dsp.SubbandSynthesisFilter(Name,Value)
```

### Description

`subSyn = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `subSyn`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`subSyn = dsp.SubbandSynthesisFilter(lpc,hpc)` returns a two-channel subband synthesis filter, `subSyn`. The object has the “LowpassCoefficients” on page 4-0 property set to `lpc` and the `HighpassCoefficients` property set to `hpc`.

`subSyn = dsp.SubbandSynthesisFilter(Name,Value)` returns a two-channel subband synthesis filter, `subSyn`, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**LowpassCoefficients — Lowpass FIR filter coefficients**`[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352]` (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of  $z$ . For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**HighpassCoefficients — Highpass FIR filter coefficients**`[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327]` (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of  $z$ . For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Fixed-Point Properties****FullPrecisionOverride — Full precision override for fixed-point arithmetic**`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

**RoundingMethod — Rounding method for fixed-point operations**`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

**Dependencies**

This property applies only if the object is not in full precision mode.

**OverflowAction — Action to take when integer input is out of range**`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

**Dependencies**

This property applies only if the object is not in full precision mode.

**CoefficientsDataType — Data type of the coefficients**`Same word length as input` (default) | `Custom`

Specify the FIR filter coefficients fixed-point data type as `Same word length as input` or `Custom`.

**CustomCoefficientsDataType — Coefficient word and fraction lengths**

numericType([],16,15) (default) | numericType

Specify the FIR filter coefficients fixed-point type as a numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the CoefficientsDataType property to Custom.

**ProductDataType — Data type of product**

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

**CustomProductDataType — Product word and fraction lengths**

numericType([],32,30) (default) | numericType

Specify the product fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the ProductDataType property to Custom.

**AccumulatorDataType — Data type of accumulator**

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator data type as Full precision, Same as input, Same as product, or Custom.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

numericType([],32,30) (default) | numericType

Specify the accumulator fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the AccumulatorDataType property to Custom.

**OutputDataType — Data type of output**

Same as accumulator (default) | Same as product | Same as input | Custom

Specify the output data type as Same as accumulator, Same as product, Same as input, or Custom.

**CustomOutputDataType — Output word and fraction lengths**

numericType([],16,14) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the OutputDataType property to Custom.

## Usage

### Syntax

```
y = subSyn(hi,lo)
```

### Description

`y = subSyn(hi, lo)` reconstructs a signal from a high-frequency subband, `hi`, and a low-frequency subband, `lo`.

### Input Arguments

#### **hi** — High-frequency subband

vector | matrix

High-frequency subband, specified as a column vector or a matrix. Both inputs must have the same size and data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

#### **lo** — Low-frequency subband

vector | matrix

Low-frequency subband, specified as a column vector or a matrix. Both inputs must have the same size and data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

### Output Arguments

#### **y** — Synthesized output

vector | matrix

Synthesized output, reconstructed as a vector or a matrix. The number of rows in the output is the sum of the number of rows of the input signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

## Decompose and Reconstruct a Signal

Decompose a signal into low frequency and high frequency subbands using the subband analysis filter. Reconstruct the signal using the subband synthesis filter.

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
subAna = dsp.SubbandAnalysisFilter(lod, hid);
subSynth = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);
```

```
[hi, lo] = subAna(u); % Two channel analysis
y = subSynth(hi, lo); % Two channel synthesis
```

Plot difference between original and reconstructed signals with filter latency compensated.

```
plot(u(1:end-7)-y(8:end));
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.

- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

# dsp.TimeScope

**Package:** dsp

(To be removed) Time domain signal display and measurement

## Description

---

**Note** `dsp.TimeScope` is not recommended. Use `timescope` instead. For more information, see “Compatibility Considerations” on page 4-1171

---

The `dsp.TimeScope` System object displays time-domain signals. You can use the scope to measure signal values, find peaks, display bilevel measurements and statistics.

To see time-domain signals in the scope:

- 1 Create the `dsp.TimeScope` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

For information on measurements and triggers, see “Configure Time Scope Block”.

Scope display features:

- Multiple signals — Plot multiple signals on the same y-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple y-axes. All the y-axes have a common time range on the x-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscaling during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.

## Creation

### Syntax

```
scope = dsp.TimeScope
```

```
scope = dsp.TimeScope(numInputs, sampleRate)
scope = dsp.TimeScope( ___, Name, Value)
```

### Description

`scope = dsp.TimeScope` returns a Time Scope System object, `scope`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`scope = dsp.TimeScope(numInputs, sampleRate)` creates a Time Scope and sets the `NumInputPorts` property to `numInputs` and the `SampleRate` property to `sampleRate`.

`scope = dsp.TimeScope( ___, Name, Value)` sets properties specified as `Name, Value` pairs.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### Frequently Used

#### **NumInputPorts** — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

#### **SampleRate** — Sample rate of inputs

1 (default) | scalar | vector

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or a numeric vector with length equal to the value of `NumInputPorts`. The inverse of the sample rate determines the spacing between points on the time axis in the displayed signal. When you set `SampleRate` to a scalar value and `NumInputPorts` is greater than 1, the object uses the same sample rate for all inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **TimeSpan** — Time span

10 (default) | positive scalar

Specify the time span, in seconds, as a positive, numeric scalar value. The time-axis limits are calculated as follows.

- Minimum time-axis limit = `min(TimeDisplayOffset)`
- Maximum time-axis limit = `max(TimeDisplayOffset) + TimeSpan`

**Tunable:** Yes

**Dependencies**

To use this property, set `FrameBasedProcessing` to `false`, or set `FrameBasedProcessing` to `true` and `TimeSpanSource` to `'Property'`.

**Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time Span**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**TimeSpanOverrunAction — Wrap or scroll when TimeSpan is overrun**

`'Wrap'` (default) | `'Scroll'`

Specify how the scope displays new data beyond the visible time span.

- **Wrap** — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.
- **Scroll** — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

**Tunable:** Yes

**Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time Span overrun action**.

Data Types: `char` | `string`

**TimeSpanSource — Source of time span**

`'Property'` (default) | `'Auto'`

Specify the source of the time span for frame-based input signals as:

- `'Property'` - The object derives the x-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties.
- `'Auto'` - The time-axis limits are derived from the `TimeDisplayOffset` and `SampleRate` properties and the `FrameSize` (number of rows in each input signal). The limits are calculated as:
  - Minimum time-axis limit =  $\min(\text{TimeDisplayOffset})$
  - Maximum time-axis limit =  $\max(\text{TimeDisplayOffset}) + \max(1/\text{SampleRate} * \text{FrameSize})$

**Tunable:** Yes

**Dependencies**

To use this property, set `FrameBasedProcessing` to `true`.

**Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time Span**.

Data Types: `char` | `string`

**AxesScaling — Axes scaling mode**`"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"`

Specify when the scope scales the axes. Valid values are:

- `"Auto"` — The scope scales the axes as needed to fit the data, both during and after simulation.
- `"Manual"` — The scope does not scale the axes automatically.
- `"OnceAtStop"` — The scope scales the axes when the simulation stops.
- `"Updates"` — The scope scales the axes once and only once after 10 updates.

**Scope Window Use**

Select **Tools > Axes Scaling**.

Data Types: `char` | `string`

**Advanced****Name — Window name**`'Time Scope' (default) | character vector | string scalar`

Specify the name of the scope as a character vector or string scalar. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the `Title` property.

**Tunable:** Yes

Data Types: `char` | `string`

**Position — Window position**`screen center (default) | [left bottom width height]`

Scope window position in pixels, specified by the size and location of the scope window as a 4-element vector of the form `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 410 pixels and height of 300 pixels. The exact position value depends on your screen resolution.

**Tunable:** Yes

**ReduceUpdates — Reduce updates to improve performance**`true (default) | false`

- `true` — The scope logs data for later use and updates the window periodically.
- `false` — The scope updates every time the scope is called.

The simulation speed is faster when this property is set to `true`.

**Tunable:** Yes

**Scope Window Use**

Select **Simulation > Reduce Updates to Improve Performance**.

**LayoutDimensions — Display layout grid dimensions**`[1,1] (default) | [numberOfRows, numberOfColumns]`

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use up to 16 rows and 16 columns.

Example: `scope.LayoutDimensions = [2,4]`

**Tunable:** Yes

#### Scope Window Use

Select **View > Layout**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### PlotType — Control the type of plot

`'Line'` (default) | `'Stairs'`

Specify the type of plot to use.

- `Line` — Line graph, similar to the `line` or `plot` function.
- `Stairs` — Stair-step graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

**Tunable:** Yes

#### Scope Window Use

Open the **Style** properties. Set **Plot type**.

Data Types: `char` | `string`

#### BufferLength — Length of buffer used for each input signal

`5000` (default) | `scalar`

Specify the size of the buffer that the scope holds in its memory cache. Memory is limited by available memory on your system. If your signal has  $M$  rows of data and  $N$  data points in each row,  $M \times N$  is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 ( $10 \times 100 \times 10$ ) as the buffer length.

#### Scope Window Use

Open the **Data History Properties**. Set **Buffer length**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### FrameBasedProcessing — Process input in frames

`true` (default) | `false`

- `true` — Enable frame-based processing.
- `false` — Enable sample-based processing.

#### Scope Window Use

Open the **Configuration Properties**. On the **Main** tab, set **Input processing**.

#### TimeUnits — Units of time axis

`'Metric'` (default) | `'Seconds'` | `'None'`

Specify the units used to describe the time axis. You can select one of the following options:

- **Metric** — In this mode, the scope converts the times on the time axis to the most appropriate measurement units. These units include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- **Seconds** — In this mode, the scope always displays the units on the time axis as seconds.
- **None** — In this mode, the scope does not display any units on the time axis. The scope only shows the word **Time** on the time axis.

**Tunable:** Yes

#### **Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time units**.

Data Types: char | string

#### **TimeDisplayOffset — Offset x-axis limits**

0 (default) | scalar | vector

Specify, in seconds, how far to move the data on x-axis. The signal value does not change, only the displayed x-axis.

If you specify this property as a scalar, then that value is the time display offset for all channels.

If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored.

**Tunable:** Yes

#### **Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time display offset**.

#### **TimeAxisLabels — Time-axis labels**

'All' (default) | 'Bottom' | 'None'

Specify how time-axis labels should appear in the scope displays as:

- **'All'** — Time-axis labels appear in all displays.
- **'Bottom'** — Time-axis labels appear in the bottom display of each column.
- **'None'** — No labels appear in any display.

**Tunable:** Yes

#### **Scope Window Use**

Open the **Configuration Properties**. On the **Time** tab, set **Time-axis labels**.

Data Types: char | string

#### **MaximizeAxes — Maximize axes control**

"Auto" (default) | "On" | "Off"

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

**Tunable:** Yes

#### Scope Window Use

Open the **Configuration Properties**. On the **Main** tab, set **Maximize axes**.

Data Types: `char` | `string`

#### Display

##### ActiveDisplay — Active display for setting properties

1 (default) | integer

Specify the active display, by integer display number, to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed.

**Tunable:** Yes

#### Scope Window Use

Open the **Configuration Properties**. On the **Display** tab, set **Active Display**.

##### Title — Display title

' ' (default) | character vector | string scalar

Display title, specified as a character vector or a string scalar.

**Tunable:** Yes

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Title**.

Data Types: `char` | `string`

##### ShowLegend — Flag to show legend

false (default) | true

Flag to show the legend, specified as `true` or `false`. To show a legend with the input names, set this property to `true`.

Use the legend to control which signals are visible. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

### Dependencies

To enable this property, set the `ViewType` property to "Spectrum" or "Spectrum and spectrogram".

### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

### ShowTimeAxisLabel — Show legend on display

`true` (default) | `false`

When you set this property to `true`, the scope displays the time-axis label. When you set this property to `false`, the scope does not display the time-axis label, but still displays tick marks and other time-axis items. This property applies only if the `TimeAxisLabels` property is `All` or `Bottom`.

**Tunable:** Yes

### Dependency

To control which display's axis is labeled, use the `ActiveDisplay` property.

### Scope Window Use

Open the **Configuration Properties**. On the **Time** tab, set **Show time-axis label**.

### ChannelNames — Channel names

empty cell (default) | cell array of character vectors | array of strings

Channel names in the input data, specified as a cell array of character vectors or an array of strings. The names you specify in this property appear in the following locations:

- Legend
- **Spectrum Analyzer Settings > Color and styling** section
- **Measurements** and **Channel Measurements** tabs

If you do not specify channel names, the Spectrum Analyzer names the channels as `Channel 1`, `Channel 2`, and so on.

**Tunable:** Yes

### Dependency

To see the channel names, set `ShowLegend` to `true`.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

Data Types: char

**ShowGrid — Grid visibility**

false (default) | true

Set this property to `true` to show gridlines on the plot.

**Tunable:** Yes

**Scope Window Use**

Open the **Configuration Properties**. On the **Display** tab, set **Show grid**.

**PlotAsMagnitudePhase — Plot signal as magnitude and phase**

false (default) | true

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

**Tunable:** Yes

**Scope Window Use**

Open the **Configuration Properties**. On the **Display** tab, select **Plot signals as magnitude and phase**.

**YLimits — y-axis limits**

[-10,10] (default) | [ymin, ymax]

Specify the y-axis limits as a two-element numeric vector, [ymin, ymax].

If `PlotAsMagnitudePhase` is `false`, the default is [-10, 10]. If `PlotAsMagnitudePhase` is `true`, the default is [0, 10].

**Tunable:** Yes

**Dependencies**

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always [-180, 180].

**Scope Window Use**

Open the **Configuration Properties**. On the **Display** tab, set **Y-limits (Minimum)** and **Y-limits (Maximum)**.

**YLabel — y-axis label**

"Amplitude" (default) | character vector | string scalar

Specify the text for the scope to display to the left of the y-axis.

**Tunable:** Yes

**Dependencies**

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values. The y-axis labels are set to "Magnitude" and "Phase" for the magnitude plot and the phase plot, respectively.

**Scope Window Use**

Open the **Configuration Properties**. On the **Display** tab, set **Y-Label**.

Data Types: char | string

**Usage****Syntax**

```
scope(signal)
scope(signal, signal2, ..., signalN)
```

**Description**

`scope(signal)` displays the signal, `signal`, in the time scope display.

`scope(signal, signal2, ..., signalN)` displays the signals `signal`, `signal2`, ..., `signalN` in the time scope display when you set the `NumInputPorts` property to `N`. In this case, `signal1`, `signal2`, ..., `signalN` can have different data types and dimensions.

**Input Arguments****signal — Input signal or signals to visualize**

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.TimeScope`. Signals can have different data types and dimensions.

Example: `scope(signal1, signal2)`

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

**Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Specific to Scopes

show      Display scope window  
hide      Hide scope window  
isVisible Determine visibility of scope

## Common to All System Objects

step      Run System object algorithm  
release   Release resources and allow changes to System object property values and input characteristics  
reset     Reset internal states of System object

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

## Examples

### Display Simple Sine Wave Input Signal

Create `dsp.SineWave` and `dsp.TimeScope` objects. Run the scope to display the signal

```
sine = dsp.SineWave('Frequency',100,'SampleRate',1000);
sine.SamplesPerFrame = 10;
scope = dsp.TimeScope('SampleRate',sine.SampleRate,'TimeSpan',0.1);
for ii = 1:10
    x = sine();
    scope(x);
end
```

Run the `release` method to allow changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```

## Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a scope.

You cannot open scope configuration dialogs if you have more than one compiled component in your application.

## Version History

### Introduced in R2011a

### R2021a: `dsp.TimeScope` will be removed

*Warns starting in R2021a*

`dsp.TimeScope` will be removed in a future release. Use `timescope` instead.

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

#### Topics

“Display Time-Domain Data”

# timescope

Display time-domain signals

## Description

The `timescope` object displays signals in the time domain.

Scope features:

- “Data Cursors” — Measure signal values using vertical and horizontal cursors.
- “Signal Statistics” — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- “Peak Finder” — Find maxima, showing the x-axis values at which they occur.
- “Bilevel Measurements” — Measure transitions, overshoots, undershoots, and cycles.
- “Triggers” — Set triggers to sync repeating signals and pause the display when events occur.

Use “Object Functions” on page 4-1182 to show, hide, and determine visibility of the scope window.

You can enable these measurements either programmatically or on the scope UI. For more details, see “Measurements” on page 4-1178.

## Creation

### Syntax

```
scope = timescope  
scope = timescope(Name=Value)
```

### Description

`scope = timescope` returns a `timescope` object, `scope`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`scope = timescope(Name=Value)` returns a `timescope` sets properties using `Name=Value` arguments. You can specify the name-value arguments in any order.

### Properties

Most properties can be changed from the `timescope` UI.

#### Frequently Used

##### SampleRate — Sample rate of inputs

1 (default) | finite numeric scalar | vector

Sampling rate of the input signal, in hertz, specified as a finite numeric scalar or vector of scalars.

The inverse of the sample rate determines the x-axis (time axis) spacing between points in the displayed signal. When the value of `NumInputPorts` is greater than 1 and the sample rate is scalar, the object uses the same sample rate for all inputs. To specify different sample rates for each input, use a vector.

You can only set this property when creating the object or after calling `release`.

##### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, specify the sample rate in the **Sample Rate** box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

##### TimeSpanSource — Source of time span

"auto" (default) | "property"

Source of the time span for frame-based input signals, specified as one of the following:

- "property" - The object derives the x-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties.
- "auto" - The x-axis limits are derived from the `TimeDisplayOffset` property, `SampleRate` property, and the number of rows in each input signal (`FrameSize` in the equations below). The limits are calculated as:
  - Minimum time-axis limit = `TimeDisplayOffset`
  - Maximum time-axis limit = `TimeDisplayOffset + max(1/SampleRate.*FrameSize)`

**Dependency**

When you set the `TimeSpan` property, `TimeSpanSource` is automatically set to "property".

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, select Auto or specify the time span in the **Time Span** box.

Data Types: `char` | `string`

**TimeSpan — Time span**

10 (default) | positive scalar

Time span, in seconds, specified as a positive, numeric scalar value. The time-axis limits are calculated as:

- Minimum time-axis limit = `TimeDisplayOffset`
- Maximum time-axis limit = `TimeDisplayOffset` + `TimeSpan`

**Dependencies**

To enable this property, set `TimeSpanSource` to "property".

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, specify the time span in the **Time Span** box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**TimeSpanOverrunAction — Data overrun behavior**

"scroll" (default) | "wrap"

Specify how the scope displays new data beyond the visible time span as either:

- "scroll" — In this mode, the scope scrolls old data to the left to make room for new data on the right of the scope display. This mode is beneficial for debugging and monitoring time-varying signals.
- "wrap" — In this mode, the scope adds data to the left of the plot after overrunning the right of the plot.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, select the overrun behavior in **Overrun Action**.

Data Types: `char` | `string`

**PlotType — Type of plot**

"line" (default) | "stairs"

Type of plot, specified as either:

- "line" — Line graph, similar to the `line` or `plot` function.
- "stairs" — Stair-step graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, select the plot type in **Plot Type**.

Data Types: char | string

### AxesScaling — Axes scaling mode

"onceatstop" (default) | "auto" | "manual" | "updates"

When this property is set to:

- "onceatstop" -- The limits are updated once at the end of the simulation (when release is called).
- "auto" -- The scope attempts to always keep the data in the display while minimizing the number of updates to the axes limits.
- "manual" -- The scope takes no action unless specified by the user.
- "updates" -- The scope scales the axes once after a set number of visual updates. The number of updates is determined by the value of the AxesScalingNumUpdates property.

You can set this property only when creating the object.

Data Types: char | string

### AxesScalingNumUpdates — Number of updates before scaling

100 (default) | real positive integer

Specify the number of updates before scaling as a real, positive scalar integer.

### Dependency

To enable this property, set AxesScaling to "updates".

Data Types: double

### Advanced

#### LayoutDimensions — Display layout grid dimensions

[1,1] (default) | [numberOfRows, numberOfColumns]

Specify the layout grid dimensions as a two-element vector: [numberOfRows, numberOfColumns]. The grid can have a maximum of 4 rows and 4 columns.

If you create a grid of multiple axes, to modify the settings of individual axes, use the ActiveDisplay.

Example: scope.LayoutDimensions = [2,4]

### Scope Window Use

On the **Scope** tab, click **Display Grid** () and select a specific number of rows and columns in the grid.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### TimeUnits — Units of x-axis

"seconds" (default) | "none" | "metric"

Specify the units used to describe the x-axis (time axis). You can select one of the following options:

- "seconds" —The scope always displays the units on the x-axis as seconds. The scope shows the word `Time(s)` on the x-axis.
- "none" — The scope does not display any units on the x-axis. The scope only shows the word `Time` on the x-axis.
- "metric" — The scope displays the units on the x-axis as `Time (s)` changing the units to day, weeks, months, or years as you plot more data points.

#### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, specify the x-axis units in **Time Units**.

Data Types: `char` | `string`

#### TimeDisplayOffset — Offset x-axis limits

0 (default) | `scalar` | `vector`

Specify, in seconds, how far to move the data on the x-axis. The signal value does not change, only the limits displayed on the x-axis change.

If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify this property as a vector, each input channel can be a different time display offset

#### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, specify the x-axis offset in **Time Offset**.

#### TimeAxisLabels — Time-axis labels

"all" (default) | "bottom" | "none"

Time-axis labels, specified as:

- "all" — Time-axis labels appear in all displays.
- "bottom" — Time-axis labels appear in the bottom display of each column.
- "none" — No labels appear in any display.

#### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, select which x-axis label to display in **Time Labels**.

Data Types: `char` | `string`

#### MaximizeAxes — Maximize axes control

"auto" (default) | "on" | "off"

Specify whether to display the scope in the maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, the tick-marks and their values appear on top of the plotted data. You can select one of the following options:

- "auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "on" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "off" — None of the axes appear maximized.

### Scope Window Use

On the scope window, click  to maximize axes, hide all labels and inset the axes values.

Data Types: `char` | `string`

### BufferLength — Buffer length

50000 (default) | positive integer

Specify the length of the buffer used for each input signal as a positive integer.

You can set this property only when creating the object.

### Scope Window Use

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Data and Axes**, specify the buffer length in the **Buffer Length** box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Measurements

### MeasurementChannel — Channel for which to obtain measurements

1 (default) | positive integer

Channel for which to obtain measurements, specified as a positive integer in the range [1 *N*], where *N* is the number of input channels.

### Scope Window Use

On the **Measurements** tab, select a **Channel**.

Data Types: `double`

### BilevelMeasurements — Bilevel measurements

`BilevelMeasurementsConfiguration` object

Bilevel measurements to measure transitions, aberrations, and cycles of bilevel signals, specified as a `BilevelMeasurementsConfiguration` object.

All `BilevelMeasurementsConfiguration` properties are tunable.

### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings** to modify the bilevel measurements.

### CursorMeasurements — Cursor measurements

`CursorMeasurementsConfiguration` object

Cursor measurements to display screen or waveform cursors, specified as a `CursorMeasurementsConfiguration` object.

All `CursorMeasurementsConfiguration` properties are tunable.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, select **Data Cursors** to enable the cursors on the display. Click **Data Cursors** to modify the cursor settings.

#### PeakFinder — Peak finder measurements

`PeakFinderConfiguration` object

Peak finder measurements to compute and display the largest calculated peak values, specified as a `PeakFinderConfiguration` object.

All `PeakFinderConfiguration` properties are tunable.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, select **Peak Finder** to enable the peak finder. Click **Peak Finder** to modify the peak finder settings.

#### SignalStatistics — Signal statistics measurements

`SignalStatisticsConfiguration` object

Signal statistics measurements to compute and display signal statistics, specified as a `SignalStatisticsConfiguration` object.

All `SignalStatisticsConfiguration` properties are tunable.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, select **Signal Statistics**. Click **Signal Statistics** to choose the statistics to compute.

#### Trigger — Trigger measurements

`TriggerConfiguration` object

Trigger measurements, specified as a `TriggerConfiguration` object. Define a trigger event to identify the simulation time of specified input signal characteristics. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals such as a pulse that occurs intermittently.

All `TriggerConfiguration` properties are tunable.

#### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, select **Enable Trigger** and click **Settings** to modify the trigger settings.

### Visualization

#### Name — Window name

"Time Scope" (default) | character vector | string scalar

Specify the name of the scope as a character vector or string scalar. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the `Title` property.

Data Types: char | string

**Position — Window position**

screen center (default) | [left bottom width height]

Scope window position in pixels, specified by the size and location of the scope window as a four-element vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values of this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 500 pixels. The exact values of the position depend on your screen resolution.

**ChannelNames — Channel names**

{ ' ' } (default) | cell array of character vectors | array of strings

Specify the input channel names as a cell array of character vectors or an array of strings. The channel names appear in the legend, and on the **Measurements** tab under **Select Channel**. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

**Dependency**

To enable this property, set ShowLegend to true.

Data Types: char

**ActiveDisplay — Active display for setting properties**

1 (default) | integer

Active display used to set properties, specified by the integer display number. The number of a display corresponds to the display's row-wise placement index. Setting this property controls which display is used for the following properties: YLimits, YLabel, ShowLegend, ShowGrid, Title, and PlotAsMagnitudePhase.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, specify the active display using **Active Display**.

**Title — Display title**

' ' (default) | character vector | string scalar

Specify the display title as a character vector or a string scalar.

**Dependency**

When you set this property, ActiveDisplay controls the display that is updated.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, specify the display title in the **Title** box.

Data Types: char | string

**YLabel — y-axis label**

"Amplitude" (default) | character vector | string scalar

Specify the text for the scope to display to the left of the y-axis.

**Dependencies**

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values "Magnitude" and "Phase", for the magnitude plot and the phase plot, respectively.

When you set this property, `ActiveDisplay` controls the display that is updated.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, specify a label for the y-axis in the **Y-Label** box.

Data Types: `char` | `string`

**YLimits — y-axis limits**

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

- If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`.
- If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`. This property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`

**Dependency**

When you set this property, `ActiveDisplay` controls the display that is updated.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, specify the limits for the y-axis in the **Y-Axis Limits** box.

**ShowLegend — Show legend**

`false` (default) | `true`

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, select **Show Legend**.

Data Types: `logical`

**ShowGrid — Grid visibility**

`true` (default) | `false`

Set this property to `true` to show grid lines on the plot.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, select **Show Grid**.

**PlotAsMagnitudePhase — Plot signal as magnitude and phase**`false` (default) | `true`

Plot signal as magnitude and phased, specified as either:

- `true` - The scope plots the magnitude and phase of the input signal on two separate axes within the same active display.
- `false` - The scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

**Scope Window Use**

On the **Scope** tab, click **Settings**. In the Time Scope Settings dialog box, under **Display and Labels**, select **Magnitude Phase Plot**.

**Object Functions**

To use an object function, specify the object as the first input argument.

|                             |  |
|-----------------------------|--|
| <code>hide</code>           | Hide scope window  |
| <code>show</code>           | Display scope window   |
| <code>isVisible</code>      | Determine visibility of scope  |
| <code>generateScript</code> | Generate MATLAB script to create scope with current settings                                   |
| <code>step</code>           | Run System object algorithm  |
| <code>release</code>        | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>          | Reset internal states of System object   |

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

**Examples****View Sine Wave on Time Scope**

Create a sinusoidal signal with two tones, one at 0.3 kHz and the other at 3 kHz.

```
t = (0:1000)'/8e3;  
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);
```

Create a `timescope` object and view the sinusoidal signal by calling the time scope object `scope`.

```
scope = timescope(SampleRate=8e3,...  
    TimeSpanSource="property",...  
    TimeSpan=0.1);  
scope(xin)
```

Run `release` to allow changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope);
```

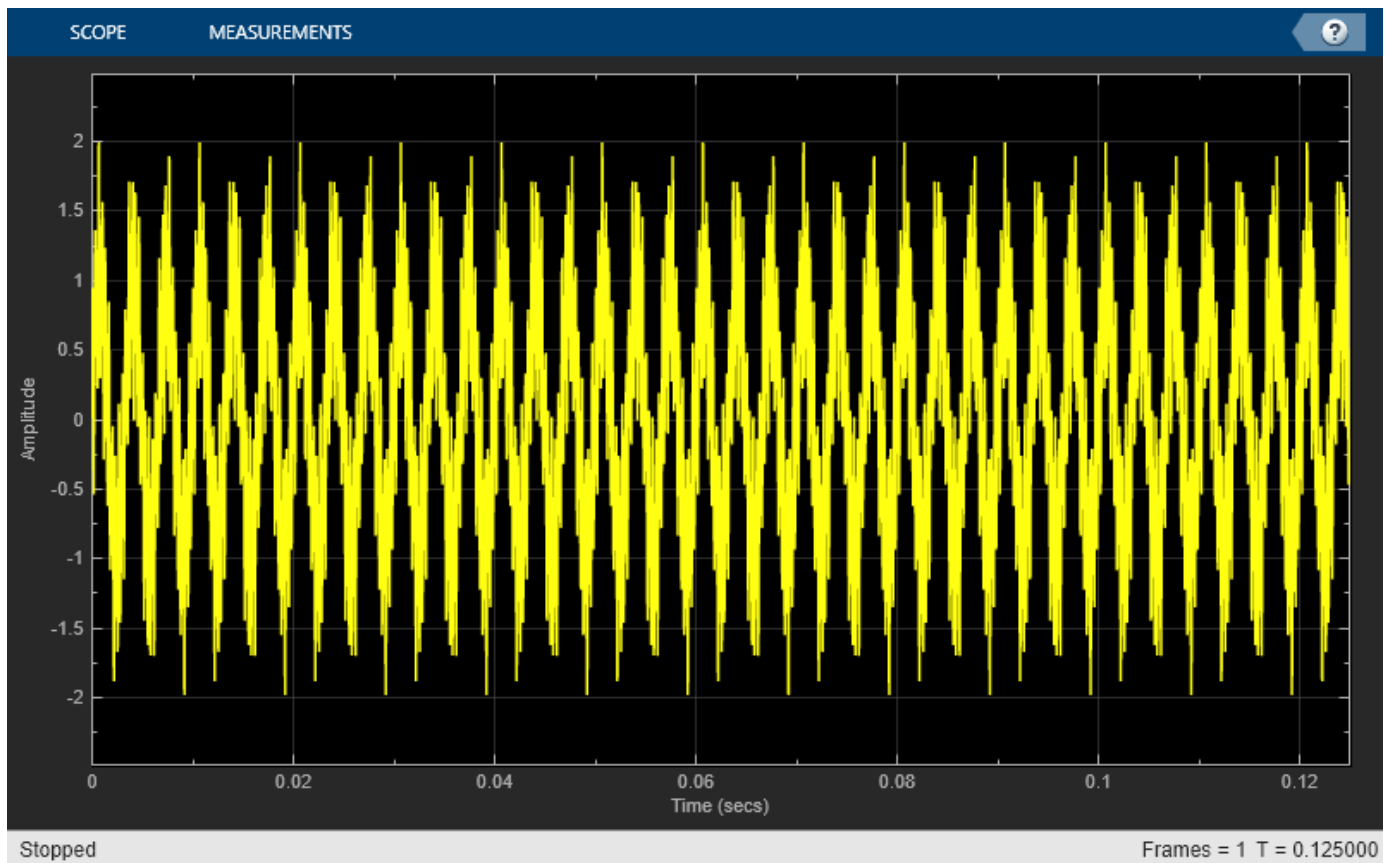

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

## Use Bilevel Measurements Panel with Clock Input Signal

### Create and Display Clock Input Signal

Load the clock data, `x` and `t`. Find the sample time `ts`.

```
load clockx  
ts = t(2)-t(1);
```

Create a `timescope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

```
scope = timescope(SampleRate=1/ts,TimeSpanSource="auto");  
scope(x);  
release(scope);
```

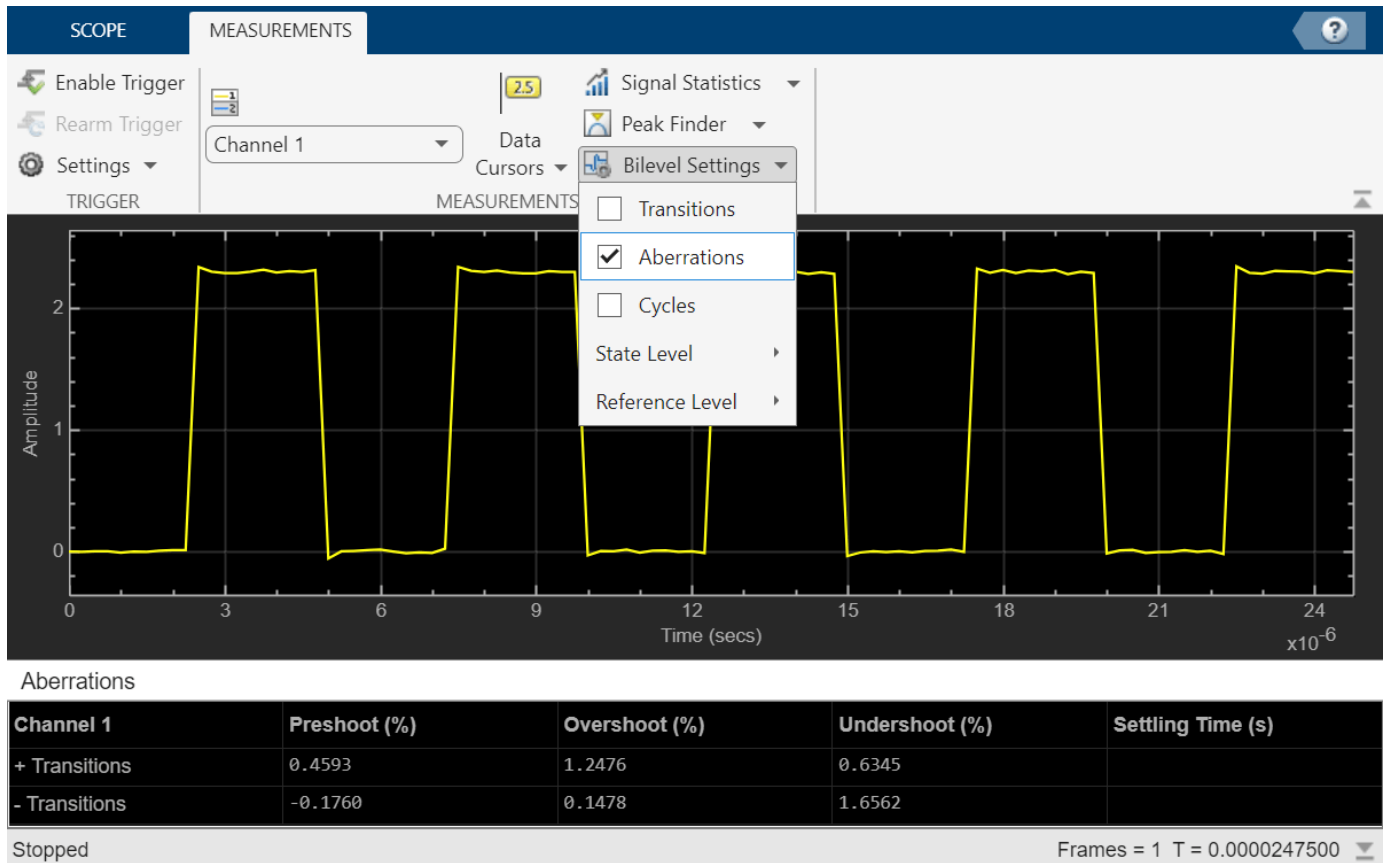

### Use Bilevel Measurements Panel to Find Settling Time

On the **Measurements** tab, under **Bilevel Settings**, select **Aberrations**.

Initially, the Time Scope does not display the **Settling Time(s)** measurement. This absence occurs because the default value of the **Settle Seek** parameter is longer than the entire simulation duration.

To change the value of the **Settle Seek (s)** parameter, click **Bilevel Settings**, and under **Reference Level**, set the settle seek value to  $2e-6$  and press **Enter**.

Time Scope now displays a rising edge **Settling Time** value of 118.392 ns.

This settling time value is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition.

Hover over the upper right corner of the scope axes and click the zoom button.

Click and drag to zoom in on one of the transitions. Set **Settle Seek (s)** to  $2e-7$  and press **Enter**.

The Time Scope updates the rising edge **Settling Time** value to reflect the new time window.

## Configure Bilevel Measurements Programmatically in Time Scope MATLAB Object

Create a sine wave and view it in the Time Scope. Programmatically compute the bilevel measurements related to signal transitions, aberrations, and cycles.

### Initialization

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

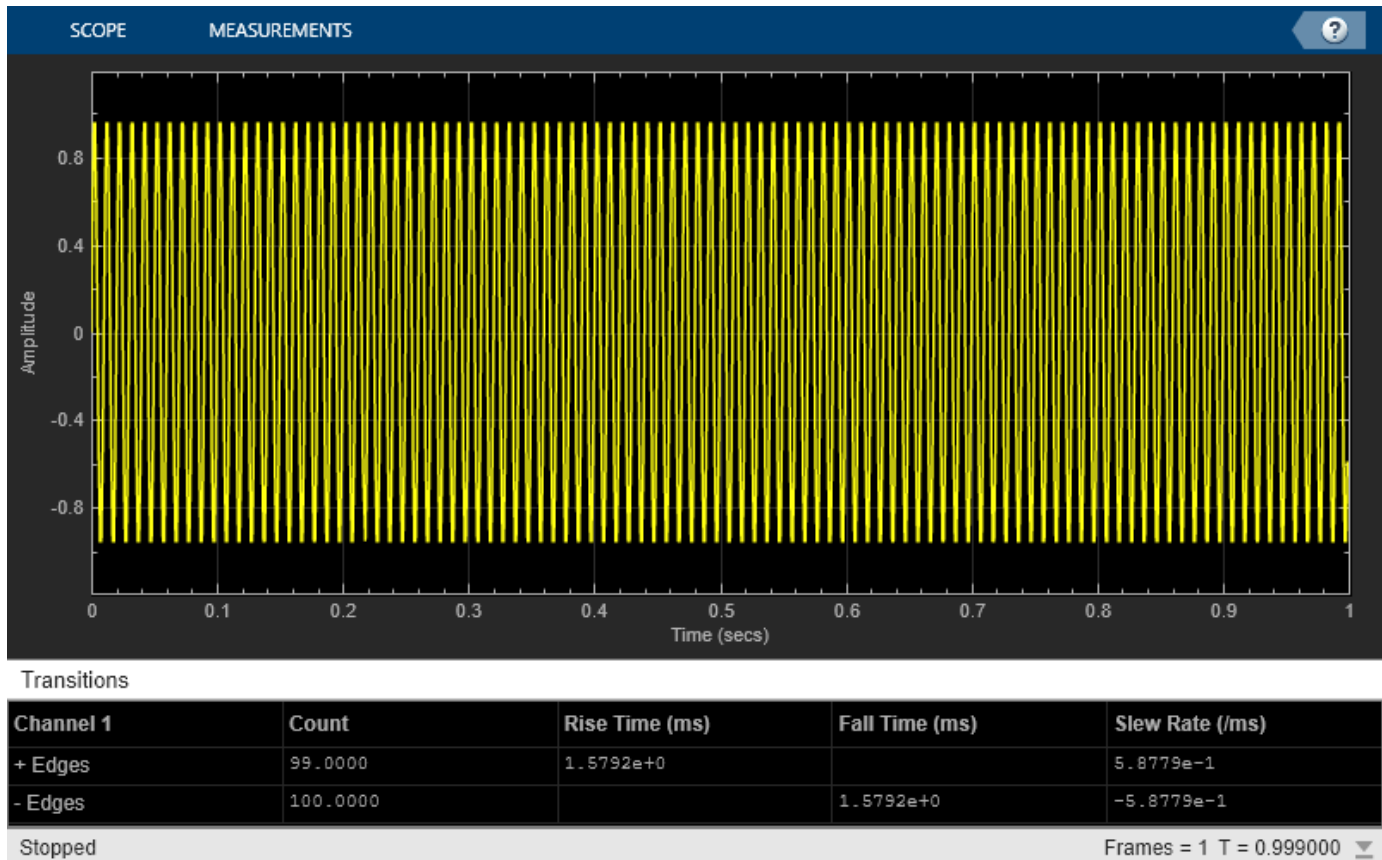

```
f = 100;
fs = 1000;
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
```

### Transition Measurements

Enable the scope to show transition measurements programmatically by setting the `ShowTransitions` property to `true`. Display the sine wave in the scope.

Transition measurements such as rise time, fall time, and slew rate appear in the **Transitions** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowTransitions = true;
scope(swv);
release(scope);
```

### Aberration Measurements

Enable the scope to show aberration measurements programmatically by setting the `ShowAberrations` property to `true`. Display the sine wave in the scope.

Aberration measurements such as preshoot, overshoot, undershoot, and settling time appear in the **Aberrations** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowAberrations = true;
scope(swv);
release(scope);
```

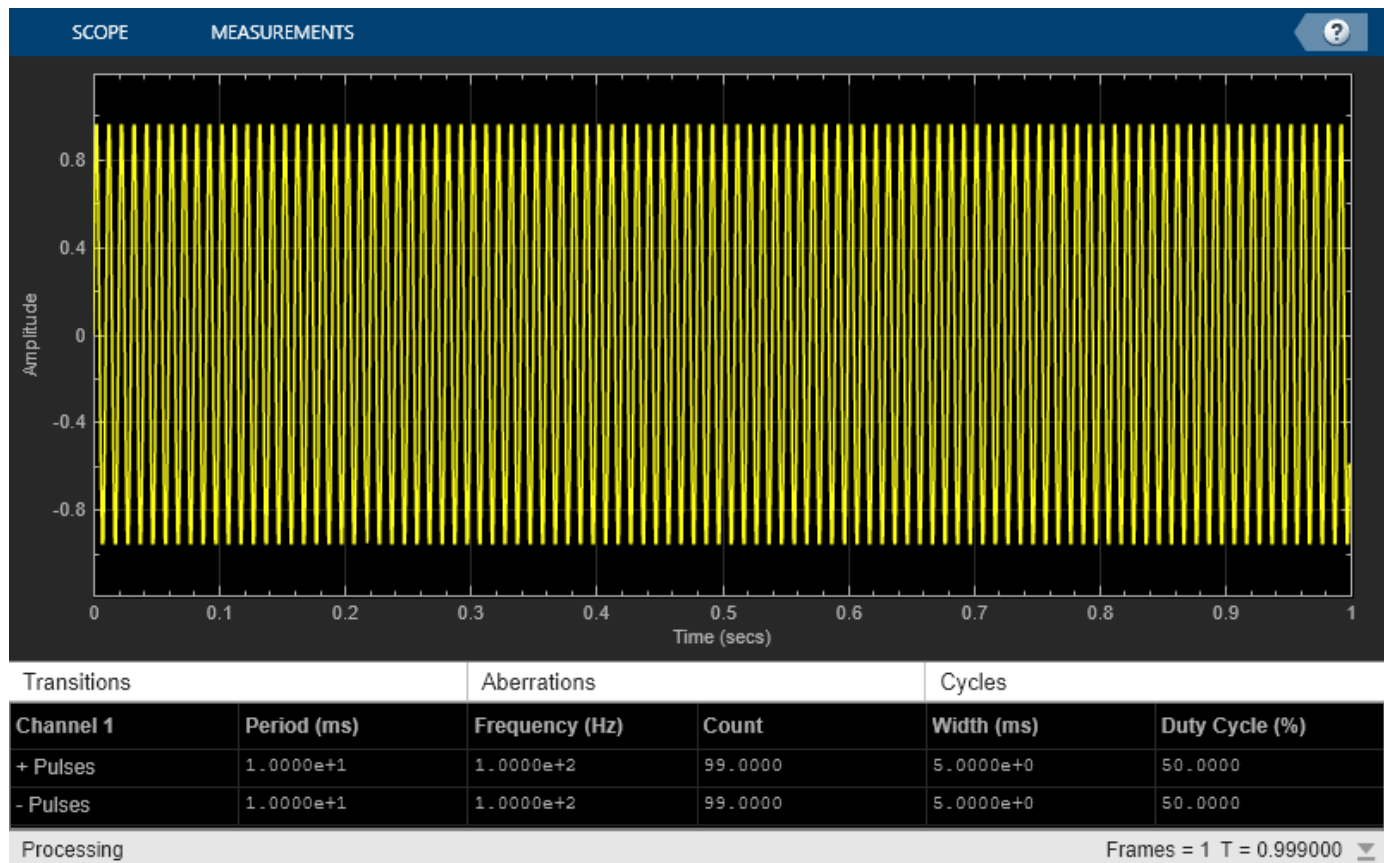

### Cycle Measurements

Enable the scope to show cycles measurements programmatically by setting the `ShowCycles` property to `true`. Display the sine wave in the scope.

Cycle measurements such as period, frequency, pulse width, and duty cycle appear in the **Cycles** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowCycles = true;
scope(svw);
release(scope);
```

### Configure Signal Statistics Programmatically in Time Scope MATLAB Object

Create a sine wave and view it in the Time Scope. Enable the scope programmatically to compute the signal statistics.

The object supports these signal statistics:

- Maximum
- Minimum
- Mean
- Median
- RMS
- Peak to peak
- Variance
- Standard deviation
- Mean square

#### Initialization

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

```
f = 100;
fs = 1000;
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
```

### Signal Statistics

Enable the scope to show signal statistics programmatically by setting the `SignalStatistics > Enabled` property to `true`.

```
scope.SignalStatistics.Enabled = true;
```

By default, the scope enables the following measurements.

```
scope.SignalStatistics
```

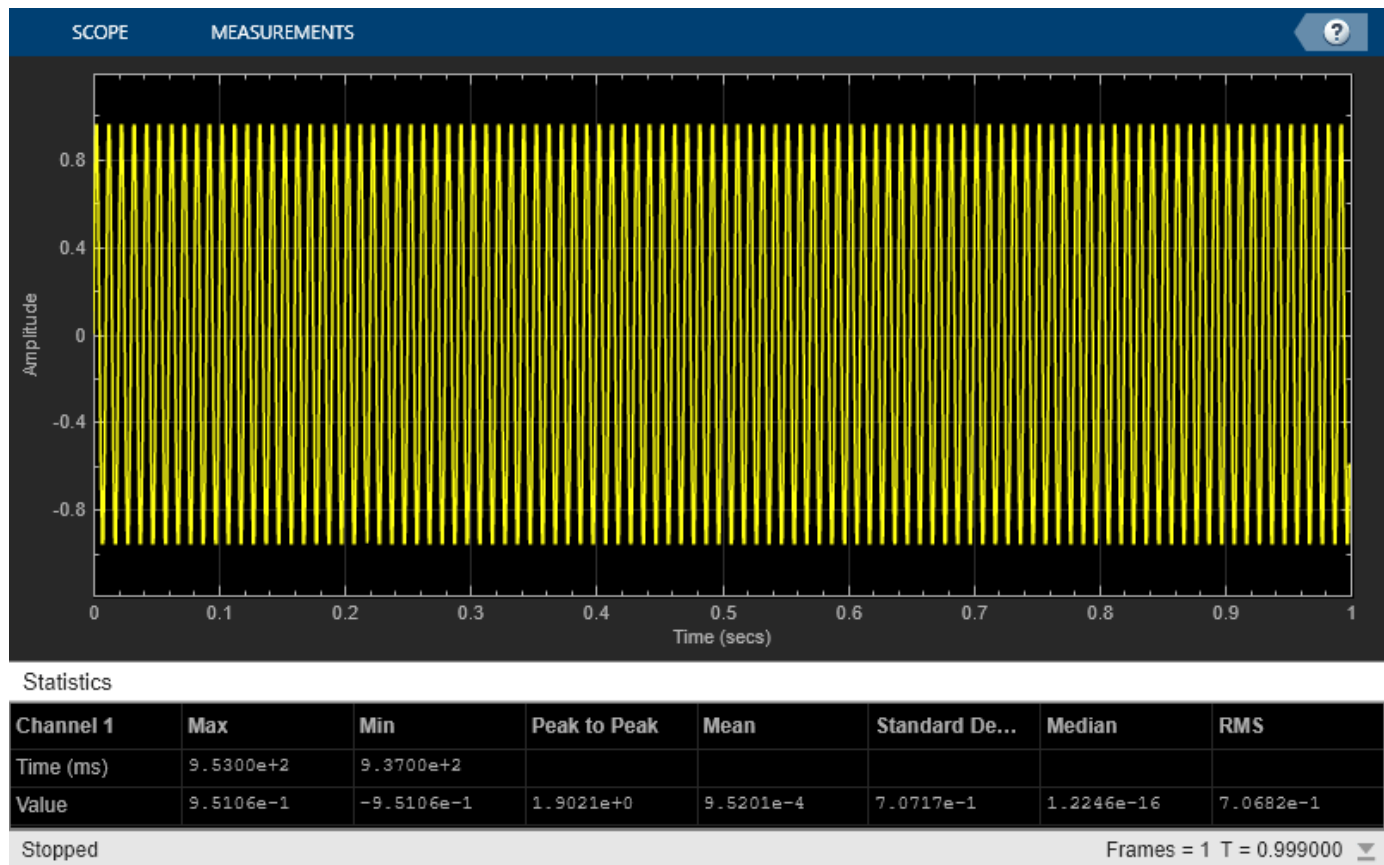

```
ans =
    SignalStatisticsConfiguration with properties:

        ShowMax: 1
        ShowMin: 1
    ShowPeakToPeak: 1
        ShowMean: 1
        ShowVariance: 0
    ShowStandardDeviation: 1
        ShowMedian: 1
        ShowRMS: 1
    ShowMeanSquare: 0
        Enabled: 1
```

Display the sine wave in the scope. A Statistics pane appears at the bottom of the scope window displaying the statistics for the portion of the signal that you can see in the scope.

If you use the zoom options on the scope, the statistics automatically adjust to the time range in the display.

```
scope(swv);
release(scope);
```

### Visualize Multiple Inputs with Different Sample Rates

This example shows how to visualize multiple inputs with different sample rates and plot the signals on multiple axes.

Generate three different sine waves and plot them in the Time Scope.

```

freq = 1/500;
t    = (0:100)'/freq;
t2   = (0:0.5:100)'/freq;
xin1 = sin(1/2*t);
xin2 = sin(1/4*t2);
xin  = sin(1/2*t2)+sin(1/4*t2);

scope = timescope(SampleRate=[freq freq/2 freq],...
    TimeSpanSource="property", ...
    TimeSpan=0.1,...
    LayoutDimensions=[2,1]);
scope(xin,xin1,xin2)

release(scope)

```

### Use Multiple Axes on Scope

This example shows how to add titles, set y-axis limits, and modify properties when you have multiple axes on your timescope object.

Use the timescope object to visualize three sine waves with two different sample rates.

```
freq = 1;
t = (0:100)'/freq;
t2 = (0:0.5:100)'/freq;
xin1 = sin(1/2*t);
xin2 = sin(1/4*t2);
xin = sin(1/2*t2)+sin(1/4*t2);

scope = timescope(SampleRate=[freq freq/2 freq],...
    TimeSpanSource="property",...
    TimeSpan=100);
scope(xin, xin1, xin2)
```

Change the layout to add a second axis. The second and third inputs automatically move to the new second axis.

```
scope.LayoutDimensions = [2,1];
```

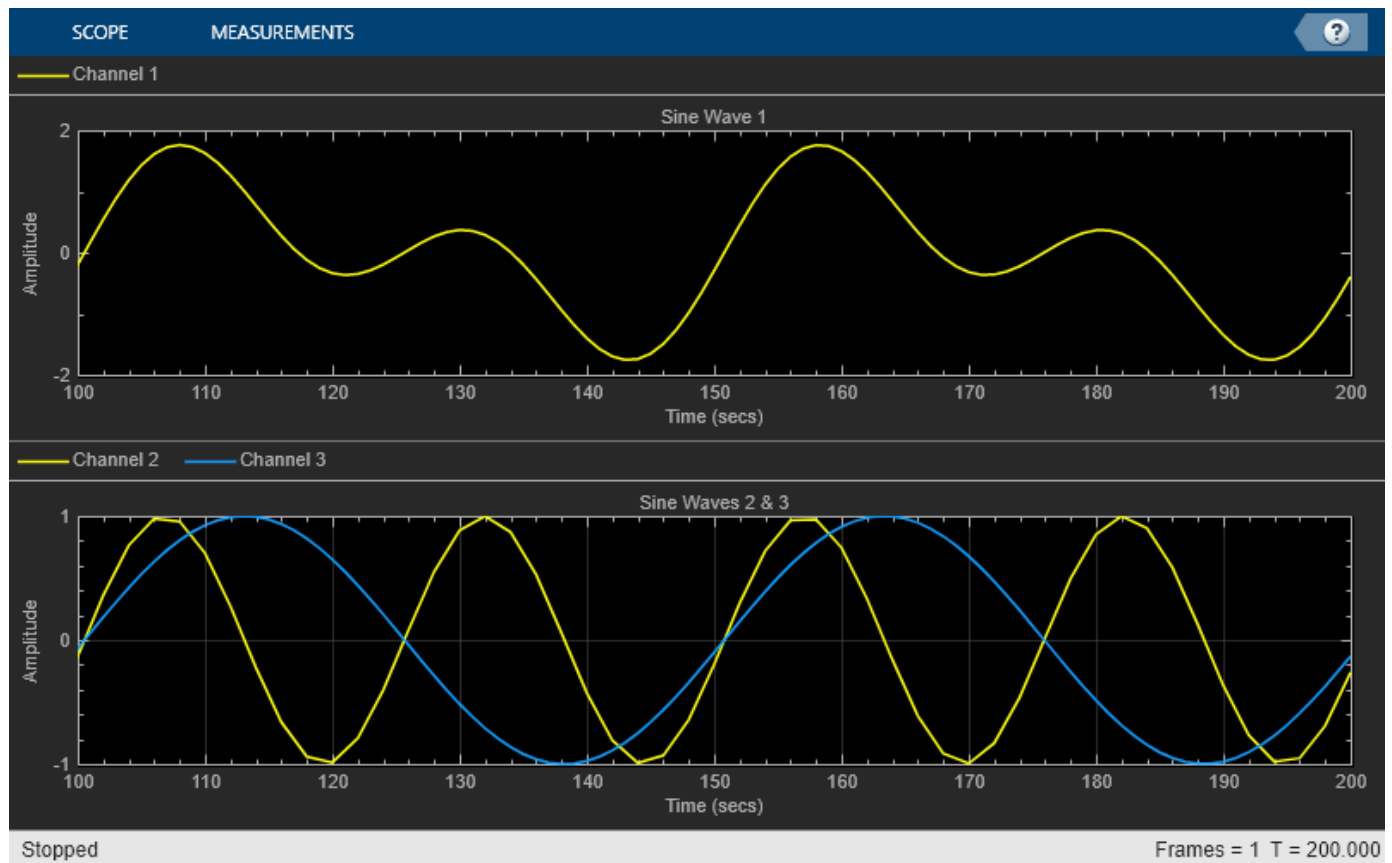

Modify the properties of the first axis.

```
scope.ActiveDisplay = 1;  
scope.ShowGrid = false;  
scope.Title = "Sine Wave 1";  
scope.YLimits = [-2,2];
```

Repeat this process to modify the second axis.

```
scope.ActiveDisplay = 2;  
scope.Title = "Sine Waves 2 & 3";  
scope.YLimits = [-1,1];  
release(scope)
```

### View Sine Wave Input Signals at Different Sample Rates and Offsets

Create a `dsp.SineWave` object. Create a `dsp.FIRDecimator` object to decimate the sine wave by 2. Create a `timescope` object with two input ports.

```
Fs = 1000; % Sample rate
sine = dsp.SineWave(Frequency=50,...
    SampleRate=Fs,...
    SamplesPerFrame=100);
decimate = dsp.FIRDecimator; % To decimate sine by 2
scope = timescope(SampleRate=[Fs Fs/2],...
    TimeDisplayOffset=[0 38/Fs],...
    TimeSpanSource="Property",...
    TimeSpan=0.25,...
    YLimits=[-1 1],...
    ShowLegend=true);
```

Call the `dsp.SineWave` object to create a sine wave signal. Use the `dsp.FIRDecimator` object to create a second signal that equals the original signal and decimate it by a factor of 2. Display the signals by calling the `timescope` object.

```
for ii = 1:2
    xsine = sine();
    xdec = decimate(xsine);
```

```

    scope(xsine,xdec)
end
release(scope)

```

Close the Time Scope window and clear the variables.

```
clear scope Fs sine decimate ii xsine xdec
```

### Display Complex-Valued Input Signal

Create a vector representing a complex-valued sinusoidal signal and a `timescope` object. Call the `scope` to display the signal.

```

fs = 1000;
t = (0:1/fs:10)';
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);
CxSineSum = cumsum(CxSine);
scope = timescope(SampleRate=fs,...
    TimeSpanSource="auto", ShowLegend=1);
scope(CxSineSum);
release(scope)

```

By default, when the input is a complex-valued signal, the Time Scope plots the real and imaginary portions on the same axes. These portions appear as different-colored lines on the same axes within the same active display.

Change the `PlotAsMagnitudePhase` property to `true` and call `release`.

The Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The top axes display magnitude and the bottom axes display the phase in degrees.

```
scope.PlotAsMagnitudePhase = true;
scope(CxSineSum);
release(scope)
```

### Display Input Signal of Changing Size

This example shows how the `timescope` object visualizes inputs that change dimensions halfway through.

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Create a `timescope` object and call the scope with two inputs to display the signal.

```
fs = 10;
sigdim2 = [ones(5*fs,1) 1+ones(5*fs,1)]; % 2-dim 0-5 s
sigdim3 = [2+ones(5*fs,1) 3+ones(5*fs,1) 4+ones(5*fs,1)]; % 3-dim 5-10 s
scope = timescope(SampleRate=fs,TimeSpanSource="property");
scope.PlotType = "stairs";
scope.TimeSpanOvverrunAction = "scroll";
scope.TimeDisplayOffset = [0 5];
scope([sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```

The size of the input signal to the Time Scope changes as the simulation progresses. When the simulation time is less than 5 seconds, the Time Scope plots only the two-channel signal `sigdim2`. After 5 seconds, the Time Scope also plots the three-channel signal `sigdim3`.

Run the `release` method to enable changes to property values and input characteristics. The scope automatically scales the axes.

```
release(scope)
```

## Find Heart Rate Using Peak Finder Panel with ECG Input Signal

Use Peak Finder pane in the Time Scope to measure heart rate.

### Create and Display ECG Signal

Use the custom ecg function to generate an electrocardiogram (ECG) signal.

type `ecg.m`

```
function x = ecg(L)
a0 = [0, 1, 40, 1, 0, -34, 118, -99, 0, 2, 21, 2, 0, 0, 0];
d0 = [0, 27, 59, 91, 131, 141, 163, 185, 195, 275, 307, 339, 357, 390, 440];
a = a0 / max(a0);
d = round(d0 * L / d0(15));
d(15) = L;
for i = 1:14
    m = d(i) : d(i+1) - 1;
    slope = (a(i+1) - a(i)) / (d(i+1) - d(i));
    x(m+1) = a(i) + slope * (m - d(i));
end

x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
```

```
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

Create a `timescope` object and call the object to display the signal. To autoscale the axes and enable changes to property values and input characteristics, call `release`.

```
scope = timescope(SampleRate=1/ts);
scope(mhb);
release(scope)
```

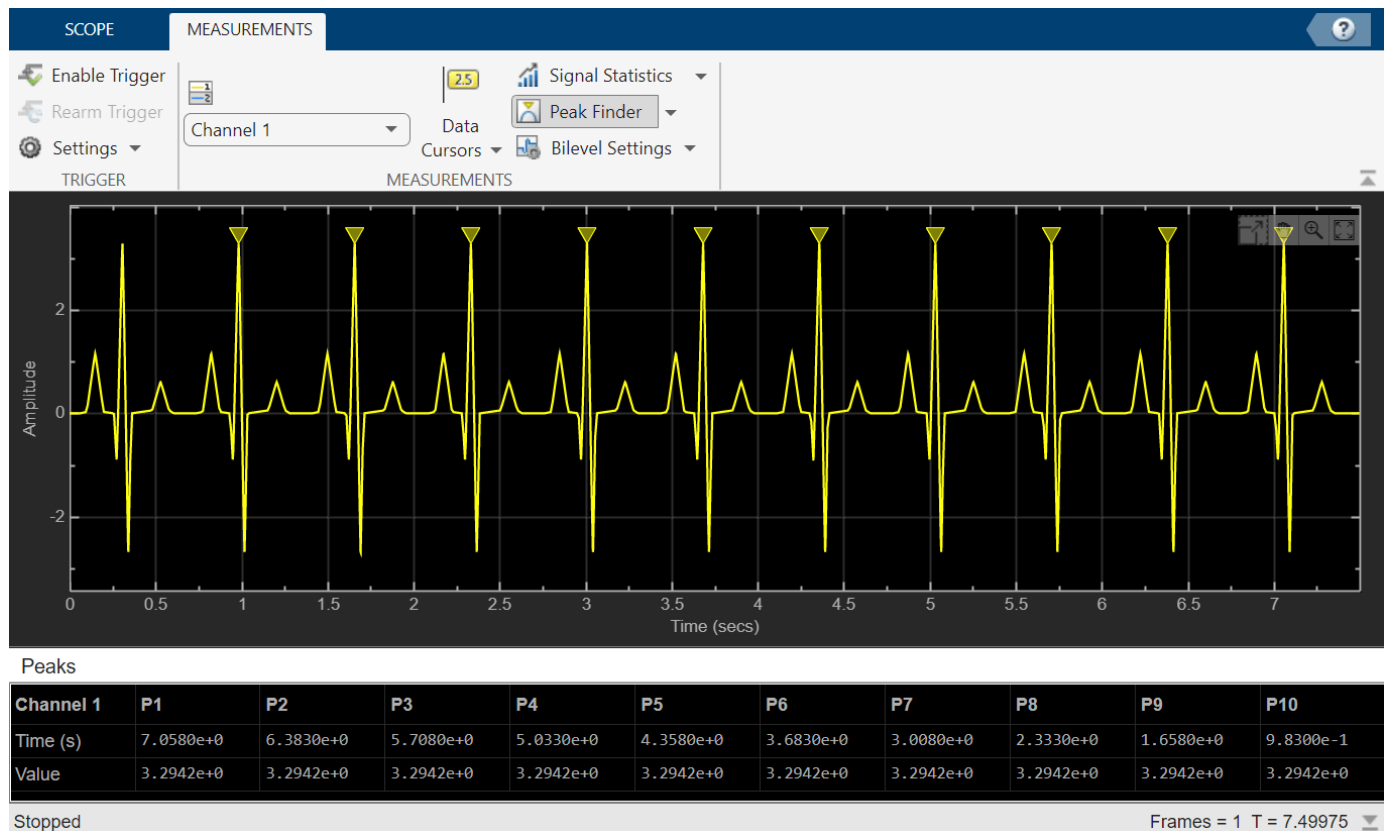

### Find Heart Rate

Use the Peak Finder measurements to measure the time between heartbeats.

In the **Measurements** tab, select **Peak Finder** to enable the peak finder measurements.

Click the **Peak Finder** arrow and set the **Num Peaks** property to 10 and hit enter.

In the **Peaks** pane at the bottom of the window, the Time Scope displays a list of ten peak amplitude values and the times at which they occur.

The list of peak values shows a constant time difference of 0.675 seconds between each heartbeat. Based on this equation, the heart rate of this ECG signal is about 89 beats per minute.

$$\frac{60 \text{ s/min}}{0.675 \text{ s/beat}} = 88.89 \text{ bpm}$$

Close the Time Scope window and remove the variables you created from the workspace.

```
clear scope x1 y1 n del mhb ts
```

## Tips

- To close the scope window and clear its associated data, use the MATLAB `clear` function.
- To hide or show the scope window, use the `hide` and `show` functions.
- Use the MATLAB `mcc` function to compile code containing a scope. You cannot open scope configuration dialogs if you have more than one compiled component in your application.

## Version History

Introduced in R2020a

**R2022b: Channel names support array of strings**

Starting in R2022b, you can specify the `ChannelNames` property of the `timescope` object as an array of strings.

```
ts = timescope(SampleRate=Fs, ChannelNames=["Input", "Lowpass Output"]);
```

# dsp.TransferFunctionEstimator

**Package:** dsp

Estimate transfer function

## Description

The `dsp.TransferFunctionEstimator` System object computes the transfer function of a system, using the Welch's averaged periodogram method.

To implement the transfer function estimation object:

- 1 Create the `dsp.TransferFunctionEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
tfe = dsp.TransferFunctionEstimator
tfe = dsp.TransferFunctionEstimator(Name,Value)
```

### Description

`tfe = dsp.TransferFunctionEstimator` returns a transfer function estimator object, that computes the transfer function of real or complex signals. This System object uses the periodogram method and Welch's averaged, modified periodogram method.

`tfe = dsp.TransferFunctionEstimator(Name,Value)` returns a transfer function estimator object with each specified property set to the specified value. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### FFTLengthSource — Source of FFT length value

'Auto' (default) | 'Property'

Specify the source of the FFT length value as either 'Auto' or 'Property'. If you set this property to 'Auto', the transfer function estimator sets the FFT length to the input frame size. If you set this property to 'Property', then specify the number of FFT points using the FFTLength property.

**FFTLength — FFT Length**

128 (default) | positive integer

Specify the length of the FFT that the transfer function estimator uses to compute spectral estimates as a positive, integer scalar.

**Dependencies**

This property applies when you set the FFTLengthSource property to 'Property'.

Data Types: double

**Window — Window function**

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser'

Specify a window function for the transfer function estimator as one of 'Rectangular', 'Chebyshev', 'Flat Top', 'Hamming', 'Hann', or 'Kaiser'.

**SidelobeAttenuation — Side lobe attenuation of window**

60 (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

**Dependencies**

This property applies when you set the Window property to 'Chebyshev' or 'Kaiser'.

Data Types: double

**FrequencyRange — Frequency range of the transfer function estimate**

'Twosided' (default) | 'onesided' | 'centered'

Specify the frequency range of the transfer function estimator as one of 'twosided', 'onesided', or 'centered'.

If you set the FrequencyRange to 'onesided', the transfer function estimator computes the one-sided transfer function of real input signals,  $x$  and  $y$ . If the FFT length,  $N_{FFT}$ , is even, the length of the transfer function estimate is  $N_{FFT}/2+1$  and is computed over the interval  $[0, SampleRate/2]$ . If  $N_{FFT}$  is odd, the length of the transfer function estimate is equal to  $(N_{FFT}+1)/2$ , and the interval is  $[0, SampleRate/2]$ .

If FrequencyRange is set to 'twosided', the transfer function estimator computes the two-sided transfer function of complex or real input signals,  $x$  and  $y$ . The length of the transfer function estimate is equal to  $N_{FFT}$  and is computed over  $[0, SampleRate]$ .

If you set the FrequencyRange to 'centered', the transfer function estimator computes the centered two-sided transfer function of complex or real input signals,  $x$  and  $y$ . The length of the transfer function estimate is equal to  $N_{FFT}$  and it is computed over  $[-SampleRate/2, SampleRate/2]$  for even lengths, and  $[-SampleRate/2, SampleRate/2]$  for odd lengths.

**AveragingMethod — Averaging method**

'Running' (default) | 'Exponential'

Specify the averaging method as 'Running' or 'Exponential'. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

### **SpectralAverages — Number of spectral averages**

8 (default) | positive integer

Specify the number of spectral averages as a positive, integer scalar. The transfer function estimator computes the current estimate by averaging the last  $N$  estimates, where  $N$  is the number of spectral averages defined in the `SpectralAverages` property.

#### **Dependencies**

This property applies when you set `AveragingMethod` to 'Running'.

Data Types: double

### **ForgettingFactor — Forgetting factor**

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

**Tunable:** Yes

#### **Dependencies**

This property applies when you set `AveragingMethod` to 'Exponential'.

Data Types: single | double

### **OutputCoherence — Magnitude squared coherence estimate**

false (default) | true

Specify `true` to compute and output the magnitude squared coherence estimate using Welch's averaged, modified periodogram method. The magnitude squared coherence estimate has values between 0 and 1 that indicate the correspondence at each frequency between two input signals. If you specify `false`, the magnitude squared coherence estimate is not computed.

## **Usage**

### **Syntax**

```
tfeEst = tfe(x,y)
[tfeEst,cxy] = tfe(x,y)
```

#### **Description**

`tfeEst = tfe(x,y)` computes the transfer function estimate, `tfeEst`, of the system with input  $x$  and output  $y$  using Welch's averaged periodogram method.

`[tfeEst,cxy] = tfe(x,y)` also computes the magnitude squared coherence estimate, `cxy`, of the system.

### Input Arguments

#### **x — First data input**

vector | matrix

First data input, specified as a vector or a matrix. *x* and *y* must have the same size and data type.

Data Types: single | double

#### **y — Second data input**

vector | matrix

Second data input, specified as a vector or a matrix. *x* and *y* must have the same size and data type.

Data Types: single | double

### Output Arguments

#### **tfeEst — Transfer function estimate**

vector | matrix

Transfer function estimate of the system for which *x* and *y* are the input and output signals, respectively.

The estimate, *tfeEst*, is equal to  $p_{xy}/p_{xx}$ , where  $p_{xy}$  is the cross-power spectral density of *x* and *y*, and  $p_{xx}$  is the power spectral density of *x*.

The transfer function estimate has the same size and data type as the input.

Data Types: single | double

#### **cxy — Coherence estimate**

vector | matrix

Magnitude squared coherence estimate of the system, returned as a vector or a matrix.

The coherence estimate, *cxy*, is equal to  $(\text{abs}(p_{xy}) . ^2) ./ (p_{xx} . *p_{yy})$ , where  $p_{xy}$  is the cross power spectral density of *x* and *y*,  $p_{xx}$  is the power spectral density of *x*, and  $p_{yy}$  is the power spectral density of *y*. For coherence to be estimated, the `OutputCoherence` property must be set to `true`.

The coherence estimate has the same size and data type as the input.

Data Types: single | double

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named *obj*, use this syntax:

```
release(obj)
```

### Specific to dsp.TransferFunctionEstimator

`getFrequencyVector`    Vector of frequencies at which estimation is done  
`getRBW`                Resolution bandwidth of spectrum

## Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

## Examples

### Estimate Transfer Function of a System Represented by an Order-64 FIR Filter

Generate a sine wave. Use the dsp.TransferFunctionEstimator System object™ to estimate the system transfer function and the dsp.ArrayPlot System object to display it.

```
sin = dsp.SineWave('Frequency',100,'SampleRate',1000);
sin.SamplesPerFrame = 1000;
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-120 5],'YLabel','Frequency Response (dB)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Transfer Function');
```

Create an FIR Filter System object of order 64 and (normalized) cutoff frequency of 1/4. Add random noise to the sine wave. Step through the System objects to obtain the data streams, and plot the log of the magnitude of the transfer function.

```
firFilt = dsp.FIRFilter('Numerator',fir1(64,1/4));
for ii = 1:100
x = sin() + 0.05*randn(1000,1);
y = firFilt(x);
Txy = tfe(x,y);
aplot(20*log10(abs(Txy)))
end
```

## Algorithms

### Welch's Method of Averaged Modified Periodograms

Give two signal inputs,  $x$  and  $y$ :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Take FFT of the signals,  $X$  and  $Y$ .
- 3 Compute the current power spectral density estimates,  $P_{xx}$ ,  $P_{yy}$ , and the current cross power spectral density estimate,  $P_{yx}$ , by taking the moving average of last  $N$  number of  $Z_1$ ,  $Z_2$ , and  $Z_3$  vectors, respectively:
  - $Z_1 = X \cdot \text{conj}(X)$
  - $Z_2 = Y \cdot \text{conj}(Y)$
  - $Z_3 = Y \cdot \text{conj}(X)$

For details on the moving average methods, see "Averaging Method" on page 4-1141.

The transfer function estimate is calculated by dividing  $P_{yx}$  by  $P_{xx}$ .

The magnitude squared coherence,  $C_{xy}$ , is defined by the following equation:

$$C_{xy} = \frac{(\text{abs}(P_{xy}) \cdot \wedge 2)}{(P_{xx} \cdot * P_{yy})}$$

## **dsp.TransitionMetrics**

**Package:** dsp

(Removed) Transition metrics of bilevel waveforms

---

**Note** `dsp.TransitionMetrics` has been removed. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `falltime`, `overshoot`, `risetime`, `settlingtime`, `slewrates`, and `undershoot` among others.

---

### **Description**

The `dsp.TransitionMetrics` object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The `dsp.TransitionMetrics` object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

- 1 Create the `dsp.TransitionMetrics` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### **Creation**

#### **Syntax**

```
tm = dsp.TransitionMetrics  
tm = dsp.TransitionMetrics(Name,Value)
```

#### **Description**

`tm = dsp.TransitionMetrics` creates a transition metrics System object, `tm`. The object computes the rise time, fall time, and width of a pulse. `TransitionMetrics` additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`tm = dsp.TransitionMetrics(Name,Value)` returns a `TransitionMetrics` System object, `tm`, with each specified property set to the specified value.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **MaximumRecordLength — Maximum samples to preserve**

1000 (default) | positive integer

Maximum samples to preserve between calls to the algorithm. This property requires a positive integer that specifies the maximum number of samples to save between calls to the algorithm. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded.

#### **Dependencies**

This property applies when `RunningMetrics` is `true` and is tunable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **PercentReferenceLevels — Reference levels**

[10 50 90] (default) | three-element row vector

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector of the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

Data Types: `double`

### **PercentStateLevelTolerance — Tolerance of state level**

2 (default) | positive scalar

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Data Types: `double`

### **PostshootOutputPort — Enable posttransition aberration metrics**

`false` (default) | `true`

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

### **PostshootSeekFactor — Postshoot seek factor**

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

**Tunable:** Yes

**Dependencies**

This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Data Types: `double`

**PreshootOutputPort — Enable pretransition aberration metrics**

`false` (default) | `true`

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

**PreshootSeekFactor — Preshoot seek factor**

3 (default) | positive scalar

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition.

**Tunable:** Yes

**Dependencies**

This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Data Types: `double`

**RunningMetrics — Enable metrics over calls**

`false` (default) | `true`

Enable metrics over all calls to the algorithm. If `RunningMetrics` is set to `false`, metrics are computed for each call to the algorithm independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to the algorithm. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to the algorithm is made with enough data to compute all enabled metrics for that transition.

**SampleRate — Sampling rate**

1 (default) | positive scalar

Sampling rate of uniformly sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero.

**Dependencies**

This property applies when the `TimeInputPort` property is set to `false`.

Data Types: `double`

**SettlingOutputPort — Enable settling metrics**

`false` (default) | `true`

Enable settling metrics. If `SettlingOutputPort` is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time the algorithm is called if the `RunningMetrics` property is set to `true`.

### **SettlingSeekDuration — Settling seek duration**

`0.02` (default) | positive scalar

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports `NaN` for all settling metrics.

**Tunable:** Yes

#### **Dependencies**

This property applies only when you set the `SettlingOutputPort` property to `true`.

Data Types: `double`

### **StateLevels — State levels**

`[0 2.3]` (default) | two-element row vector

Low- and high-state levels. This property is a two-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform.

**Tunable:** Yes

Data Types: `double`

### **StateLevelsSource — State level source**

`'Property'` (default) | `'Auto'`

Auto or manual state level computation. If the `StateLevelsSource` property is set to `'Auto'`, the first record sent to the algorithm uses the `dsp.StateLevels` object with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

### **TimeInputPort — Time input**

`false` (default) | `true`

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to the algorithm to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

## Usage

### Syntax

```
pulse = tm(x)
[pulse,cycle] = tm(x)
[pulse,transition] = tm(x)
[pulse,preshoot] = tm(x)
[pulse,postshoot] = tm(x)
[pulse,settling] = tm(x)
[pulse,cycle,transition,preshoot,postshoot,settling] = tm(x)
[ ___ ] = tm(x,T)
```

### Description

`pulse = tm(x)` returns a structure array, `pulse`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `x`.

`[pulse,cycle] = tm(x)` returns a structure array, `cycle`, when you set the `CycleOutputPort` property to `true`. The fields of `cycle` contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `x`.

`[pulse,transition] = tm(x)` returns a structure array, `transition`, when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns, which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`[pulse,preshoot] = tm(x)` returns a structure array, `preshoot`, when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `postshoot` structure.

`[pulse,postshoot] = tm(x)` returns a structure array, `postshoot`, when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`[pulse,settling] = tm(x)` returns a structure, `settling`, when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

`[pulse,cycle,transition,preshoot,postshoot,settling] = tm(x)` which returns the `pulse`, `cycle`, `transition`, `preshoot`, `postshoot`, and `settling` structure arrays when the `CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

`[ ___ ] = tm(x,T)` performs the above metrics with respect to a sampled signal, whose sample values, `x`, and sample instants, `T`, are real-valued column vectors of the same length. The additional input `T` applies only when you set the `TimeInputPort` property to `true`.

## Input Arguments

### **x** — Input signal

column vector

Input signal, specified as a real-valued column vector.

Data Types: `double`

### **T** — Sampling instants

column vector

Sampling instants, specified as a real-valued column vector. Set `TimeInputPort` to `true` to enable an additional real input column vector to the object algorithm to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

### Dependencies

This input is applicable when you set the `TimeInputPort` property to `true`.

Data Types: `double`

## Output Arguments

### **pulse** — Complete pulses

structure

Complete pulses, returned as a structure whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `x`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

The `pulse` output contains the following fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

Data Types: `struct`

### **cycle** — Complete pulse periods

structure

Complete pulse periods, returned when you set the `CycleOutputPort` property to `true`. The pulse periods are returned as a structure whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued

column vector input, `x`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `x` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to the algorithm detects the next transition.

The `cycle` output contains the following fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse.
- `Frequency` — Reciprocal of the period.
- `Separation` — Durations between the mid-reference level crossings of the first and second transitions of each pulse.
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the `width` parameter of the `pulse` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse.

Data Types: `struct`

### **transition — Transition metrics**

`structure`

Transition metrics, returned as a structure array, when you set the `TransitionOutputPort` property to `true`. The fields of `transition` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

The `transition` output contains the following fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- `SlewRate` — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- `MiddleCross` — Linearly interpolated instant where the transition first crosses the mid-reference level
- `LowerCross` — Linearly interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly interpolated instant where the signal crosses the upper-reference level

Data Types: `struct`

### **preshoot — Preshoot metrics**

`structure`

Preshoot metrics, returned as a structure array, when you set the `PreshootOutputPort` property to `true`. The fields of `preshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `preshoot` output contains the following fields:

- **Overshoot** — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- **Undershoot** — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- **OvershootLevel** — Level of the overshoot
- **UndershootLevel** — Level of the undershoot
- **OvershootInstant** — Instant that corresponds to the overshoot
- **UndershootInstant** — Instant that corresponds to the undershoot

Data Types: `struct`

### **postshoot — Postshoot metrics**

structure

Postshoot metrics, returned as a structure array, when you set the `PostshootOutputPort` property to `true`. The fields of `postshoot` contain real-valued two-column matrices whose row length corresponds to the number of transitions found in the input waveform.

The `postshoot` output contains the following fields:

- **Overshoot** — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- **Undershoot** — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- **OvershootLevel** — Level of the overshoot
- **UndershootLevel** — Level of the undershoot
- **OvershootInstant** — Instant that corresponds to the overshoot
- **UndershootInstant** — Instant that corresponds to the undershoot

Data Types: `struct`

### **settling — Settling metrics**

structure

Settling metrics for each transition, returned as a structure array, when you set the `SettlingOutputPort` property to `true`. The fields of `settling` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

The `settling` output contains the following fields:

- **Duration** — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- **Instant** — Instant in time where the signal enters and remains within the specified tolerance.
- **Level** — Level of the waveform where it enters and remains within the specified tolerance.

Data Types: `struct`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.TransitionMetrics`

`plot` (To be removed) Plot pulse signal and metrics

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Transition and Preshoot Information of a 2.3 V Step Waveform

**Note:** If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz. Load the data.

```
load('transitionex.mat','x');
```

Construct the `dsp.TransitionMetrics` object. Set the `SampleRate` property to 4 MHz and the `StateLevelsSource` property to 'Auto' to estimate the state levels from the data. Set the `PreshootOutputPort` property to `true` to output pretransition aberration metrics when you call the object.

```
tm = dsp.TransitionMetrics('SampleRate',4e6, ...  
                           'StateLevelsSource','Auto', ...  
                           'PreshootOutputPort',true)
```

```
tm =  
dsp.TransitionMetrics with properties:
```

```
    StateLevelsSource: 'Auto'  
        StateLevels: [0 2.3000]  
PercentStateLevelTolerance: 2  
    PercentReferenceLevels: [10 50 90]  
        RunningMetrics: false  
        TimeInputPort: false  
        SampleRate: 4000000  
    PreshootOutputPort: true  
    PreshootSeekFactor: 3  
    PostshootOutputPort: false  
    SettlingOutputPort: false
```

Call the object to compute the transition and preshoot information. Plot the result.

```
[transition,preshoot] = tm(x)

transition = struct with fields:
    Duration: 1.7800e-07
    Polarity: 1
    SlewRate: 1.0310e+07
    MiddleCross: 5.1250e-06
    LowerCross: 5.0360e-06
    UpperCross: 5.2140e-06

preshoot = struct with fields:
    Overshoot: 4.8050
    Undershoot: 6.1798
    OvershootLevel: 0.1020
    UndershootLevel: -0.1500
    OvershootInstant: 4.7500e-06
    UndershootInstant: 5.0000e-06

plot(tm)
```

## Version History

### Introduced in R2012a

#### **R2021b: dsp.TransitionMetrics System object will be removed**

*Warns starting in R2021b*

dsp.TransitionMetrics System object will be removed in a future release. Use functions from “Pulse and Transition Metrics” instead. Functions in this set include `falltime`, `overshoot`, `risetime`, `settlingtime`, `slewrate`, and `undershoot` among others.

#### **R2023a: dsp.TransitionMetrics System object has been removed**

*Errors starting in R2023a*

The dsp.TransitionMetrics System object has been removed. Use functions from “Pulse and Transition Metrics” instead. This set includes functions such as `falltime`, `overshoot`, `risetime`, `settlingtime`, `slewrate`, and `undershoot` among others.

## dsp.UDPReceiver

**Package:** dsp

Receive UDP packets from the network

### Description

The `dsp.UDPReceiver` System object receives UDP packets over a UDP network from an IP address specified in the `RemoteIPAddress` property. The object then saves the data to its internal buffer. The amount of data (number of elements) received in each UDP packet can vary. The maximum number of bytes the object can receive without losing data is set by the `ReceiveBufferSize` property. The `MaximumMessageLength` property specifies the maximum number of samples each data packet can contain. The `LocalIPPort` on which the object receives the data is tunable in generated code but not tunable during simulation. For an example, see “Tune the UDP Port Number in MATLAB” on page 4-1227.

Due to the nature of the UDP transmission protocol, the receiver is not guaranteed to receive all the data packets that you send using the `dsp.UDPSender` object.

To receive UDP packets from the network:

- 1 Create the `dsp.UDPReceiver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
udpr = dsp.UDPReceiver  
udpr = dsp.UDPReceiver(Name,Value)
```

#### Description

`udpr = dsp.UDPReceiver` returns a UDP receiver object that receives UDP packets from a specified port.

`udpr = dsp.UDPReceiver(Name,Value)` returns a UDP receiver object with each specified property set to the specified value. Enclose each property name in single quotes.

#### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **LocalIPPort — Local port on which to receive data**

25000 (default) | [1, 65535]

Port on which to receive the data, specified as a scalar in the range [1, 65535]. This property is tunable in generated code but not tunable during simulation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **RemoteIPAddress — Address from which to accept data**

'0.0.0.0' (default) | character vector containing a valid IP address | string scalar

Address from which to accept data, specified as a character vector or a string scalar containing a valid IP address. Entering a specific IP address blocks UDP packets from other addresses. The default, '0.0.0.0', indicates that the data can be accepted from any remote IP address.

Data Types: char

### **ReceiveBufferSize — Size of internal buffer**

8192 bytes (default) | [1, 67108864]

Size of the internal buffer that receives UDP packets, specified in bytes as a scalar in the range [1, 67108864]. If the number of bytes received exceeds this value, the buffer overflows and the contents are truncated.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **MaximumMessageLength — Maximum size of output message**

255 (default) | [1, 65507]

Maximum length of the output message, specified in samples as a positive scalar in the range [1, 65507]. Set this property to a value equal to or greater than the data size of the UDP packet. If you receive more samples than specified in this property, the excess data is truncated.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **MessageDataType — Data type of the message**

'uint8' (default) | 'double' | 'single' | 'int8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'logical'

Data type of the vector elements in the message output, specified as a MATLAB built-in data type.

Match the data type with the data input used to create the UDP packets.

Data Types: char

### **IsMessageComplex — Complexity of message**

false (default) | true

Complexity of the message, specified as either true or false.

Set this property to true if the received message is complex. Set the property to false if the received message is real.

Data Types: logical

## Usage

### Syntax

```
dataR = udpr()
```

### Description

`dataR = udpr()` receives one UDP packet from the network.

### Output Arguments

#### **dataR — Data received**

scalar | vector

Data received from the network, returned as one packet. The “MaximumMessageLength” on page 4-0 property specifies the maximum number of bytes each data packet can contain. Length of the data received is the number of bytes received from the network.

The data is received as complex data if the `IsMessageComplex` property is set to `true`.

If the packet gets dropped during transmission and the receiver does not receive the packet, the `dataR` output is empty.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Byte Transmission Using UDP

Send and receive UDP packets using the `dsp.UDPSender` and `dsp.UDPReceiver` System objects. Calculate the number of bytes successfully transmitted.

Set the `RemoteIPPort` of UDP sender and the `LocalIPPort` of the UDP receiver to 31000. Set the length of the data vector to 128 samples, which is less than the value of the `MaximumMessageLength` property of the receiver. To prevent the loss of packets, call the `setup` method on the receiver object before the first call to the object algorithm.

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);  
udps = dsp.UDPSender('RemoteIPPort',31000);
```

```
setup(udpr);
```

```
bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

In each loop of iteration, send and receive a packet of data. At the end of the loop, use the `fprintf` function to print the number of bytes sent by the sender and the number of bytes received by the receiver.

```
for k = 1:20
    dataSent = uint8(255*rand(1,dataLength));
    bytesSent = bytesSent + dataLength;
    udps(dataSent);
    dataReceived = [];
    while (isempty(dataReceived))
        dataReceived = udpr();
    end
    bytesReceived = bytesReceived + length(dataReceived);
end
```

```
release(udps);
release(udpr);
```

```
fprintf('Bytes sent:      %d\n', bytesSent);
```

```
Bytes sent:      2560
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes received: 2560
```

### Tune the UDP Port Number in MATLAB

The local IP port number of the `dsp.UDPReceiver` object and the remote IP port number of the `dsp.UDPSender` object are tunable in the generated code. Generate a MEX file from the receiver function which contains the algorithm to receive sine wave data over a UDP network. Change the remote IP port number of the UDP receiver without regenerating the MEX file. Verify the number of bytes sent and received over the network.

**Note:** This example runs only in R2017a or later.

The input to the receiver function is the local IP port number of the `dsp.UDPReceiver` System object™. The output of this function is the number of bytes received from the UDP network.

```
type receiver
```

```
function [bytesReceived] = receiver(portnumber)
```

```
persistent udpRx
```

```
if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
```

```
end
```

```
udpRx.LocalIPPort = portnumber;  
dataReceived = udpRx();  
bytesReceived = length(dataReceived);
```

The `dsp.UDPSender` object with `remoteIPPort` number set to 65000 sends the data over the UDP network. The `dsp.UDPReceiver` object with `LocalIPPort` number set to 65000 receives the data from the UDP network. The data is a sine wave containing 250 samples per frame.

```
portnumber = 65000;  
udpSend = dsp.UDPSender('RemoteIPPort',portnumber);  
sine = dsp.SineWave('SamplesPerFrame',250);
```

```
bytesSent = 0;  
bytesReceived = 0;  
dataLength = 250;
```

```
for i = 1:10  
dataSent = sine();  
bytesSent = bytesSent + dataLength;  
udpSend(dataSent);  
bytesReceived = bytesReceived + receiver(portnumber);  
end  
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 2250
```

The data is sent and received successfully over the UDP network. The initial data is dropped due to overhead.

Generate a MEX file from the `receiver.m` function.

```
codegen receiver -args {65000}
```

```
Code generation successful.
```

Release the sender and change the `RemotePort` number to 25000. The `LocalIPPort` number of the receiver continues to be 65000. Since the port numbers are different, the data is not transmitted successfully.

```
release(udpSend)  
portnumberTwo = 25000;  
udpSend.RemoteIPPort = portnumberTwo;  
bytesReceived = 0;  
bytesSent = 0;  
for i = 1:10  
dataSent = sine();  
bytesSent = bytesSent + dataLength;  
udpSend(dataSent);  
bytesReceived = bytesReceived + receiver_mex(portnumber);  
end  
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 0
```

Clear the MEX file and change the local IP port number of the receiver to 25000. Clearing the MEX enables the receiver port number to change without having to regenerate the MEX. The port numbers of the sender and receiver match. Verify if the data is transmitted successfully.

```
clear mex %#ok
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver_mex(portnumberTwo);
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 2250
```

The data is transmitted successfully over the UDP network. The initial data is dropped due to overhead.

### Transmit Complex Data over UDP Network

Compute the STFT of a sine wave and transmit the complex STFT data over a UDP network. At the receiver side, compute the ISTFT of the received data. Visualize the data sent and the data received using a time scope.

The `dsp.UDPSender` object can send complex data. In order to enable the `dsp.UDPReceiver` object to receive complex data, set the `IsMessageComplex` property to `true`.

```
udps = dsp.UDPSender('RemoteIPPort',31000);
udpr = dsp.UDPReceiver('LocalIPPort',31000,...
    'IsMessageComplex',true,...
    'MessageDataType','double');
```

```
setup(udpr);
```

```
bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

Initialize the `dsp.STFT` and `dsp.ISTFT` System objects with a periodic hann window of length 120 samples and an overlap length of 60 samples. Set the FFT length to 128.

```
winLen = 120;
overlapLen = 60;
```

```
frameLen = winLen-overlapLen;
```

```
stf = dsp.STFT(...  
    'Window',hann(winLen,'periodic'),...  
    'OverlapLength',overlapLen,'FFTLength',128);  
istf = dsp.ISTFT(...  
    'Window',hann(winLen,'periodic'),...  
    'OverlapLength',overlapLen,...  
    'WeightedOverlapAdd',0);
```

The input is a sinusoidal signal with a frequency of 100 Hz, a sample rate of 1000 Hz, and with 60 samples per each signal frame.

```
sine = dsp.SineWave(...  
    'SamplesPerFrame',winLen-overlapLen,...  
    'Frequency',100);
```

Initialize a timescope object with a sample rate of 1000 Hz and a time span of 0.09. The Delay object corrects the overlap length while comparing the input with the reconstructed output signal.

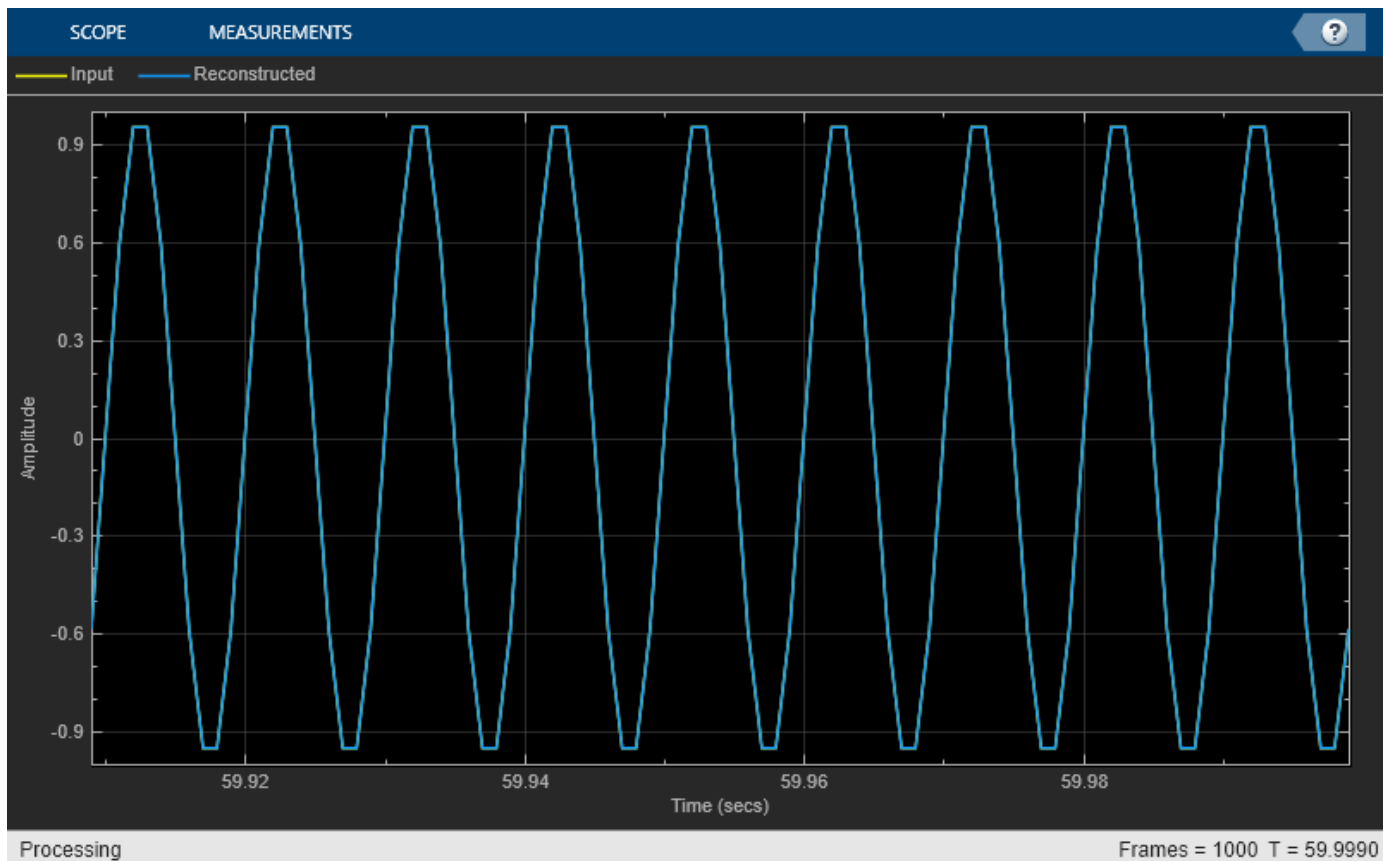

```
ts = timescope('SampleRate',1000,...  
    'ShowLegend',true,...  
    'YLimits',[-1 1],...  
    'TimeSpanSource','Property',...  
    'TimeSpan',.09,...  
    'ChannelNames',{'Input','Reconstructed'});  
dly = dsp.Delay('Length',overlapLen);
```

Transmit complex STFT data of the sine wave over the UDP network. Due to the undependable nature of the UDP protocol, the data packets can get lost during transmission. The receiver is not guaranteed to receive all the data that you send.

Compute the ISTFT of the received data. Compare the input  $x$  to the reconstructed output  $y$ . Due to the latency introduced by the objects, the reconstructed output is shifted in time compared to the input. Therefore, to compare, take the norm of the difference between the reconstructed output  $y$  and the previous input,  $x_{prev}$ .

Visualize the signals using a time scope. You can see that the reconstructed signal overlaps very closely with the input signal.

```
n = zeros(1,1e3);  
xprev = 0;  
for k = 1:1e3  
    x = sine();  
    X = stf(x);  
    bytesSent = bytesSent + length(X);  
    udps(X);  
    dataReceived = [];  
    while (isempty(dataReceived))  
        dataReceived = udpr();  
    end  
    if (~isempty(dataReceived))  
        y = istf(dataReceived);  
    end  
    n(1,k) = norm(y-xprev);  
    xprev = x;  
    bytesReceived = bytesReceived + length(dataReceived);  
    ts([dly(x),y]);  
end
```

The norm of the difference is very small, indicating that the output signal is a perfectly reconstructed version of the input signal.

```
max(abs(n))
```

```
ans = 4.0270e-14
```

Release the UDP objects.

```
release(udps);
release(udpr);
```

Some of the packets sent can be lost during transmission due to the lossy nature of the UDP protocol. To check for loss, compare the bytes sent to the bytes received.

```
fprintf('Bytes sent:    %d\n', bytesSent);
```

```
Bytes sent:    128000
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes received: 128000
```

## Version History

Introduced in R2012a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The `LocalIPPort` property is tunable in generated code but not tunable during simulation.

# dsp.UDPSender

**Package:** dsp

Send UDP packets to network

## Description

The `dsp.UDPSender` object sends data packets over the network using the User Datagram Protocol (UDP). UDP is a simple message-based connectionless protocol. The protocol sends data packets in one direction from source to destination without verifying the readiness of the receiver. The protocol has no handshaking mechanism. The data packets can get dropped for several reasons. There is no acknowledgement, retransmission, or timeout in UDP. However, UDP is a very simple transmission protocol and is suitable for time-sensitive applications where dropping packets is preferable to waiting for packets delayed due to retransmission.

To send UDP packets to the network:

- 1 Create the `dsp.UDPSender` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
udps = dsp.UDPSender  
udps = dsp.UDPSender(Name, Value)
```

### Description

`udps = dsp.UDPSender` returns a UDP sender object that sends UDP packets to a specified port.

`udps = dsp.UDPSender(Name, Value)` returns a UDP sender object, `udps`, with each property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### RemoteIPAddress — Remote address to which to send data

'127.0.0.1' (default) | character vector containing a valid IP address | string scalar

Specify the remote (that is, host) IP address to which the data is sent. The default is '127.0.0.1', which is the local host.

Data Types: char

### **RemoteIPPort — Remote port to which to send data**

25000 (default) | integer in the range [1, 65535]

Specify the port at the remote IP address to which the data is sent. This property is tunable in generated code but not tunable during simulation.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **LocalIPPortSource — Source of local IP port**

Auto (default) | Property

Specify how to determine the local IP port on the host as Auto or Property. If you specify Auto, the object selects the port dynamically from the available ports. If you specify Property, the object uses the source specified in the LocalIPPort property.

### **LocalIPPort — Local port from which to send data**

25000 (default) | integer in the range [1, 65535]

Specify the port from which to send data.

### **Dependencies**

This property applies when you set the LocalIPPortSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **SendBufferSize — Size of internal buffer**

8192 bytes (default) | integer in the range [1, 67108864]

Size of the internal buffer that sends UDP packets, specified in bytes as an integer in the range [1, 67108864].

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## **Usage**

### **Syntax**

y = udps(Packet)

### **Description**

y = udps(Packet) sends one UDP packet, Packet, to the network.

Since the object sends the data over the UDP network, the data packets can get lost during transmission and the receiver is not guaranteed to receive all the data that you send. You can receive the data using the dsp.UDPReceiver object.

### **Input Arguments**

#### **Packet — Data sent**

scalar | vector

The object sends one UDP packet to the network per call.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm  
`release` Release resources and allow changes to System object property values and input characteristics  
`reset` Reset internal states of System object

## Examples

### Byte Transmission Using UDP

Send and receive UDP packets using the `dsp.UDPsender` and `dsp.UDPReceiver` System objects. Calculate the number of bytes successfully transmitted.

Set the `RemoteIPPort` of UDP sender and the `LocalIPPort` of the UDP receiver to 31000. Set the length of the data vector to 128 samples, which is less than the value of the `MaximumMessageLength` property of the receiver. To prevent the loss of packets, call the `setup` method on the receiver object before the first call to the object algorithm.

```
udpr = dsp.UDPReceiver('LocalIPPort',31000);
udps = dsp.UDPsender('RemoteIPPort',31000);
```

```
setup(udpr);
```

```
bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

In each loop of iteration, send and receive a packet of data. At the end of the loop, use the `fprintf` function to print the number of bytes sent by the sender and the number of bytes received by the receiver.

```
for k = 1:20
    dataSent = uint8(255*rand(1,dataLength));
    bytesSent = bytesSent + dataLength;
    udps(dataSent);
    dataReceived = [];
    while (isempty(dataReceived))
        dataReceived = udpr();
    end
    bytesReceived = bytesReceived + length(dataReceived);
end
```

```
release(udps);
release(udpr);

fprintf('Bytes sent:      %d\n', bytesSent);
Bytes sent:      2560

fprintf('Bytes received: %d\n', bytesReceived);
Bytes received: 2560
```

### Tune the UDP Port Number in MATLAB

The local IP port number of the `dsp.UDPReceiver` object and the remote IP port number of the `dsp.UDPSender` object are tunable in the generated code. Generate a MEX file from the `receiver` function which contains the algorithm to receive sine wave data over a UDP network. Change the remote IP port number of the UDP receiver without regenerating the MEX file. Verify the number of bytes sent and received over the network.

**Note:** This example runs only in R2017a or later.

The input to the `receiver` function is the local IP port number of the `dsp.UDPReceiver` System object™. The output of this function is the number of bytes received from the UDP network.

```
type receiver

function [bytesReceived] = receiver(portnumber)

persistent udpRx

if isempty(udpRx)
    udpRx = dsp.UDPReceiver('MessageDataType','double');
end

udpRx.LocalIPPort = portnumber;
dataReceived = udpRx();
bytesReceived = length(dataReceived);
```

The `dsp.UDPSender` object with `remoteIPPort` number set to 65000 sends the data over the UDP network. The `dsp.UDPReceiver` object with `LocalIPPort` number set to 65000 receives the data from the UDP network. The data is a sine wave containing 250 samples per frame.

```
portnumber = 65000;
udpSend = dsp.UDPSender('RemoteIPPort',portnumber);
sine = dsp.SineWave('SamplesPerFrame',250);

bytesSent = 0;
bytesReceived = 0;
dataLength = 250;

for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver(portnumber);
```

```
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 2250
```

The data is sent and received successfully over the UDP network. The initial data is dropped due to overhead.

Generate a MEX file from the receiver.m function.

```
codegen receiver -args {65000}
```

```
Code generation successful.
```

Release the sender and change the RemotePort number to 25000. The LocalIPPort number of the receiver continues to be 65000. Since the port numbers are different, the data is not transmitted successfully.

```
release(udpSend)
portnumberTwo = 25000;
udpSend.RemoteIPPort = portnumberTwo;
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver_mex(portnumber);
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

```
Number of bytes received: 0
```

Clear the MEX file and change the local IP port number of the receiver to 25000. Clearing the MEX enables the receiver port number to change without having to regenerate the MEX. The port numbers of the sender and receiver match. Verify if the data is transmitted successfully.

```
clear mex %#ok
bytesReceived = 0;
bytesSent = 0;
for i = 1:10
    dataSent = sine();
    bytesSent = bytesSent + dataLength;
    udpSend(dataSent);
    bytesReceived = bytesReceived + receiver_mex(portnumberTwo);
end
fprintf('Number of bytes sent: %d', bytesSent);
```

```
Number of bytes sent: 2500
```

```
fprintf('Number of bytes received: %d', bytesReceived);
```

Number of bytes received: 2250

The data is transmitted successfully over the UDP network. The initial data is dropped due to overhead.

### Transmit Complex Data over UDP Network

Compute the STFT of a sine wave and transmit the complex STFT data over a UDP network. At the receiver side, compute the ISTFT of the received data. Visualize the data sent and the data received using a time scope.

The `dsp.UDPSender` object can send complex data. In order to enable the `dsp.UDPReceiver` object to receive complex data, set the `IsMessageComplex` property to `true`.

```
udps = dsp.UDPSender('RemoteIPPort',31000);  
udpr = dsp.UDPReceiver('LocalIPPort',31000,...  
    'IsMessageComplex',true,...  
    'MessageDataType','double');
```

```
setup(udpr);
```

```
bytesSent = 0;  
bytesReceived = 0;  
dataLength = 128;
```

Initialize the `dsp.STFT` and `dsp.ISTFT` System objects with a periodic hann window of length 120 samples and an overlap length of 60 samples. Set the FFT length to 128.

```
winLen = 120;  
overlapLen = 60;  
  
frameLen = winLen-overlapLen;  
stf = dsp.STFT(...  
    'Window',hann(winLen,'periodic'),...  
    'OverlapLength',overlapLen,'FFTLength',128);  
istf = dsp.ISTFT(...  
    'Window',hann(winLen,'periodic'),...  
    'OverlapLength',overlapLen,...  
    'WeightedOverlapAdd',0);
```

The input is a sinusoidal signal with a frequency of 100 Hz, a sample rate of 1000 Hz, and with 60 samples per each signal frame.

```
sine = dsp.SineWave(...  
    'SamplesPerFrame',winLen-overlapLen,...  
    'Frequency',100);
```

Initialize a `timescope` object with a sample rate of 1000 Hz and a time span of 0.09. The `Delay` object corrects the overlap length while comparing the input with the reconstructed output signal.

```
ts = timescope('SampleRate',1000,...  
    'ShowLegend',true,...  
    'YLimits',[-1 1],...  
    'TimeSpanSource','Property',...  
    'TimeSpan',.09,...
```

```

    'ChannelNames',{ 'Input', 'Reconstructed'});
dly = dsp.Delay('Length',overlapLen);

```

Transmit complex STFT data of the sine wave over the UDP network. Due to the undependable nature of the UDP protocol, the data packets can get lost during transmission. The receiver is not guaranteed to receive all the data that you send.

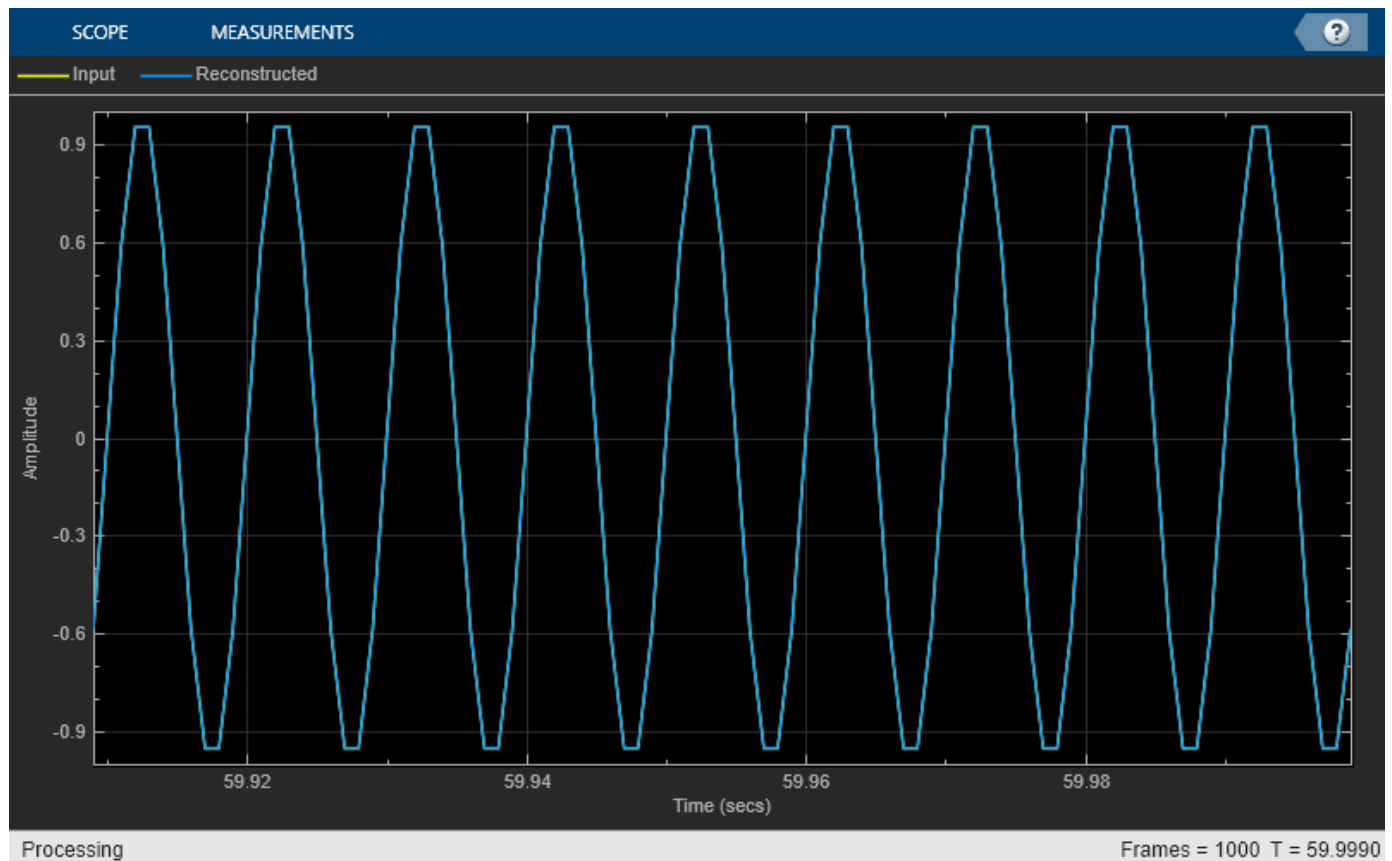

Compute the ISTFT of the received data. Compare the input  $x$  to the reconstructed output  $y$ . Due to the latency introduced by the objects, the reconstructed output is shifted in time compared to the input. Therefore, to compare, take the norm of the difference between the reconstructed output  $y$  and the previous input,  $x_{\text{prev}}$ .

Visualize the signals using a time scope. You can see that the reconstructed signal overlaps very closely with the input signal.

```

n = zeros(1,1e3);
xprev = 0;
for k = 1:1e3
    x = sine();
    X = stf(x);
    bytesSent = bytesSent + length(X);
    udps(X);
    dataReceived = [];
    while (isempty(dataReceived))
        dataReceived = udpr();
    end
    if (~isempty(dataReceived))
        y = istf(dataReceived);
    end
    n(1,k) = norm(y-xprev);
    xprev = x;
    bytesReceived = bytesReceived + length(dataReceived);
    ts([dly(x),y]);
end

```

The norm of the difference is very small, indicating that the output signal is a perfectly reconstructed version of the input signal.

```
max(abs(n))
```

```
ans = 4.0270e-14
```

Release the UDP objects.

```
release(udps);
release(udpr);
```

Some of the packets sent can be lost during transmission due to the lossy nature of the UDP protocol. To check for loss, compare the bytes sent to the bytes received.

```
fprintf('Bytes sent:    %d\n', bytesSent);
```

```
Bytes sent:    128000
```

```
fprintf('Bytes received: %d\n', bytesReceived);
```

```
Bytes received: 128000
```

## Version History

Introduced in R2012a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

The `RemoteIPPort` property is tunable in generated code but not tunable during simulation.

## **dsp.UniformDecoder**

**Package:** dsp

(Removed) Decode integer input into floating-point output

---

**Note** `dsp.UniformDecoder` has been removed. Use `udecode` instead. For more information, see “Compatibility Considerations”.

---

### **Description**

The `dsp.UniformDecoder` System object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

To decode an integer input into a floating-point output:

- 1 Create the `dsp.UniformDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### **Creation**

#### **Syntax**

```
ud = dsp.UniformDecoder
ud = dsp.UniformDecoder(peakvalue,numbits)
ud = dsp.UniformDecoder( ____,Name,Value)
```

#### **Description**

`ud = dsp.UniformDecoder` returns a uniform decoder, `ud`, that performs the inverse operation of the `dsp.UniformEncoder` object, reconstructing quantized floating-point values from encoded integer input.

`ud = dsp.UniformDecoder(peakvalue,numbits)` returns a uniform decoder, `ud`, with the `PeakValue` property set to `peakvalue` and the `NumBits` property set to `numbits`.

`ud = dsp.UniformDecoder( ____,Name,Value)` returns a uniform decoder, `ud`, with the `PeakValue` property set to `peakvalue`, `NumBits` property set to `numbits`, and other properties set to the specified values.

#### **Properties**

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### **PeakValue — Largest amplitude represented in encoded input**

1 (default) | nonnegative scalar

Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the `dsp.UniformEncoder` object, set the `PeakValue` property in both objects to the same value. For more information on setting this property, see the `PeakValue` property description on the `dsp.UniformEncoder` page.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NumBits — Number of input bits used to encode data**

3 (default) | integer in the range [2, 32]

Specify the number of bits used to encode the input data as an integer value between 2 and 32. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the `dsp.UniformEncoder` object, set the `NumBits` property in both objects to the same value. For more information on setting this property, see the `NumBits` property description on the `dsp.UniformEncoder` page.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **OverflowAction — Action to take when integer input is out of range**

'Saturate' (default) | 'Wrap'

Specify the behavior of the uniform decoder when the integer input is out of range as 'Saturate' or 'Wrap'. The value of the `NumBits` property specifies the representable range of the input.

### **OutputDataType — Output data type**

'double' (default) | 'single'

Data type of the output, specified as 'single' or 'double'.

## **Usage**

### **Syntax**

$Y = ud(X)$

### **Description**

$Y = ud(X)$  reconstructs quantized floating-point output  $Y$  from the encoded integer input  $X$ .

### **Input Arguments**

#### **X — Encoded integer input**

vector | matrix

Encoded integer input, specified as a vector or a matrix.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

## Output Arguments

### Y — Decoded output

vector | matrix

Decoded floating-point output, returned as a vector or a matrix. The data type of the output is determined by the `OutputDataType` property.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Decode Sequence

```
ue = dsp.UniformEncoder('PeakValue',2,'NumBits',4,...  
                        'OutputDataType','Signed integer');  
x = (0:0.25:2)'; % Create an input sequence  
ud = dsp.UniformDecoder('PeakValue',2,'NumBits',4);  
x_encoded = ue(x);
```

Check that the last element has been saturated.

```
x_decoded = ud(x_encoded);
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Decoder block reference page. The object properties correspond to the block parameters.

## dsp.UniformEncoder

**Package:** dsp

(Removed) Quantize and encode floating-point input into integer output

---

**Note** `dsp.UniformEncoder` has been removed. Use `uencode` instead. For more information, see “Compatibility Considerations”.

---

### Description

The `dsp.UniformEncoder` System object quantizes floating-point input, using the precision you specify in the `NumBits` property, and encodes the quantized input into integer output. The operations of the uniform encoder adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

To quantize and encode a floating-point input into an integer output:

- 1 Create the `dsp.UniformEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
ue = dsp.UniformEncoder
ue = dsp.UniformEncoder(peakvalue,numbits)
ue = dsp.UniformEncoder( ____,Name,Value)
```

#### Description

`ue = dsp.UniformEncoder` returns a uniform encoder, `ue`, that quantizes floating-point input samples and encodes them as integers using  $2N$ -level quantization, where  $N$  is an integer.

`ue = dsp.UniformEncoder(peakvalue,numbits)` returns a uniform encoder, `ue`, with the `PeakValue` property set to `peakvalue` and the `NumBits` property set to `numbits`.

`ue = dsp.UniformEncoder( ____,Name,Value)` returns a uniform encoder, `ue`, with the `PeakValue` property set to `peakvalue`, the `NumBits` property set to `numbits`, and other specified properties set to the specified values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

### PeakValue — Largest input amplitude to be encoded

1 (default) | nonnegative scalar

Specify the largest input amplitude to be encoded, as a nonnegative numeric scalar. If the real or imaginary input are outside of the interval  $[-P, (1 - 2^{(1-B)})P]$ , where  $P$  is the peak value and  $B$  is the value of the NumBits property, the uniform encoder saturates (independently for complex inputs) at those limits.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### NumBits — Number of bits needed to represent output

8 (default) | integer in the range [2, 32]

Specify the number of bits needed to represent the integer output as an integer value between 2 and 32. The number of levels at which the uniform encoder quantizes the floating-point input is  $2^B$ , where  $B$  is the number of bits.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### OutputDataType — Data type of output

'Unsigned integer' (default) | 'Signed integer'

Specify the data type of the output as 'Unsigned integer' or 'Signed integer'. Unsigned outputs are uint8, uint16, or uint32, and signed outputs are int8, int16, or int32. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval  $[0, 2^{(B-1)}]$  when you set this property to 'Unsigned integer', and in the interval  $[-2^{(B-1)}, 2^{(B-1)} - 1]$  when you set this property to 'Signed integer'. The variable  $B$  in both expressions corresponds to the value of the NumBits property.

## Usage

### Syntax

$Y = \text{ue}(X)$

### Description

$Y = \text{ue}(X)$  quantizes and encodes the input  $X$  to output  $Y$ .

### Input Arguments

#### X — Data input

vector | matrix

Data input, specified as a vector or a matrix. The input  $X$  can be real or complex and double-, or single-precision values.

Data Types: single | double

## Output Arguments

### Y — Encoded data

vector | matrix

Quantized and encoded output, returned as a vector or a matrix.

The uniform encoder chooses the output data type according to the table.

| Number of Bits | Unsigned Integer | Signed Integer |
|----------------|------------------|----------------|
| 2 to 8         | uint8            | int8           |
| 9 to 16        | uint16           | int16          |
| 17 to 32       | uint32           | int32          |

The row in the table corresponds to the value of the NumBits property, and the column in the table corresponds to the value of the OutputDataType property.

Data Types: int8 | int16 | int32 | uint8 | uint16 | uint32

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

## Common to All System Objects

step     Run System object algorithm  
 release   Release resources and allow changes to System object property values and input characteristics  
 reset     Reset internal states of System object

## Examples

### Encode Number Sequence

```
ue = dsp.UniformEncoder;
ue.PeakValue = 2;
ue.NumBits = 4;
ue.OutputDataType = 'Signed integer';
x = (-1:0.01:1)'; % Create an input sequence
x_encoded = ue(x);
plot(x, x_encoded, '.')
xlabel('Input')
ylabel('Encoded Output')
grid
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Encoder block reference page. The object properties correspond to the block parameters.

## Version History

### Introduced in R2012a

#### R2021b: dsp.UniformEncoder System object will be removed

*Warns starting in R2021b*

dsp.UniformEncoder System object will be removed in a future release. Use the uencode function instead.

#### R2023a: dsp.UniformEncoder System object has been removed

*Errors starting in R2023a*

The dsp.UniformEncoder System object has been removed. Use the uencode function instead.

### Update Code

This table shows how to update existing code to use the uencode function.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <p><b>Encode a sequence</b></p> <pre>ue = dsp.UniformEncoder(PeakValue=2,NumBits=4,OutputDataType='Signed'); x = (0:0.25:2)'; x_encoded = ue(x);</pre> <p><b>Decode the encoded sequence</b></p> <pre>ud = dsp.UniformDecoder(PeakValue=2,NumBits=4); x_decoded = ud(x_encoded);</pre> | <p><b>Encode a sequence</b></p> <pre>x_encodedFn = uencode(x,4,2,'signed');</pre> <p><b>Decode the encoded sequence</b></p> <pre>x_decodedFn = udecode(x_encodedFn,4,2);</pre> |

## dsp.UpperTriangularSolver

**Package:** dsp

(Removed) Solve upper-triangular matrix equation

---

**Note** `dsp.UpperTriangularSolver` has been removed. Use the `mldivide` function or the `\` operator instead. For more information, see “Compatibility Considerations”.

---

### Description

The `UpperTriangularSolver` object solves  $UX = B$  for  $X$  when  $U$  is a square, upper-triangular matrix with the same number of rows as  $B$ .

To solve  $UX = B$ :

- 1 Create the `dsp.UpperTriangularSolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
uptriang = dsp.UpperTriangularSolver
uptriang = dsp.UpperTriangularSolver(Name, Value)
```

#### Description

`uptriang = dsp.UpperTriangularSolver` returns a linear system solver, `uptriang`, used to solve  $UX = B$  where  $U$  is an upper (or unit-upper) triangular matrix.

`uptriang = dsp.UpperTriangularSolver(Name, Value)` returns a linear system solver, `uptriang`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### **OverwriteDiagonal — Replace diagonal elements of input with ones**

false (default) | true

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input,  $U$ , with ones. This property is useful when matrix  $U$  is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the  $D$  matrix.

### **RealDiagonalElements — Indicate that diagonal of complex input is real**

`false` (default) | `true`

When you set this property to `true`, the linear system solver optimizes computation speed if the input  $U$  is complex, but its diagonal elements are real. Set this property to either `true` or `false`.

#### **Dependencies**

This property applies only when you set the `OverwriteDiagonal` property to `false`.

### **Fixed-Point Properties**

#### **RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

#### **OverflowAction — Overflow action for fixed-point operations**

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

#### **ProductDataType — Data type of product**

`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

#### **CustomProductDataType — Product word and fraction lengths**

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

#### **Dependencies**

This property applies only when you set the `ProductDataType` property to `Custom`.

#### **AccumulatorDataType — Data type of accumulator**

`Full precision` (default) | `Same as first input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`.

#### **CustomAccumulatorDataType — Accumulator word and fraction lengths**

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

#### **Dependencies**

This property applies only when you set the `AccumulatorDataType` property to `Custom`.

**OutputDataType — Data type of output**

Same as first input (default) | Custom

Specify the output data type as Same as first input or Custom.

**CustomOutputDataType — Output word and fraction lengths**

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

**Usage****Syntax** $X = \text{uptriang}(U,B)$ **Description** $X = \text{uptriang}(U,B)$  computes the solution,  $X$ , of the matrix equation  $UX = B$ , where  $U$  is a square, upper-triangular matrix with the same number of rows as the matrix  $B$ .**Input Arguments****U — Upper-triangular matrix**

matrix

Upper-triangular square matrix of size  $M$ -by- $M$ .

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

**B — Input B**

vector | matrix

Input  $B$  in the equation  $UX = B$ , where  $B$  is an  $M$ -by- $N$  matrix.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: single | double | int8 | int16 | int32 | int64 | fi

**Output Arguments****X — Solution of equation**

vector | matrix

Solution of the  $UX = B$  equation, returned as an  $M$ -by- $N$  output matrix. The object uses only the elements in the upper triangle of input  $U$  and ignores the lower elements. When you set `OverwriteDiagonal` to `true`, the object replaces the elements on the diagonal of the input,  $U$ , with ones.

If the matrix is of fixed-point data type, it must be signed fixed point.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Solve an Upper Triangular Matrix

```
rng(1)
uptriang = dsp.UpperTriangularSolver;
u = triu(rand(4,4));
b = rand(4,1);
```

Check that result is the solution to the linear equations.

```
x1 = u\b
```

```
x1 = 4×1
```

```
0.0632
1.3991
0.3156
0.2955
```

```
x = uptriang(u,b)
```

```
x = 4×1
0.0632
1.3991
0.3156
0.2955
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Backward Substitution block reference page. The object properties correspond to the block parameters.

# dsp.VariableBandwidthFIRFilter

**Package:** dsp

Variable bandwidth FIR filter

## Description

The `dsp.VariableBandwidthFIRFilter` object filters each channel of the input using FIR filter implementations. It does so while having the capability of tuning the bandwidth.

To filter each channel of the input:

- 1 Create the `dsp.VariableBandwidthFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
vbw = dsp.VariableBandwidthFIRFilter  
vbw = dsp.VariableBandwidthFIRFilter(Name=Value)
```

### Description

`vbw = dsp.VariableBandwidthFIRFilter` returns a variable bandwidth FIR filter object which independently filters each channel of the input over successive calls to the object. The filter cutoff frequency can be tuned during the filtering operation. The variable bandwidth FIR filter is designed using the window method.

`vbw = dsp.VariableBandwidthFIRFilter(Name=Value)` returns a variable bandwidth FIR filter with additional properties specified by one or more `Name-Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. For example, `FilterOrder=50` sets the filter order to 50.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **FilterOrder — FIR filter order**

30 (default) | even positive integer

FIR filter order, specified as an even positive integer. This property is nontunable.

Data Types: `double` | `single`

### **FilterType — Type of filter response**

'Lowpass' (default) | 'Highpass' | 'Bandpass' | 'Bandstop'

Type of filter response, specified as one of these options:

- 'Lowpass'
- 'Highpass'
- 'Bandpass'
- 'Bandstop'

### **CutoffFrequency — Filter cutoff frequency**

512 (default) | positive scalar

Filter cutoff frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the cutoff frequency is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the cutoff frequency is in normalized frequency units. The value must be a positive scalar less than `1.0`.

**Tunable:** Yes

### **Dependencies**

To enable this property, set `FilterType` to 'Lowpass' or 'Highpass'.

Data Types: `double` | `single`

### **Window — Window function**

'Hann' (default) | 'Hamming' | 'Chebyshev' | 'Kaiser'

Window function used to design the FIR filter, specified as one of these options:

- 'Hann'
- 'Hamming'
- 'Chebyshev'
- 'Kaiser'

### **KaiserWindowParameter — Kaiser window parameter**

0.5 (default) | real scalar

Kaiser window parameter, specified as a real scalar.

### **Dependencies**

To enable this property, set the `Window` property to 'Kaiser'.

Data Types: `double` | `single`

**CenterFrequency — Center frequency of filter**

11025 (default) | positive scalar

Center frequency of filter, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the center frequency is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the center frequency is in normalized frequency units. The value must be a positive scalar less than `1.0`.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `FilterType` property to 'Bandpass' or 'Bandstop'.

Data Types: double | single

**Bandwidth — Filter bandwidth**

7680 (default) | positive scalar

Filter bandwidth, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the filter bandwidth is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the filter bandwidth is in normalized frequency units. The value must be a positive scalar less than `1.0`.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `FilterType` property to 'Bandpass' or 'Bandstop'.

Data Types: double | single

**SidelobeAttenuation — Chebyshev window sidelobe attenuation**

60 (default) | positive scalar

Chebyshev window sidelobe attenuation, specified as a real positive scalar in dB.

**Dependencies**

To enable this property, set the `Window` property to 'Chebyshev'.

Data Types: double | single

**NormalizedFrequency — Flag to set frequencies in normalized units**

false (default) | true

Flag to set frequencies in normalized units, specified as one of these values:

- `true` -- The filter cutoff frequency, center frequency, and the filter bandwidth must be in the normalized frequency units and less than `1.0`.

- `false` -- The filter cutoff frequency, center frequency, and the filter bandwidth are in Hz. You can specify the input sample rate through the `SampleRate` property.

Data Types: `logical`

### **SampleRate** — Input sample rate

44100 (default) | positive scalar

Input sample rate, specified as a positive scalar in Hz.

#### **Dependency**

To enable this property, set `NormalizedFrequency` to `false`.

Data Types: `double` | `single`

## **Usage**

### **Syntax**

`y = vbw(x)`

#### **Description**

`y = vbw(x)` filters the input signal `x` using the variable bandwidth FIR filter to produce the output `y`. The variable bandwidth FIR filter object operates on each channel, which means the object filters every column of the input signal independently over successive calls to the algorithm.

#### **Input Arguments**

##### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `double` | `single`

#### **Output Arguments**

##### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

## **Object Functions**

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

## Specific to dsp.VariableBandwidthFIRFilter

|          |  |
|----------|--|
| freqz    | Frequency response of discrete-time filter System object     |

| reset   | Reset internal states of System object   |

## Examples

### Filtering Through a Variable Bandwidth Bandpass FIR Filter

Tune the center frequency and the bandwidth of the FIR bandpass filter. Filter a sinusoidal signal through this filter.

Define a bandpass variable bandwidth FIR filter. Specify an input sample rate of 44100 Hz. Initialize a dsp.TransferFunctionEstimator object to estimate the transfer function of the filter from the input and output signals. To visualize the transfer function, initialize a dsp.ArrayPlot object.

```
Fs = 44100;
vbw = dsp.VariableBandwidthFIRFilter(FilterType='Bandpass',...
    FilterOrder=100,...
    SampleRate=Fs,...
    CenterFrequency=1e4,...
    Bandwidth=4e3);
tfe = dsp.TransferFunctionEstimator(FrequencyRange='onesided');
aplot = dsp.ArrayPlot(PlotType='Line',...
    Xoffset=0,...
    YLimits=[-120 5], ...
    SampleIncrement=44100/1024,...
    YLabel='Frequency Response (dB)',...
    XLabel='Frequency (Hz)',...
    Title='System Transfer Function');
```

Generate a sine wave signal with a frame length of 1024. Tune the bandwidth and the center frequency of the filter. Pass the signal through this filter. Estimate the transfer function of the filter using the input and the generated output. Plot the system transfer function using an array plot.

```
FrameLength = 1024;
sine = dsp.SineWave(SamplesPerFrame=FrameLength);
for i=1:500
    % Generate input
    x = sine() + randn(FrameLength,1);
    % Pass input through the filter
    y = vbw(x);
    % Transfer function estimation
```

```

h = tfe(x,y);
% Plot transfer function
aplot(20*log10(abs(h)))
% Tune bandwidth and center frequency of the FIR filter
if (i==250)
    vbw.CenterFrequency = 5000;
    vbw.Bandwidth = 2000;
end
end
end

```

## Algorithms

### FIR Transformations

All transformations assume a lowpass filter of length  $2N+1$ .

#### Lowpass to Lowpass

Consider an ideal lowpass brickwall filter with normalized cutoff frequency  $\omega_{c1}$ . By taking the inverse discrete Fourier transform of the ideal frequency response, and clipping the resulting sequence to length  $2N+1$ , the impulse response is:

for  $n = 0$

$$h_{LP}(n) = \frac{\omega_c}{\pi} \cdot w(0)$$

for  $1 \leq |n| \leq N$

$$h_{LP}(n) = \frac{\sin(\omega_c n)}{\pi n} \cdot w(n)$$

where  $w(n)$  is the window vector. Tune the lowpass filter coefficients to a new cutoff frequency  $\omega_{c2}$  as follows:

for  $n = 0$

$$h_{LP}(n) = \frac{\omega_{c2}}{\pi} \cdot w(0)$$

for  $1 \leq |n| \leq N$

$$h_{LP}(n) = \frac{\sin(\omega_{c2} n)}{\pi n} \cdot w(n)$$

You do not need to recompute the window every time you tune the cutoff frequency.

### Lowpass to Highpass

Assuming a lowpass filter with normalized 6-dB cutoff frequency  $\omega_c$ , you can obtain a highpass filter with the same cutoff frequency by taking the complementary of the lowpass frequency response:

$$H_{HP}(e^{j\omega}) = 1 - H_{LP}(e^{j\omega})$$

Taking the inverse discrete Fourier transform of the above response, you have the following highpass filter coefficients:

for  $n = 0$

$$h_{hp}(n) = 1 - h_{LP}(n)$$

for  $1 \leq |n| \leq N$

$$h_{hp}(n) = -h_{LP}(n)$$

### Lowpass to Bandpass

Obtain a bandpass filter centered at frequency  $\omega_0$  by shifting the lowpass response:

$$H_{BP}(e^{j\omega}) = H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)})$$

The bandwidth of the resulting bandpass filter is  $2\omega_c$ , as measured between the two cutoff frequencies of the bandpass filter. The equivalent bandpass filter coefficients are then:

$$h_{BP}(n) = (e^{j\omega_0 n} + e^{-j\omega_0 n})h_{LP}(n)$$

which can be written as:

$$h_{BP}(n) = 2\cos(\omega_0 n)h_{LP}(n)$$

### Lowpass to Bandstop

You can transform a lowpass filter to a bandstop filter by combining the highpass and bandpass transformations. First make the filter bandpass by shifting the lowpass response, and then invert it to get a bandstop response centered at  $\omega_0$ .

$$H_{BS}(e^{j\omega}) = 1 - (H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)}))$$

This yields the following coefficients:

for  $n = 0$

$$h_{BS}(n) = 1 - 2\cos(\omega_0 n)h_{LP}(n)$$

for  $1 \leq |n| \leq N$

$$h_{BS}(n) = -2\cos(\omega_0 n)h_{LP}(n)$$

### Generalized Transformation

You can combine these transformations to transform a lowpass filter to a lowpass, highpass, bandpass, or bandstop filter with arbitrary cutoffs.

For example, to transform a lowpass filter with cutoff  $\omega_{c1}$  to a highpass with cutoff  $\omega_{c2}$ , you first apply the lowpass-to-lowpass transformation to get a lowpass filter with cutoff  $\omega_{c2}$ , and then apply the lowpass-to-highpass transformation to get the highpass with cutoff  $\omega_{c2}$ .

To get a bandpass filter with center frequency  $\omega_0$  and bandwidth  $\beta$ , we first apply the lowpass-to-lowpass transformation to go from a lowpass with cutoff  $\omega_c$  to a lowpass with cutoff  $\beta/2$ , and then apply the lowpass-to-bandpass transformation to get the desired bandpass filter. You can use the same approach for a bandstop filter.

## Version History

### Introduced in R2014a

#### R2023a: Support for normalized frequencies

When you set the `NormalizedFrequency` property to `true`, you can specify the filter cutoff frequency, center frequency, and the filter bandwidth in normalized frequency units (0 to 1).

When you set the `NormalizedFrequency` property to `true` while creating the object, the frequency values are automatically set to normalized frequency units using the default sample rate of 44100 Hz.

```
vbFIRFilter = dsp.VariableBandwidthFIRFilter(NormalizedFrequency=true)
```

```
vbFIRFilter =  
    dsp.VariableBandwidthFIRFilter with properties:
```

```
        FilterOrder: 30  
        FilterType: 'Lowpass'  
        CutoffFrequency: 0.0232  
        Window: 'Hann'  
        NormalizedFrequency: true
```

When you set the `NormalizedFrequency` property to `true` after you create the object, the frequencies must be manually set to the normalized frequency values before you run the object algorithm.

```
vbFIRFilter = dsp.VariableBandwidthFIRFilter
```

```
vbFIRFilter =  
    dsp.VariableBandwidthFIRFilter with properties:
```

```

    FilterOrder: 30
    FilterType: 'Lowpass'
    CutoffFrequency: 512
    Window: 'Hann'
    NormalizedFrequency: false
    SampleRate: 44100

```

To specify the normalized frequency values, set `NormalizedFrequency` to `true` and manually convert the frequency values in Hz to normalized values using the input sample rate in Hz. For example, if the input sample rate is 44100 Hz, the corresponding values in normalized units are computed using these equations.

```

vbFIRFilter.NormalizedFrequency = true;
vbFIRFilter.CutoffFrequency = 512/(44100/2)

```

```

vbFIRFilter =
    dsp.VariableBandwidthFIRFilter with properties:

```

```

    FilterOrder: 30
    FilterType: 'Lowpass'
    CutoffFrequency: 0.0232
    Window: 'Hann'
    NormalizedFrequency: true

```

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

**Package:** dsp

Variable bandwidth IIR filter

## Description

The `dsp.VariableBandwidthIIRFilter` object filters each channel of the input using IIR filter implementations. It does so while having the capability of tuning the bandwidth.

To filter each channel of the input:

- 1 Create the `dsp.VariableBandwidthIIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
vbwIIR = dsp.VariableBandwidthIIRFilter  
vbwIIR = dsp.VariableBandwidthIIRFilter(Name=Value)
```

### Description

`vbwIIR = dsp.VariableBandwidthIIRFilter` returns a variable bandwidth IIR filter object which independently filters each channel of the input over successive calls to the algorithm. This System object uses a specified IIR filter implementation. The filter passband frequency can be tuned during the filtering operation. The variable bandwidth IIR filter is designed using the elliptical method. The filter is tuned using IIR spectral transformations based on allpass filters.

`vbwIIR = dsp.VariableBandwidthIIRFilter(Name=Value)` returns a variable bandwidth IIR filter with additional properties specified by one or more `Name=Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. For example, `PassbandFrequency=512` sets the passband frequency to 512 Hz.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### **FilterType — Type of filter response**

'Lowpass' (default) | 'Highpass' | 'Bandpass' | 'Bandstop'

Type of filter response, specified as one of these options:

- 'Lowpass'
- 'Highpass'
- 'Bandpass'
- 'Bandstop'

### **FilterOrder — IIR filter order**

8 (default) | positive integer

IIR filter order, specified as a positive integer.

Data Types: double | single

### **PassbandFrequency — Filter passband frequency**

512 (default) | positive scalar

Filter passband frequency, specified as a positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the passband frequency is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the passband frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the `FilterType` property to 'Lowpass' or 'Highpass'.

Data Types: double | single

### **CenterFrequency — Filter center frequency**

11025 (default) | positive scalar

Filter center frequency, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the center frequency is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the center frequency is in normalized frequency units. The value must be a positive scalar less than 1.0.

**Tunable:** Yes

#### **Dependencies**

To enable this property, set the `FilterType` property to 'Bandpass' or 'Bandstop'.

Data Types: double | single

**Bandwidth — Filter bandwidth**

7680 (default) | positive scalar

Filter bandwidth, specified as a real positive scalar in Hz or in normalized frequency units.

If you set the `NormalizedFrequency` property to:

- `false` -- The value of the filter bandwidth is in Hz. The value must be less than half the `SampleRate` property value.
- `true` -- The value of the filter bandwidth is in normalized frequency units. The value must be a positive scalar less than `1.0`.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `FilterType` property to 'Bandpass' or 'Bandstop'.

Data Types: double | single

**PassbandRipple — Filter passband ripple**

1 (default) | positive scalar

Filter passband ripple, specified as a real positive scalar in dB.

Data Types: double | single

**StopbandAttenuation — Filter Stopband attenuation**

60 (default) | positive scalar

Filter stopband attenuation, specified as a real positive scalar in dB.

Data Types: double | single

**NormalizedFrequency — Specify frequencies in normalized units**`false` (default) | `true`

When you set this property to:

- `true` -- The filter passband frequency, center frequency, and the filter bandwidth must be in the normalized frequency units and less than `1.0`.
- `false` -- The filter passband frequency, center frequency, and the filter bandwidth are in Hz. You can specify the input sample rate through the `SampleRate` property.

Data Types: logical

**SampleRate — Input sample rate**

44100 (default) | positive scalar

Input sample rate, specified as a positive scalar in Hz.

**Dependency**

To enable this property, set `NormalizedFrequency` to `false`.

Data Types: double | single

## Usage

### Syntax

```
y = vbwIIR(x)
```

### Description

`y = vbwIIR(x)` filters the real or complex input signal `x` using a variable bandwidth IIR filter to produce the output `y`. The variable bandwidth IIR filter object operates on each channel, which means the object filters every column of the input signal independently over successive calls to the algorithm.

### Input Arguments

#### **x** — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: double | single

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: double | single

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to `dsp.VariableBandwidthIIRFilter`

## Examples

### Filtering Through a Variable Bandwidth Bandpass IIR Filter

Tune the center frequency and the bandwidth of the IIR bandpass filter. Filter a sinusoidal signal through this filter.

Define a bandpass variable bandwidth IIR filter. Specify an input sample rate of 44100 Hz. Initialize a `dsp.TransferFunctionEstimator` object to estimate the transfer function of the filter from the input and output signals. To visualize the transfer function, initialize a `dsp.ArrayPlot` object.

```
Fs = 44100;
vbwiir = dsp.VariableBandwidthIIRFilter(FilterType='Bandpass',...
    FilterOrder=8,...
    SampleRate=Fs,...
    CenterFrequency=1e4,...
    Bandwidth=4e3);
tfe = dsp.TransferFunctionEstimator(FrequencyRange='onesided');
aplot = dsp.ArrayPlot(PlotType='Line',...
    XOffset=0,...
    YLimits=[-120 5], ...
    SampleIncrement=44100/1024,...
    YLabel='Frequency Response (dB)',...
    XLabel='Frequency (Hz)',...
    Title='System Transfer Function');
```

Generate a sine wave signal with a frame length of 1024. Tune the bandwidth and the center frequency of the filter. Pass the signal through this filter. Estimate the transfer function of the filter using the input and the generated output. Plot the system transfer function on Array Plot.

```
FrameLength = 1024;
sine = dsp.SineWave(SamplesPerFrame=FrameLength);
for i = 1:500
    % Generate input
    x = sine() + randn(FrameLength,1);
    % Pass input through the filter
    y = vbwiir(x);
    % Transfer function estimation
    h = tfe(x,y);
    % plot transfer function
    aplot(20*log10(abs(h)))
    % Tune bandwidth and center frequency of the IIR filter
    if (i==250)
        vbwiir.CenterFrequency = 5000;
        vbwiir.Bandwidth = 2000;
    end
end
```

## Algorithms

This filter covers frequency transformations. The algorithm designs a lowpass IIR prototype using the elliptical method by specifying its order, passband frequency, passband ripple, and stopband attenuation. The passband ripple and stopband attenuation are equal to the values of the `PassbandRipple` and `StopbandAttenuation` properties. The algorithm sets the prototype passband frequency to 0.5. If the `FilterType` property is 'Lowpass' or 'Highpass', the order of the prototype filter is equal to the value of `FilterOrder`. If the `FilterType` property is 'Bandpass' or 'Bandstop', the order of the prototype filter is equal to `FilterOrder/2`. The prototype is a Direct Form II Transposed cascade of second-order sections (Biquad filter). The prototype is transformed into the desired filter using the algorithms used in "Digital Frequency Transformations". Each prototype SOS section is transformed separately. When `FilterType` is 'Lowpass' or 'Highpass', the resulting filter remains a Direct Form II Transposed cascade of second order sections. If the `FilterType` is 'Bandpass' or 'Bandstop', the resulting filter is a cascade of Direct Form II Transposed cascade of fourth order sections.

## Version History

Introduced in R2014a

**R2023a: Support for normalized frequencies**

When you set the `NormalizedFrequency` property to `true`, you can specify the filter passband frequency, center frequency, and the filter bandwidth in normalized frequency units (0 to 1).

When you set the `NormalizedFrequency` property to `true` while creating the object, the frequency values are automatically set to normalized frequency units using the default sample rate of 44100 Hz.

```
vbIIRFilter = dsp.VariableBandwidthIIRFilter(NormalizedFrequency=true)
```

```
vbIIRFilter =  
    dsp.VariableBandwidthIIRFilter with properties:
```

```
        FilterType: 'Lowpass'  
        FilterOrder: 8  
        PassbandFrequency: 0.0232  
        PassbandRipple: 1  
        StopbandAttenuation: 60  
        NormalizedFrequency: true
```

When you set the `NormalizedFrequency` property to `true` after you create the object, the frequencies must be manually set to the normalized frequency values before you run the object algorithm.

```
vbIIRFilter = dsp.VariableBandwidthIIRFilter
```

```
vbIIRFilter =  
    dsp.VariableBandwidthIIRFilter with properties:
```

```
        FilterType: 'Lowpass'  
        FilterOrder: 8  
        PassbandFrequency: 512  
        PassbandRipple: 1  
        StopbandAttenuation: 60  
        NormalizedFrequency: false  
        SampleRate: 44100
```

To specify the normalized frequency values, set `NormalizedFrequency` to `true` and manually convert the frequency values in Hz to normalized values using the input sample rate in Hz. For example, if the input sample rate is 44100 Hz, the corresponding values in normalized units are computed using these equations.

```
vbIIRFilter.NormalizedFrequency = true;  
vbIIRFilter.PassbandFrequency = 512/(44100/2)
```

```
vbIIRFilter =  
    dsp.VariableBandwidthIIRFilter with properties:
```

```
        FilterType: 'Lowpass'  
        FilterOrder: 8  
        PassbandFrequency: 0.0232  
        PassbandRipple: 1  
        StopbandAttenuation: 60  
        NormalizedFrequency: true
```

# dsp.VariableFractionalDelay

**Package:** dsp

Delay input by time-varying fractional number of sample periods

## Description

The `dsp.VariableFractionalDelay` System object delays the input signal by a specified number of fractional samples along each channel of the input. The object can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Signal Delay Using Multitap Fractional Delay” on page 4-1285.

The object interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set the “InterpolationMethod” on page 4-0 property to 'Linear', 'FIR', or 'Farrow'. The object supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample. You can also specify the maximum value of the delay by using the “MaximumDelay” on page 4-0 property. Delay values greater than the maximum are clipped to the maximum.

To delay the input by a time-varying fractional number of sample periods:

- 1 Create the `dsp.VariableFractionalDelay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
vfd = dsp.VariableFractionalDelay
vfd = dsp.VariableFractionalDelay(Name,Value)
```

### Description

`vfd = dsp.VariableFractionalDelay` creates a variable fractional delay System object that delays a discrete-time input by a time-varying fractional number of sample periods, as specified by the second input.

`vfd = dsp.VariableFractionalDelay(Name,Value)` creates a variable fractional delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.VariableFractionalDelay('MaximumDelay',50);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

**InterpolationMethod — Method of interpolation**

'Linear' (default) | 'FIR' | 'Farrow'

Method of interpolation, specified as one of the following. Using this method, the object interpolates the signal to obtain new samples at noninteger sampling intervals.

- 'Linear' -- The object uses linear interpolation.
- 'FIR' -- The object implements a polyphase FIR interpolation filter to interpolate values.
- 'Farrow' -- The object uses the LaGrange method to interpolate values.

For more details on these methods, see “Algorithms” on page 4-1295.

**FilterHalfLength — Half-length of FIR interpolation filter**

4 (default) | positive integer in the range [1 65535]

Half-length of FIR interpolation filter, specified as a positive integer in the range [1 65535].

For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

**Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | fi

**FilterLength — Length of Farrow filter**

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure, specified as an integer greater than or equal to 2. If the length equals 2, the filter performs linear interpolation. The filter length value determines the order of the polynomial used for lagrange interpolation.

Example: 4

Example: 10

**Dependencies**

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'Farrow'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**InterpolationPointsPerSample — Number of interpolation points per input sample**

10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed, specified as a positive integer in the range [2 65535].

Example: 20

Example: 5

### Dependencies

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Bandwidth — Normalized input bandwidth

1 (default) | real scalar in the range (0 1]

Normalized input bandwidth at which to constrain the interpolated output samples, specified as a real scalar in the range (0 1]. A value of 1 equals the Nyquist frequency, or half the sampling frequency,  $F_s$ . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above  $F_s/4$ , you can specify a value of 0.5.

Example: 0.5

Example: 0.8

### Dependencies

This property applies only when you set the “InterpolationMethod” on page 4-0 property to 'FIR'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | fi

### InitialConditions — Initial values in the memory

0 (default) | scalar | 1-by- $N$ -by- $D$  array | 1-by- $N$ -by- $(D+L)$  array

Initial values in the memory of the object, specified as a scalar or an array. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions. The object treats each of the  $N$  input columns as a frame containing  $M$  sequential time samples from an independent channel.

For an  $M$ -by- $N$  input matrix,  $U$ , you can set the InitialConditions property as follows :

- To specify fixed initial conditions, specify InitialConditions as a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the “InterpolationMethod” on page 4-0 property.
  - When InterpolationMethod is set to 'Linear', specify InitialConditions as a 1-by- $N$ -by- $D$ , where  $D$  is the value of the “MaximumDelay” on page 4-0 property.
  - When InterpolationMethod is set to 'FIR' or 'Farrow', specify InitialConditions as a 1-by- $N$ -by- $(D+L)$  array, where  $D$  is the value of the MaximumDelay property. For FIR interpolation,  $L$  is the value of the FilterHalfLength property. For Farrow interpolation,  $L$  equals the floor of half the value of the FilterLength property:  $\text{floor}(\text{FilterLength}/2)$ .

Example: 1

Example: randn(1,3,104)

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**MaximumDelay — Maximum delay**

`100` (default) | integer in the range [0 65535]

Maximum delay that the object can produce for any sample, specified as an integer in the range [0 65535]. The object clips input delay values greater than `MaximumDelay` to that maximum value.

Example: `100`

Example: `10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**FIRSmallDelayAction — Action to take for small input delay values when object uses FIR interpolation method**

`'Clip to the minimum value necessary for centered kernel'` (default) | `'Switch to linear interpolation if kernel cannot be centered'`

Action taken for small input delay values when the object uses the FIR interpolation method.

**Dependencies**

This property applies only when you set the `InterpolationMethod` property to `'FIR'`.

**FarrowSmallDelayAction — Action to take for small input delay values when object uses Farrow interpolation method**

`'Clip to the minimum value necessary for centered kernel'` (default) | `'Use off-centered kernel'`

Action taken for small input delay values when the object uses the farrow interpolation method.

**Dependencies**

This property applies only when you set the `InterpolationMethod` property to `'Farrow'`.

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

`'Zero'` (default) | `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'`

Rounding mode for fixed-point operations, specified as one of the following:

- `'Zero'`
- `'Ceiling'`
- `'Convergent'`
- `'Floor'`
- `'Nearest'`
- `'Round'`
- `'Simplest'`

For more details, see rounding mode.

**OverflowAction — Overflow action for fixed-point operations**

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

### **CoefficientsDataType — Data type of the coefficients**

'Same word length as input' (default) | 'Custom'

Data type of the coefficients in this object, specified as one of the following:

- 'Same word length as input' -- The object specifies the coefficients word length to be the same as that of the input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The coefficients data type is specified as a custom numeric type through the "CustomCoefficientsDataType" on page 4-0 property.

For more information on the coefficients data type this object uses, see the "Fixed Point" on page 4-1291 section.

### **CustomCoefficientsDataType — Coefficient word and fraction lengths**

numericType([],32) (default)

Coefficient word and fraction lengths, specified as an autosigned numeric type with a word length of 32.

Example: numericType([],16)

#### **Dependencies**

This property applies only when you set "CoefficientsDataType" on page 4-0 to 'Custom'.

### **ProductPolynomialValueDataType — Data type of the product polynomial value**

'Same as first input' (default) | 'Custom'

Data type of the product polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the product polynomial value data type to be the same as that of the data input.
- 'Custom' -- The product polynomial value data type is specified as a custom numeric type through the "CustomProductPolynomialValueDataType" on page 4-0 property.

For more information on the product polynomial value data type this object uses, see the "Fixed Point" on page 4-1291 section.

#### **Dependencies**

This property applies when you set "InterpolationMethod" on page 4-0 to 'Farrow'.

### **CustomProductPolynomialValueDataType — Word and fraction lengths of product polynomial value**

numericType([],32,10) (default)

Word and fraction lengths of the product polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericity([],30,5)`

**Dependencies**

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “ProductPolynomialValueDataType” on page 4-0 to 'Custom'.

**AccumulatorPolynomialValueDataType — Data type of the accumulator polynomial value**

'Same as first input' (default) | 'Custom'

Data type of the accumulator polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the accumulator polynomial value data type to be the same as that of the data input.
- 'Custom' -- The accumulator polynomial value data type is specified as a custom numeric type through the “CustomAccumulatorPolynomialValueDataType” on page 4-0 property.

For more information on the accumulator polynomial value data type that this object uses, see the “Fixed Point” on page 4-1291 section.

**Dependencies**

This property applies when you set “InterpolationMethod” on page 4-0 to 'Farrow'.

**CustomAccumulatorPolynomialValueDataType — Word and fraction lengths of accumulator polynomial value**

`numericity([],32,10)` (default)

Word and fraction lengths of the accumulator polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numericity([],30,5)`

**Dependencies**

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “AccumulatorPolynomialValueDataType” on page 4-0 to 'Custom'.

**MultiplicandPolynomialValueDataType — Data type of multiplicand polynomial value**

'Same as first input' (default) | 'Custom'

Data type of multiplicand polynomial value, specified as one of the following:

- 'Same as first input' -- The object specifies the multiplicand polynomial value data type to be the same as that of the data input.
- 'Custom' -- The multiplicand polynomial value data type is specified as a custom numeric type through the “CustomMultiplicandPolynomialValueDataType” on page 4-0 property.

For more information on the multiplicand polynomial value data type that this object uses, see the “Fixed Point” on page 4-1291 section.

**Dependencies**

This property applies when you set “InterpolationMethod” on page 4-0 to 'Farrow'.

### CustomMultiplicandPolynomialValueDataType — Word and fraction lengths of multiplicand polynomial value

`numerictype([],32,10)` (default)

Word and fraction lengths of the multiplicand polynomial value, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numerictype([],30,5)`

#### Dependencies

This property applies only when you set “InterpolationMethod” on page 4-0 to 'Farrow' and “MultiplicandPolynomialValueDataType” on page 4-0 to 'Custom'.

### ProductDataType — Data type of product output

'Same as first input' (default) | 'Custom'

Data type of the product output in this object, specified as one of the following:

- 'Same as first input' -- The object specifies the product output data type to be the same as that of the data input.
- 'Custom' -- The product output data type is specified as a custom numeric type through the “CustomProductDataType” on page 4-0 property.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 4-1291 section.

### CustomProductDataType — Word and fraction lengths of product data type

`numerictype([],32,10)` (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numerictype([],30,5)`

#### Dependencies

This property applies only when you set “ProductDataType” on page 4-0 to 'Custom'.

### AccumulatorDataType — Data type of accumulation operation

'Same as product' (default) | 'Same as first input' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- 'Same as product' -- The object specifies the accumulator data type to be the same as that of the product output data type.
- 'Same as first input' -- The object specifies the accumulator data type to be the same as that of the data input.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the “CustomAccumulatorDataType” on page 4-0 property.

For more information on the accumulator data type this object uses, see the “Fixed Point” on page 4-1291.

### CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

`numerictype([],32,10)` (default)

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numerictype([],30,5)`

### Dependencies

This property applies only when you set “AccumulatorDataType” on page 4-0 to 'Custom'.

### OutputDataType — Data type of object output

'Same as accumulator' (default) | 'Same as first input' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The object specifies the output data type to be the same as that of the accumulator output data type.
- 'Same as first input' -- The object specifies the output data type to be the same as that of the data input.
- 'Custom' -- The output data type is specified as a custom numeric type through the “CustomOutputDataType” on page 4-0 property.

For more information on the output data type this object uses, see the “Fixed Point” on page 4-1291 section.

### CustomOutputDataType — Word and fraction lengths of output data type

`numerictype([],32,10)` (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 10.

Example: `numerictype([],30,5)`

### Dependencies

This property applies only when you set “OutputDataType” on page 4-0 to 'Custom'.

## Usage

### Syntax

```
vfdOut = vfd(input,d)
```

### Description

`vfdOut = vfd(input,d)` delays the input to the variable fractional delay System object by `d` samples. `d` must be less than or equal to the value you specify in the “MaximumDelay” on page 4-0 property of the object.

Delay values greater than the specified maximum delay are clipped appropriately. Each column of the input is treated as an independent channel.

### Input Arguments

#### input — Data input

vector | matrix

Data input, specified as a vector or matrix. The data input must have the same data type as the delay input.

This object supports variable-size input signal, that is, you can change the input frame size (number of rows)  $N$  even after calling the algorithm. However, the number of channels  $L$  must remain constant. For an example, see “Variable-Size Signal Support for Input and Delay Signals” on page 4-1290.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### **d** — Delay input

scalar | vector | matrix |  $N$ -D array

Delay input, specified as a scalar, vector, matrix, or  $N$ -D array. The delay can be an integer or a fractional value. When the delay input is a fractional value, the object interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This object supports variable-size delay signal, that is, you can change the first dimension of the delay signal even after calling the algorithm. However, the number of channels  $L$  and the number of taps per channel  $P$  must remain constant. For an example, see “Variable-Size Signal Support for Input and Delay Signals” on page 4-1290.

The table shows the effect of the dimension of the delay input on the data input.

| Data Input   | Delay Input  | Output       | Effect of Delay Input on Data Input   |
|--|--------------|--------------|---|
| $N$ -by-1 (one channel with frame size equal to $N$ )      | scalar       | $N$ -by-1    | One delay value applied to the input channel  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by-1    | $N$ -by-1    | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | 1-by- $P$    | $N$ -by- $P$ | $P$ taps per channel. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by- $P$ | $N$ -by- $P$ | $P$ taps per channel. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | scalar       | $N$ -by- $L$ | One delay value applied to all input channels   |

| Data Input   | Delay Input           | Output                | Effect of Delay Input on Data Input  |
|--|-----------------------|-----------------------|--|
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$             | $N$ -by- $L$          | Unique delay value for each input channel  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1             | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.                                    |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$          | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Different delay values for each input channel.                                |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by-1-by- $P$        | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Same delay for all channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$ -by- $P$    | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies across channels.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1-by- $P$     | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.      |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$ -by- $P$ | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel. |

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Output Arguments

#### vfdOut — Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size, data type, and complexity of the output match the size, data type, and complexity of the data input.

The table shows how the data input and delay input dimensions affect the output dimensions:

| <b>Data Input</b>  | <b>Delay Input</b> | <b>Output</b>         | <b>Effect of Delay Input on Data Input</b>  |
|--|--------------------|-----------------------|---|
| $N$ -by-1 (one channel with frame size equal to $N$ )      | scalar             | $N$ -by-1             | One delay value applied to the input channel  |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by-1          | $N$ -by-1             | Delay value varies within the frame from sample to sample   |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | 1-by- $P$          | $N$ -by- $P$          | $P$ taps per channel. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector. |
| $N$ -by-1 (one channel with frame size equal to $N$ )      | $N$ -by- $P$       | $N$ -by- $P$          | $P$ taps per channel. In addition, delay varies within each frame from sample to sample.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | scalar             | $N$ -by- $L$          | One delay value applied to all input channels   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$          | $N$ -by- $L$          | Unique delay value for each input channel   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1          | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Same set of delay values for all channels.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$       | $N$ -by- $L$          | Delay value varies within the frame from sample to sample. Different delay values for each input channel.   |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by-1-by- $P$     | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Same tap for all channels.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | 1-by- $L$ -by- $P$ | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Taps vary across channels.  |
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by-1-by- $P$  | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.                                     |

| Data Input   | Delay Input           | Output                | Effect of Delay Input on Data Input  |
|--|-----------------------|-----------------------|--|
| $N$ -by- $L$ ( $L$ channels with frame size equal to $N$ ) | $N$ -by- $L$ -by- $P$ | $N$ -by- $L$ -by- $P$ | $L$ channels. $P$ taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel. |

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Specific to dsp.VariableFractionalDelay

`info` Characteristic information about valid delay range

`generatehdl` Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

### Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

## Examples

### Signal Delay using Variable Fractional Delay

Delay a signal by a varying fractional number of sample periods.

```
sr = dsp.SignalSource;
vfd = dsp.VariableFractionalDelay;
sink = dsp.SignalSink;

for ii = 1:10
    delayedsig = vfd(sr(), ii/10);
    sink(delayedsig);
end

sigd = sink.Buffer;
```

The output `sigd` corresponds to the values of the delayed signal that are sampled at fixed-time intervals. To plot the time instants at which the amplitudes of signal samples are constant, treat the signals as the sampling instants.

```
stem(sr.Signal,1:10,'b')
hold on;
stem(sigd.',1:10,'r');
legend('Original signal', ...
      'Variable fractional delayed signal', ...
      'Location','best')
```

### Signal Delay Using Multitap Fractional Delay

Delay the input signal using the `dsp.VariableFractionalDelay` object. Each delay value is unique and can vary from sample to sample within a frame, and can vary across channels. You can compute multiple delayed versions of the same input signal concurrently by passing a delay input with the appropriate dimension.

Consider the input to be a random signal with one channel and a frame size of 10. Apply a delay of 4.8 and 8.2 samples concurrently.

```
vfd = dsp.VariableFractionalDelay
vfd =
  dsp.VariableFractionalDelay with properties:
```

```
InterpolationMethod: 'Linear'  
InitialConditions: 0  
MaximumDelay: 100
```

Show all properties

```
in = randn(10,1)
```

```
in = 10×1

```

Each channel in the output is delayed by 4.8 and 8.2 samples, respectively. The object uses the 'Linear' interpolation method to compute the delayed value. For more details, see 'Algorithms' in the `dsp.VariableFractionalDelay` object page.

For the same delay vector, if the input has 2 channels, each element of the delay vector is applied on the corresponding channel in the input.

```
release(vfd);  
in = randn(10,2)

     0.5308    -0.8317
```

To compute multiple delayed versions of the two-dimensional input signal, pass the delay vector as a three-dimensional array. The third dimension contains the taps or delays to apply on the signal. If you pass a non-singleton third dimension (1-by-1-by- $P$ ), where  $P$  represents the number of taps, the same tap is applied across all the channels. Pass the delays [4.8 8.2] in the third dimension.

```
clear delayVec;
delayVec(1,1,1) = 4.8;
delayVec(1,1,2) = 8.2;
whos delayVec
```

| Name     | Size  | Bytes | Class  | Attributes |
|----------|-------|-------|--------|------------|
| delayVec | 1x1x2 | 16    | double |            |

`delayVec` is a 1-by-1-by-2 array. Pass the two-dimensional input to the `dsp.VariableFractionalDelay` object with this delay vector.

```
release(vfd);
outcase3 = vfd(in,delayVec)
```

```
outcase3 =
outcase3(:,:,1) =

|----------|--------|-------|--------|------------|
| outcase3 | 10x2x2 | 320   | double |            |

`outcase3(:, :, 1)` represents the input signal delayed by 4.8 samples. `outcase3(:, :, 2)` represents the input signal delayed by 8.2 samples. The same delay is applied across all the channels.

In addition, if you pass a non-singleton second dimension (1-by- $L$ -by- $P$ ), where  $L$  is the number of input channels, taps vary across channels. Apply the delay vectors [2.3 3.5] and [4.4 5.6] to compute the two delayed versions of the input signal.

```

Delay varies across each element in a channel. Same set of delay values apply across all channels. `delayVec(:,1,1)` applies to the first delayed signal and `delayVec(:,1,2)` applies to the second delayed signal.

### Variable-Size Signal Support for Input and Delay Signals

`dsp.VariableFractionalDelay` System object supports variable-size input and delay signals. That is, you can change the dimension of the input signal and the delay signal even after calling the algorithm. You can change the dimensions of one or both the signals simultaneously. Together, they must make sure that the number of output channels (number of columns) remains constant.

#### Variable-Size Support for Input Signal

The number of samples in each frame of the input signal can change. However, the number of input channels must remain constant.

Create a `dsp.VariableFractionalDelay` object. Pass an input signal of size [256 1] and a delay of 1.4 to the object algorithm. In subsequent calls to the algorithm, change the input frame size to 128, 512, and 64, respectively

```
vfd = dsp.VariableFractionalDelay;  
vfd(randn(256,1),1.4);  
vfd(randn(128,1),1.4);  
vfd(randn(512,1),1.4);  
vfd(randn(64,1),1.4);
```

The output frame size (number of rows) changes according to the input frame size. The number of output channels in each of these cases is 1.

To change the number of input channels, release the object.

```
release(vfd);
```

Call the algorithm with a two-channel input and vary the input frame size in subsequent calls.

```
vfd(randn(256,2),1.4);  
vfd(randn(128,2),1.4);
```

#### Variable-Size Support for Delay Signal

In addition to the input, the delay signal can also vary. That is, you can change one or both of the dimensions of the delay signal after calling the algorithm. However, the object must make sure that the resulting number of output channels remains constant. The delay signal can be a scalar, vector, matrix, or an N-D array.

```
release(vfd);  
vfd(randn(512,2),randn(512,2));  
vfd(randn(128,2),[1.4 1.7]);
```

```
vfd( randn(256,2) , randn(256,1) );
vfd( randn(128,2) , 1.4 );
```

In each of these cases, the number of output channels is 2. To apply different delays on the input signal, release the object.

```
release(vfd);
vfd( randn(256,1) , randn(256,7) );
vfd( randn(512,1) , randn(512,7) );
vfd( randn(100,1) , randn(100,7) );
vfd( randn(100,1) , randn(1,7) );
```

The output in each of these cases is [256 7], [512 7], [100 7], and [100 7], respectively.

## More About

### Fixed Point

The diagrams in the following sections show the data types used within the dsp.VariableFractionalDelay object for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the object and cannot be directly specified on the object interface.

| Data Type             | Word Length                               | Fraction Length         |
|-----------------------|---|-------------------------|
| vf data type          | Same word length as the coefficients      | Same as the word length |
| HoldInteger data type | Same word length as the input delay value | 0 bits                  |
| Integer data type     | 32 bits                                   | 0 bits                  |

**Note** When the input is fixed point, all internal data types are signed fixed point.

### Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the variable fractional delay algorithm.

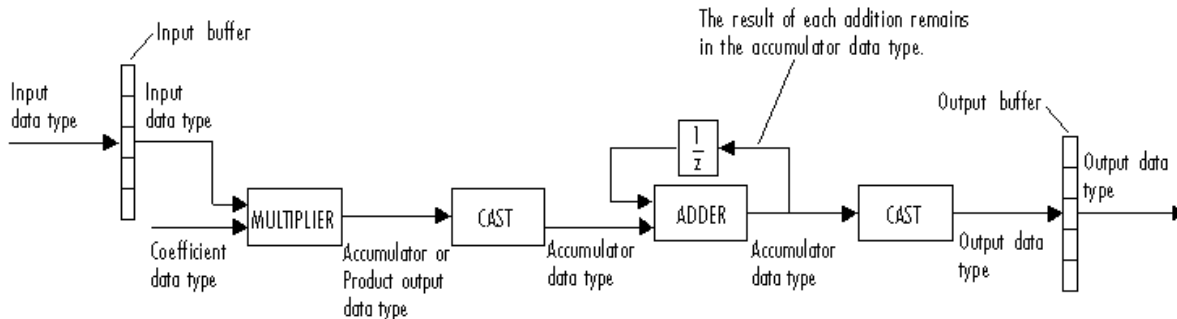

### FIR Interpolation Mode

The following diagram illustrates how the variable fractional delay object selects the arm of the polyphase filter structure that most closely matches the fractional delay value ( $v_f$ ).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

You can set the coefficient, product output, accumulator, and output data types in the object. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The object stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see "Multiplication Data Types".

**Farrow Interpolation Mode**

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to 'Clip to the minimum value necessary for centered kernel'

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to 'Use off-centered kernel'

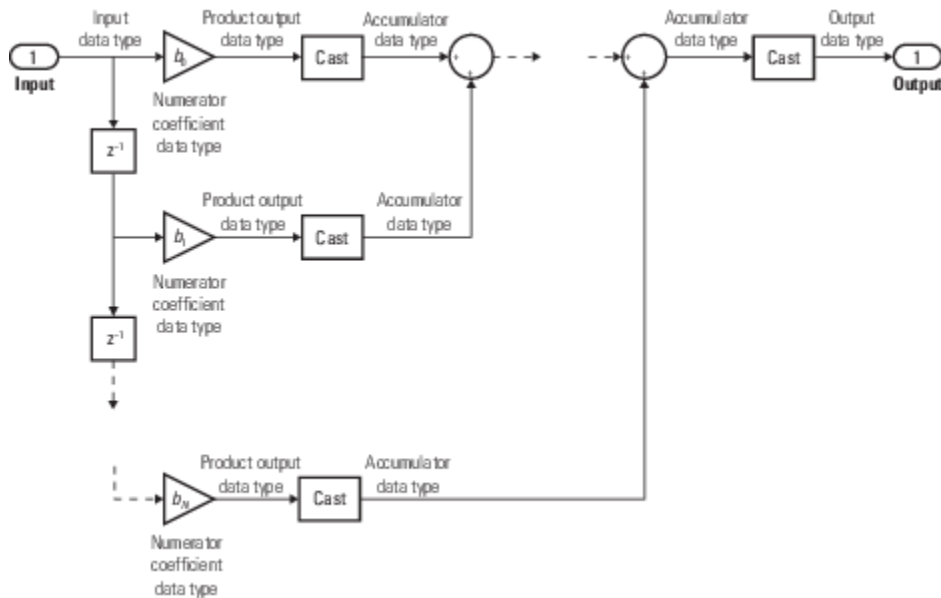

Diff is computed from the integer part of the delay value ( $v_i$ ) and the farrow filter length ( $N$ ) according to the following equation:

$$Diff = v_i - \left( \frac{N - 1}{2} \right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the FIR direct form filter.

## Algorithms

When you specify a fractional delay value, the algorithm uses a linear, FIR, or Farrow interpolation method to interpolate signal values at noninteger sample intervals.

### Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector,  $y$ , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- $i$  -- Index of the current sample
- $v$  -- Fractional delay
- $v_i$  -- Integer part of the delay
- $v_f$  -- Fractional part of the delay
- $U$  -- Input data vector
- $y$  -- Output data vector
- $U(i - v_i)$ ,  $U(i - v_i - 1)$  -- Two samples in memory nearest to the specified delay
- $i - v_i$  -- Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the  $D_{max} + 1$  most recent samples received at the input for each channel, where  $D_{max}$  is the maximum delay specified.  $U$  represents the stored samples.

### FIR Interpolation Mode

In the FIR interpolation mode, the variable fractional delay stores the  $D_{max}+P+1$  most recent samples received at the input for each channel, where  $P$  is the specified interpolation filter half-length.

In this mode, the object provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P - 1, \quad i = 0, 1, \dots, L - 1$$

If  $v$  is less than  $P - 1$ , the behavior depends on the FIR small delay value action setting. You can specify the object's behavior when the input delay value is too small to center the kernel (less than  $P-1$ ), by setting the FIR small delay value action setting:

- **Clip to the minimum value necessary for centered kernel** -- The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- **Switch to linear interpolation if kernel cannot be centered** -- Fractional delays are computed using linear interpolation when the input delay value is less than  $P-1$ .

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the  $L$  filter arms of the polyphase structure is  $2P$ . In most cases, using values of  $P$  between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length ( $P$ ) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length ( $P$ ) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample ( $L$ ) increases the number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above  $F_s/4$ , you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

---

**Note** You can consider each of the  $L$  interpolation filters to correspond to one output phase of an upsample-by- $L$  FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

---

### Farrow Interpolation Mode

In Farrow interpolation mode, the algorithm uses the LaGrange method to interpolate values.

The order of the polynomial used for the interpolation is based on the number of data points used in the Lagrange interpolation. This value is specified in the FilterLength property.

To specify the behavior when the input delay value is too small to center the kernel (less than  $\frac{N}{2} - 1$ ), use the Farrow small delay action setting.

- **Clip to the minimum value necessary for centered kernel** -- The algorithm clips small input delay values to the smallest value necessary to keep the kernel centered. This option yields more accurate interpolation values.
- **Use off-centered kernel** -- The fractional delays are computed using a Farrow filter with an off-centered kernel. The results for input delay values less than  $\frac{N}{2} - 1$  are less accurate than the results achieved by keeping the kernel centered.

When the length of the farrow filter is 2, the filter performs linear interpolation.

## Version History

Introduced in R2012a

### Extended Capabilities

#### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

#### HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Delay input by time-varying integer number of sample periods

## Description

The `dsp.VariableIntegerDelay` System object delays input by time-varying integer number of sample periods.

To delay the input by a time-varying integer number of sample periods:

- 1 Create the `dsp.VariableIntegerDelay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
vid = dsp.VariableIntegerDelay
vid = dsp.VariableIntegerDelay(Name,Value)
```

### Description

`vid = dsp.VariableIntegerDelay` returns a variable integer delay System object, `vid`, that delays discrete-time input by a time-varying integer number of sample periods.

`vid = dsp.VariableIntegerDelay(Name,Value)` returns a variable integer delay System object with each specified property set to the specified value.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

### MaximumDelay — Maximum delay

100 (default) | positive integer scalar

Specify the maximum delay the object can produce for any sample. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**InitialConditions — Initial values in memory**

0 (default) | scalar | 1-by- $N$ -by- $D$  array

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on whether you want fixed or time-varying initial conditions.

For an  $M$ -by- $N$  frame-based input matrix  $U$ , you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by- $N$ -by- $D$ , where  $D$  is the value of the `MaximumDelay` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Usage****Syntax**

```
vidOut = vid(input,d)
```

**Description**

`vidOut = vid(input,d)` delays the input by  $d$  samples, where  $d$  should be less than or equal to the value specified in the `MaximumDelay` property and greater than or equal to 0. Delay values outside this range are clipped appropriately and non-integer delays are rounded to the nearest integer values. Each column of the input is treated as an independent channel

**Input Arguments****input — Data input**

vector | matrix

Data input, specified as a vector or matrix.

This object supports variable-size input signal. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

**d — Delay input**

scalar | vector | matrix

Delay input, specified as a scalar, vector, or matrix. The delay is an integer value.

For an  $M$ -by-1 or a 1-by- $N$  data input vector, the delay can be a:

- Scalar
- Vector -- The length and the orientation of the delay vector match the length and the orientation of the data input.

For an  $M$ -by- $N$  matrix data input, the delay can be a:

- Column vector -- The length of the vector is  $M$ .
- Row vector -- The length of the vector is  $N$ .
- Matrix -- Delay must be an  $M$ -by- $N$  matrix.

The dimensions of the delay signal can change according to the supported dimensions listed in the table. The table also shows how delay signal is applied to the input signal.

| Data Input   | Delay Input  | Output       | Effect of Delay Input on Data Input   |
|--|--------------|--------------|---|
| $M$ -by-1 (one channel with frame size equal to $M$ )      | scalar       | $M$ -by-1    | One delay value applied to the input channel  |
| $M$ -by-1 (one channel with frame size equal to $M$ )      | $M$ -by-1    | $M$ -by-1    | Delay value varies within the frame from sample to sample   |
| 1-by- $N$ ( $N$ channels with frame size equal to 1)       | scalar       | 1-by- $N$    | One delay value applied to all the $N$ channels   |
| 1-by- $N$ ( $N$ channels with frame size equal to 1)       | 1-by- $N$    | 1-by- $N$    | Unique delay value for each input channel   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | scalar       | $M$ -by- $N$ | One delay value applied to all input channels   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | 1-by- $N$    | $M$ -by- $N$ | Unique delay value for each input channel   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | $M$ -by-1    | $M$ -by- $N$ | Delay value varies within the frame from sample to sample. Same set of delay values for all channels. |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | $M$ -by- $N$ | $M$ -by- $N$ | Unique delay value for each element in the matrix   |

Example: [2 3 4 5]

Example: [2;3;4;5]

Example: [5]

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

### Output Arguments

#### vidOut – Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The size, data type, and complexity of the output match the size, data type, and complexity of the data input, “input” on page 4-0 .

The table shows how the data input and delay input dimensions affect the output dimensions:

| Data Input   | Delay Input  | Output       | Effect of Delay Input on Data Input   |
|--|--------------|--------------|---|
| $M$ -by-1 (one channel with frame size equal to $M$ )      | scalar       | $M$ -by-1    | One delay value applied to the input channel  |
| $M$ -by-1 (one channel with frame size equal to $M$ )      | $M$ -by-1    | $M$ -by-1    | Delay value varies within the frame from sample to sample   |
| 1-by- $N$ ( $N$ channels with frame size equal to 1)       | scalar       | 1-by- $N$    | One delay value applied to all the $N$ channels   |
| 1-by- $N$ ( $N$ channels with frame size equal to 1)       | 1-by- $N$    | 1-by- $N$    | Unique delay value for each input channel   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | scalar       | $M$ -by- $N$ | One delay value applied to all input channels   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | 1-by- $N$    | $M$ -by- $N$ | Unique delay value for each input channel   |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | $M$ -by-1    | $M$ -by- $N$ | Delay value varies within the frame from sample to sample. Same set of delay values for all channels. |
| $M$ -by- $N$ ( $N$ channels with frame size equal to $M$ ) | $M$ -by- $N$ | $M$ -by- $N$ | Unique delay value for each element in the matrix   |

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

### Common to All System Objects

- step     Run System object algorithm
- release   Release resources and allow changes to System object property values and input characteristics
- reset     Reset internal states of System object

## Examples

## Delay a Signal with VariableIntegerDelay Object

Delay a signal by a varying number of integer sample periods.

```
vid = dsp.VariableIntegerDelay;

yout = zeros(100,1);
x     = (1:100).';

for k=1:10
    range = (k-1)*10+1:k*10;
    yout(range) = vid(x(range),k);
end

stem(x,'b')
hold on;
stem(yout,'r')
legend('Original Signal', 'Variable Integer Delayed Signal')
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page.

(Removed) Vector quantizer codeword for given index value

---

**Note** dsp.VectorQuantizerDecoder has been removed.

---

## Description

The `VectorQuantizerDecoder` object associates each input index value with a codeword, a column vector of quantized output values defined in the `Codebook` property. Each column of the `Codebook` property is a codeword. When you input multiple index values into this object, the object outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select to enter the code book values via the `Codebook` property or as an input to the object.

To obtain the vector quantizer codeword for a given index value:

- 1 Create the `dsp.VectorQuantizerDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
vqdec = dsp.VectorQuantizerDecoder  
vqdec = dsp.VectorQuantizerDecoder(Name,Value)
```

### Description

`vqdec = dsp.VectorQuantizerDecoder` creates a vector quantizer decoder System object, `vqdec`, that returns a vector quantizer codeword corresponding to a given, zero-based index value.

`vqdec = dsp.VectorQuantizerDecoder(Name,Value)` returns a vector quantizer decoder, `vqdec`, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**CodebookSource — Source of codebook values**

Property (default) | Input port

Specify the codebook source as `Property` or `Input port`. When you select `Property`, the object reads the codebook from the `Codebook` property. When you select `Input port`, the object reads the codebook from the input argument `C`.

**Codebook — Matrix of codewords**

[1.5 13.3 136.4 6.8; 2.5 14.3 137.4 7.8; 3.5 15.3 138.4 8.8] (default) | matrix

Specify quantized output values as a  $k$ -by- $N$  matrix, where  $k \geq 1$  and  $N \geq 1$ . Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

**Tunable:** Yes**Dependencies**

This property applies when you set the `CodebookSource` property to `Property`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**OutputDataType — Data type of codebook and quantized output**

double (default) | Same as input | single | Custom

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single`, or `Custom`. If this property is set to `Custom`, the data type is specified by the `CustomOutputDataType` property.

**Dependencies**

This property applies only when you set `CodebookSource` to `Property`.

**Fixed-Point Properties****CustomOutputDataType — Output word and fraction lengths**

numerictype(true,16) (default) | numerictype

Specify the output fixed-point type as a signed or unsigned `numerictype` object.

**Dependencies**

This property applies only when you set the `OutputDataType` property to `Custom`.

**Usage****Syntax**
$$Q = \text{vqdec}(I)$$

$Q = \text{vqdec}(I, C)$

### Description

$Q = \text{vqdec}(I)$  returns the quantized output values  $Q$  corresponding to the input indices  $I$ .

$Q = \text{vqdec}(I, C)$  uses input  $C$  as the codebook values when the CodebookSource property is Input port.

### Input Arguments

#### I — Indices

scalar | row vector

Input indices, specified as a scalar or a row vector.

The input to this object is a vector of index values, where  $0 \leq \text{index} < N$  and  $N$  is the number of columns of the codebook matrix. The object sets any index values less than 0 to 0 and any index values greater than or equal to  $N$  to  $N - 1$ .

Data Types: int8 | int16 | int32 | uint8 | uint16 | uint32

#### C — Codebook values

scalar | vector | matrix

Codebook values, specified as a scalar, vector, or matrix.

### Dependencies

This input is enabled only when the CodebookSource property is set to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

### Output Arguments

#### Q — Quantized output values

scalar | vector | matrix

Quantized output values, returned as a scalar, vector, or matrix. Each column of  $Q$  is a codeword whose index in the codebook matches the element specified in the  $I$  matrix.

The codebook is zero based. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

For example, if the codebook is

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

and the  $I$  vector is  $[1 \ 0 \ 3 \ 2 \ 1 \ 0]$ , the output  $Q$  matrix is

$$\begin{bmatrix} 13.3 & 1.5 & 6.8 & 136.4 & 13.3 & 1.5 \\ 14.3 & 2.5 & 7.8 & 137.4 & 14.3 & 2.5 \\ 15.3 & 3.5 & 8.8 & 138.4 & 15.3 & 3.5 \end{bmatrix}$$

If the CodebookSource is set to 'Property', the data type of Q is determined by the OutputDataType property.

If the CodebookSource is set to 'Input port', the output Q has the same data type as the codebook input C.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fi

### Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

### Common to All System Objects

|         |  |
|---------|--|
| step    | Run System object algorithm  |
| release | Release resources and allow changes to System object property values and input characteristics |
| reset   | Reset internal states of System object   |

### Examples

#### Determine Vector Quantizer Codeword

Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook.

```
vqdec = dsp.VectorQuantizerDecoder;  
vqdec.Codebook = [1 10 100;2 20 200;3 30 300];  
indices = uint8([1 0 2 0]);  
qout = vqdec(indices)
```

```
qout = 3x4
```

```
    10     1    100     1  
    20     2    200     2  
    30     3    300     3
```

### Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

- There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than 0 to 0 and any index values greater than or equal to N to N-1.

### Version History

Introduced in R2012a

**R2021b: dsp.VectorQuantizerDecoder System object will be removed**

*Warns starting in R2021b*

`dsp.VectorQuantizerDecoder` System object will be removed in a future release.

**R2023a: dsp.VectorQuantizerDecoder System object has been removed**

*Errors starting in R2023a*

The `dsp.VectorQuantizerDecoder` System object has been removed.

**Extended Capabilities****C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

## dsp.VectorQuantizerEncoder

**Package:** dsp

(Removed) Vector quantization encoding

---

**Note** dsp.VectorQuantizerEncoder has been removed.

---

### Description

The VectorQuantizerEncoder object performs vector quantization encoding. The object finds the nearest codeword by computing a distortion based on Euclidean or weighted Euclidean distance.

To perform vector quantization encoding:

- 1 Create the dsp.VectorQuantizerEncoder object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

### Creation

#### Syntax

```
vgenc = dsp.VectorQuantizerEncoder  
vgenc = dsp.VectorQuantizerEncoder(Name,Value)
```

#### Description

vgenc = dsp.VectorQuantizerEncoder returns a vector quantizer encoder System object, vgenc. This object finds a zero-based index of the nearest codeword for each given input column vector.

vgenc = dsp.VectorQuantizerEncoder(Name,Value) returns a vector quantizer encoder System object, vgenc, with each specified property set to the specified value.

### Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

#### CodebookSource — Source of codebook values

Property (default) | Input port

Specify how to determine the codebook values as `Property` or `Input port`.

### Codebook — Matrix of codewords

[1.5 13.3 136.4 6.8; 2.5 14.3 137.4 7.8; 3.5 15.3 138.4 8.8] (default) | matrix

Specify the codebook to which the input column vector or matrix is compared, as a  $k$ -by- $N$  matrix. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The codeword vectors must have the same number of rows as the input. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

**Tunable:** Yes

### Dependencies

This property applies when you set the `CodebookSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### DistortionMeasure — Distortion calculation method

Squared error (default) | Weighted squared error

Specify how to calculate the distortion as `Squared error` or `Weighted squared error`. If you set this property to `Squared error`, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to `Weighted squared error`, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

### WeightsSource — Source of weighting factor

`Property` (default) | `Input port`

Specify how to determine weighting factor as `Property` or `Input port`.

### Dependencies

This property applies when you set the `DistortionMeasure` property to `Weighted squared error`.

### Weights — Weighting factor

[1 1 1] (default) | vector

Specify the weighting factor as a vector of length equal to the number of rows of the input.

**Tunable:** Yes

### Dependencies

This property applies when you set the `DistortionMeasure` property to `Weighted squared error` and `WeightsSource` property is `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**TiebreakerRule — Behavior when input column vector is equidistant from two codewords**

Choose the lower index (default) | Choose the higher index

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to Choose the lower index or Choose the higher index.

**CodewordOutputPort — Enable output of codeword value**

false (default) | true

Set this property to true to output the codeword vectors nearest to the input column vectors.

**QuantizationErrorOutputPort — Enable output of quantization error**

false (default) | true

Set this property to true to output the quantization error value that results when the object represents the input column vector by the nearest codeword.

**OutputIndexDataType — Data type of index output**

int32 (default) | int8 | uint8 | int16 | uint16 | uint32

Specify the data type of the index output as: int8, uint8, int16, uint16, int32, uint32.

**Fixed-Point Properties****RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest or Zero.

**OverflowAction — Overflow action for fixed-point operations**

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

**ProductDataType — Source of product word and fraction lengths**

Same as input (default) | Custom

Specify the product fixed-point data type as Same as input or Custom.

**CustomProductDataType — Product word and fraction lengths**

numericType([], 16, 15) (default) | numericType

Specify the product fixed-point type as a scaled numericType object with a Signedness of Auto.

**Dependencies**

This property applies when you set the ProductDataType property to Custom.

**AccumulatorDataType — Source of accumulator word and fraction lengths**

Same as product (default) | Same as input | Custom

Specify the accumulator fixed-point data type as Same as product, Same as input, or Custom.

**CustomAccumulatorDataType — Accumulator word and fraction lengths**

numericType([], 16, 15) (default) | numericType

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

### Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

## Usage

### Syntax

```
Index = vqenc(Input)
Index = vqenc(Input,Codebook)
Index = vqenc( ____,Weights)
[Index,Codeword] = vqenc( ____)
[Index,Qerr] = vqenc( ____)
```

### Description

`Index = vqenc(Input)` returns `Index`, a scalar or column vector representing the quantization region(s) to which `Input` belongs.

`Index = vqenc(Input,Codebook)` uses the codebook given in input `Codebook`, a  $k$ -by- $N$  matrix with  $N$  codewords each of length  $k$ . This option is available when the `CodebookSource` property is `Input port`.

`Index = vqenc( ____,Weights)` uses the input vector `Weights` to emphasize or de-emphasize certain input values when calculating the distortion measure. `Weights` must be a vector of length equal to the number of rows of `Input`. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[Index,Codeword] = vqenc( ____)` outputs the `Codeword` values that correspond to each index value when the `CodewordOutputPort` property is `true`. This syntax can be used with any of the previous input syntaxes.

`[Index,Qerr] = vqenc( ____)` outputs the quantization error `Qerr` for each input value when the `QuantizationErrorOutputPort` property is `true`.

### Input Arguments

#### Input — Data input

column vector | matrix

Data input, specified as a column vector of size  $k$ -by-1 or a matrix of size  $k$ -by- $M$ , where  $k$  is the length of each codeword in the codebook.

The number of rows in the data input, the length of the `Weights` vector, and the length of the codeword vector must all be the same value. All inputs to the object must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

#### Codebook — Codebook values

column vector | matrix

Codebook values, specified as a column vector of size  $k$ -by-1 or a matrix of size  $k$ -by- $N$ , where  $k$  is the length of each codeword and  $N$  is the number of codewords.

The length of the codeword vector, the number of rows in the data input, and the length of the `Weights` vector must all be the same value. All inputs to the object must have the same data type.

**Dependencies**

This input applies when the `CodebookSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**Weights — Measure of emphasis**

vector

The object uses the `Weights` vector to emphasize or de-emphasize certain input values when calculating the distortion measure.

The length of the `Weights` vector must equal the number of rows in the data input and the length of the codeword. All inputs to the object must have the same data type.

**Dependencies**

This input applies when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**Output Arguments****Index — Indices of nearest codeword vectors**

scalar | row vector

Indices of the nearest codeword vectors, returned as a scalar or a row vector. The object compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The object finds the codeword vector nearest to the input column vector and returns its zero-based index. When the input is a matrix, the indices of the nearest codeword vectors are horizontally concatenated.

The object finds the nearest codeword by calculating the distortion using the method specified in `DistortionMeasure` property.

Data Types: `int32`

**Codeword — Codeword**

column vector | matrix

Codeword values that correspond to each index value, returned as a column vector or a matrix. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

**Dependencies**

This output is enabled when the `CodewordOutputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

**Qerr — Quantization error**

scalar | row vector

Quantization error, returned as a scalar or a row vector. The quantization error results when the object represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

### Dependencies

This output is enabled when the `QuantizationErrorOutputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Find Indices of Nearest Codewords

Find the indices of nearest codewords based on Euclidean distances.

```
vqenc = dsp.VectorQuantizerEncoder(...
    'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
    'CodewordOutputPort', true, ...
    'QuantizationErrorOutputPort', true, ...
    'OutputIndexDataType', 'uint8');
```

Generate an input signal with some additive noise

```
x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = vqenc(x);
plot(cw(1,:), cw(2,:), 'r0', x(1,:), x(2,:), 'g.');
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Encoder block reference page. The object properties correspond to the block parameters.

## Version History

**Introduced in R2012a**

**R2021b: `dsp.VectorQuantizerEncoder` System object will be removed**

*Warns starting in R2021b*

`dsp.VectorQuantizerEncoder` System object will be removed in a future release.

**R2023a: `dsp.VectorQuantizerEncoder` System object has been removed**

*Errors starting in R2023a*

The `dsp.VectorQuantizerEncoder` System object has been removed.

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

# dsp.Window

**Package:** dsp

(Removed) Apply window to input signal

---

**Note** dsp.Window has been removed. Use the window function instead. For more information, see “Compatibility Considerations”.

---

## Description

The Window object applies a window to an input signal.

To apply a window to an input signal:

- 1 Create the dsp.Window object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
win = dsp.Window
win = dsp.Window(WINDOW)
win = dsp.Window(WINDOW,Name,Value)
```

### Description

`win = dsp.Window` returns a window object, `win`, that applies a Hamming window with symmetric sampling.

`win = dsp.Window(WINDOW)` returns a window object with the `WindowFunction` property set to `WINDOW`.

`win = dsp.Window(WINDOW,Name,Value)` returns a window object with the `WindowFunction` property set to `WINDOW` and with other specified properties set to the specified values.

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

**WindowFunction — Type of window**

'Hamming' (default) | 'Bartlett' | 'Blackman' | 'Boxcar' | 'Chebyshev' | 'Hann' | 'Hanning' | 'Kaiser' | 'Taylor' | 'Triang'

Specify the type of window to apply. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object and run the generated code, this property is not tunable.

**Tunable:** Yes

**WeightsOutputPort — Enable output of window weights**

false (default) | true

Set this property to `true` to output the window weights. The weights are an  $M$ -by-1 vector with  $M$  equal to the first dimension of the input.

**StopbandAttenuation — Level of stopband attenuation in decibels**

50 (default) | nonnegative scalar

Specify the level of stopband attenuation in decibels, specified as a nonnegative scalar.

**Tunable:** Yes

**Dependencies**

This property only applies when the `WindowFunction` property is 'Chebyshev'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Beta — Kaiser window parameter**

10 (default) | scalar

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response.

**Tunable:** Yes

**Dependencies**

This property only applies when `WindowFunction` property is 'Kaiser'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**NumConstantSidelobes — Number of constant sidelobes**

4 (default) | positive integer

Specify the number of constant sidelobes as an integer greater than zero.

**Tunable:** Yes

**Dependencies**

This property only applies when `WindowFunction` property is 'Taylor'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**MaximumSidelobeLevel — Maximum sidelobe level relative to mainlobe**

-30 (default) | nonpositive scalar

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is -30, which produces sidelobes with peaks 30 dB down from the mainlobe peak.

**Tunable:** Yes

**Dependencies**

This property only applies when WindowFunction property is 'Taylor'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Sampling — Window sampling for generalized-cosine windows**

'Symmetric' (default) | 'Periodic'

Specify the window sampling for generalized-cosine windows as 'Symmetric' or 'Periodic'. If you run this object in simulation, this property is tunable. When you generate code from a function or script that contains this object, and run the generated code, this property is not tunable.

**Tunable:** Yes

**Dependencies**

This property only applies when WindowFunction property is 'Blackman', 'Hamming', 'Hann', or 'Hanning'.

**Fixed-Point Properties**

**FullPrecisionOverride — Full precision override for fixed-point arithmetic**

true (default) | false

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set FullPrecisionOverride to false, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

**RoundingMethod — Rounding method for fixed-point operations**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding method.

**Dependencies**

This property applies only if the object is not in full precision mode.

**OverflowAction — Overflow action for fixed-point operations**

'Wrap' (default) | 'Saturate'

Specify the overflow action.

**Dependencies**

This property applies only if the object is not in full precision mode.

**WindowDataType — Window word and fraction lengths**

'Same word length as input' (default) | 'Custom'

Specify the window fixed-point data type.

**CustomWindowDataType — Window word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the window fixed-point type as a numerictype object with a Signedness of Auto.

**Dependencies**

This property applies when you set the WindowDataType property to 'Custom'.

**ProductDataType — Product word and fraction lengths**

'Full precision' (default) | 'Same as input' | 'Custom'

Specify the product fixed-point data type as one of 'Full precision', 'Same as input', or 'Custom'.

**CustomProductDataType — Product word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

**Dependencies**

This property applies when you set the ProductDataType property to 'Custom'.

**OutputDataType — Output data type**

'Same as product' (default) | 'Same as input' | 'Custom'

Specify the output fixed-point data type as one of 'Same as product', 'Same as input', 'Custom'.

**CustomOutputDataType — Output word and fraction lengths**

numerictype([],16,15) (default) | numerictype

Specify the output fixed-point type as a numerictype object with a Signedness of Auto.

**Dependencies**

This property applies when you set the OutputDataType property to Custom.

**Usage****Syntax**

```
Y = win(X)
[Y,W] = win(X)
```

**Description**

Y = win(X) generates the windowed output, Y, of the input, X, using the specified window.

[Y,W] = win(X) returns the window values W when the WeightsOutputPort property is true.

## Input Arguments

### X — Data input

vector | matrix

Data input, specified as a vector or a matrix.

This object supports only frame-based processing. To see the effect of the window, the data must have a frame size of at least 2 in each channel.

When the input is fixed-point, it must be signed fixed point with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Output Arguments

### Y — Windowed output

vector | matrix

Windowed output, returned as vector or a matrix.

When the input is an integer, the word length and fraction length of the output, Y is calculated using the following:

$$Y_{WL} = 2X_{WL}$$

$$Y_{FL} = X_{WL} + X_{FL} - 1$$

where,

- $Y_{WL}$  -- Output word length.
- $Y_{FL}$  -- Output fraction length.
- $X_{WL}$  -- Input word length.
- $X_{FL}$  -- Input fraction length. In case of signed integers, this value is 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

### W — Window values

column vector

Window values, returned as a column vector. The number of elements in the column vector is equal to the frame size (number of rows) of the input signal.

When the input is an integer, the word length and fraction length of the output, W is calculated using the following:

$$W_{WL} = X_{WL}$$

$$W_{FL} = Y_{FL} - X_{FL}$$

where,

- $W_{WL}$  -- Window word length.
- $W_{FL}$  -- Window fraction length.
- $Y_{FL}$  -- Output fraction length.

- $X_{FL}$  -- Input fraction length. In case of signed integers, this value is 0.

### Dependencies

This output appears only when the `WeightsOutputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Apply Hamming Window

```
win = dsp.Window( ...  
    'WindowFunction','Hamming', ...  
    'WeightsOutputPort',true);  
x = rand(64,1);  
[y,w] = win(x);
```

View the window's time and frequency domain responses.

```
wvtool(w)
```

## Algorithms

This object implements the algorithm, inputs, and outputs described on the Window Function block reference page. The object properties correspond to the block parameters, except:

- **Operation** — The `dsp.Window` object does not support the `Generate window` option.
- **Operation** — The `Generate and apply window` option on the block corresponds to the `WeightsOutputPort` property set to `true` on the `dsp.Window` object.
- The `dsp.Window` object only supports frame-based processing.

## Version History

**Introduced in R2012a**

**R2021b: `dsp.Window` System object will be removed**

*Warns starting in R2021b*

`dsp.Window` System object will be removed in a future release. Use the `window` function instead.

### R2023a: `dsp.Window` System object has been removed

*Errors starting in R2023a*

The `dsp.Window` System object has been removed. Use the `window` function instead.

### Update Code

This table shows how to update existing code to use the `window` function.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| <p><b>Hamming window</b></p> <pre>N = 64; win = dsp.Window( ...     WindowFunction='Hamming', ...     WeightsOutputPort=true); x = rand(N,1); [y,w] = win(x);</pre> <p>The object designs the window and applies it to the input data. <code>y</code> stores the windowed data.</p> <p>Visualize the window using <b>WVTool</b>.</p> <pre>wvtool(w)</pre> | <p><b>Hamming window</b></p> <pre>wfn = window(@hamming,N); isequal(w,wfn)</pre> <pre>ans = 1x1     1</pre> <p><code>wvtool(wfn)</code></p> <p>Apply the window to the data.</p> <pre>yfn = wfn.*x; isequal(y,yfn)</pre> <pre>ans = 1x1     1</pre> |

## Extended Capabilities

# dsp.ZeroCrossingDetector

**Package:** dsp

Detect zero crossings

## Description

The `dsp.ZeroCrossingDetector` System object counts the number of times the signal crosses zero, or changes sign. To detect if a signal in a given channel crosses zero, the object looks for the following conditions, where,  $x_{i-l}$  is the current signal value and  $x_{i-1}$  is the previous signal value:

- $x_i < 0$  and  $x_{i-1} > 0$
- $x_i > 0$  and  $x_{i-1} < 0$
- For some positive integer  $L$ ,  $x_i < 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} > 0$ , where  $0 \leq l \leq L$ .
- For some positive integer  $L$ ,  $x_i > 0$ ,  $x_{i-l} = 0$ , and  $x_{i-L-1} < 0$ , where  $0 \leq l \leq L$ .

For the first input value,  $x_{i-1}$  and  $x_{i-2}$  are zero.

To count the number of times a signal crosses zero or changes sign:

- 1 Create the `dsp.ZeroCrossingDetector` object.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
zcd = dsp.ZeroCrossingDetector
```

### Description

`zcd = dsp.ZeroCrossingDetector` returns a zero crossing detection object that calculates the number of times the signal crosses zero.

### Usage

### Syntax

```
zcdOut = zcd(input)
```

### Description

`zcdOut = zcd(input)` calculates the number of zero crossings of the input. Each column of the input is treated as an independent channel.

## Input Arguments

### input — Data input

vector | matrix

Data input whose zero crossings are counted by the object, specified as a vector or a matrix.

Example: `rand(20,1) - 0.3`

Example: `rand(20,2) - 0.3`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

## Output Arguments

### zcdOut — Number of zero crossings

scalar | row vector

Number of zero crossings in the data input, returned as one of the following:

- scalar -- When the data input is a column vector, the scalar output is the number of zero crossings in the data input..
- row vector -- When the data input is a matrix, each element in the row vector output is the number of zero crossings in the corresponding column of the data input.

Example: 10

Example: [9,6]

Data Types: `uint32`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Determine Number of Zero Crossings

Find the number of zero crossings in electrocardiogram data.

```
EcgData = ecg(500)';
zcd = dsp.ZeroCrossingDetector;
numZeroCross = zcd(EcgData)
```

```
numZeroCross = uint32  
4
```

```
plot(1:500,EcgData,'b',[0 500],[0 0],'r','linewidth',2)
```

## Version History

`dsp.PhaseExtractor`

# dsp.ZoomFFT

**Package:** dsp

High-resolution FFT of a portion of a spectrum

## Description

The `dsp.ZoomFFT` System object computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor  $D$ , and sampling rate  $F_s$ , you can choose the bandwidth of frequencies to analyze  $BW$ , where  $BW = F_s/D$ . You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of  $F_s$  and the FFT length ( $L$ ). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of  $D$ , the new sampling rate,  $F_{sd}$ , is  $F_s/D$ , and the new frame size (and FFT length) is  $L_d = L/D$ . The resolution of the decimated signal is  $F_{sd}/L_d = F_s/L$ . To achieve a higher resolution of the shorter band, use the original FFT length,  $L$ , instead of the decimated FFT length,  $L_d$ .

To compute the FFT of a portion of the spectrum:

- 1 Create the `dsp.ZoomFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

## Creation

### Syntax

```
zfft = dsp.ZoomFFT
zfft = dsp.ZoomFFT(d)
zfft = dsp.ZoomFFT(d, Fc)
zfft = dsp.ZoomFFT(d, Fc, Fs)
zfft = dsp.ZoomFFT(Name, Value)
```

### Description

`zfft = dsp.ZoomFFT` creates a zoom FFT System object, `zfft`, that performs an FFT on a portion of the input signal's frequency range. The object determines the frequency range over which to perform the FFT using the specified center frequency and decimation factor values.

`zfft = dsp.ZoomFFT(d)` creates a zoom FFT object with the "DecimationFactor" on page 4-0 property set to `d`.

`zfft = dsp.ZoomFFT(d, Fc)` creates a zoom FFT object with the “DecimationFactor” on page 4-0 property set to `d`, and the “CenterFrequency” on page 4-0 property set to `Fc`.

`zfft = dsp.ZoomFFT(d, Fc, Fs)` creates a zoom FFT object with the “DecimationFactor” on page 4-0 property set to `d`, the “CenterFrequency” on page 4-0 property set to `Fc`, and the “SampleRate” on page 4-0 property set to `Fs`.

`zfft = dsp.ZoomFFT(Name, Value)` creates a zoom FFT object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `zfft = dsp.ZoomFFT(2, 2e3, 48e3, 'FFTLength', 64);`

## Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

### **DecimationFactor — Decimation factor**

2 (default) | positive integer

Decimation factor  $D$ , specified as a positive integer. This value specifies the factor by which the object reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **CenterFrequency — Center frequency**

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range  $(-\text{SampleRate}/2, \text{SampleRate}/2)$ .

Example: 0.5

Example: 10

**Tunable:** Yes

Data Types: `single` | `double`

### **FFTLength — FFT length**

[] (default) | positive integer

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the decimation factor,  $L/D$ . The default, [], specifies an FFT length that equals the ratio,  $L/D$ .

Example: 24

Example: 52

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

Data Types: `single` | `double`

## Usage

### Syntax

```
zfftOut = zfft(input)
```

### Description

`zfftOut = zfft(input)` computes the zoom FFT of the input. Each column of the input is treated as an independent channel. The object computes the FFT of each channel of the input signal independently over time.

### Input Arguments

#### input — Data input

vector | matrix

Data input for which the object computes the zoom FFT, specified as a vector or a matrix of size  $P$ -by- $Q$ . The number of input rows  $P$  can be arbitrary and does not have to be a multiple of the decimation factor  $D$ .

This object supports variable-size input signals, that is, the frame length (number of rows) of the signal can change even when the object is locked. However, the number of channels (columns) must remain constant.

Data Types: `single` | `double`

### Output Arguments

#### zfftOut — Zoom FFT output

vector | matrix

Zoom FFT output, returned as a vector or matrix.

If the FFT length is set to auto, for an input matrix of size  $P$ -by- $Q$ :

- If  $P$  is not a multiple of the decimation factor  $D$ , the output signal has an upper bound size of  $\text{ceil}(P/D)$ -by- $Q$ .
- If  $P$  is a multiple of the decimation factor, then the output is of size  $(P/D)$ -by- $Q$ .

The number of channels (columns) does not change.

If you specify a numeric value in the `FFTLength` property, the output frame size equals the specified FFT length. The output data type matches the input data type.

Data Types: `single` | `double`

## Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

## Common to All System Objects

|                      |  |
|----------------------|--|
| <code>step</code>    | Run System object algorithm  |
| <code>release</code> | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>   | Reset internal states of System object   |

## Examples

### Compute FFT of a Subband Using Zoom FFT

Compute FFT of the [1500 Hz 2500 Hz] subband using zoom FFT for a signal sampled at 48 kHz.

#### Initialization

Set the center frequency to 2 kHz and the bandwidth of interest to 1 kHz. The bandwidth is centered at the center frequency. The decimation factor is the ratio of the input sample rate, 48 kHz, and the bandwidth of interest, 1 kHz. Choose an FFT length of 64. Set the input frame size to be the decimation factor times the FFT length. Create a `dsp.ZoomFFT` object with the specified decimation factor, center frequency, sample rate, and FFT length.

```
Fs = 48e3;  
CF = 2e3;  
BW = 1e3;  
D = Fs/BW;  
fftlen = 64;  
L = D * fftlen;  
zfft = dsp.ZoomFFT(D,CF,Fs,'FFTLength',fftlen);
```

#### Frequencies

The FFT is computed over frequencies starting at 1500 Hz and spaced by  $Fs/(D * fftLen)$  Hz apart, which is the resolution or the minimum frequency that can be discriminated. The number of frequencies at which the zoom FFT is computed equals the FFT length.

```
Fsd = Fs/D;  
F = CF + (Fsd/fftlen)*(0:fftlen-1)-Fsd/2;
```

#### Initialize the Scope

Create an array plot to show the frequencies in `F`.

```

ap = dsp.ArrayPlot('XDataMode','Custom','CustomXData',F,...
    'YLabel','z .* conj(z)','XLabel','Frequency (Hz)','YLimits',[0 1.1e3],...
    'Title',sprintf('Decimation Factor = %d. Center Frequency = %d Hz. Resolution = %f Hz',D, CF

```

### Sine Wave Generator

Create a sine wave with frequencies at 1625 Hz, 2000 Hz, and 2125 Hz.

```

tones = [1625 2000 2125];
sine = dsp.SineWave('SampleRate',Fs,'Frequency',tones,'SamplesPerFrame',L);

```

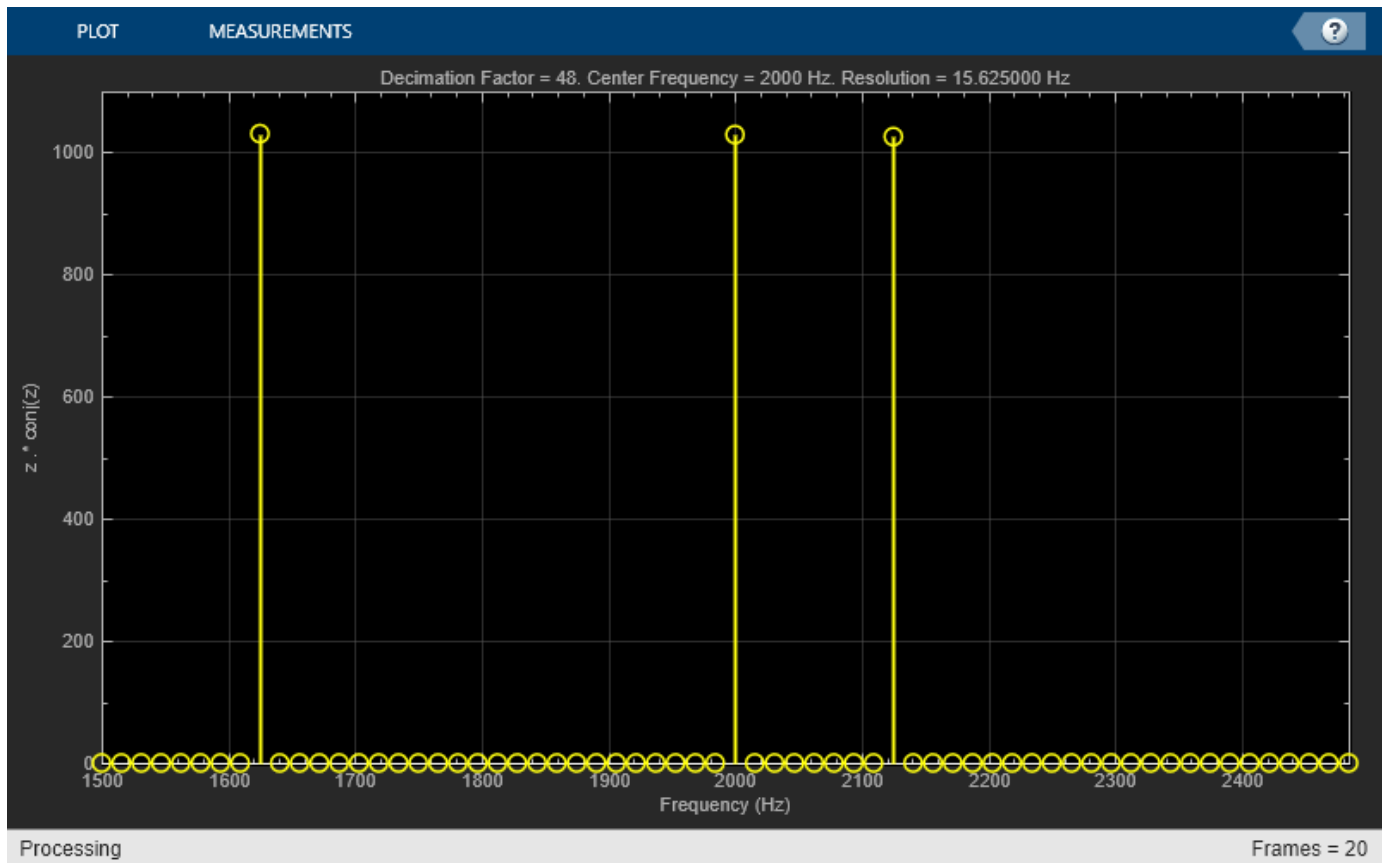

### Streaming

Pass a noisy sine wave with a sample rate of 48 kHz. Compute the zoom FFT of this sine wave in the subband [1500 Hz 2500 Hz]. Rearrange the Fourier transform by shifting the zero-frequency component to the center of the array. View the tones at 1625 Hz, 2000 Hz, and 2125 Hz in the array plot.

```

for i = 1:1000
    x = sum(sine(),2)+1e-1*randn(L,1);
    z = zfft(x);
    z = fftshift(z);
    ap(z.*conj(z));
end

```

### Compute Zoom FFT of Variable-Size Inputs

The `dsp.ZoomFFT` object accepts variable-size inputs as long as the input is a multiple of the decimation factor. The number of input channels cannot change.

Create a `dsp.ZoomFFT` object with a decimation factor of 4, center frequency of 2 kHz, and an input sample rate of 48 kHz. Pass a random input with  $4 \times 64$  rows and 2 columns. Vary the number of rows to  $4 \times 128$  and  $4 \times 32$ . The resulting FFT lengths are 64, 128, and 32, respectively. The size of the outputs is  $[64 \ 2]$ ,  $[128 \ 2]$ , and  $[32 \ 2]$ , respectively.

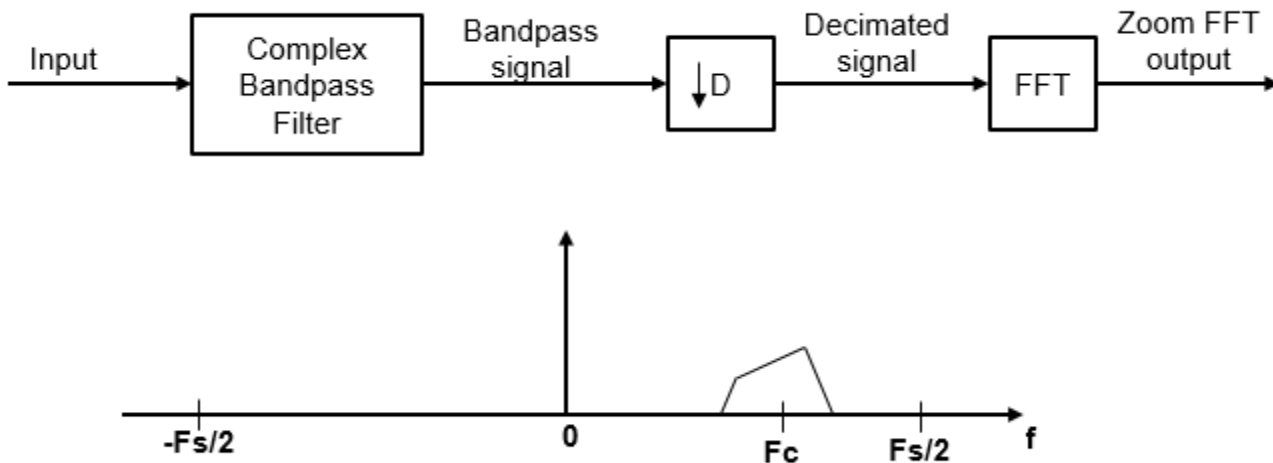

```
zfft = dsp.ZoomFFT(4,2e3,48e3);
y1 = zfft(randn(4*64,2));
y2 = zfft(randn(4*128,2));
y3 = zfft(randn(4*32,2));
```

Set the FFT length as 256 and pass variable-size inputs. The size of all the outputs is  $[256 \ 2]$ .

```
release(zfft);
zfft.FFTLength = 256;
y4 = zfft(randn(4*64,2));
y5 = zfft(randn(4*128,2));
y6 = zfft(randn(4*32,2));
```

### Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band  $[F1, F2]$  of the original input signal, sampled at the rate  $F_s$  Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at  $F_c = (F1 + F2)/2$ , with the bandwidth  $BW = F2 - F1$ , and then downsample the signal by a factor of  $D = \text{floor}(F_s/BW)$ , the desired band comes down to the baseband.

If  $F_c$  cannot be expressed in the form of  $k \times F_s/D$ , where  $k$  is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to  $F_d$ .

$$F_d = F_c - (F_s/D) \times \text{floor}((D \times F_c + F_s/2)/F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate, multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

## Version History

Introduced in R2017b

### R2023a: Support for arbitrary input frame length

This object supports an input signal with an arbitrary frame length, so the input frame length does not have to be a multiple of the decimation factor.

## References

- [1] Harris, F.J. *Multirate Signal Processing for Communication Systems*. Prentice Hall, 2004, pp. 208–209.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

In the code you generate from this object, the zoom FFT output is a fixed-size signal if the input signal is fixed size and is a multiple of the decimation factor. If the input is not a multiple of the decimation factor or if the input is a variable-size signal, then the zoom FFT output is of variable-size.

# SpectrumAnalyzerConfiguration

Configure Spectrum Analyzer block

## Description

The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.

## Creation

`MyScopeConfiguration = get_param(gcbh, 'ScopeConfiguration')` constructs a new spectrum analyzer configuration object. You must first select the block in the model or provide the full path to the block.

## Properties

### Frequently Used

#### NumInputPorts — Number of input ports

"1" (default) | character vector | string scalar

Number of input ports on a scope block, specified as a character vector or string scalar. The maximum number of input ports that you can specify is 96.

#### Scope Window Use

This parameter is available only from the **Property Inspector**. To launch the **Property Inspector**, click the **Modeling** tab of the Simulink model window that contains the Spectrum Analyzer block. In the **Design** section, click the drop-down arrow and select **Property Inspector**. The **Property Inspector** window opens on the right. If you select the Spectrum Analyzer block, the **Property Inspector** window shows the corresponding parameters. In the parameters that show up, specify the **Number of input ports** parameter.

Data Types: char | string

#### InputDomain — Domain of input signal

"Time" (default) | "Frequency"

The domain of the input signal you want to visualize, specified as "Time" or "Frequency". If you visualize time-domain signals, the Spectrum Analyzer transforms the signal to the frequency spectrum based on the algorithm specified in the `Method` property.

#### Scope Window Use

In the **Estimation** tab on the Spectrum Analyzer toolstrip, set **Input Domain** to Time or Frequency.

Data Types: char | string

**SpectrumType — Spectrum type**

"Power" (default) | "Power density" | "RMS"

Spectrum type, specified as one of these:

"Power" — Power spectrum

"Power density" — Power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 Hz.

"RMS" — Root mean square. The root mean square shows the square root of the mean square. Use this option to view the frequency of voltage or current signals.

**Tunable:** Yes

**Dependency**

To enable this property, set `InputDomain` to "Time".

**Scope Window Use**

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, select **Spectrum**. Click **Spectrum** to select Power, Power Density, or RMS.

To enable these options, set the **Input Domain** on the **Estimation** tab to Time.

Data Types: char | string

**ViewType — Viewer type**

"Spectrum" (default) | "Spectrogram" | "Spectrum and spectrogram"

Viewer type, specified as one of these values:

- "Spectrum" — Show the power spectrum.
- "Spectrogram" — Show frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.
- "Spectrum and Spectrogram" — Show spectrum and spectrogram.

To learn more about how the Spectrum Analyzer computes the spectrum and spectrogram, see the "Algorithms" on page 2-1335 section in the Spectrum Analyzer block reference page.

**Tunable:** Yes

**Scope Window Use**

In the **Analyzer** tab on the Spectrum Analyzer toolstrip, select **Spectrum**, **Spectrogram**, or both.

Data Types: char | string

**SampleRateSource — Source of input sample rate**

"Inherited" (default) | "Property"

Source of the input sample rate, specified as one of these:

- "Inherited" — Spectrum Analyzer inherits the input sample rate from the model.

- "Property" — Specify the sample rate input directly using the `SampleRate` property.

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **Sample Rate (Hz)** to `Inherited` or specify a finite scalar.

Data Types: `char` | `string`

#### SampleRate — Sample rate of input

`"10e3"` (default) | character vector of a positive scalar | string scalar of a positive scalar

Sample rate of the input signal in Hz, specified as a character vector or a string scalar of a positive scalar.

#### Dependency

To enable this property, set `SampleRateSource` to `"Property"`.

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, specify **Sample Rate (Hz)** to a finite scalar.

Data Types: `char` | `string`

#### Method — Spectrum estimation method

`"Filter Bank"` (default) | `"Welch"`

Spectrum estimation method, specified as one of the following:

- `"Filter bank"` -- Use an analysis filter bank to estimate the power spectrum. Compared to Welch's method, this method has a lower noise floor, better frequency resolution, lower spectral leakage, and requires fewer samples per update.
- `"Welch"` -- Use Welch's method of averaged modified periodograms.

For more information on these methods, see "Algorithms" on page 2-1335.

**Tunable:** Yes

#### Dependency

To enable this property, set `InputDomain` to `"Time"`.

#### Scope Window Use

In the **Estimation** tab of the Spectrum Analyzer toolstrip, set **Method** to `Filter bank` or `Welch`.

To enable this parameter, set **Input Domain** to `Time` in the **Estimation** tab.

Data Types: `char` | `string`

#### PlotAsTwoSidedSpectrum — Option to plot a two-sided spectrum

`true` (default) | `false`

Option to plot a two-sided spectrum, specified as one of the following:

- `true` — Compute and plot two-sided spectral estimates. When the input signal is complex valued, you must set this property to `true`.

- `false` — Compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued.

When you set this property to `false`, the Spectrum Analyzer uses power-folding. The y-axis values are twice the amplitude that they would be if you were to set this property to `true`, except at 0 and the Nyquist frequency. A one-sided power spectral density (PSD) contains the total power of the signal in the frequency interval from DC to half the Nyquist rate. For more information, see `pwelch`.

**Tunable:** Yes

### Scope Window Use

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) of the Spectrum Analyzer toolstrip. In the **Trace Options** section, select **Two-Sided Spectrum** to compute and plot two-sided spectral estimates.

Data Types: `logical`

### FrequencyScale — Scale to display frequency

"Linear" (default) | "Log"

Scale to display frequency, specified as one of the following:

- "Linear" — Use a linear scale to display frequencies on the x-axis. To use the "Linear" option, you must also set the `PlotAsTwoSidedSpectrum` property to `true`.
- "Log" — Use a logarithmic scale to display frequencies on the x-axis. To use the "Log" option, you must also set the `PlotAsTwoSidedSpectrum` property to `false`.

**Tunable:** Yes

### Scope Window Use

Click the **Spectrum** tab or the **Spectrogram** tab (if enabled) on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Frequency Scale** to Linear or Log.

To set the **Frequency Scale** to Log, clear the **Two-Sided Spectrum** check box in the **Trace Options** section in the **Spectrum** or the **Spectrogram** tab (if enabled). If you select the **Two-Sided Spectrum** check box, then you must set the **Frequency Scale** to Linear.

Data Types: `char` | `string`

### PlotType — Plot type to display normal traces

"Line" (default) | "Stem"

Plot type to display normal traces, specified as "Line" or "Stem". Normal traces are traces that display free-running spectral estimates.

**Tunable:** Yes

### Dependencies

To enable this property, set:

- `ViewType` to "Spectrum" or "Spectrum and spectrogram".
- `PlotNormalTrace` to `true`.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip, navigate to the **Configuration** section and click **Settings**. In the Spectrum Analyzer Settings window, under **Display and Labels**, set **Plot Type** to Line or Stem.

To enable the **Plot Type**, you must:

- Select **Spectrum** in the **Views** section of the **Analyzer** tab.
- Enable the **Normal Trace** check box in the **Trace Options** section of the **Spectrum** tab.

Data Types: char | string

**AxesScaling — Axes scaling mode**

"Auto" (default) | "Manual" | "OnceAtStop" | "Updates"

Axes scaling mode, specified as one of these:

- "Auto" — The scope scales the axes to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes after a specific number of visual updates. It determines the number of updates using the `AxesScalingNumUpdates` property.

**Tunable:** Yes

Data Types: char | string

**AxesScalingNumUpdates — Number of updates before scaling**

"100" (default) | character vector of a positive integer | string scalar of a positive integer

Number of updates before scaling, specified as a character vector or a string scalar of a positive integer.

**Tunable:** Yes

**Dependency**

To enable this property, set `AxesScaling` to "Updates".

Data Types: char | string

**Advanced****RBWSource — Source of resolution bandwidth value**

"Auto" (default) | "Property" | "InputPort"

Source of the resolution bandwidth (RBW) value, specified as one of these:

- "Auto" — The Spectrum Analyzer adjusts the spectral estimation resolution to ensure that there are 1024 RBW intervals over the defined frequency span.
- "Property" — Specify the resolution bandwidth directly using the RBW property.
- "InputPort" — An input port appears on the Spectrum Analyzer block through which you specify the RBW. You can use this option only for frequency inputs.

**Tunable:** Yes

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **RBW (Hz)** to Auto, Input port or to a positive scalar.

Data Types: char | string

**RBW — Resolution bandwidth**

"9.76" (default) | character vector of a positive scalar | string scalar of a positive scalar

Resolution bandwidth (RBW) in Hz, specified as a character vector or a string scalar of a positive scalar. Specify the value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW satisfies this condition:

$$\frac{span}{RBW} > 2$$

You can specify the overall span in different ways based on how you set the FrequencySpan property.

RBW controls the spectral resolution of the displayed signal. The RBW value determines the spacing between frequencies that can be resolved. A smaller value gives a higher spectral resolution and lowers the noise floor, that is, the Spectrum Analyzer can resolve frequencies that are closer to each other. However, this comes at the cost of a longer sweep time.

**Tunable:** Yes

**Dependency**

To enable this property, set RBWSource to "Property".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **RBW (Hz)** to a positive scalar.

Data Types: char | string

**FilterSharpness — Sharpness of lowpass filter**

"0.3" (default) | character vector of a nonnegative scalar in the range [0,1] | string scalar of a nonnegative scalar in the range [0,1]

Sharpness of the prototype lowpass filter, specified as a character vector or a string scalar of a real nonnegative scalar in the range [0,1].

Increasing the filter sharpness decreases the spectral leakage and gives a more accurate power reading.

**Tunable:** Yes

**Dependencies**

To enable this property, set:

- InputDomain to "Time".

- Method to "Filter Bank".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Resolution** section, move the **Sharpness** slider.

To enable this parameter, set **Input Domain** to Time and **Method** to Filter bank in the **Estimation** tab.

Data Types: char | string

#### FrequencySpan — Frequency span mode

"Full" (default) | "Span and center frequency" | "Start and stop frequencies"

Frequency span mode, specified as one of the following:

- "Full" -- The Spectrum Analyzer computes and plots the spectrum over the entire "Nyquist Frequency Interval" on page 2-1340.
- "Span and center frequency" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- "Start and stop frequencies" -- The Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

**Tunable:** Yes

#### Dependency

To enable this property, set InputDomain to "Time".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Full, Span and Center Frequency, or Start and Stop Frequencies.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

#### Span — Frequency span to compute spectrum

"10e3" (default) | character vector of a real positive scalar | string scalar of a real positive scalar

Frequency span over which the Spectrum Analyzer computes and plots the spectrum, specified as a character vector or a string scalar of a real positive scalar in Hz. The overall span, defined by this property and the CenterFrequency property, must fall within the "Nyquist Frequency Interval" on page 2-1340.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- InputDomain to "Time".
- FrequencySpan to "Span and center frequency".

Data Types: char | string

### CenterFrequency — Center of frequency span

"0" (default) | character vector of a real scalar | string scalar of a real scalar

Center of the frequency span over which the Spectrum Analyzer computes and plots the spectrum, specified as a character vector or a string scalar of a real scalar in Hz. The overall frequency span, defined by Span and this property, must fall within the “Nyquist Frequency Interval” on page 2-1340.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- InputDomain to "Time".
- FrequencySpan to "Span and center frequency".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Span and Center Frequency and **Center Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

### StartFrequency — Start frequency to compute spectrum

"-5e3" (default) | character vector of a real scalar | string scalar of a real scalar

Starting frequency value in the frequency interval over which the Spectrum Analyzer computes and plots the spectrum, specified as a character vector or a string scalar of a real scalar in Hz. The overall span, which is defined by this property and StopFrequency, must fall within the “Nyquist Frequency Interval” on page 2-1340.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- InputDomain to "Time".
- FrequencySpan to "Start and stop frequencies".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Start Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

### StopFrequency — Stop frequency to compute spectrum

"5e3" (default) | character vector of a real scalar | string scalar of a real scalar

Ending frequency value in the frequency interval over which the Spectrum Analyzer computes and plots the spectrum, specified as a character vector or a string scalar of a real scalar in Hz. The overall

span, which is defined by this property and the `StartFrequency` property, must fall within the "Nyquist Frequency Interval" on page 2-1340.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- `InputDomain` to "Time".
- `FrequencySpan` to "Start and stop frequencies".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Stop Frequency (Hz)** to a real scalar.

To enable the **Frequency Span**, set **Input Domain** to Time.

Data Types: char | string

#### OverlapPercent — Overlap percentage

"0" (default) | character vector of a real scalar in the range [0 100] | string scalar of a real scalar in the range [0 100)

Overlap percentage between the previous and current buffered data segments, specified as a character vector or string scalar of a real scalar in the range [0 100). The overlap creates a window segment that the Spectrum Analyzer uses to compute a spectral estimate.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- `InputDomain` to "Time".
- `Method` to "Welch"

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Overlap (%)**.

To enable the **Overlap (%)**, set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: char | string

#### Window — Window function

"Hann" (default) | "Rectangular" | "Chebyshev" | "Flat Top" | "Hamming" | "Kaiser" | "Blackman-Harris" | "Custom"

Specify a window function for the spectral estimator. You can select one of the window options in the following table or specify a custom window. For more information on the window functions, click the link to the function reference page in the Signal Processing Toolbox documentation.

| Window Option     | Corresponding Signal Processing Toolbox Function |
|-------------------|--|
| "Rectangular"     | rectwin  |
| "Chebyshev"       | chebwin  |
| "Flat Top"        | flattopwin                                       |
| "Hamming"         | hamming  |
| "Hann"            | hann   |
| "Kaiser"          | kaiser   |
| "Blackman-Harris" | blackmanharris                                   |

To set your own spectral estimation window, set this property to "Custom" and specify a custom window function in the CustomWindow property.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- InputDomain to "Time".
- Method to "Welch"

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Window**.

To enable the **Window**, set **Input Domain** to Time and **Method** to Welch in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: char | string

#### CustomWindow — Name of custom window function

"hann" (default) | character vector | string scalar

Name of the custom window function, specified as a character vector or string scalar. The name of the custom window function must be on the MATLAB path. Use this property if you want to customize the window using additional properties available with the Signal Processing Toolbox version of the window function.

**Tunable:** Yes

#### Example

Define and use a custom window function.

```
function w = my_hann(L)
    w = hann(L, 'periodic')
end

scope.Window = 'Custom';
scope.CustomWindow = 'my_hann'
```

**Dependency**

To use this property, set Window to "Custom".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, for the **Window**, enter the name of the custom window function.

Data Types: char | string

**SidelobeAttenuation — Sidelobe attenuation of window**

"60" (default) | character vector of real positive scalar | string scalar of real positive scalar

Sidelobe attenuation of the window in decibels (dB), specified as a character vector or a string scalar of a positive scalar greater than or equal to 45.

**Tunable:** Yes

**Dependency**

To enable this property, set Window to "Chebyshev" or "Kaiser".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Window Options** section, set the **Attenuation (dB)**.

To enable the **Attenuation (dB)**, set:

- **Input Domain** to Time
- **Method** to Welch
- **Window** to either Chebyshev or Kaiser in the **Estimation** tab on the Spectrum Analyzer toolstrip.

Data Types: char | string

**AveragingMethod — Smoothing method**

"VBW" (default) | "Exponential"

Averaging method, specified as one of the following:

- "VBW" — Video bandwidth method. The object uses a lowpass filter to smooth the trace and decrease noise. Use the VBWSource and VBW properties to specify the VBW value.
- "Exponential" — Weighted average of samples. The object computes the average over samples weighted by an exponentially decaying forgetting factor. Use the ForgettingFactor property to specify the weighted forgetting factor.

For more information, see "Averaging Method" on page 2-1343.

**Tunable:** Yes

**Dependency**

To enable this property, set InputDomain to "Time".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **Averaging Method** to VBW or Exponential.

To enable the **Averaging Method**, set **Input Domain** to Time.

Data Types: char | string

**VBWSource — Source of video bandwidth**

"Auto" (default) | "Input port" | "Property"

Source of the video bandwidth (VBW), specified as one of these options:

- "Auto" — The Spectrum Analyzer adjusts the VBW such that the equivalent forgetting factor is 0.9.
- "Input port" -- An input port appears on the scope and you can specify the VBW value through this port.
- "Property" — The Spectrum Analyzer adjusts the VBW using the value specified in the VBW property.

For more details on the video bandwidth method, see "Averaging Method" on page 2-1343.

**Tunable:** Yes

**Dependency**

To enable this property, set InputDomain to "Time" and AveragingMethod to "VBW".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **VBW (Hz)** to either Auto or a positive real scalar less than or equal to **Sample Rate (Hz)/2**.

To enable the **VBW (Hz)**, set **Input Domain** to Time and **Averaging Method** to VBW.

Data Types: char | string

**VBW — Video bandwidth**

"9.76" (default) | character vector of a positive scalar | string scalar of a positive scalar

Video bandwidth, specified as a character vector or a string scalar of a positive scalar less than or equal to SampleRate/2. For more information on the video bandwidth method, see "Averaging Method" on page 2-1343.

**Tunable:** Yes

**Dependency**

To enable this property, set VBWSource to "Property".

**Scope Window Use**

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, set **VBW (Hz)** to either Auto or enter a positive real scalar that is less than or equal to **Sample Rate (Hz)/2**.

To enable the **VBW (Hz)**, set **Input Domain** to Time and **Averaging Method** to VBW.

Data Types: double

### ForgettingFactor — Weighting forgetting factor

"0.9" (default) | string scalar of scalar in the range (0,1] | character vector of scalar in the range (0,1]

Forgetting factor of the exponential weighted averaging method, specified as a character vector or string scalar of a real scalar in the range (0,1].

**Tunable:** Yes

#### Dependency

To enable this property, set:

- InputDomain to "Time"
- AveragingMethod to "Exponential"

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Averaging** section, adjust the **Forgetting Factor** slider.

To enable the **Forgetting Factor**, set **Input Domain** to Time and **Averaging Method** to Exponential.

Data Types: char | string

### FrequencyVectorSource — Source of frequency vector

"Auto" (default) | "Property" | "InputPort"

Source of the frequency vector, specified as one of the following:

- "Auto" — The Spectrum Analyzer computes the frequency vector based on the frame size of the input signal and the specified sample rate. For more details, see "Frequency Vector" on page 2-1341.
- "Property" — Enter a custom vector in the FrequencyVector property.
- "InputPort" — An input port appears on the Spectrum Analyzer block. Specify the frequency vector input through this port.

**Tunable:** Yes

#### Dependency

To enable this property, set InputDomain to "Frequency".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Frequency (Hz)** to Auto, Input port, or a monotonically increasing vector of length equal to the input signal frame size.

To enable the **Frequency (Hz)**, set **Input Domain** to Frequency.

Data Types: char | string

### FrequencyVector — Custom frequency vector

`[-5000 5000]` (default) | monotonically increasing vector

Custom frequency vector, specified as a monotonically increasing vector. This vector determines the x-axis in the display. The vector must be monotonically increasing and must have the same length as the input signal frame size.

**Tunable:** Yes

#### Dependency

To enable this property, set:

- `InputDomain` to "Frequency".
- `FrequencyVectorSource` to "Property".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Frequency (Hz)** to a monotonically increasing vector of length equal to the input signal frame size.

To enable the **Frequency (Hz)**, set **Input Domain** to Frequency.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### InputUnits — Units of frequency input

`"dBm"` (default) | `"dBV"` | `"dBW"` | `"Vrms"` | `"Watts"` | `"None"`

Units of the frequency-domain input, specified as `"dBm"`, `"dBV"`, `"dBW"`, `"Vrms"`, `"Watts"`, or `"none"`. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit in the `SpectrumUnits` property.

**Tunable:** Yes

#### Dependency

To enable this property, set `InputDomain` to "Frequency".

#### Scope Window Use

Click the **Estimation** tab on the Spectrum Analyzer toolstrip. In the **Domain** section, set **Input Unit**.

To enable the **Input Unit**, set **Input Domain** to Frequency.

Data Types: `char` | `string`

### SpectrumUnits — Units of the spectrum

`"dBm"` (default) | `"dBFS"` | `"dBV"` | `"dBW"` | `"Vrms"` | `"Watts"` | `"dBm/Hz"` | `"dBW/Hz"` | `"dBFS/Hz"` | `"Watts/Hz"` | `"Auto"`

Units of the spectrum, specified as one of these:

- `"dBm"`
- `"dBFS"`
- `"dBV"`
- `"dBW"`

- "Vrms"
- "Watts"
- "dBm/Hz"
- "dBW/Hz"
- "dBFS/Hz"
- "Watts/Hz"
- "Auto"

The Spectrum Analyzer displays power values in the units you select in this property.

**Tunable:** Yes

**Dependency**

The available spectrum units depend on the value you specify in the SpectrumType property.

| InputDomain | SpectrumType    | Allowed SpectrumUnits                        |
|-------------|-----------------|--|
| "Time"      | "Power"         | "dBm", "dBW", "dBFS", "Watts"                |
|             | "Power density" | "dBm/Hz", "dBW/Hz", "dBFS/Hz", "Watts/Hz"    |
|             | "RMS"           | "dBV", "Vrms"                                |
| "Frequency" | —               | "Auto", "dBm", "dBV", "dBW", "Vrms", "Watts" |

If you set the InputDomain property to "Frequency" and the SpectrumUnits property to "Auto", the Spectrum Analyzer assumes the spectrum units to be equal to input units specified in the InputUnits property. If you set InputDomain to "Time" and SpectrumUnits to any option other than "Auto", then the Spectrum Analyzer converts the units specified in InputUnits to the units specified in SpectrumUnits.

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set **Spectrum Unit**.

Data Types: char | string

**FullScaleSource — Source of dBFS scaling factor**

"Auto" (default) | "Property"

Source of dBFS scaling factor, specified as one of these:

- "Auto" -- The Spectrum Analyzer adjusts the scaling factor based on the input data.
- "Property" -- Specify the full-scale scaling factor using the FullScale property.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- InputDomain to "Time"

- SpectrumType to "Power" or "Power density"
- SpectrumUnits to "dBFS" or "dBFS/Hz" (when spectrum type is set to "Power density")

### Scope Window Use

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Full Scale** to either **Auto** or a positive scalar.

To enable the **Full Scale**:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

Data Types: char | string

### FullScale — dBFS full scale value

"1" (default) | character vector of a positive scalar | string scalar of a positive scalar

dBFS full scale value, specified as a character vector or a string scalar of a real positive scalar.

**Tunable:** Yes

### Dependency

To enable this property, set:

- InputDomain to "Time"
- SpectrumType to "Power" or "Power density"
- SpectrumUnits to "dBFS" or "dBFS/Hz" (when spectrum type is set to "Power density")
- FullScaleSource to "Property"

### Scope Window Use

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set the **Full Scale** to either **Auto** or enter a positive scalar.

To enable the **Full Scale**:

- In the **Analyzer** tab, set the spectrum type to Power or Power Density.
- In the **Estimation** tab, set **Input Domain** to Time.
- In the **Spectrum** tab, set **Spectrum Unit** to dBFS or dBFS/Hz (when spectrum type is set to Power Density).

Data Types: char | string

### ReferenceLoad — Reference load to compute power levels

"1" (default) | character vector of a real positive scalar | string scalar of a real positive scalar

Reference load to compute the power levels, specified as a character vector or a string scalar of a positive scalar in Ohms.

**Tunable:** Yes

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip. In the **Scale** section, set **Reference Load ( $\Omega$ )**.

Data Types: char | string

**FrequencyOffset — Frequency offset**

"0" (default) | numeric scalar character vector | numeric vector character vector | numeric scalar string scalar | numeric vector string scalar

Frequency offset, specified as one of these:

- Numeric scalar — Apply the same frequency offset to all channels, specified as a character vector or a string scalar in Hz.
- Numeric vector — Apply a specific frequency offset for each channel, specified as a character vector or a string scalar in Hz. The vector length must be equal to the number of input channels.

The frequency-axis values are offset by the values specified in this property. The overall span must fall within the "Nyquist Frequency Interval" on page 2-1340. You can control the overall span in different ways based on how you set the FrequencySpan property.

**Tunable:** Yes

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Bandwidth** section, set **Offset (Hz)**.

Data Types: char | string

**TreatMby1SignalsAsOneChannel — Option to treat unoriented input signal as a column vector**

true (default) | false

Option to treat unoriented input signal as a column vector, specified as true or false. Set this property to true to treat  $M$ -by-1 and unoriented inputs as a column vector or one channel. Set this property to false to treat  $M$ -by-1 and unoriented inputs as a 1-by- $M$  row vector.

Data Types: logical

**Spectrogram****SpectrogramChannel — Channel for which spectrogram is plotted**

"1" (default) | character vector of a positive scalar integer | string scalar of a positive scalar integer

Channel for which the Spectrum Analyzer plots the spectrogram, specified as a character vector or string scalar of a positive scalar integer in the range  $[1 N]$ , where  $N$  is the number of input channels.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Channel** section, select a **Channel**.

Data Types: char | string

**TimeResolutionSource — Source of the time resolution value**

"Auto" (default) | "Property"

Source of the time resolution value of each spectrogram line, , specified as "Auto" or "Property". The TimeResolution property shows the time resolution for the different frequency resolution methods and time resolution properties.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Resolution (s)** to Auto or enter a positive scalar.

To enable the **Time Resolution (s)**, select **Spectrogram** in the **Analyzer** tab.

Data Types: char | string

**TimeResolution — Time resolution**

"1e-3" (default) | character vector of a positive scalar | string scalar of a positive scalar

Time resolution of each spectrogram line, specified as a character vector or a string scalar of a positive scalar and expressed in seconds.

The Spectrum Analyzer determines the time resolution value based on the frequency resolution method, RBW, and time resolution properties.

| Method               | RBW              | Time Resolution  | Resulting Time Resolution in Seconds  |
|----------------------|------------------|------------------|---|
| Welch or Filter Bank | Auto             | Auto             | 1/RBW   |
| Welch or Filter Bank | Auto             | Manually entered | 1/Time Resolution Hz  |
| Welch or Filter Bank | Manually entered | Auto             | 1/RBW seconds   |
| Welch or Filter Bank | Manually entered | Manually entered | Equal to or greater than the minimum attainable time resolution 1/RBW. The Spectrum Analyzer combines several spectral estimates into one spectrogram line to obtain the desired time resolution. It uses interpolation to obtain time resolution values that are not integer multiples of 1/RBW. |

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to "Spectrogram" or "Spectrum and spectrogram"
- TimeResolutionSource to "Property"

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Resolution (s)** to Auto or enter a positive scalar.

To enable the **Time Resolution (s)**, select **Spectrogram** in the **Analyzer** tab.

Data Types: char | string

**TimeSpanSource — Source of time span value**

"Auto" (default) | "Property"

Source of the time span of the spectrogram, specified as "Auto" or "Property". If you set this property to "Auto", the spectrogram displays 100 spectrogram lines at any given time. If you set this property to "Property", the spectrogram uses the time duration you specify in seconds in the TimeSpan property.

**Tunable:** Yes

**Dependency**

To enable this property, set ViewType to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Span (s)** to Auto or enter a positive scalar.

Data Types: char | string

**TimeSpan — Time span**

"0.1" (default) | character vector of a positive scalar | string scalar of a positive scalar

Time span of the spectrogram display in seconds, specified as a character vector or string scalar of a positive scalar. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

**Tunable:** Yes

**Dependency**

To enable this property, set:

- ViewType to "Spectrogram" or "Spectrum and spectrogram".
- TimeSpanSource to "Property".

**Scope Window Use**

Click the **Spectrogram** tab on the Spectrum Analyzer toolstrip. In the **Time Options** section, set the **Time Span (s)** to Auto or enter a positive scalar.

Data Types: char | string

### Measurements

#### MeasurementChannel — Channel for which to obtain measurements

"1" (default) | character vector | string scalar

Channel over which the measurements are obtained, specified as a character vector or a string scalar which evaluates to a positive integer less than or equal to 100. The highest number you can specify is equal to the number of channels (columns) in the input signal.

**Tunable:** Yes

#### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel** section, select a **Channel**.

Data Types: char | string

#### ChannelMeasurements — Channel measurements

ChannelMeasurementsConfiguration object

Channel measurements, specified as a ChannelMeasurementsConfiguration object. Enable channel measurements to compute and display the occupied bandwidth or adjacent channel power ratio. All ChannelMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

#### Dependency

To enable this property, set ViewType to "Spectrum" or "Spectrum and spectrogram".

#### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip and modify the measurement settings.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

#### CursorMeasurements — Cursor measurements

CursorMeasurementsConfiguration object

Cursor measurements, specified as a CursorMeasurementsConfiguration object. Enable cursor measurements to display waveform cursors. All CursorMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

#### Dependency

To enable this property, set ViewType to "Spectrum" or "Spectrum and spectrogram".

#### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the cursor measurements in the **Cursors** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### **DistortionMeasurements — Distortion measurements**

DistortionMeasurementsConfiguration object

Distortion measurements, specified as a DistortionMeasurementsConfiguration object. Enable distortion measurements to compute and display the harmonic distortion and intermodulation distortion. All DistortionMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

#### **Dependency**

To enable this property, set ViewType to "Spectrum" or "Spectrum and spectrogram".

#### **Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the distortion measurements in the **Distortion** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### **PeakFinder — Peak finder measurement**

PeakFinderConfiguration object

Peak finder measurement, specified as a PeakFinderConfiguration object. Enable peak finder to compute and display the largest calculated peak values. All PeakFinderConfiguration properties are tunable.

**Tunable:** Yes

#### **Dependency**

To enable this property, set ViewType to "Spectrum" or "Spectrum and spectrogram".

#### **Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip and modify the peak finder measurements in the **Peaks** section.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

### **SpectralMask — Spectral mask configuration**

SpectralMaskConfiguration object

Spectral mask configuration, specified as a SpectralMaskConfiguration object. Use the spectral mask configuration to draw upper, lower, or upper and lower mask lines in the power and power-density plots. All SpectralMaskConfiguration properties are tunable.

**Tunable:** Yes

#### **Dependency**

To enable this property, set:

- ViewType to "Spectrum" or "Spectrum and spectrogram".
- SpectrumType to either "Power" or "Power density".

**Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip and modify the settings.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose either Power or Power Density.

**Visualization****Name — Caption to display in spectrum Analyzer window**

"Spectrum Analyzer" (default) | character vector | string scalar

Caption to display in the scope window, specified as a character vector or string scalar.

**Tunable:** Yes

Data Types: char | string

**Position — Window position**

screen center (default) | [left bottom width height]

Spectrum Analyzer window position in pixels, specified by the size and location of the scope window as a four-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property.

By default, the window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The exact center coordinates depend on your screen resolution.

**Tunable:** Yes

**MaximizeAxes — Maximize axes control**

"Auto" (default) | "On" | "Off"

Maximize axes control, specified as one of the following:

- "Auto" -- The Spectrum Analyzer maximizes axes only if the display does not contain any labels or title annotations.
- "On" -- The Spectrum Analyzer maximizes axes in all displays.
- "Off" -- The Spectrum Analyzer does not maximize axes in any display.

**Tunable:** Yes

**Scope Window Use**

Click the  control on the Spectrum Analyzer display to maximize the axes.

Data Types: char | string

**PlotNormalTrace — Normal trace flag**

true (default) | false

Normal trace flag, specified as true or false.

To remove normal traces from the display, set this property to `false`. These traces display the free-running spectral estimates. The Spectrum Analyzer continues its spectral computations even when you set this property to `false`.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Normal Trace** check box in the **Trace Options** section.

To enable the **Normal Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**PlotMaxHoldTrace – Maximum-hold trace flag**

`false` (default) | `true`

Maximum-hold trace flag, specified as `false` or `true`.

To compute and plot the maximum-hold spectrum of each input channel, set this property to `true`. The Spectrum Analyzer computes the maximum-hold spectrum at each frequency bin by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Max-Hold Trace** check box in the **Trace Options** section.

To enable the **Max-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**PlotMinHoldTrace – Minimum-hold trace flag**

`false` (default) | `true`

Minimum-hold trace flag, specified as `false` or `true`.

To compute and plot the minimum-hold spectrum of each input channel, set this property to `true`. The Spectrum Analyzer computes the minimum-hold spectrum at each frequency bin by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Spectrum** tab on the Spectrum Analyzer toolstrip and select the **Min-Hold Trace** check box in the **Trace Options** section.

To enable the **Min-Hold Trace** check box, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**Title — Display title**

`''` (default) | character vector | string scalar

Display title, specified as a character vector or a string scalar.

**Tunable:** Yes

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Title**.

Data Types: `char` | `string`

**YLabel — Y-axis label**

`''` (default) | character vector | string scalar

y-axis label, specified as a character vector or a string scalar. The Spectrum Analyzer displays the label to the left of the y-axis.

Regardless of the value of this property, Spectrum Analyzer always displays power units as one of the `SpectrumUnits` values.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and labels**, enter **Y-Label**.

To enable the **Y-Label**, select **Spectrum** in the **Analyzer** tab.

Data Types: `char` | `string`

**YLimits — Y-axis limits**

`[-80, 20]` (default) | `[ymin ymax]`

y-axis limits, specified as a two-element numeric vector of the form `[ymin ymax]`. The units of the y-axis limits depend on the `SpectrumUnits` property.

Example: `scope.YLimits = [-10,20]`

**Tunable:** Yes

**Dependencies**

- To enable this property, set the `ViewType` property to "Spectrum" or "Spectrum and spectrogram".
- The units directly depend upon the `SpectrumUnits` property.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Y-Axis Limits**.

To enable the **Y-Axis Limits**, select **Spectrum** in the **Analyzer** tab.

**ColorLimits — Color limits of the spectrogram**

`[-80, 20]` (default) | `[colorMin colorMax]`

Color limits of the spectrogram, specified as a two-element numeric vector of the form `[colorMin colorMax]`. The units of the color limits directly depend upon the `SpectrumUnits` property.

Example: `scope.ColorLimits = [-10,20]`

**Tunable:** Yes

**Dependencies**

- To enable this property, set the `ViewType` property to "Spectrogram" or "Spectrum and spectrogram".
- The units directly depend upon the `SpectrumUnits` property.

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Color Limits**.

To enable the **Color Limits**, select **Spectrogram** in the **Analyzer** tab.

**Colormap — Color lookup table**

`"jet"` (default) | `"bone"` | `"cool"` | `"copper"` | `"gray"` | `"hot"` | `"parula"` | three-column matrix

Color lookup table, specified as a valid colormap name or a three-column matrix with values in the range `[0,1]` defining RGB triplets.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ViewType` property to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that opens up, under **Display and Labels**, enter **Color Map**.

To enable the **Color Map**, select **Spectrogram** in the **Analyzer** tab.

Data Types: `double` | `char` | `string`

### ShowGrid — Flag to show grid

`true` (default) | `false`

Flag to show the grid, specified as `true` or `false`. Set this property to `true` to show grid lines in the plot.

**Tunable:** Yes

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolbar. In the **Configuration** section, click **Settings**. In the Spectrum Analyzer Settings window that appears, under **Display and Labels**, select **Show Grid**.

Data Types: `logical`

### ChannelNames — Channel names

empty cell (default) | cell array of character vectors | array of strings

Channel names in the input data, specified as a cell array of character vectors or an array of strings. The names you specify in this property appear in the following locations:

- Legend
- **Spectrum Analyzer Settings > Color and styling** section
- **Measurements** and **Channel Measurements** tabs

If you do not specify channel names, the Spectrum Analyzer names the channels as `Channel 1`, `Channel 2`, and so on.

**Tunable:** Yes

#### Dependency

To see the channel names, set `ShowLegend` to `true`.

#### Scope Window Use

Click the **Analyzer** tab on the Spectrum Analyzer toolbar. To see the legend, click **Legend** in the **Configuration** section.

Data Types: `char`

### ShowLegend — Flag to show legend

`false` (default) | `true`

Flag to show the legend, specified as `true` or `false`. To show a legend with the input names, set this property to `true`.

Use the legend to control which signals are visible. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ViewType` property to "Spectrum" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the legend, click **Legend** in the **Configuration** section.

To enable the **Legend**, select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

**ShowColorbar — Flag to show color bar**

`true` (default) | `false`

Flag to show the color bar, specified as `true` or `false`.

**Tunable:** Yes

**Dependencies**

To enable this property, set the `ViewType` property to "Spectrogram" or "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. To see the color bar, click **Colorbar** in the **Configuration** section.

To enable the **Colorbar**, select **Spectrogram** in the **Analyzer** tab.

Data Types: `logical`

**AxesLayout — Orientation of the spectrum and spectrogram**

`"Vertical"` (default) | `"Horizontal"`

Layout of the axes, specified as one of "Vertical" or "Horizontal". A vertical layout stacks the spectrum above the spectrogram. A horizontal layout places the spectrum next to the spectrogram.

**Tunable:** Yes

**Dependency**

To enable this property, set `ViewType` to "Spectrum and spectrogram".

**Scope Window Use**

Click the **Analyzer** tab on the Spectrum Analyzer toolstrip. Select **Spectrum** and **Spectrogram**. In the **Configuration** section, select and update **Layout**.

Data Types: `char` | `string`

**OpenAtSimulationStart — Flag to open scope when simulation starts**

`true` (default) | `false`

Flag to open scope when simulation starts, specified as `true` or `false`.

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening when you simulate the model.

#### Scope Window Use

This parameter is available only from the **Property Inspector**. To launch the **Property Inspector**, click the **Modeling** tab of the Simulink model window that contains the Spectrum Analyzer block. In the **Design** section, click the drop-down arrow and select **Property Inspector**. The **Property Inspector** window opens on the right. If you select the Spectrum Analyzer block, the **Property Inspector** window shows the corresponding parameters. In the parameters that show up, select or clear the **Open at simulation start** parameter.

Data Types: `logical`

#### Visible — Visibility of the Spectrum Analyzer

`false` (default) | `true`

Set this property to `true` to display the spectrum analyzer window, and to `false` to hide the spectrum analyzer window.

Data Types: `logical`

## Examples

### Construct Spectrum Analyzer Configuration Object

Create a new Simulink® model with a randomly generated name.

```
sysname=char(randi(26,1,7)+96);  
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param` function to retrieve the default Spectrum Analyzer block configuration properties.

```
config = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
config =  
SpectrumAnalyzerBlockConfiguration with properties:
```

```
    NumInputPorts: '1'  
    InputDomain: 'Time'  
    SpectrumType: 'Power'  
    ViewType: 'Spectrum'  
    SampleRateSource: 'Inherited'  
    Method: 'Filter bank'  
    PlotAsTwoSidedSpectrum: 1  
    FrequencyScale: 'Linear'  
    PlotType: 'Line'  
    AxesScaling: 'Auto'
```

Advanced

```
    RBWSource: 'Auto'
```

```

        FilterSharpness: '0.3'
        FrequencySpan: 'Full'
        AveragingMethod: 'VBW'
            VBWSource: 'Auto'
        SpectrumUnits: 'dBm'
        ReferenceLoad: '1'
        FrequencyOffset: '0'
    TreatMby1SignalsAsOneChannel: 1

Spectrogram
    No properties.

Measurements
    MeasurementChannel: '1'
    ChannelMeasurements: [1x1 ChannelMeasurementsConfiguration]
    CursorMeasurements: [1x1 CursorMeasurementsConfiguration]
    DistortionMeasurements: [1x1 DistortionMeasurementsConfiguration]
    PeakFinder: [1x1 PeakFinderConfiguration]
    SpectralMask: [1x1 SpectralMaskConfiguration]

Visualization
    Name: 'SpectrumAnalyzer'
    Position: [240 262 800 500]
    MaximizeAxes: 'Auto'
    PlotNormalTrace: 1
    PlotMaxHoldTrace: 0
    PlotMinHoldTrace: 0
    Title: ''
    YLabel: ''
    YLimits: [-80 20]
    ShowGrid: 1
    ChannelNames: {' '}
    ShowLegend: 0
    OpenAtSimulationStart: 1
    Visible: 0

```

### Obtain Measurements Data Programmatically for Spectrum Analyzer Block

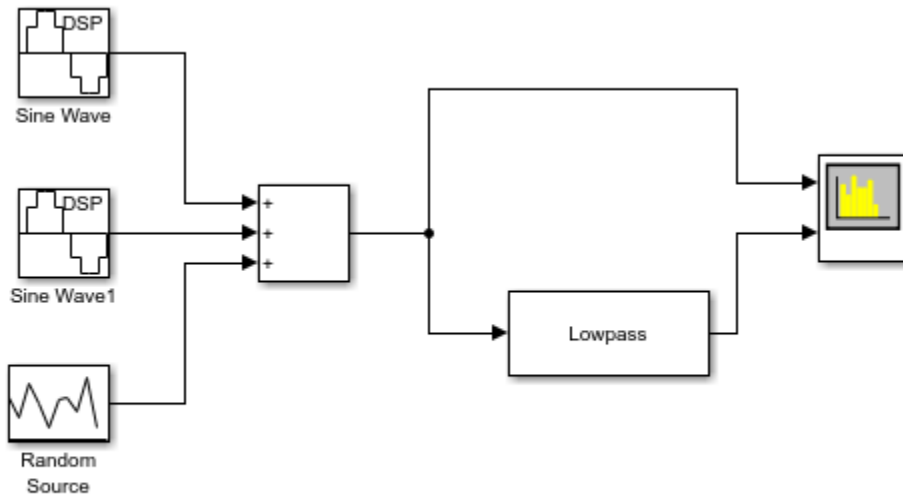

Compute and display the power spectrum of a noisy sinusoidal input signal using the Spectrum Analyzer block. Measure the cursor placements, adjacent channel power ratio, distortion, and peak values in the spectrum by enabling these block configuration properties:

- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements
- PeakFinder

### Open and Inspect the Model

Filter a streaming noisy sinusoidal input signal using a Lowpass Filter block. The input signal consists of two sinusoidal tones: 1 kHz and 15 kHz. The noise is white Gaussian noise with a mean of 0 and a variance of 0.05. The sampling frequency is 44.1 kHz. Open the model and inspect the parameter values in the blocks.

```
model = 'spectrumanalyzer_measurements.slx';  
open_system(model)
```

Copyright 2018-2022 The MathWorks, Inc.

Access the configuration properties of the Spectrum Analyzer block using the `get_param` function.

```
sablock = 'spectrumanalyzer_measurements/Spectrum Analyzer';  
cfg = get_param(sablock, 'ScopeConfiguration');
```

### Enable Measurements Data

To obtain the measurements, set the `Enabled` property to `true`.

```
cfg.CursorMeasurements.Enabled = true;  
cfg.ChannelMeasurements.Enabled = true;  
cfg.DistortionMeasurements.Enabled = true;  
cfg.PeakFinder.Enabled = true;
```

### Simulate the Model

Run the model. The Spectrum Analyzer block compares the original spectrum with the filtered spectrum.

```
sim(model)
```

The panes at the bottom of the spectrum analyzer window display the measurements that you have enabled.

### Use `getMeasurementsData` function

Use the `getMeasurementsData` function to obtain the measurements programmatically.

```
data = getMeasurementsData(cfg)
```

```
data =
```

```
1x5 table
```

```
SimulationTime
```

```
9.9962
```

```
PeakFinder
```

```
1x1 struct
```

```
CursorMeasurements
```

```
1x1 struct
```

```
ChannelMeasurements
```

```
1x1 struct
```

```
DistortionMeasurements
```

```
1x1 struct
```

The values shown in the measurement panels match the values shown in `data`. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

As an example, compare the peak values. Verify that the peak values obtained by `data.PeakFinder` match with the values in the spectrum analyzer window.

```
peakvalues = data.PeakFinder.Value  
frequencieskHz = data.PeakFinder.Frequency/1000
```

```
peakvalues =
```

```
    26.8653  
    26.2638  
    -3.4329
```

```
frequencieskHz =
```

```
    15.0015  
     1.0049  
     3.7755
```

### Spectral Mask in Spectrum Analyzer Block

Create a new model based on the `dsp_basic_filter` template. Add a spectral mask to the Spectrum Analyzer block in the model. Run the model.

Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing. The **Spectral Mask** panel shows what percentage of the time the mask is succeeding, which mask is failing, how many times the mask(s) failed, and which channels are causing the failure.

```
[~,mdl] = fileparts(tempname);  
open_system(new_system(mdl,'FromTemplate','dsp_basic_filter'));  
saBlock = find_system(mdl,'BlockType','SpectrumAnalyzer');  
  
scopeConfig = get_param(saBlock{1},'ScopeConfiguration');  
upperMask = [0 50; 1200 50; 1200 -10; 24000 -10];  
scopeConfig.SpectralMask.UpperMask = upperMask;  
scopeConfig.SpectralMask.LowerMask = -100;  
scopeConfig.SpectralMask.EnabledMasks = 'upper-and-lower';  
sim(mdl,StopTime='20');
```

## Version History

Introduced in R2013a

### **R2023a: Spectrum Analyzer with improved responsiveness and toolstrip interface in Simulink**

In R2023a, the Spectrum Analyzer block is more responsive and its toolstrip interface provides you easy access to spectral analysis, estimation, and measurements.

# BilevelMeasurementsConfiguration

Measure transitions, aberrations, and cycles of bilevel signals

## Description

Use the `BilevelMeasurementsConfiguration` object to measure transitions, aberrations, and cycles of bilevel signals. You can also specify the bilevel settings such as high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level.

You can control bilevel measurements from the toolbar or from the command line. To modify bilevel measurements from the toolbar, in the **Measurements** tab, click **Bilevel Settings** and select the measurements you want to display. A panel appears at the bottom of the Time Scope window showing all the measurements you enabled.

| Transitions |             | Aberrations    |         | Cycles     |                |
|-------------|-------------|----------------|---------|------------|----------------|
| Channel 1   | Period (ms) | Frequency (Hz) | Count   | Width (ms) | Duty Cycle (%) |
| + Pulses    | 1.0000e+1   | 1.0000e+2      | 99.0000 | 5.6149e+0  | 56.1485        |
| - Pulses    | 1.0000e+1   | 1.0000e+2      | 99.0000 | 4.3851e+0  | 43.8515        |

Stopped Frames = 1 T = 0.999000

## Creation

### Syntax

```
bilevelMeas = BilevelMeasurementsConfiguration()
```

### Description

`bilevelMeas = BilevelMeasurementsConfiguration()` creates a bilevel measurements configuration object.

### Properties

All properties are tunable.

#### AutoStateLevel — Automatic detection of high- and low-state levels

`true` (default) | `false`

Automatic detection of high- and low-state levels, specified as `true` or `false`. Set this property to `true` so that the scope automatically detects high- and low-state levels in the bilevel waveform. When you set this property to `false`, you can specify values for the high- and low- state levels manually using the `HighStateLevel` and `LowStateLevel` properties.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **State Level**, and select **Auto State Level**.

Data Types: `logical`

#### HighStateLevel — High-state level

2.3 (default) | nonnegative scalar

High-state level, specified as a nonnegative scalar. The high-state level denotes a positive polarity.

If the initial transition of a pulse is positive-going, the pulse has positive polarity. The terminating state of a positive-polarity (positive-going) pulse is more positive than the originating state.

This figure shows a positive-polarity pulse.

### Dependency

To enable this property, set `AutoStateLevel` to `false`.

### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **State Level**, clear **Auto State Level** and specify a nonnegative scalar in the **High** box.

Data Types: `double`

### LowStateLevel — Low-state level

0 (default) | nonnegative scalar

High-state level, specified as a nonnegative scalar. The low-state level denotes a negative polarity.

If the initial transition of a pulse is negative-going, the pulse has negative polarity. The terminating state of a negative-polarity (negative-going) pulse is more negative than the originating state.

This figure shows a negative-polarity pulse.

### Dependency

To enable this property, set `AutoStateLevel` to `false`.

### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **State Level**, clear **Auto State Level** and specify a nonnegative scalar in the **Low** box.

Data Types: `double`

### StateLevelTolerance — Tolerance level of state

2 (default) | positive scalar in the range (0 100)

Tolerance level of the state, specified as a positive scalar in the range (0 100).

This value determines how much a signal can deviate from the low- or high-state level before it is considered to be outside that state. Specify this value as a percentage of the difference between the high- and low-state levels. For more details, see “State-Level Tolerances” on page 4-1377.

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **State Level**, specify a positive scalar less than 100 in the **State Level Tol. (%)** box.

Data Types: double

**UpperReferenceLevel — Upper-reference level**

90 (default) | positive scalar in the range (0 100)

Upper-reference level, specified as a positive scalar in the range (0 100). The scope uses the upper-reference level to compute the start of a fall time or the end of a rise time. Specify this value as a percentage of the difference between the high- and low-state levels.

If  $S_1$  is the low-state level,  $S_2$  is the high-state level, and  $U$  is the upper-reference level, the waveform value corresponding to the upper-reference level is

$$S_1 + \frac{U}{100}(S_2 - S_1).$$

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **Reference Level**, specify a positive scalar less than 100 in the **Upper Ref. Level (%)** box.

Data Types: double

**MidReferenceLevel — Mid-reference level**

50 (default) | positive scalar in the range (0 100)

Mid-reference level, specified as a positive scalar in the range (0 100). The scope uses the mid-reference level to determine when a transition occurs. Specify this value as a percentage of the difference between the high- and low-state levels.

The mid-reference level in a bilevel waveform with low-state level  $S_1$  and high-state level  $S_2$  is

$$S_1 + \frac{1}{2}(S_2 - S_1)$$

This figure shows the mid-reference level as a horizontal line, and shows its corresponding mid-reference level instant as a vertical line.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **Reference Level**, specify a positive scalar less than 100 in the **Mid Ref. Level (%)** box.

Data Types: double

#### LowerReferenceLevel<sub>L</sub> — Lower-reference level

10 (default) | positive scalar in the range (0 100)

Lower-reference level, specified as a positive scalar in the range (0 100). The scope uses the lower-reference level to compute the end of a fall time or the start of a rise time. Specify this value as a percentage of the difference between the high- and low-state levels.

If  $S_1$  is the low-state level,  $S_2$  is the high-state level, and  $L$  is the lower-reference level, the waveform value corresponding to the lower-reference level is

$$S_1 + \frac{L}{100}(S_2 - S_1).$$

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **Reference Level**, specify a positive scalar less than 100 in the **Lower Ref. Level (%)** box.

Data Types: double

#### SettleSeek — Time duration over which to search for a settling time

0.02 (default) | positive scalar

Time duration over which the scope searches for a settling time, specified as a positive scalar in seconds.

#### Scope Window Use

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings**. Under **Reference Level**, specify a positive scalar in the **Settle Seek (s)** box.

Data Types: double

**ShowTransitions — Enable transition measurements**`false (default) | true`

Enable transition measurements, specified as `true` or `false`. For more information on the transition measurements that the scope displays, see “Transitions Pane” (Simulink).

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings** and select **Transitions**. A **Transitions** pane opens at the bottom of the Time Scope window to show the transition measurements.

Data Types: `logical`

**ShowAberrations — Enable aberration measurements**`false (default) | true`

Enable aberration measurements, specified as `true` or `false`. Aberration measurements include distortion and damping measurements such as preshoot, overshoot, and undershoot. For more information on the aberration measurements that the scope displays, see “Overshoots / Undershoots Pane” (Simulink).

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings** and select **Aberrations**. An **Aberrations** pane opens at the bottom of the Time Scope window to show the aberration measurements.

Data Types: `logical`

**ShowCycles — Enable cycle measurements**`false (default) | true`

Enable cycle measurements, specified as `true` or `false`. These measurements are related to repetitions or trends in the displayed portion of the input signal. For more information on the cycle measurements, see “Cycles Pane” (Simulink).

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, click **Bilevel Settings** and select **Cycles**. A **Cycles** pane opens at the bottom of the Time Scope window to show the cycle measurements.

Data Types: `logical`

## Examples

**Configure Bilevel Measurements Programmatically in Time Scope MATLAB Object**

Create a sine wave and view it in the Time Scope. Programmatically compute the bilevel measurements related to signal transitions, aberrations, and cycles.

**Initialization**

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

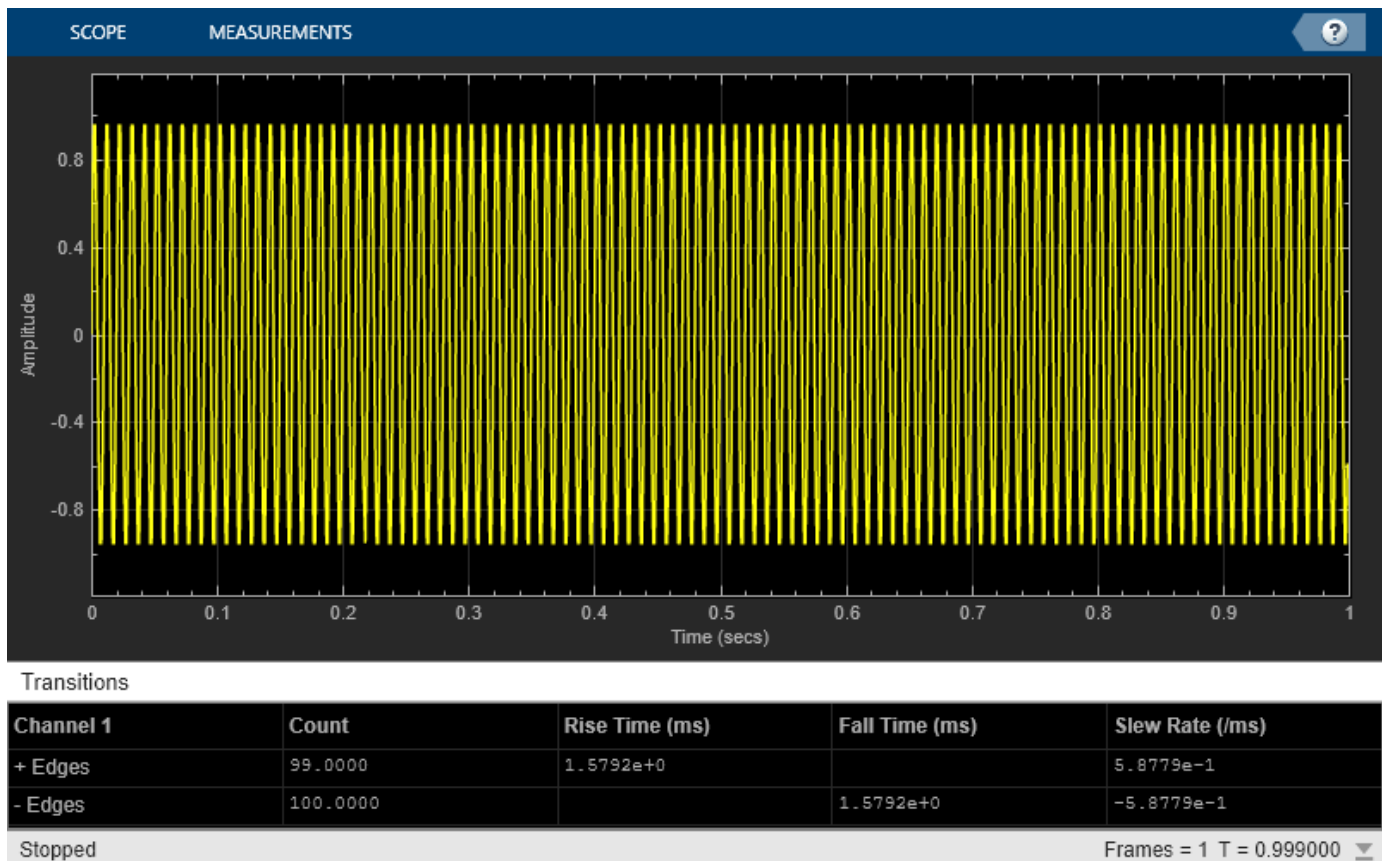

```
f = 100;
fs = 1000;
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
```

### Transition Measurements

Enable the scope to show transition measurements programmatically by setting the `ShowTransitions` property to `true`. Display the sine wave in the scope.

Transition measurements such as rise time, fall time, and slew rate appear in the **Transitions** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowTransitions = true;
scope(swv);
release(scope);
```

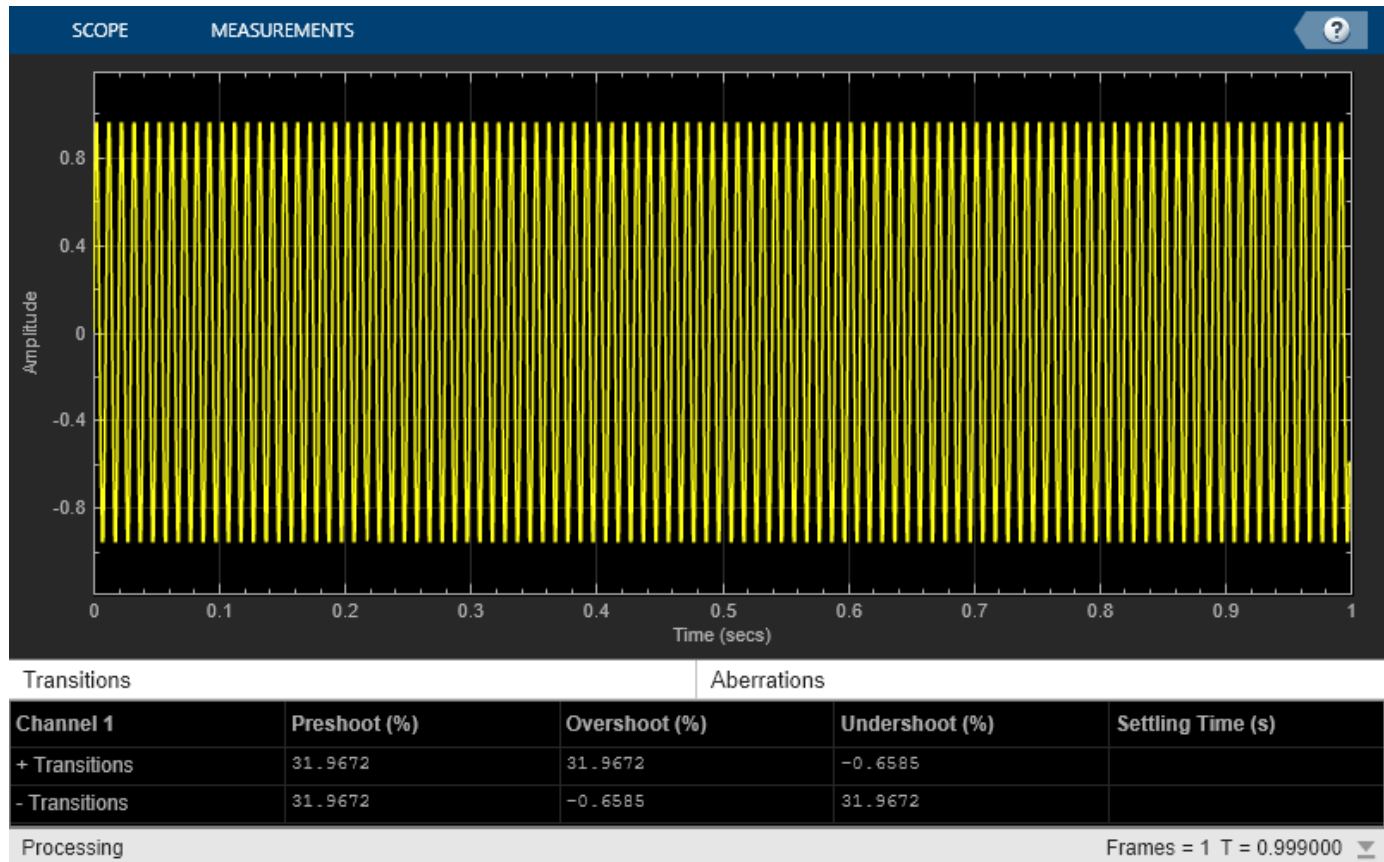

### Aberration Measurements

Enable the scope to show aberration measurements programmatically by setting the `ShowAberrations` property to `true`. Display the sine wave in the scope.

Aberration measurements such as preshoot, overshoot, undershoot, and settling time appear in the **Aberrations** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowAberrations = true;
scope(svw);
release(scope);
```

### Cycle Measurements

Enable the scope to show cycles measurements programmatically by setting the `ShowCycles` property to `true`. Display the sine wave in the scope.

Cycle measurements such as period, frequency, pulse width, and duty cycle appear in the **Cycles** pane at the bottom of the scope.

```
scope.BilevelMeasurements.ShowCycles = true;
scope(svw);
release(scope);
```

## More About

### State-Level Tolerances

You can specify lower- and upper-state boundaries for each state level. Define the boundaries as the state level plus or minus a scalar multiple of the difference between the high state and the low state. To provide a useful tolerance region, specify the scalar as a small number such as 2/100 or 3/100. In general, the  $\alpha\%$  region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1),$$

where  $S_1$  is the low-state level and  $S_2$  is the high-state level. Replace the first term in the equation with  $S_2$  to obtain the  $\alpha\%$  tolerance region for the high state.

This figure shows lower and upper 5% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The thick dashed lines indicate the estimated state levels.

# SignalStatisticsConfiguration

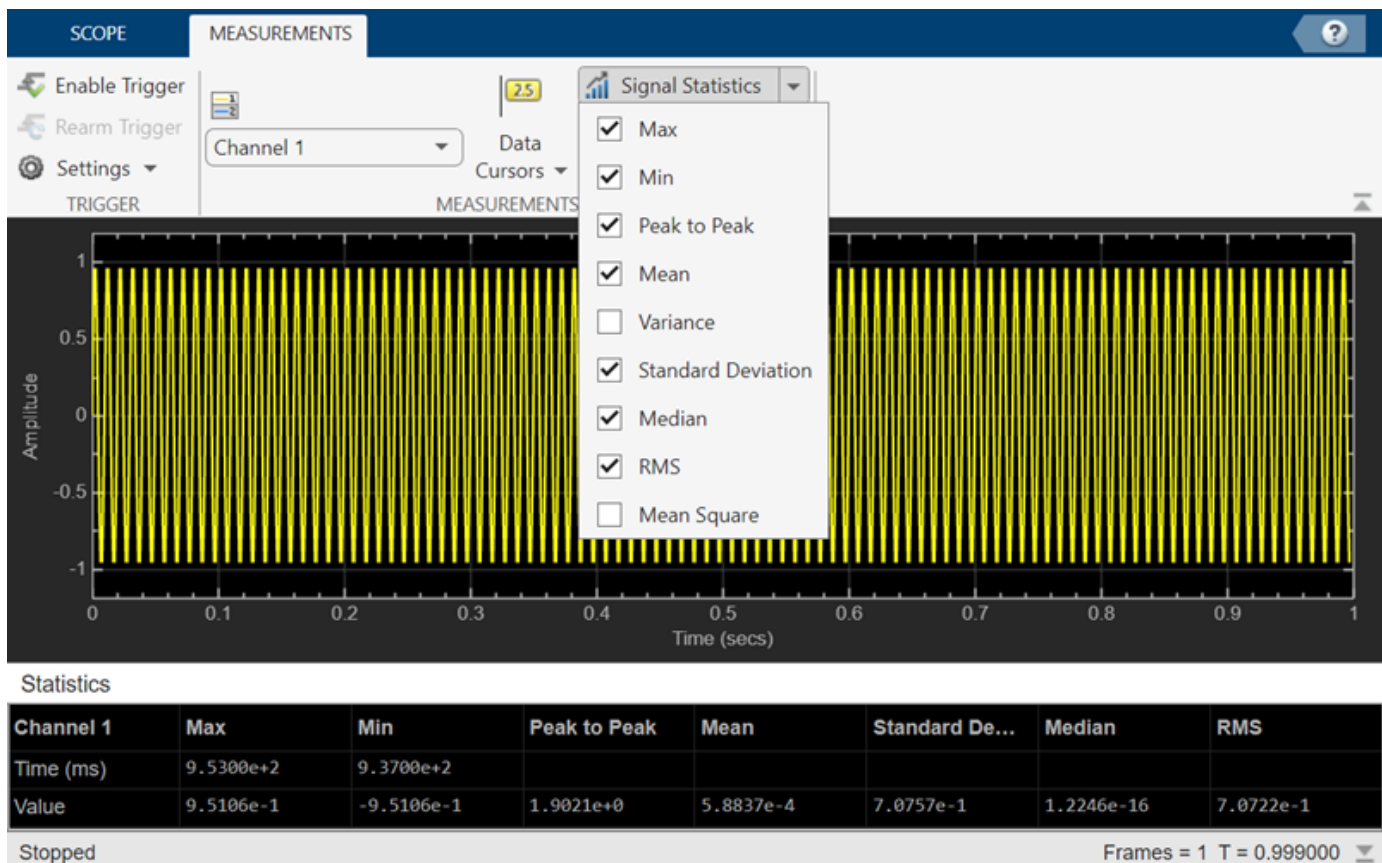

Compute and display signal statistics

## Description

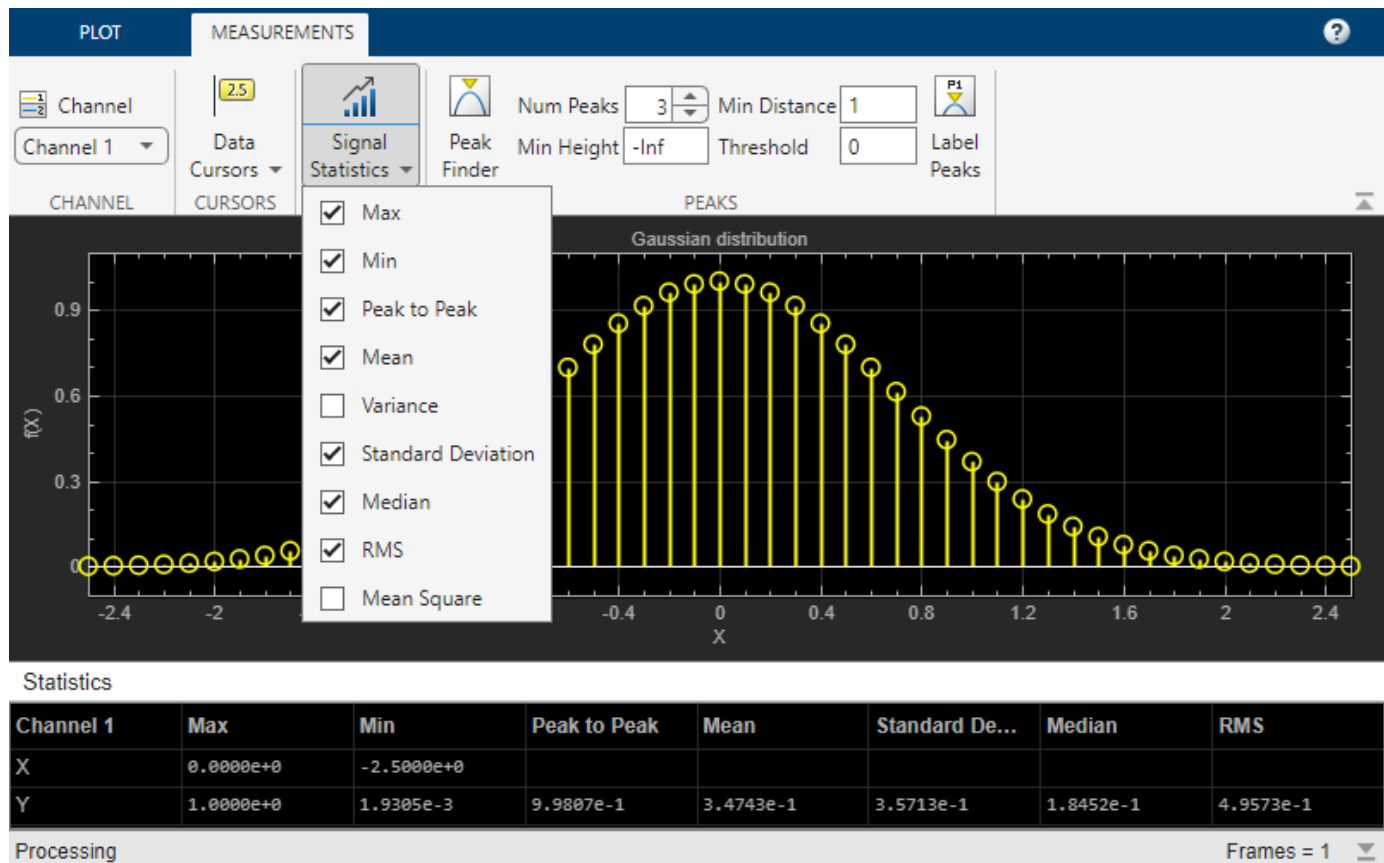

Use the `SignalStatisticsConfiguration` object to measure signal statistics such as maximum, minimum, peak-to-peak value, mean, variance, standard deviation, median, RMS, and mean square.

You can enable the scope to compute and display signal statistics from the toolstrip or from the command line. To enable from the scope interface, click the **Measurements** tab, and then click **Signal Statistics**. A statistics panel appears at the bottom of the scope window. To enable specific statistics, click the **Signal Statistics** drop-down list and select a statistic from the options. The **Statistics** panel shows those statistics.

### Time Scope

### Array Plot

## Creation

### Syntax

```
signalStats = SignalStatisticsConfiguration()
```

### Description

`signalStats = SignalStatisticsConfiguration()` creates a signal statistics configuration object `signalStats`.

### Properties

All properties are tunable.

#### ShowMax — Compute and display maximum

true (default) | false

Compute and display the maximum value, specified as `true` or `false`. The scope computes and displays the maximum value of the portion of the input signal that is currently on display in the scope.

**Scope Window Use**

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Max**.

Data Types: `logical`

**ShowMin — Compute and display minimum**

`true` (default) | `false`

Compute and display the minimum value, specified as `true` or `false`. The scope computes and displays the minimum value of the portion of the input signal that is currently on display in the scope.

**Scope Window Use**

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Min**.

Data Types: `logical`

**ShowPeakToPeak — Compute and display peak-to-peak values**

`true` (default) | `false`

Compute and display the peak-to-peak values, specified as `true` or `false`. The scope computes and displays the peak-to-peak values from the portion of the input signal that is currently on display in the scope.

**Scope Window Use**

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Peak to Peak**.

Data Types: `logical`

**ShowMean — Compute and display mean**

`true` (default) | `false`

Compute and display the mean value, specified as `true` or `false`. The scope computes and displays the mean value of the portion of the input signal that is currently on display in the scope.

**Scope Window Use**

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Mean**.

Data Types: `logical`

**ShowVariance — Compute and display variance**

`false` (default) | `true`

Compute and display the variance, specified as `true` or `false`. The scope computes and displays the variance of the portion of the input signal that is currently on display in the scope.

**Scope Window Use**

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Variance**.

Data Types: `logical`

**ShowStandardDeviation — Compute and display standard deviation**

`true` (default) | `false`

Compute and display the standard deviation, specified as `true` or `false`. The scope computes and displays the standard deviation of the portion of the input signal that is currently on display in the scope.

### Scope Window Use

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Standard Deviation**.

Data Types: `logical`

### ShowMedian — Compute and display median

`true` (default) | `false`

Compute and display the median, specified as `true` or `false`. The scope computes and displays the median of the portion of the input signal that is currently on display in the scope.

### Scope Window Use

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Median**.

Data Types: `logical`

### ShowRMS — Compute and display RMS

`true` (default) | `false`

Compute and display the RMS, specified as `true` or `false`. The scope computes and displays the RMS of the portion of the input signal that is currently on display in the scope.

### Scope Window Use

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **RMS**.

Data Types: `logical`

### ShowMeanSquare — Compute and display mean square

`false` (default) | `true`

Compute and display the mean square, specified as `true` or `false`. The scope computes and displays the mean square of the portion of the input signal that is currently on display in the scope.

### Scope Window Use

On the **Measurements** tab, select **Signal Statistics** and then click **Signal Statistics** to select **Mean Square**.

Data Types: `logical`

### Enabled — Enable signal statistics measurements

`false` (default) | `true`

Enable signal statistics measurements, specified as `true` or `false`. Set this property to `true` to enable signal statistics measurements.

### Scope Window Use

On the **Measurements** tab, select **Signal Statistics**().

Data Types: `logical`

## Examples

### Configure Signal Statistics Programmatically in Time Scope MATLAB Object

Create a sine wave and view it in the Time Scope. Enable the scope programmatically to compute the signal statistics.

The object supports these signal statistics:

- Maximum
- Minimum
- Mean
- Median
- RMS
- Peak to peak
- Variance
- Standard deviation
- Mean square

### Initialization

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

```
f = 100;
fs = 1000;
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
```

### Signal Statistics

Enable the scope to show signal statistics programmatically by setting the `SignalStatistics > Enabled` property to `true`.

```
scope.SignalStatistics.Enabled = true;
```

By default, the scope enables the following measurements.

```
scope.SignalStatistics
```

```
ans =
    SignalStatisticsConfiguration with properties:

        ShowMax: 1
        ShowMin: 1
    ShowPeakToPeak: 1
        ShowMean: 1
        ShowVariance: 0
```

```
ShowStandardDeviation: 1
    ShowMedian: 1
    ShowRMS: 1
    ShowMeanSquare: 0
    Enabled: 1
```

Display the sine wave in the scope. A Statistics pane appears at the bottom of the scope window displaying the statistics for the portion of the signal that you can see in the scope.

If you use the zoom options on the scope, the statistics automatically adjust to the time range in the display.

```
scope(swv);
release(scope);
```

# TriggerConfiguration

Trigger measurements properties for scope

## Description

Use the TriggerConfiguration object to define a trigger event to identify the simulation time of specified input signal characteristics. You can use trigger events to stabilize periodic signals such as a sine wave or capture nonperiodic signals such as a pulse that occurs intermittently.

You can enable the trigger events either from the Time Scope toolstrip or from the command line. To enable a trigger event from the toolstrip, open the **Measurements** tab and click **Enable Trigger**.

## Creation

## Syntax

```
trigger = TriggerConfiguration()
```

## Description

`trigger = TriggerConfiguration()` creates a trigger configuration object `trigger`.

## Properties

All properties are tunable.

For more information on these triggers and the associated parameters, see “Source/Type and Levels/ Timing Panes” (Simulink).

### Mode — Display update mode

"auto" (default) | "normal" | "once"

Display update mode, specified as one of these:

- "auto" -- Display data from the last trigger event. If no event occurs after one time span, display the last available data.
- "normal" -- Display data from the last trigger event. If no event occurs, the display remains blank.
- "once" -- Display data from the last trigger event and freeze the display. If no event occurs, the

display remains blank. Click the **Rearm** button (  ) to look for the next trigger event.

### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, click **Settings** and set **Mode** to one of the available options.

Data Types: char | string

### Type — Type of trigger

"edge" (default) | "pulse-width" | "transition" | "runt" | "window" | "timeout"

Type of trigger, specified as one of the following:

- "edge" -- Trigger when the signal crosses a threshold.
- "pulse-width" -- Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.
- "transition" -- Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.
- "runt" -- Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.
- "window" -- Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.
- "timeout" -- Trigger when a signal stays above or below a threshold longer than a specified time.

### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, click **Settings** and set **Type** to one of the available options.

Data Types: char | string

### **Polarity — Trigger polarity**

"rising" (default) | "falling" | "either" | "positive" | "negative" | "rise-time" | "fall-time" | "inside" | "outside"

Trigger polarity, specified as one of the following:

- "rising", "falling", or "either" -- When Type is set to "edge" or "timeout".
- "positive", "negative", or "either" -- When Type is set to "pulse-width" or "runt".
- "rise-time", "fall-time", or "either" -- When Type is set to "transition".
- "inside", "outside", or "either" -- When Type is set to "window".

### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings** and set **Polarity** to one of the available options.

Data Types: char | string

### **AutoLevel — Automatic thresholding**

true (default) | false

Automatic thresholding of edge-triggered signal, specified as true or false. When you set this property to false, specify the threshold manually using the **Level** property.

### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, select **Auto Level**.

Data Types: logical

### **Position — Horizontal position of trigger**

50 (default) | positive scalar in the range (0 100]

Horizontal position of the trigger on the screen, specified as a positive scalar in the range (0 100].

### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings** and specify a positive scalar less than or equal to 100 in the **Position (%)** box.

Data Types: double

### **Level — Threshold of edge-triggered signal**

0 (default) | real scalar

Threshold of an edge-triggered signal, specified as a finite real scalar.

### **Dependency**

To enable this property, set **AutoLevel** to false and **Type** to "edge" or "timeout".

### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, clear **Auto Level** and specify a real scalar in the **Level** box.

To enable this property, set **Type** to Edge or Timeout.

Data Types: double

### Hysteresis – Noise reject value

0 (default) | real scalar

Noise reject value, specified as a finite real scalar. For more information on hysteresis, see “Hysteresis of Trigger Signals” (Simulink).

#### Dependency

To enable this property, set `AutoLevel` to false and `Type` to "edge" or "timeout".

#### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, clear **Auto Level** and specify a real scalar in the **Hysteresis** box.

To enable this property, set **Type** to Edge or Timeout.

Data Types: double

### LowLevel – Lower trigger level of window-triggered signal

0.2 (default) | real scalar

Lower trigger level of window-triggered signal, specified as a finite real scalar.

#### Dependency

To enable this property, set `AutoLevel` to false and `Type` to "pulse-width", "transition", "runt", or "window".

#### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, clear **Auto Level** and specify a real scalar in the **Low** box.

To enable this property, set **Type** to Pulse Width, Transition, Runt, or Window.

Data Types: double

### HighLevel – Higher trigger level of window-triggered signal

2.3 (default) | real scalar

Higher trigger level of window-triggered signal, specified as a finite real scalar.

#### Dependency

To enable this property, set `AutoLevel` to false and `Type` to "pulse-width", "transition", "runt", or "window".

#### Scope Window Use

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, clear **Auto Level** and specify a real scalar in the **High** box.

To enable this property, set **Type** to Pulse Width, Transition, Runt, or Window.

Data Types: double

### **MinPulseWidth — Minimum pulse width for pulse or runt-triggered signal**

0 (default) | nonnegative scalar

Minimum pulse width for a pulse or runt-triggered signal, specified as a nonnegative scalar.

#### **Dependency**

To enable this property, set **Type** to "pulse-width" or "runt".

#### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, specify a nonnegative scalar in the **Min Width (s)** box.

To enable this property, set **Type** to Pulse Width or Runt.

Data Types: double

### **MaxPulseWidth — Maximum pulse width for pulse or runt-triggered signal**

Inf (default) | nonnegative scalar

Maximum pulse width for a pulse or runt-triggered signal, specified as a nonnegative scalar.

#### **Dependency**

To enable this property, set **Type** to "pulse-width" or "runt".

#### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, specify a nonnegative scalar in the **Max Width (s)** box.

To enable this property, set **Type** to Pulse Width or Runt.

Data Types: double

### **MinDuration — Minimum duration for transition or window-triggered signal**

0 (default) | nonnegative scalar

Minimum duration for a transition or window-triggered signal, specified as a nonnegative scalar.

#### **Dependency**

To enable this property, set **Type** to "transition" or "window".

#### **Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, specify a nonnegative scalar in the **Min Time (s)** box.

To enable this property, set **Type** to Transition or Window.

Data Types: double

### **MaxDuration — Maximum duration for transition or window-triggered signal**

Inf (default) | nonnegative scalar

Maximum time duration for a transition or window-triggered signal, specified as a nonnegative scalar.

**Dependency**

To enable this property, set **Type** to "transition" or "window".

**Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, specify a nonnegative scalar in the **Max Time (s)** box.

To enable this property, set **Type** to Transition or Window.

Data Types: double

**Timeout — Timeout duration**

0 (default) | nonnegative scalar

Timeout duration for a timeout-triggered signal, specified as a nonnegative scalar.

**Dependency**

To enable this property, set **Type** to "timeout".

**Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Level Settings**, specify a nonnegative scalar in the **Timeout (s)** box.

To enable this property, set **Type** to Timeout.

Data Types: double

**Delay — Trigger offset**

0 (default) | real scalar

Trigger offset in seconds, specified as a finite real scalar.

**Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Delay/Holdoff**, specify a real scalar in the **Delay (s)** box.

Data Types: double

**Holdoff — Minimum time between triggers**

0 (default) | nonnegative scalar

Minimum time between trigger events, specified as a finite nonnegative scalar.

**Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Settings**. Under **Delay/Holdoff**, specify a nonnegative scalar in the **Holdoff (s)** box.

Data Types: double

**Channel — Trigger channel**

1 (default) | positive integer

Trigger channel, specified as a positive integer.

**Scope Window Use**

On the **Measurements** tab, in the **Measurements** section, select a channel.

Data Types: double

**Enabled — Enable trigger**

false (default) | true

Enable trigger, specified as true or false. Set this property to true to enable trigger.

**Scope Window Use**

On the **Measurements** tab, in the **Trigger** section, click **Enable Trigger**.

Data Types: logical

**Examples****Enable Trigger Programmatically in Time Scope MATLAB Object**

View a sine wave in the Time Scope window. This sine wave is streaming constantly in the display and cannot be captured without stabilization. To stabilize the sine wave, enable a trigger event programmatically on the scope display using the Enabled property of the TriggerConfiguration object. Alternatively, you can enable the trigger by clicking the **Enable Trigger** button on the **Measurements** tab of the toolbar.

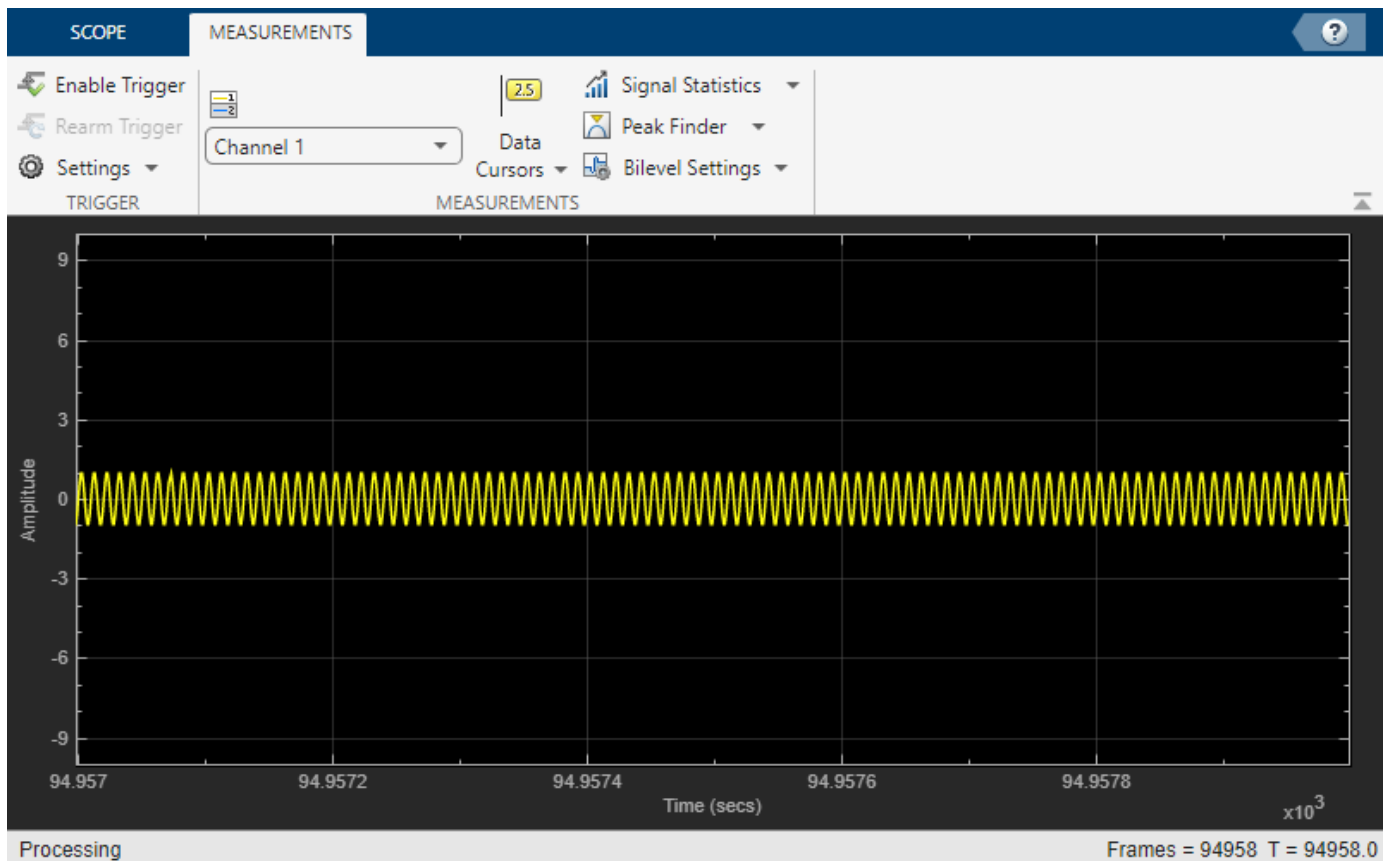

**Create Sine Wave**

Create the input sine wave using the sin function. Create a timescope MATLAB object to display the signal. Set the TimeSpan property to 1 second.

```
f = 100;  
fs = 1000;  
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';  
scopeNoTrigger = timescope(SampleRate=fs,...  
    TimeSpanSource="property", ...  
    TimeSpan=1);
```

Display the sine wave in the scope. You can see that the signal in the scope is constantly moving.

```
while(1)  
    scopeNoTrigger(swv)  
end  
release(scopeNoTrigger)
```

## Enable Trigger

Now enable a trigger event to stabilize the signal.

You can enable the trigger event in the scope during simulation or enable the trigger event programmatically when creating the object.

To use the programmatic approach, create another `timescope` object and enable the trigger event programmatically while creating the object.

```
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
scope.Trigger.Enabled = true;
scope.Trigger.Type = "transition";
scope.Trigger
```

TriggerConfiguration with properties:

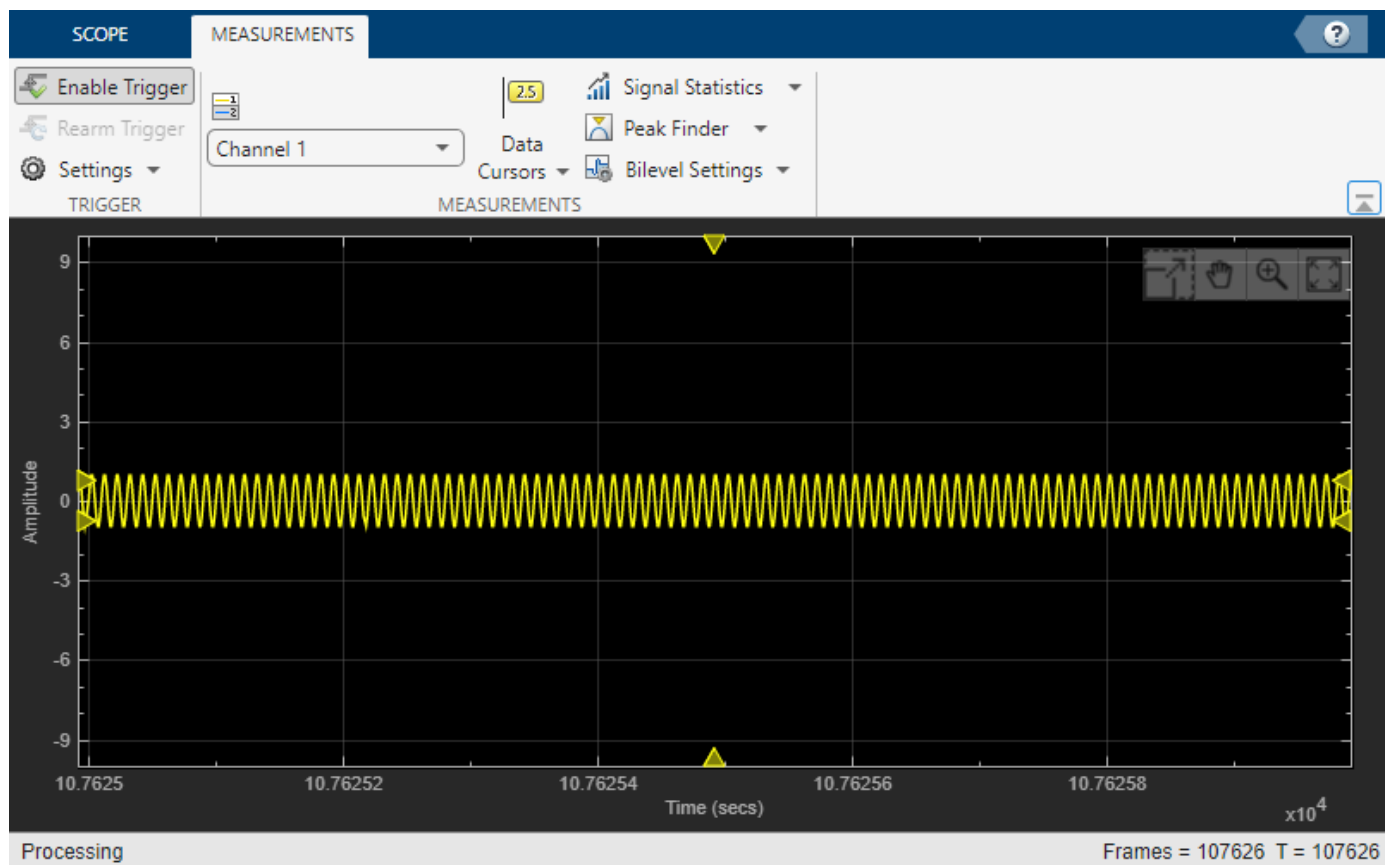

```
Mode: 'auto'
Type: 'transition'
Polarity: 'rise-time'
AutoLevel: 1
Position: 50
LowLevel: 0.2000
HighLevel: 2.3000
MinDuration: 0
```

```
MaxDuration: Inf
Delay: 0
Holdoff: 0
Channel: 1
Enabled: 1
```

Stream in the sine wave signal again.

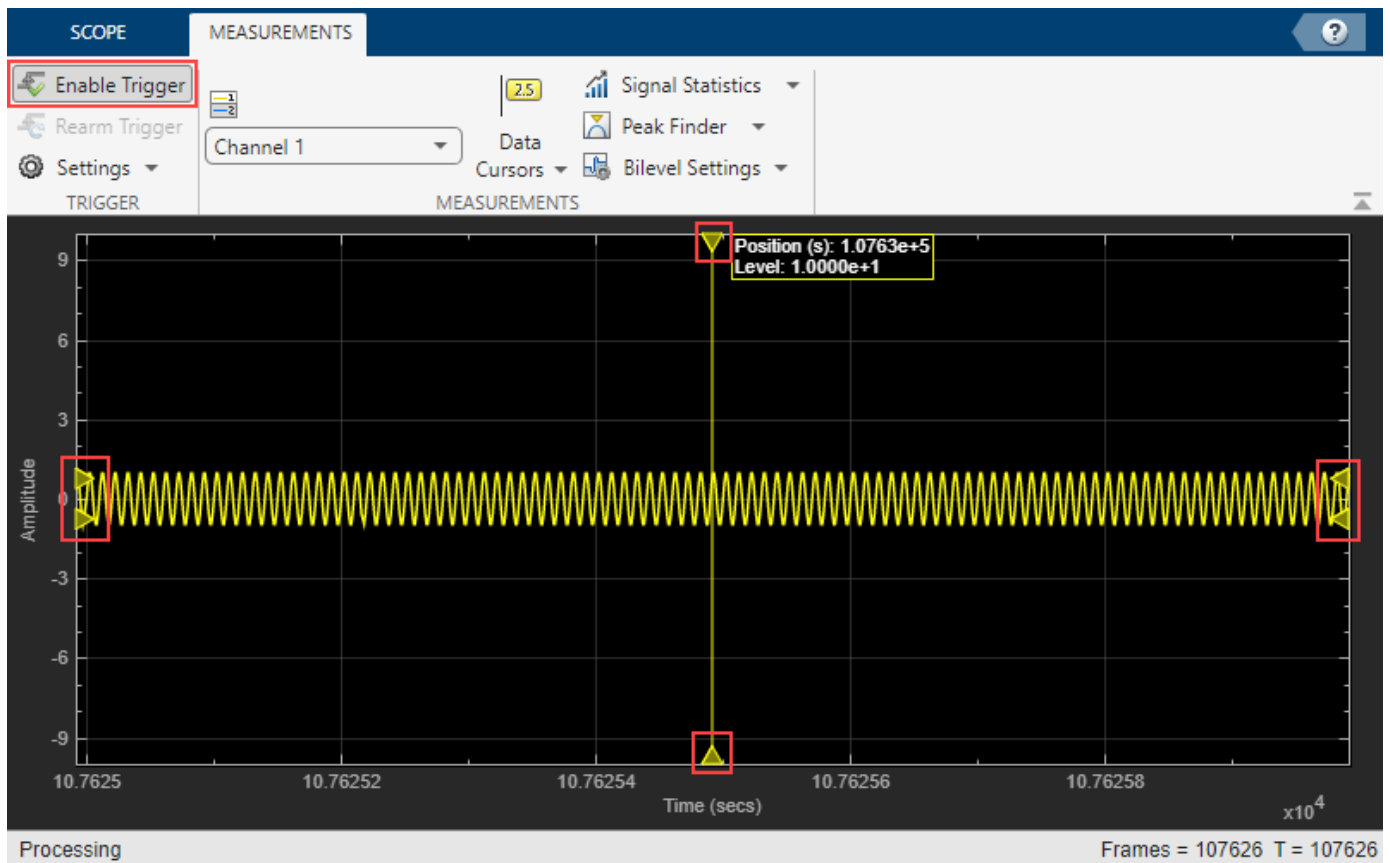

```
while(1)
    scope(svw)
end
release(scope)
```

The display freezes once you enable the trigger.

The triangle markers show the trigger positions and levels. For more information on the trigger, hover over the triangle.

## ChannelMeasurementsConfiguration

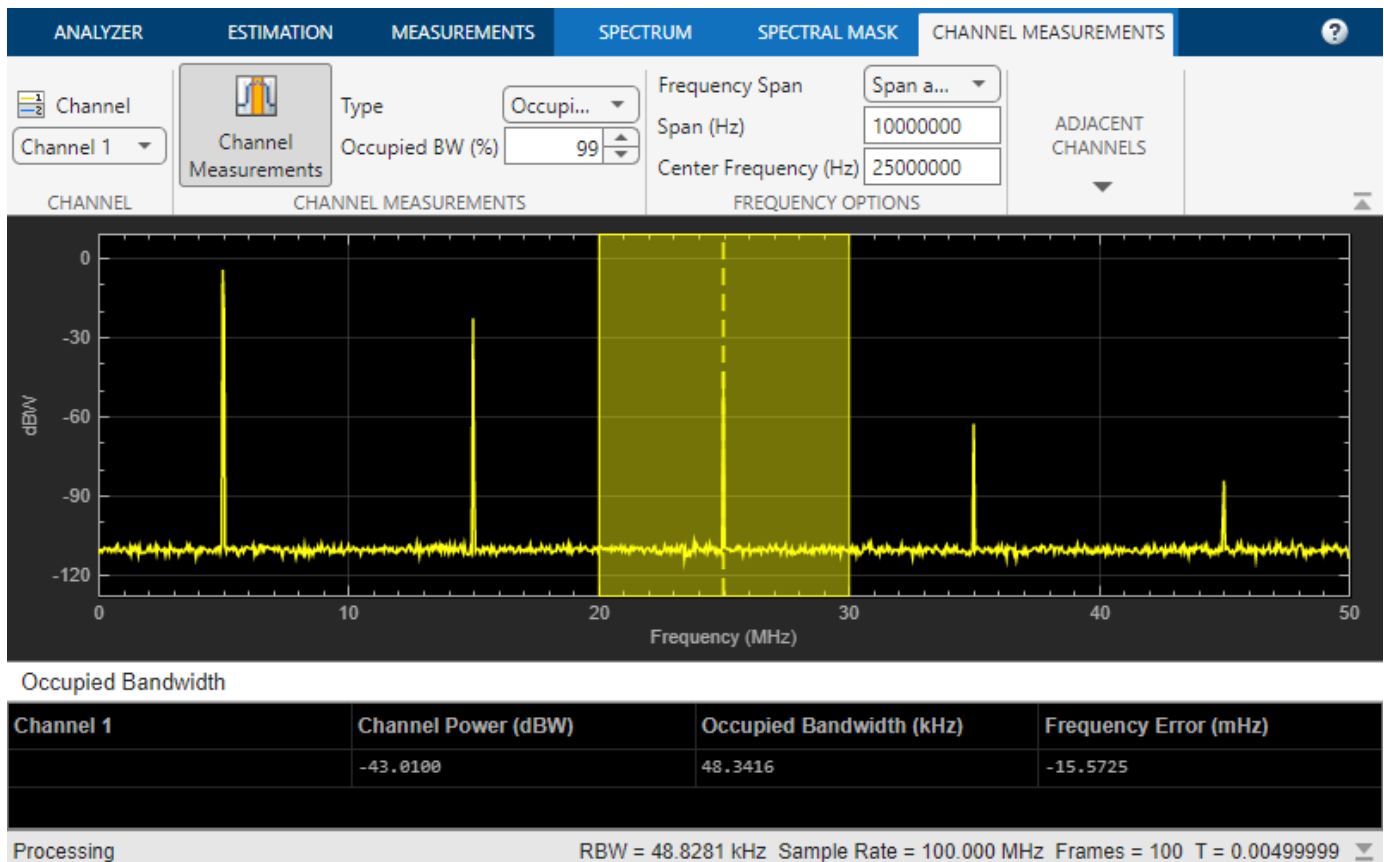

Compute and display occupied bandwidth or adjacent channel power ratio on the Spectrum Analyzer

### Description

Use the ChannelMeasurementsConfiguration object to compute and display the occupied bandwidth or adjacent channel power ratio on the Spectrum Analyzer.

You can specify the occupied bandwidth or adjacent channel power ratio (ACPR) settings, frequency span, center frequency, and start and stop frequencies, and control the channel measurement settings from the Spectrum Analyzer toolstrip or from the command line. Both the spectrumAnalyzer object and the SpectrumAnalyzerConfiguration object support the ChannelMeasurementsConfiguration object in the command line.

To modify the channel measurement settings on the Spectrum Analyzer toolstrip, click the **Channel Measurements** tab.

## Creation

### Syntax

```
channMeas = ChannelMeasurementsConfiguration()
```

### Description

`channMeas = ChannelMeasurementsConfiguration()` creates a channel measurements configuration object `channMeas`.

### Properties

All properties are tunable.

#### Type — Type of measurement data to display

"occupied-bandwidth" (default) | "acpr"

Type of measurement data to display, specified as either "occupied-bandwidth" or "acpr".

#### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to either Occupied BW or ACPR.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: char | string

### FrequencySpan — Frequency span mode

"span-and-center-frequency" (default) | "start-and-stop-frequencies"

Frequency span mode, specified as one of the following:

- "span-and-center-frequency" -- Measure over a frequency range specified in Span Hz and around the frequency value specified in CenterFrequency property.
- "start-and-stop-frequencies" -- Measure over the frequency range [StartFrequency, StopFrequency].

#### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to either Span and Center Frequency or Start and Stop Frequencies.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: char | string

### Span — Frequency span

2000 (default) | positive scalar

Frequency span over which the object computes the channel measurements, specified as a positive scalar in Hz.

#### Dependency

To enable this property, set the FrequencySpan property to "span-and-center-frequency".

#### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Span and Center Frequency and **Span (Hz)** to a positive scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### CenterFrequency — Center frequency of span

0 (default) | real scalar

Center frequency of the span over which the object computes the channel measurements, specified as a real scalar in Hz.

#### Dependency

To enable this property, set the FrequencySpan property to "span-and-center-frequency".

#### Scope Window Use

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Span and Center Frequency and **Center Frequency (Hz)** to a real scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### **StartFrequency — Start frequency**

-1000 (default) | real scalar

Start frequency over which the object computes the channel measurements, specified as a real scalar in Hz.

#### **Dependency**

To enable this property, set the FrequencySpan property to "start-and-stop-frequencies".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Start Frequency (Hz)** to a real scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### **StopFrequency — Stop frequency**

1000 (default) | real scalar

Stop frequency over which the object computes the channel measurements, specified as a real scalar in Hz.

#### **Dependency**

To enable this property, set the FrequencySpan property to "start-and-stop-frequencies".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Frequency Options** section, set **Frequency Span** to Start and Stop Frequencies and **Stop Frequency (Hz)** to a real scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### **PercentOccupiedBW — Percentage of power to compute occupied bandwidth**

99 (default) | positive scalar

Percentage of power over which the object computes the occupied bandwidth, specified as a positive scalar.

#### **Dependency**

To enable this property, set the Type property to "occupied-bandwidth".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to Occupied BW and **Occupied BW (%)** to a positive scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### **AdjacentBW — Adjacent channel bandwidth**

1000 (default) | positive scalar

Adjacent channel bandwidth, specified as a positive scalar.

#### **Dependency**

To enable this property, set the Type property to "acpr".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to ACPR. In the **Adjacent Channels** section, set **Adjacent BW (Hz)** to a positive scalar.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

### **FilterShape — Filter shape**

"none" (default) | "gaussian" | "rrc"

Filter shape for main and adjacent channels, specified as "none", "gaussian", or "rrc".

#### **Dependency**

To enable this property, set the Type property to "acpr".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to ACPR. In the **Adjacent Channels** section, set **Filter Shape**.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: char | string

### **FilterCoeff — Channel filter coefficient**

0.5 (default) | real scalar in range [0, 1]

Channel filter coefficient, specified as a real scalar in the range [0, 1].

#### **Dependency**

To enable this property, set the Type property to "acpr" and the FilterShape property to either "gaussian" or "rrc".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to ACPR.

In the **Adjacent Channels** section, set:

- **Filter Shape** to RRC and specify **Roll-off Factor** as a real scalar in the range [0,1].
- **Filter Shape** to Gaussian and specify **BT Product** as a real scalar in the range [0,1].

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

#### **NumOffsets — Number of adjacent channel pairs**

2 (default) | positive integer in range [1, 12]

Number of adjacent channel pairs, specified as a positive integer in the range [1, 12].

#### **Dependency**

To enable this property, set the Type property to "acpr".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to ACPR. In the **Adjacent Channels** section, set **Num Pairs** to a positive integer in the range [1, 12].

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

#### **ACPROffsets — Frequency of adjacent channel relative to center frequency of main channel**

[2000 3500] (default) | vector

Frequency of the adjacent channel relative to the center frequency of the main channel, specified as a real vector of length equal to the number of offset pairs specified in NumOffsets.

#### **Dependency**

To enable this property, set the Type property to "acpr".

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, set **Type** to ACPR. In the **Adjacent Channels** section, set **Offset (Hz)**.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

#### **Enabled — Channel measurements flag**

false (default) | true

Channel measurements flag, specified as true or false.

#### **Scope Window Use**

Click the **Channel Measurements** tab on the Spectrum Analyzer toolstrip. In the **Channel Measurements** section, select **Channel Measurements**.

The **Channel Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: logical

## **Examples**

### Obtain Measurements Data Programmatically for spectrumAnalyzer object

Compute and display the power spectrum of a noisy sinusoidal input signal using the spectrumAnalyzer MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- PeakFinder
- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements

#### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two dsp.SinWave System objects to generate these two frequencies. Create a spectrumAnalyzer object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SinWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SinWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
    PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...
    YLimits=[-120 40],ShowLegend=true);
```

#### Enable Measurements Data

To obtain the measurements, set the Enabled property to true.

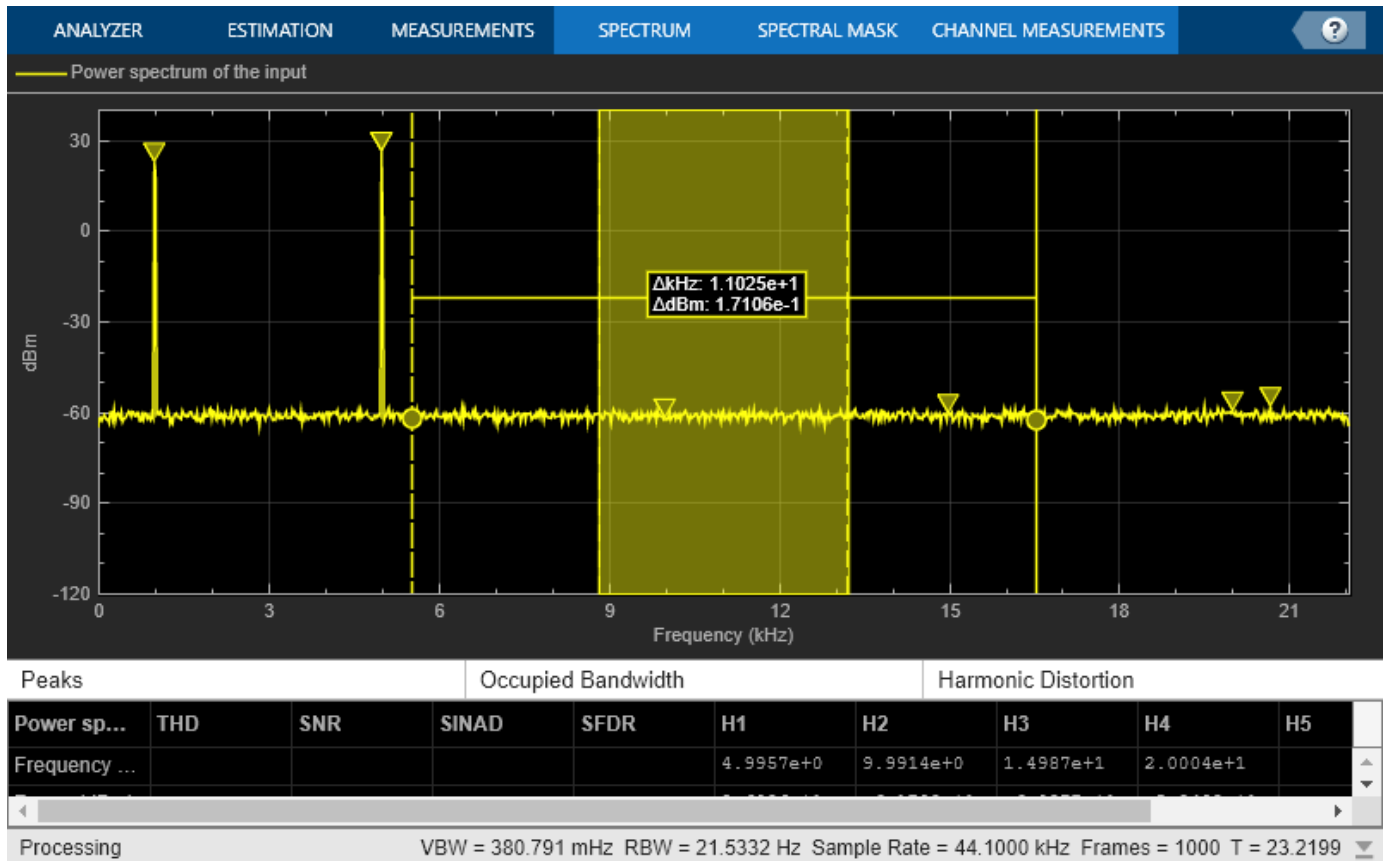

```
SA.CursorMeasurements.Enabled = true;
SA.ChannelMeasurements.Enabled = true;
SA.PeakFinder.Enabled = true;
SA.DistortionMeasurements.Enabled = true;
```

#### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrumAnalyzer object. Measure the characteristics of the spectrum. Use the getMeasurementsData function to obtain these measurements programmatically. The isNewDataReady function returns true when there is new spectrum data. Store the measured data in the variable data.

```
data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    NoisyInput = Input + 0.001*randn(1024,1);
    SA(NoisyInput);
    if SA.isNewDataReady
        data = [data;getMeasurementsData(SA)];
    end
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

Use the `PeakFinder` property to obtain peak values. Verify that the peak values in the last time step of `data` match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3x1
```

```
26.3957
22.7830
-57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```

# CursorMeasurementsConfiguration

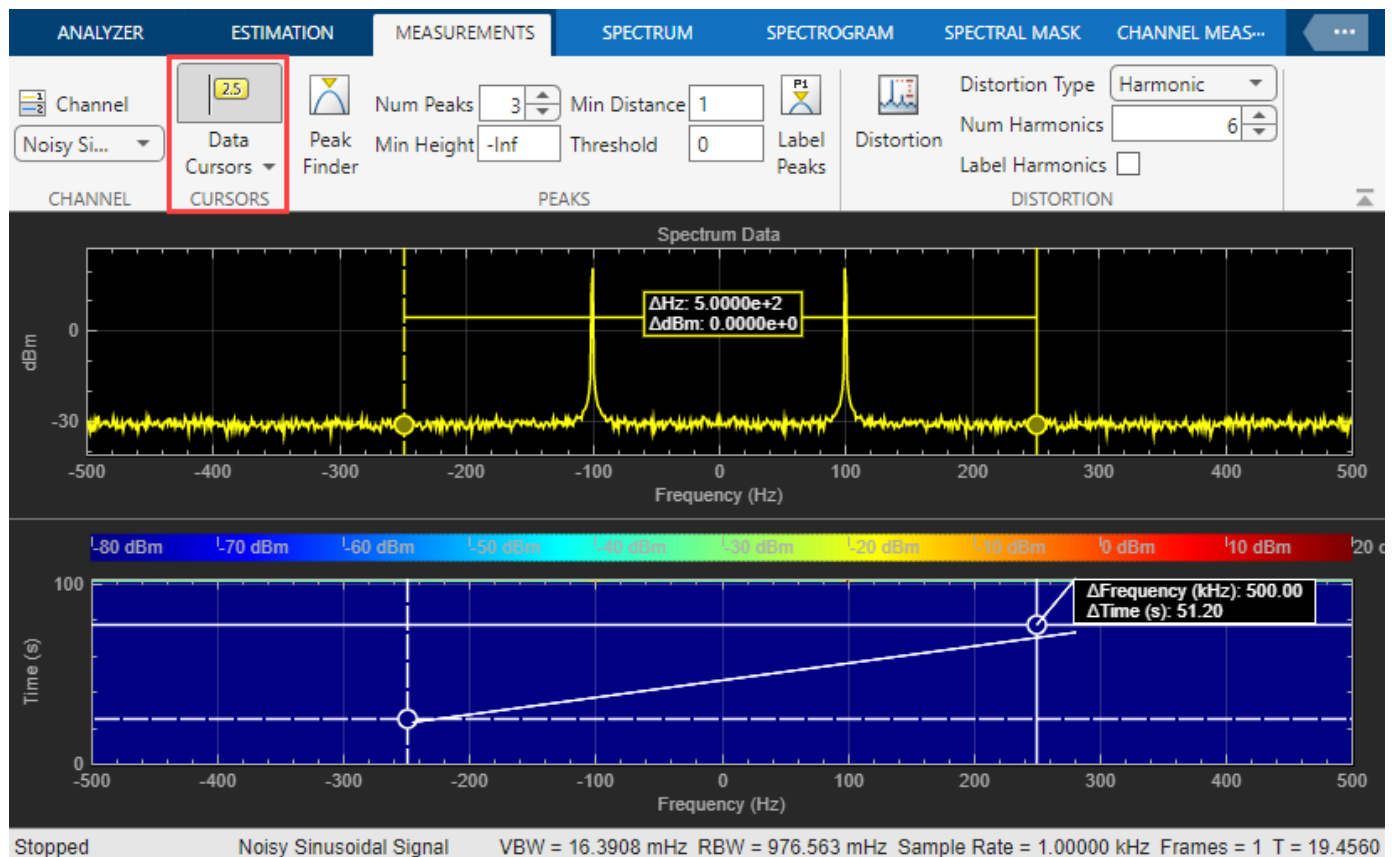

Measure signal values using vertical waveform cursors that track along the signal

## Description

Use the CursorMeasurementsConfiguration object to enable waveform cursors. You can control the cursor settings from the toolbar of the scope or from the command line.

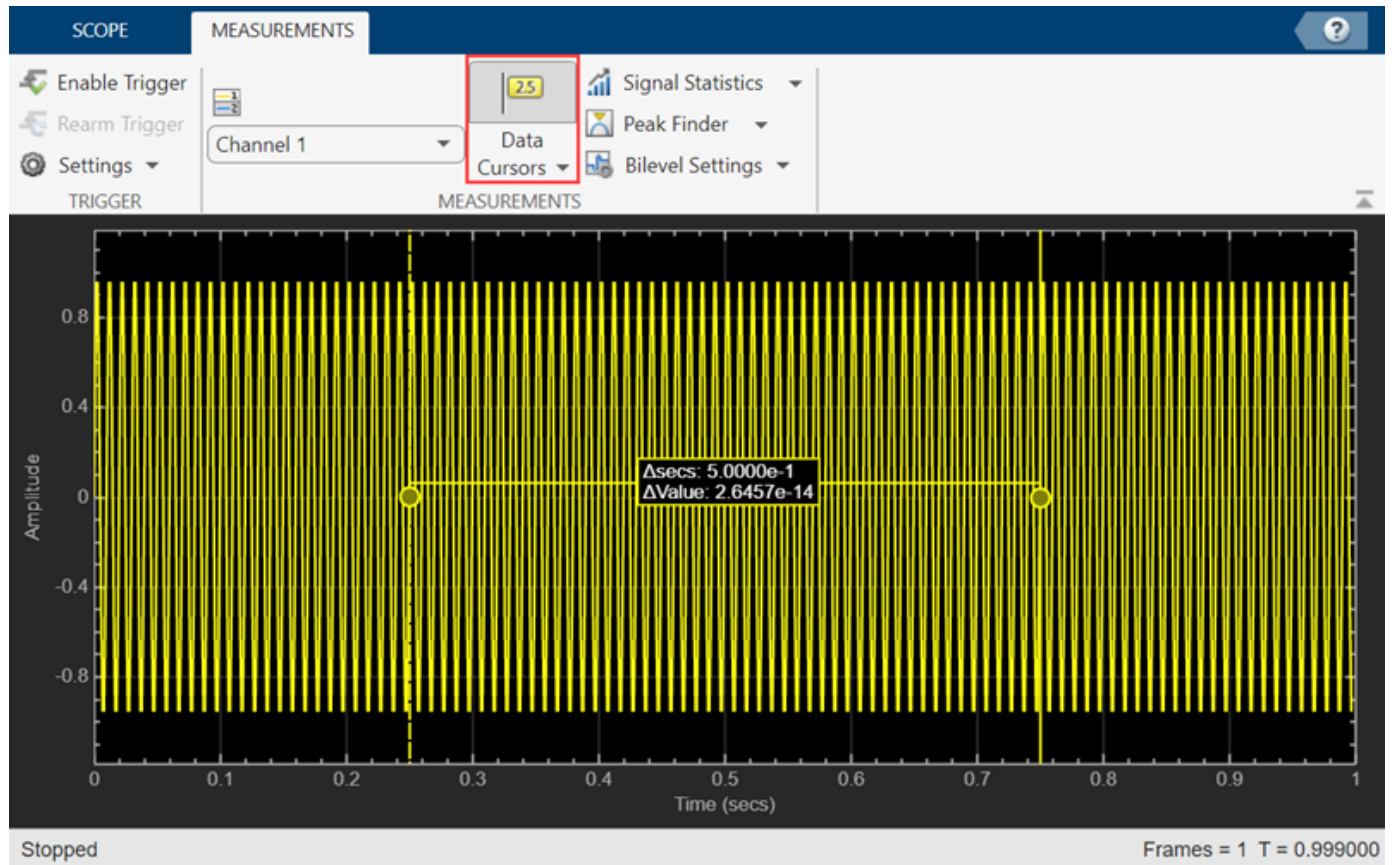

To display vertical cursors on each signal and to modify the cursor settings in the scope UI, click the **Measurements** tab and enable **Data Cursors**. Each cursor tracks a vertical line along the signal. The scope displays the difference between x- and y-values of the signal at the two cursors in the box between the cursors. The cursors appear only when the scope has at least one signal in its display. You can use the mouse to move the vertical cursors left and right.

### Spectrum Analyzer Toolstrip

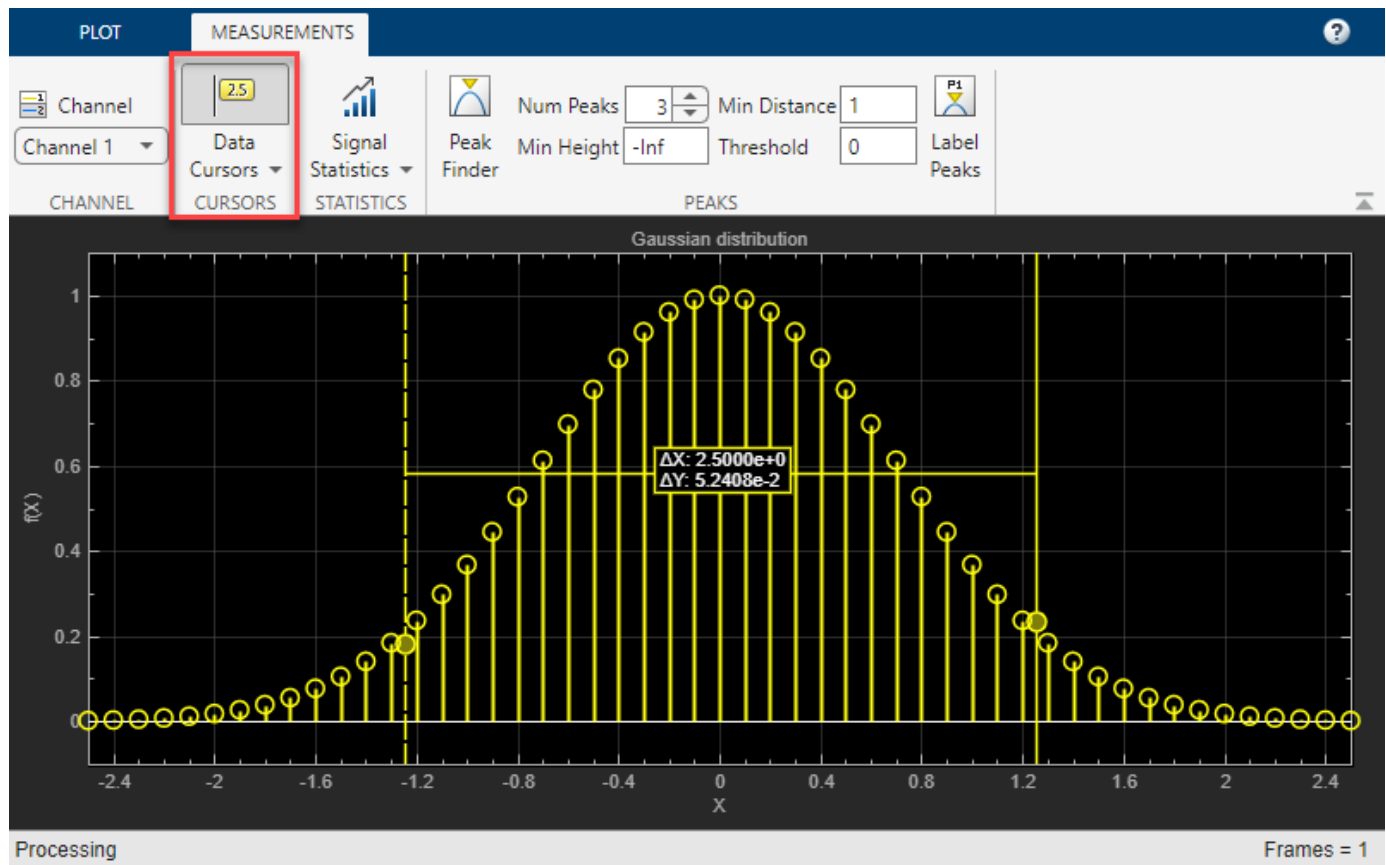

### Time Scope Toolstrip

## 4 System Objects

Array Plot Toolstrip

Dynamic Filter Visualizer Toolstrip

## Creation

### Syntax

```
cursormeas = CursorMeasurementsConfiguration()
```

### Description

`cursormeas = CursorMeasurementsConfiguration()` creates a cursor measurements configuration object.

### Properties

All properties are tunable.

#### XLocation — x-coordinates of the cursors

[2 8] (default) | two-element vector

x-coordinates of the cursors, specified as a two-element vector of real numbers.

**Scope Window Use**

On the **Measurements** tab, select **Data Cursors** and then click **Data Cursors** to specify the two elements in X location properties.

Data Types: `double`

**SnapToData — Position cursors on signal data points**

`false` (default) | `true`

Position cursors on the signal data points, specified as `true` or `false`.

**Scope Window Use**

On the **Measurements** tab, select **Data Cursors** and then click **Data Cursors** to select **Snap to data**.

Data Types: `logical`

**LockSpacing — Lock spacing between cursors**

`false` (default) | `true`

Lock spacing between cursors, specified as `true` or `false`. Set this property to `true` to lock the frequency difference between the cursors.

**Scope Window Use**

On the **Measurements** tab, select **Data Cursors** and then click **Data Cursors** to select **Lock cursor spacing**.

Data Types: `logical`

**Enabled — Enable cursor measurements**

`false` (default) | `true`

Enable cursor measurements, specified as `true` or `false`. Set this property to `true` to enable cursor measurements.

**Scope Window Use**

On the **Measurements** tab, select **Data Cursors**.

Data Types: `logical`

**Examples****Configure Cursor Measurements Programmatically in Time Scope MATLAB Object**

Create a sine wave and view it in the Time Scope. Enable data cursors programmatically.

**Initialization**

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

```
f = 100;
fs = 1000;
```

```
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';
scope = timescope(SampleRate=fs,...
    TimeSpanSource="property",...
    TimeSpan=1);
```

### Data Cursors

Enable data cursors in the scope programmatically by setting the Enabled property of the CursorMeasurementsConfiguration object to true.

```
scope.CursorMeasurements.Enabled = true;
scope(swv);
release(scope)
```

### Obtain Measurements Data Programmatically for spectrumAnalyzer object

Compute and display the power spectrum of a noisy sinusoidal input signal using the spectrumAnalyzer MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- PeakFinder
- CursorMeasurements
- ChannelMeasurements

- DistortionMeasurements

### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two `dsp.SineWave` System objects to generate these two frequencies. Create a `spectrumAnalyzer` object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SineWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SineWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
    PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...
    YLimits=[-120 40],ShowLegend=true);
```

### Enable Measurements Data

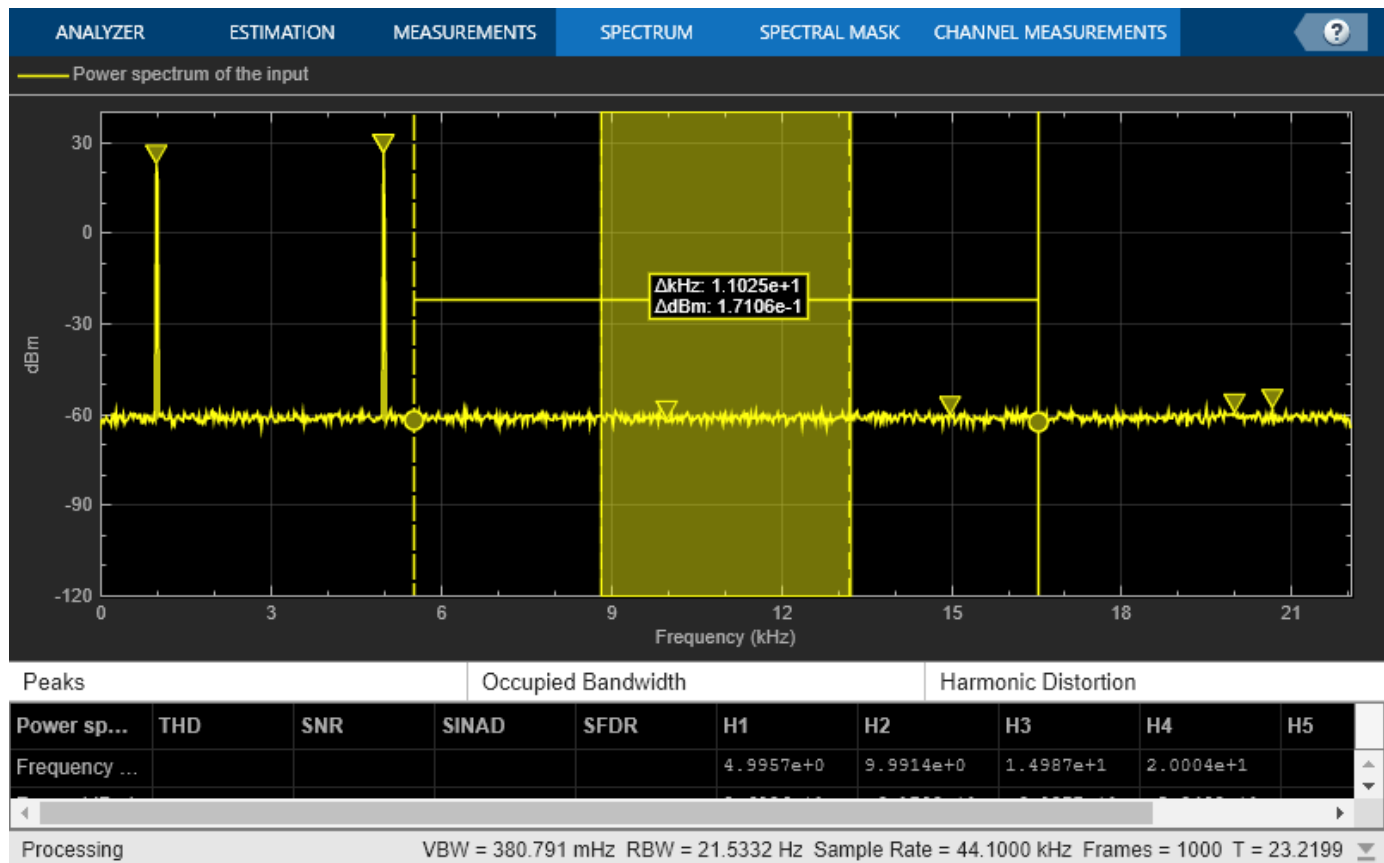

To obtain the measurements, set the `Enabled` property to `true`.

```
SA.CursorMeasurements.Enabled = true;
SA.ChannelMeasurements.Enabled = true;
SA.PeakFinder.Enabled = true;
SA.DistortionMeasurements.Enabled = true;
```

### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the `spectrumAnalyzer` object. Measure the characteristics of the spectrum. Use the `getMeasurementsData` function to obtain these measurements programmatically. The `isNewDataReady` function returns `true` when there is new spectrum data. Store the measured data in the variable `data`.

```
data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    NoisyInput = Input + 0.001*randn(1024,1);
    SA(NoisyInput);
    if SA.isNewDataReady
        data = [data;getMeasurementsData(SA)];
    end
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of data to obtain the various measurements programmatically.

### Compare Peak Values

Use the PeakFinder property to obtain peak values. Verify that the peak values in the last time step of data match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3×1
```

```
26.3957
22.7830
-57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3×1
```

```
4.9957
0.9905
20.6719
```

## Obtain Measurements Data Programmatically for Spectrum Analyzer Block

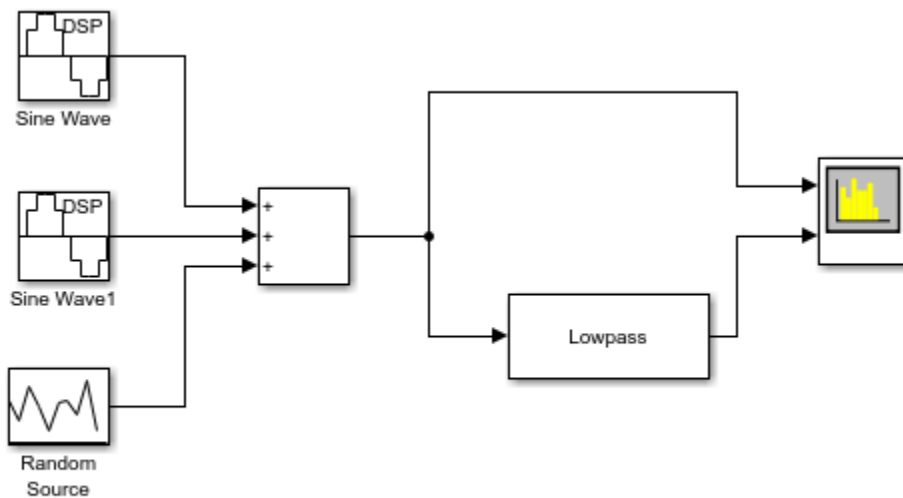

Compute and display the power spectrum of a noisy sinusoidal input signal using the Spectrum Analyzer block. Measure the cursor placements, adjacent channel power ratio, distortion, and peak values in the spectrum by enabling these block configuration properties:

- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements
- PeakFinder

## Open and Inspect the Model

Filter a streaming noisy sinusoidal input signal using a Lowpass Filter block. The input signal consists of two sinusoidal tones: 1 kHz and 15 kHz. The noise is white Gaussian noise with a mean of 0 and a variance of 0.05. The sampling frequency is 44.1 kHz. Open the model and inspect the parameter values in the blocks.

```
model = 'spectrumanalyzer_measurements.slx';
open_system(model)
```

Copyright 2018-2022 The MathWorks, Inc.

Access the configuration properties of the Spectrum Analyzer block using the `get_param` function.

```
sablock = 'spectrumanalyzer_measurements/Spectrum Analyzer';
cfg = get_param(sablock, 'ScopeConfiguration');
```

## Enable Measurements Data

To obtain the measurements, set the Enabled property to true.

```
cfg.CursorMeasurements.Enabled = true;
cfg.ChannelMeasurements.Enabled = true;
cfg.DistortionMeasurements.Enabled = true;
cfg.PeakFinder.Enabled = true;
```

## Simulate the Model

Run the model. The Spectrum Analyzer block compares the original spectrum with the filtered spectrum.

```
sim(model)
```

The panes at the bottom of the spectrum analyzer window display the measurements that you have enabled.

### Use `getMeasurementsData` function

Use the `getMeasurementsData` function to obtain the measurements programmatically.

```
data = getMeasurementsData(cfg)
```

```
data =
```

```
1x5 table
```

```
SimulationTime
```

## Version History

### Introduced in R2022a

#### R2022b: Enhancements to Data Cursor Measurements

Starting in R2022b, the `CursorMeasurementsConfiguration` object has a new `LockSpacing` property. Use this property to lock the spacing between waveform cursors in the scope window.

In the **Measurements** tab of the scope UI window, these data cursor settings are new:

- **Lock cursor spacing** -- This setting corresponds to the `LockSpacing` property in the `CursorMeasurementsConfiguration` object.
- **X location** -- These fields are enabled and correspond to the `XLocation` property in the `CursorMeasurementsConfiguration` object.

#### R2022b: Support for waveform cursors in spectrogram mode

Starting in R2022b, the Spectrum Analyzer supports data cursors even when the scope shows only the spectrogram display.

In the command line, you can edit the `CursorMeasurementsConfiguration` object when you set the `ViewType` property of the `spectrumAnalyzer` object to "spectrogram".

#### R2023a: Support for Spectrum Analyzer block

The `SpectrumAnalyzerConfiguration` object now supports the `CursorMeasurementsConfiguration` object. The `CursorMeasurementsConfiguration` object enables you to obtain and modify the cursor measurements of the Spectrum Analyzer block programmatically from the command line.

# DistortionMeasurementsConfiguration

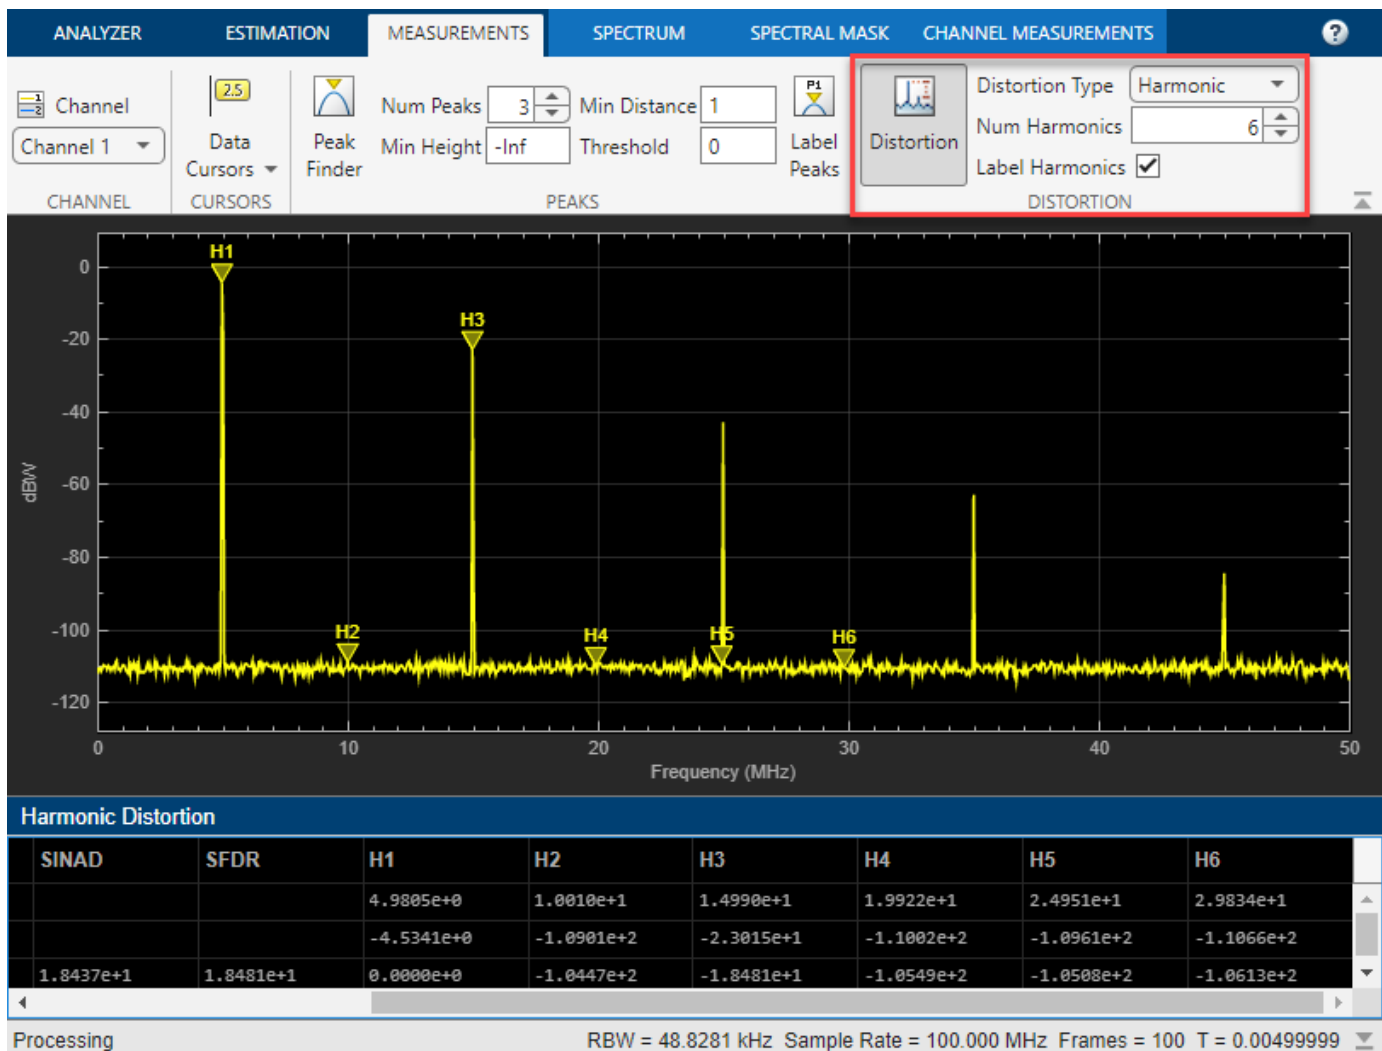

Compute and display harmonic and intermodulation distortion

## Description

Use the `DistortionMeasurementsConfiguration` object to compute and display harmonic and intermodulation distortion.

You can specify the distortion type, number of harmonics, and label the harmonics. You can control the distortion settings from the Spectrum Analyzer toolstrip or from the command line. Both the `spectrumAnalyzer` object and the `SpectrumAnalyzerConfiguration` object support the `DistortionMeasurementsConfiguration` object in the command line.

To modify the distortion settings in the Spectrum Analyzer toolstrip, click the **Measurements** tab and edit the settings in the **Distortion** section.

## Creation

### Syntax

```
distmeas = DistortionMeasurementsConfiguration()
```

### Description

`distmeas = DistortionMeasurementsConfiguration()` creates a distortion measurements configuration object `distmeas`.

### Properties

All properties are tunable.

#### Type — Type of measurement to display

"harmonic" (default) | "intermodulation"

Type of measurement data to display, specified as "harmonic" or "intermodulation".

#### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Distortion** section, set **Distortion Type** to Harmonic or Intermodulation.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: char | string

#### NumHarmonics — Number of harmonics to measure

6 (default) | positive integer

Number of harmonics to measure, specified as a positive integer less than or equal to 99.

#### Dependency

To enable this property, set Type to "harmonic".

#### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Distortion** section, set **Num Harmonics** to a positive integer less than or equal to 99.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: double

#### LabelValues — Label values

false (default) | true

Label harmonics (for harmonic distortion) and frequencies (for intermodulation distortion), specified as true or false.

#### Scope Window Use

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Distortion** section, select **Label Harmonics**.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

#### **Enabled — Enable distortion measurements**

`false` (default) | `true`

Enable distortion measurements, specified as `true` or `false`.

#### **Scope Window Use**

Click the **Measurements** tab on the Spectrum Analyzer toolstrip. In the **Distortion** section, select **Distortion**.

The **Measurements** tab appears when you select **Spectrum** in the **Analyzer** tab.

Data Types: `logical`

## **Examples**

### **Obtain Measurements Data Programmatically for spectrumAnalyzer object**

Compute and display the power spectrum of a noisy sinusoidal input signal using the `spectrumAnalyzer` MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- `PeakFinder`
- `CursorMeasurements`
- `ChannelMeasurements`
- `DistortionMeasurements`

#### **Initialization**

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two `dsp.SineWave` System objects to generate these two frequencies. Create a `spectrumAnalyzer` object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SineWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SineWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
    PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...
    YLimits=[-120 40],ShowLegend=true);
```

#### **Enable Measurements Data**

To obtain the measurements, set the `Enabled` property to `true`.

```
SA.CursorMeasurements.Enabled = true;
SA.ChannelMeasurements.Enabled = true;
SA.PeakFinder.Enabled = true;
SA.DistortionMeasurements.Enabled = true;
```

### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrumAnalyzer object. Measure the characteristics of the spectrum. Use the getMeasurementsData function to obtain these measurements programmatically. The isNewDataReady function returns true when there is new spectrum data. Store the measured data in the variable data.

```
data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    NoisyInput = Input + 0.001*randn(1024,1);
    SA(NoisyInput);
    if SA.isNewDataReady
        data = [data;getMeasurementsData(SA)];
    end
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of data to obtain the various measurements programmatically.

## Compare Peak Values

Use the `PeakFinder` property to obtain peak values. Verify that the peak values in the last time step of data match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3×1
```

```
    26.3957
```

```
    22.7830
```

```
   -57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3×1
```

```
    4.9957
```

```
    0.9905
```

```
   20.6719
```

## Version History

**Introduced in R2022a**

### **R2023a: Support for Spectrum Analyzer block**

The `SpectrumAnalyzerConfiguration` object now supports the `DistortionMeasurementsConfiguration` object. The `DistortionMeasurementsConfiguration` object enables you to obtain and modify the distortion measurements of the Spectrum Analyzer block programmatically from the command line. For more details, see “DistortionMeasurements” on page 4-0 .

## See Also

`spectrumAnalyzer` | `SpectrumAnalyzerConfiguration`

## PeakFinderConfiguration

Compute and display the largest calculated peak values on the scope display

### Description

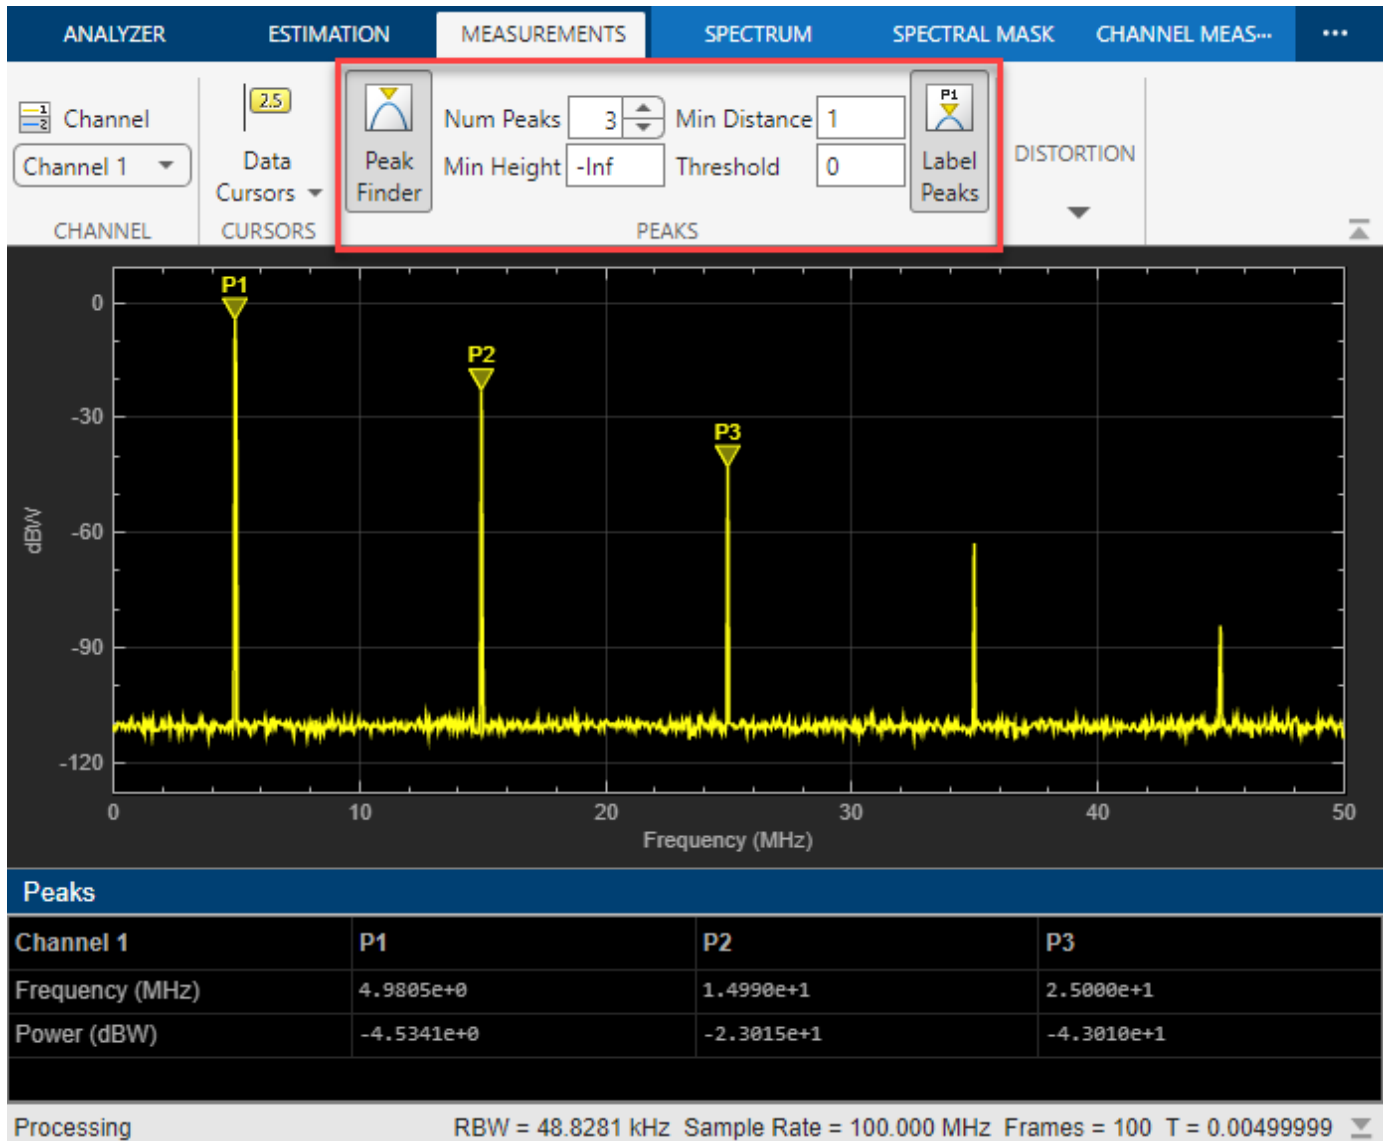

Use the `PeakFinderConfiguration` object to compute and display peaks in the scope. The scope computes and displays peaks for only the portion of the input signal that is currently on display in the scope.

You can specify the number of peaks you want the scope to display, the minimum height above which you want the scope to detect peaks, the minimum distance between peaks, and label the peaks. You can control the peak finder settings from the scope toolbar or from the command line. The algorithm defines a peak as a local maximum with lower values present on either side of the peak. It does not consider end points as peaks. For more information on the algorithm, see the `findpeaks` function.

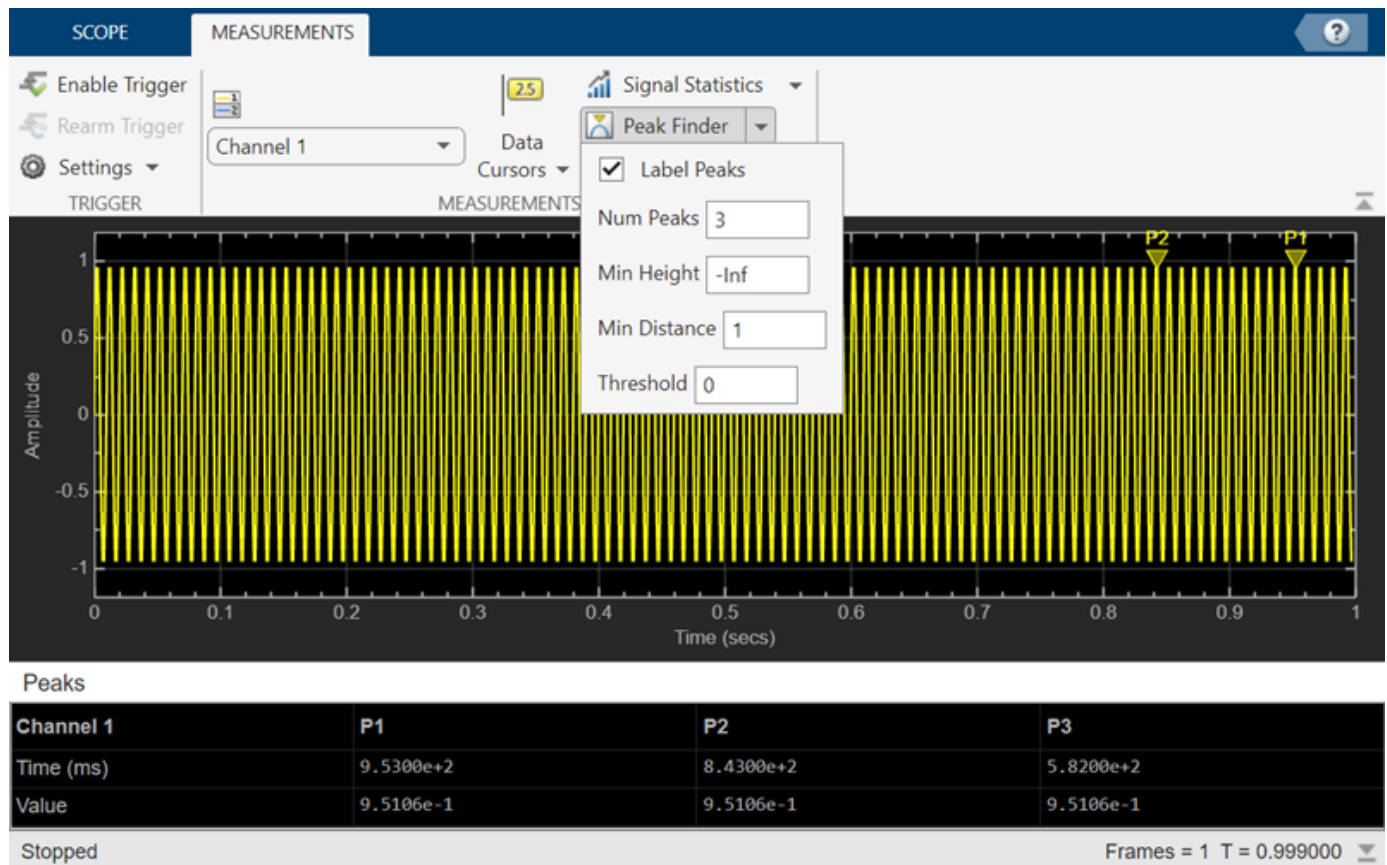

To modify the peak finder settings in the scope interface, click the **Measurements** tab and enable **Peak Finder**. Once you enable the **Peak Finder**, an arrow appears on the plot at each maxima and a Peaks panel appears at the bottom of the scope window.

The `SpectrumAnalyzerConfiguration` object supports the `PeakFinderConfiguration` object in the command line.

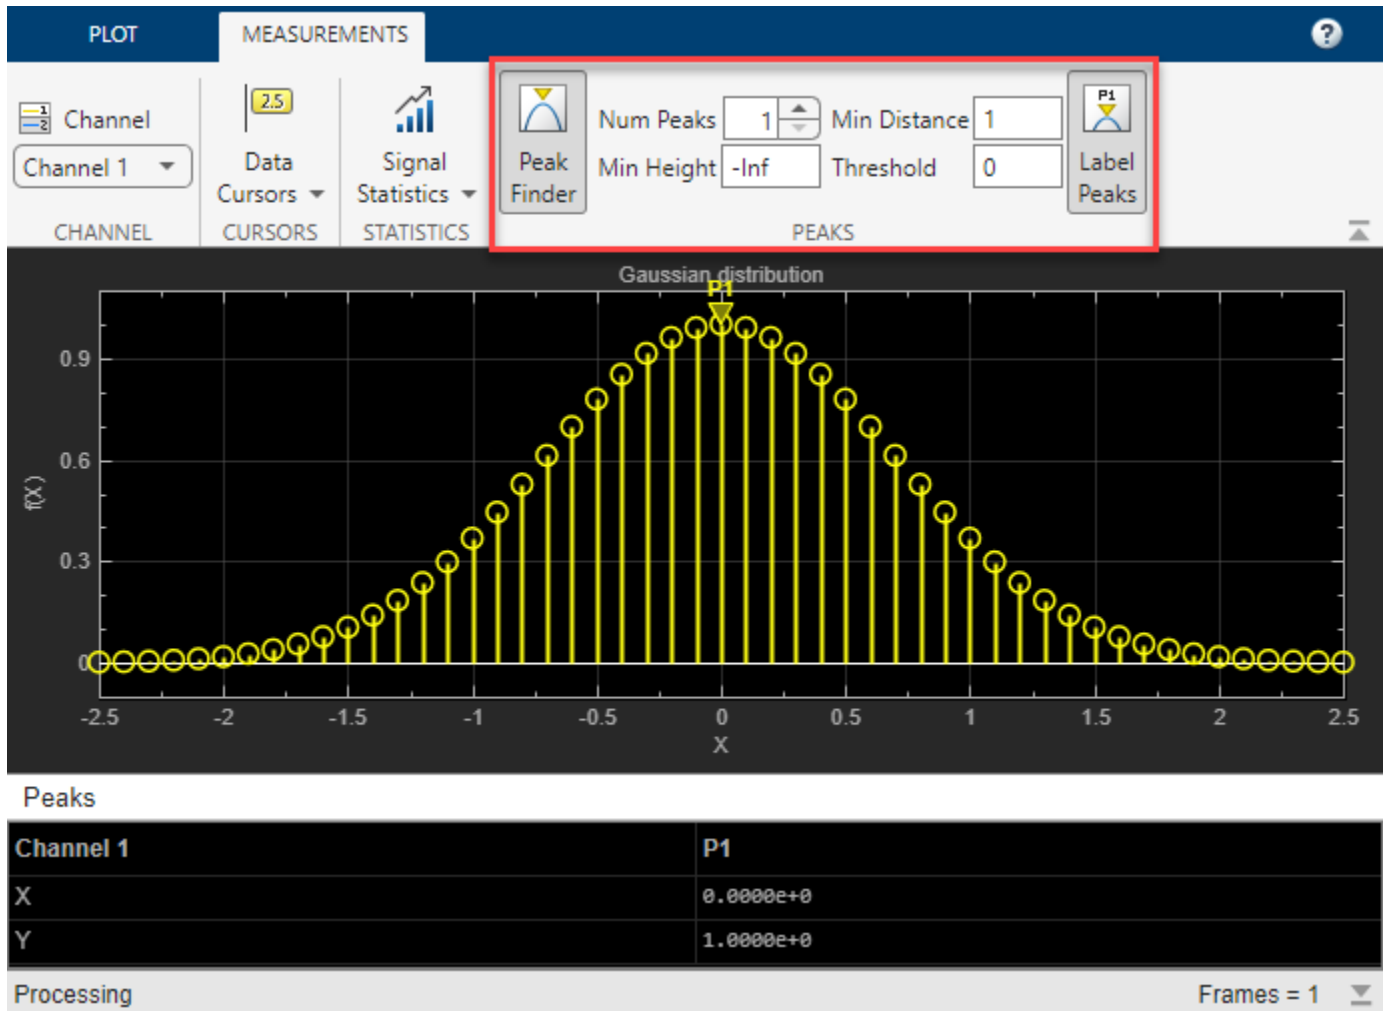

### Spectrum Analyzer Toolbar

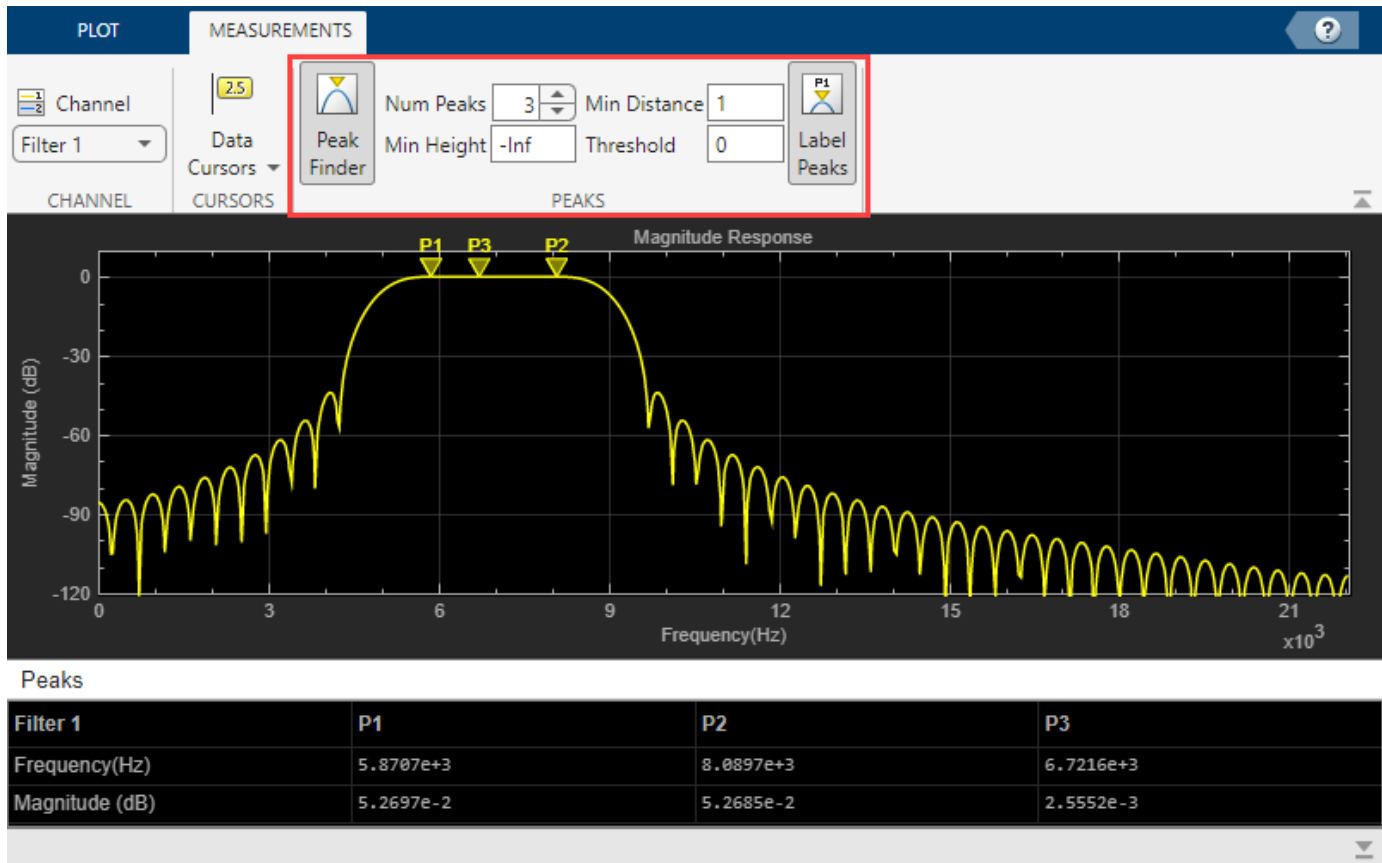

### Time Scope Toolstrip

**Array Plot Toolstrip**

### Dynamic Filter Visualizer Toolstrip

## Creation

### Syntax

```
pkfinder = PeakFinderConfiguration()
```

### Description

`pkfinder = PeakFinderConfiguration()` creates a peak finder configuration object.

### Properties

All properties are tunable.

#### MinHeight — Level above which scope detects peaks

-Inf (default) | real scalar value

Level above which the scope detects peaks, specified as a real scalar.

#### Scope Window Use

On the **Measurements** tab, select **Peak Finder**. In the peak finder settings, specify a real scalar in the **Min Height** box.

Data Types: double

**NumPeaks — Maximum number of peaks to show**

3 (default) | positive integer less than 100

Maximum number of peaks to show, specified as a positive integer less than 100.

**Scope Window Use**

On the **Measurements** tab, select **Peak Finder**. In the peak finder settings, specify a positive integer less than 100 in the **Num Peaks** box.

Data Types: double

**MinDistance — Minimum number of samples between adjacent peaks**

1 (default) | positive integer

Minimum number of samples between adjacent peaks, specified as a positive integer.

**Scope Window Use**

On the **Measurements** tab, select **Peak Finder**. In the peak finder settings, specify a positive integer in the **Min Distance** box.

Data Types: double

**Threshold — Minimum difference in height of peak and its neighboring samples**

0 (default) | nonnegative scalar

Minimum difference in the height of the peak and its neighboring samples, specified as a nonnegative scalar.

**Scope Window Use**

On the **Measurements** tab, select **Peak Finder**. In the peak finder settings, specify a nonnegative scalar in the **Threshold** box.

Data Types: double

**LabelPeaks — Label found peaks**

false (default) | true

Label found peaks, specified as true or false. The scope displays the labels (**P1**, **P2**, ...) above the arrows in the plot.

**Scope Window Use**

On the **Measurements** tab, select **Peak Finder**. In the peak finder settings, select **Label Peaks**.

Data Types: logical

**LabelFormat — Coordinates to display**

"x + y" (default) | "x" | "y"

Coordinates to display next to the calculated peak value, specified as "x", "y", or "x + y".

Data Types: char | string

**Enabled — Enable peak finder measurements**

false (default) | true

Enable peak finder measurements, specified as `true` or `false`. Set this property to `true` to enable the peak finder measurements.

### Scope Window Use

On the **Measurements** tab, select **Peak Finder**.

Data Types: `logical`

## Examples

### Enable Peak Finder Programmatically in a Time Scope Object

Create a sine wave and view it in the Time Scope. Enable the peak finder programmatically.

#### Initialization

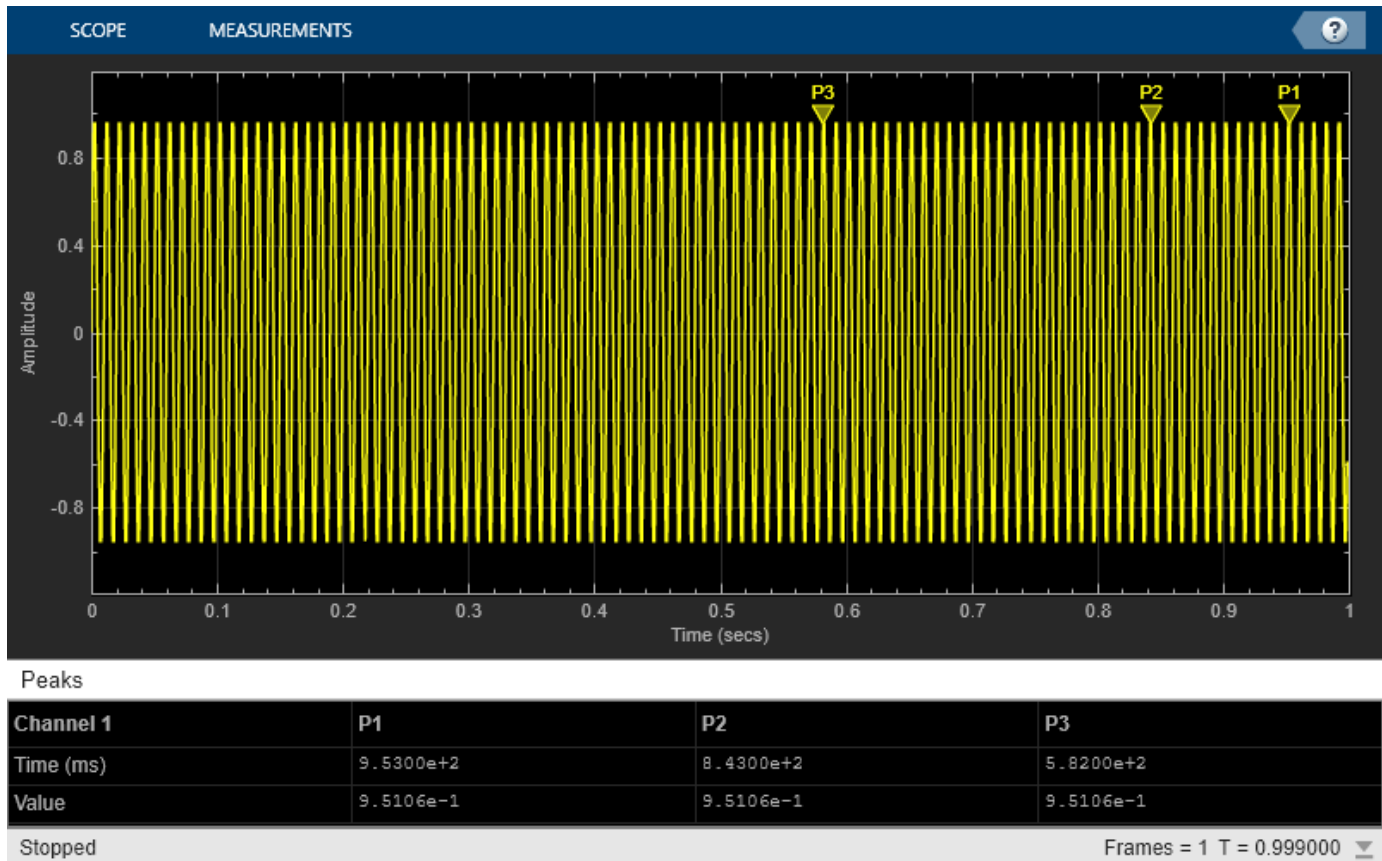

Create the input sine wave using the `sin` function. Create a `timescope` MATLAB® object to display the signal. Set the `TimeSpan` property to 1 second.

```
f = 100;  
fs = 1000;  
swv = sin(2.*pi.*f.*(0:1/fs:1-1/fs)).';  
scope = timescope(SampleRate=fs,...  
    TimeSpanSource="property", ...  
    TimeSpan=1);
```

#### Peaks

Enable the peak finder and label the peaks. Set the scope to show three peaks and label them.

```
scope.PeakFinder.Enabled = true;  
scope.PeakFinder.LabelPeaks = true;  
scope(swv)  
release(scope)
```

### Obtain Measurements Data Programmatically for spectrumAnalyzer object

Compute and display the power spectrum of a noisy sinusoidal input signal using the spectrumAnalyzer MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- PeakFinder
- CursorMeasurements
- ChannelMeasurements
- DistortionMeasurements

### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two dsp.SineWave System objects to generate these two frequencies. Create a spectrumAnalyzer object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SineWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SineWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
```

```
PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...  
YLimits=[-120 40],ShowLegend=true);
```

### Enable Measurements Data

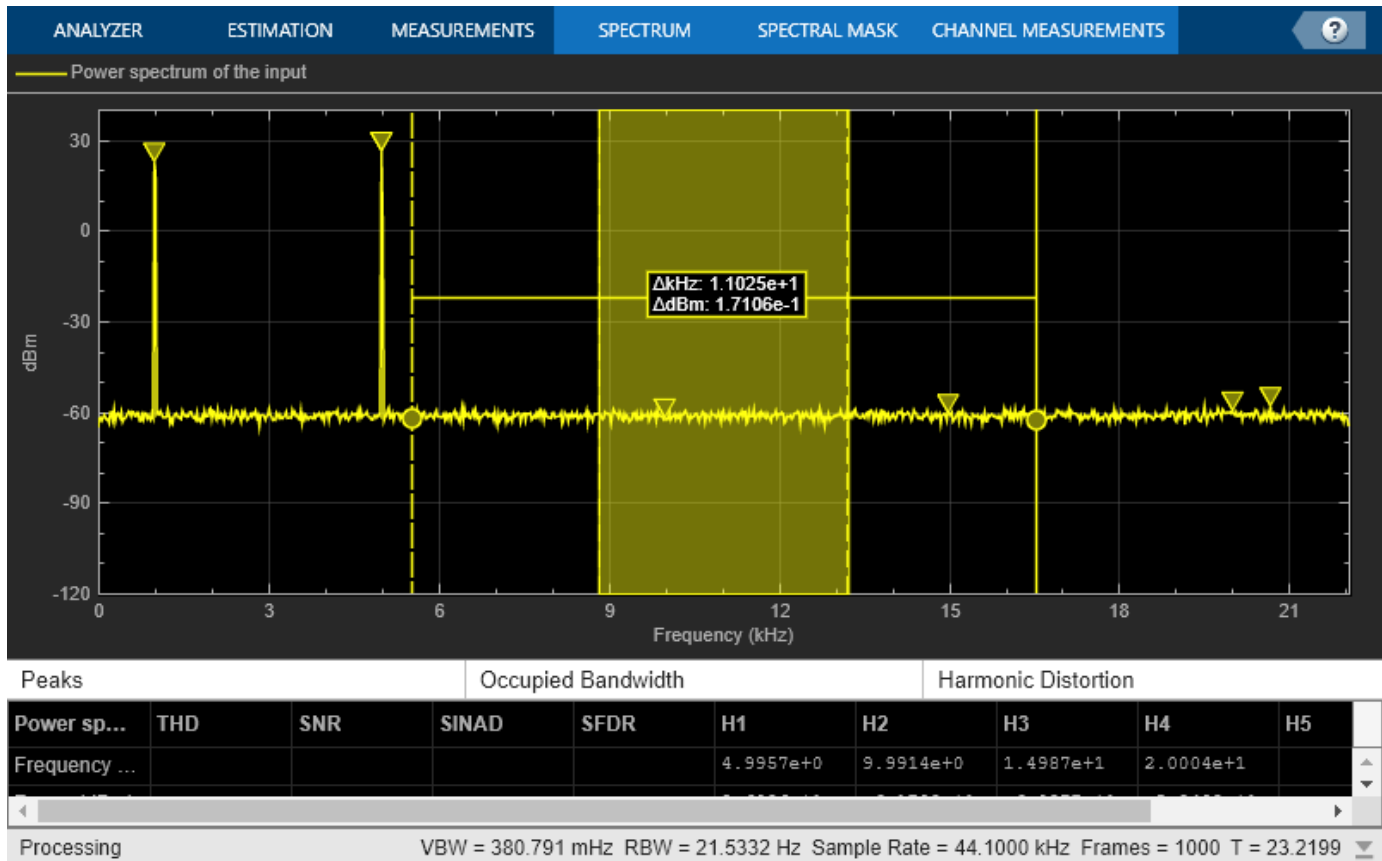

To obtain the measurements, set the Enabled property to true.

```
SA.CursorMeasurements.Enabled = true;  
SA.ChannelMeasurements.Enabled = true;  
SA.PeakFinder.Enabled = true;  
SA.DistortionMeasurements.Enabled = true;
```

### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrumAnalyzer object. Measure the characteristics of the spectrum. Use the getMeasurementsData function to obtain these measurements programmatically. The isNewDataReady function returns true when there is new spectrum data. Store the measured data in the variable data.

```
data = [];  
for Iter = 1:1000  
    Sinewave1 = Sineobject1();  
    Sinewave2 = Sineobject2();  
    Input = Sinewave1 + Sinewave2;  
    NoisyInput = Input + 0.001*randn(1024,1);  
    SA(NoisyInput);  
    if SA.isNewDataReady  
        data = [data;getMeasurementsData(SA)];  
    end  
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

Use the `PeakFinder` property to obtain peak values. Verify that the peak values in the last time step of `data` match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3x1
```

```
26.3957
22.7830
-57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3x1
```

```
4.9957
0.9905
```

# SpectralMaskSpecification

Display upper and lower spectral mask lines on the Spectrum Analyzer

## Description

Masks are overlaid on the spectrum. If the mask is green, the signal is passing the mask limits. If the mask is red, the signal is failing the mask limits.

You can check the status of the spectral mask from the scope toolbar, the command-line, or event listeners:

- To modify the spectral mask and see the spectral mask status, in the scope toolbar, select the spectral mask button, . In the **Spectral Mask** pane that opens, you can modify the masks and see details about what percentage of the time the mask is succeeding, which mask is failing, how many times the mask failed, and which channels are causing the failure.
- To get the current status of the spectral masks, call the function `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events”.

## Creation

### Syntax

```
mask = SpectralMaskSpecification()
mask = SpectralMaskSpecification(Name, Value)
```

### Description

`mask = SpectralMaskSpecification()` creates a spectral mask object `mask`.

`mask = SpectralMaskSpecification(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `mask = SpectralMaskSpecification("EnabledMasks", "Lower")`.

### Properties

All properties are tunable.

#### **EnabledMasks** — Spectral mask to enable

"None" (default) | "Lower" | "Upper" | "Upper and lower"

Specify which spectral masks to enable, specified as a character vector or string.

Data Types: char | string

**UpperMask — Limit for upper spectral mask**

Inf (default) | scalar | two-column matrix

Limit for upper spectral mask, specified as a scalar or two-column matrix.

If `UpperMask` is a scalar, the upper limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer.

If `UpperMask` is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

**Dependency**

To apply offsets to the power and frequency values, use the `ReferenceLevel` and `MaskFrequencyOffset` property values, respectively.

**LowerMask — Limit for lower spectral mask**

-Inf (default) | scalar | two-column matrix

Limit for the lower spectral mask, specified as a scalar or two-column matrix.

If `LowerMask` is a scalar, the lower limit mask uses the power value of the scalar for all frequency values applicable to the Spectrum Analyzer.

If `LowerMask` is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

**Dependency**

To apply offsets to the power and frequency values, use the `ReferenceLevel` and `MaskFrequencyOffset` property values, respectively.

**ReferenceLevel — Reference level for mask power values**

"Custom" (default) | "Spectrum peak"

Reference level for mask power values, specified as either "Custom" or "Spectrum peak".

When `ReferenceLevel` is "Custom", the `CustomReferenceLevel` property value is used as the reference to the power values, in dB<sub>r</sub>, in the `UpperMask` and `LowerMask` properties.

When `ReferenceLevel` is "Spectrum peak", the peak value of the current spectrum of the `SelectedChannel` is used.

**CustomReferenceLevel — Custom reference level**

0 (default) | real numeric scalar

Custom reference level, specified as a real numeric scalar, in the same units as the power units. The reference level is the value to which the power values in the `UpperMask` and `LowerMask` properties are referenced.

This property applies when `ReferenceLevel` is set to "Custom". This property uses the same units as the `PowerUnits` property of the Spectrum Analyzer.

**SelectedChannel — Input channel to use as mask level**

1 (default) | integer

Input channel with peak spectrum to use as the mask reference level, specified as an integer. This property applies when ReferenceLevel is set to "Spectrum peak".

### MaskFrequencyOffset — Frequency offset

0 (default) | finite numeric scalar

Frequency offset, specified as a finite, numeric scalar. Frequency offset is the amount of offset to apply to frequency values in the UpperMask and LowerMask properties.

## Examples

### Spectral Mask with dsp.SpectrumAnalyzer

This example shows how to create and use a spectral mask with the dsp.SpectrumAnalyzer object.

Create an upper spectral mask, set the reference level matrix, and add it to a Spectrum Analyzer object.

```
mask = SpectralMaskSpecification();
mask.EnabledMasks = 'Upper';
mask.UpperMask = [...
    0 -17; ...
    90 -17; ...
    90 30; ...
    110 30; ...
    110 -17; ...
    500 -17];

scope = dsp.SpectrumAnalyzer('PlotAsTwoSidedSpectrum',false,...
    'ShowLegend',true);
scope.SpectralMask = mask;
scope.SpectralMask

ans =
    SpectralMaskSpecification with properties:

        EnabledMasks: 'Upper'
        UpperMask: [6x2 double]
        LowerMask: -Inf
        ReferenceLevel: 'Custom'
        CustomReferenceLevel: 0
        MaskFrequencyOffset: 0

Events for class SpectralMaskSpecification: MaskTestFailed
```

Run the spectrum analyzer using a sine wave spectrum. In the Spectral Mask panel, you can see how the spectrum succeeded or failed to stay within your spectral mask.

```
sine = dsp.SineWave('Frequency',[98 100],'SampleRate',1000);
sine.SamplesPerFrame = 1024;
scope.SampleRate = sine.SampleRate;

for i=1:100
    scope(sine() + 0.05*randn(1024,2));
```

```
end
release(scope)
```

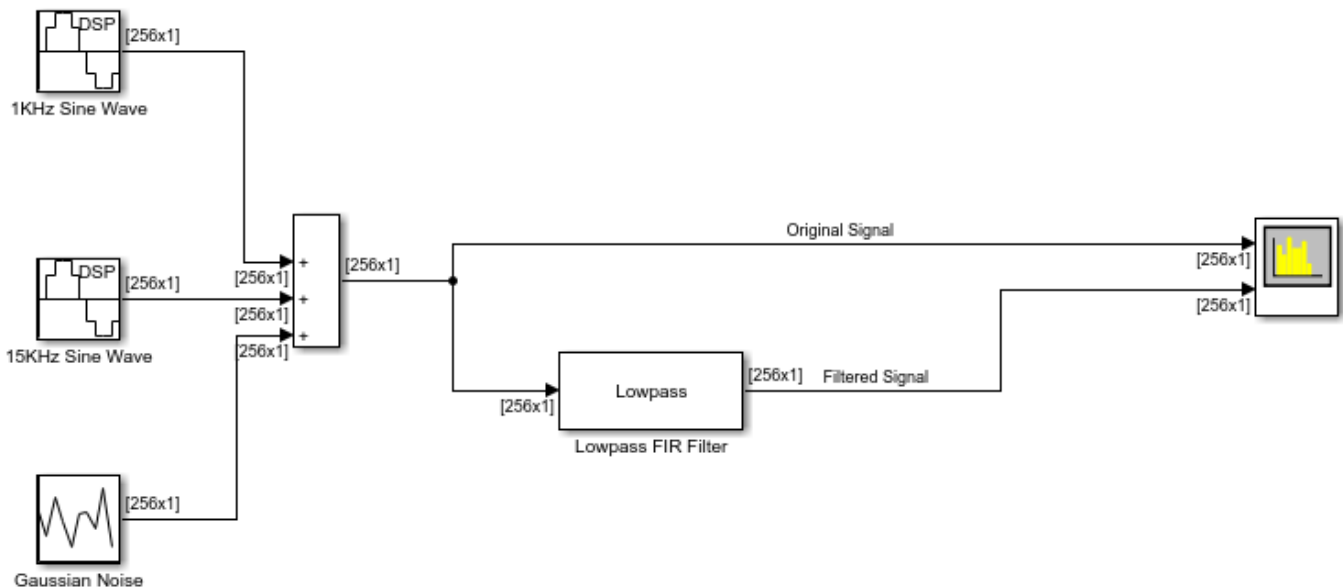

### Spectral Mask in Spectrum Analyzer Block

Create a new model based on the `dsp_basic_filter` template. Add a spectral mask to the Spectrum Analyzer block in the model. Run the model.

Masks are overlaid on the spectrum. If the mask is green, the signal is passing. If the mask is red, the signal is failing. The **Spectral Mask** panel shows what percentage of the time the mask is succeeding, which mask is failing, how many times the mask(s) failed, and which channels are causing the failure.

```
[~,mdl] = fileparts(tempname);
open_system(new_system(mdl,'FromTemplate','dsp_basic_filter'));
saBlock = find_system(mdl,'BlockType','SpectrumAnalyzer');

scopeConfig = get_param(saBlock{1},'ScopeConfiguration');
upperMask = [0 50; 1200 50; 1200 -10; 24000 -10];
scopeConfig.SpectralMask.UpperMask = upperMask;
scopeConfig.SpectralMask.LowerMask = -100;
scopeConfig.SpectralMask.EnabledMasks = 'upper-and-lower';
sim(mdl,StopTime='20');
```

## Version History

Introduced in R2016b

## SpectralMaskConfiguration

Display upper and lower spectral mask lines in the Spectrum Analyzer

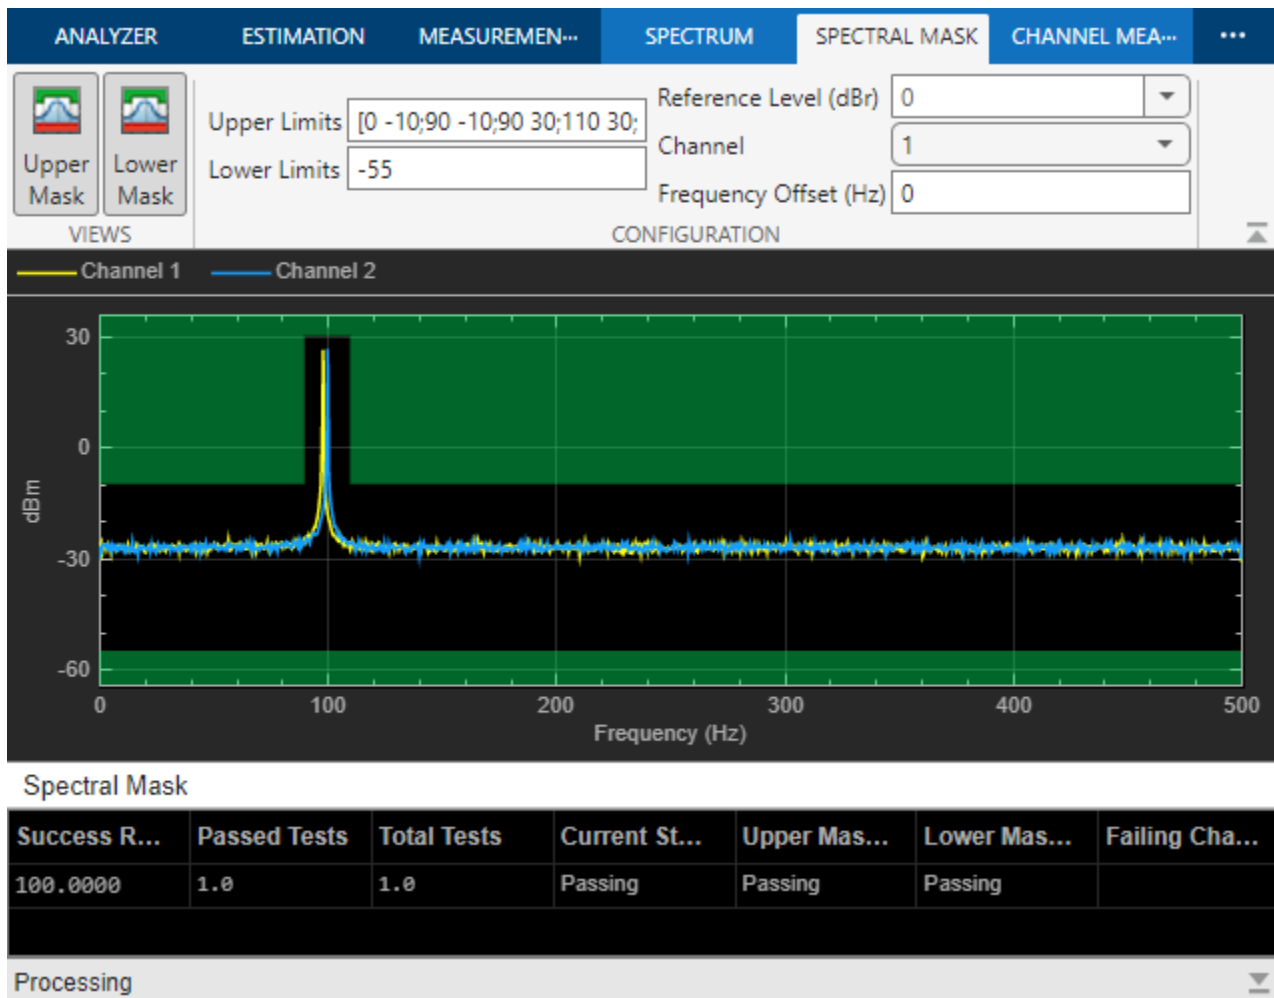

### Description

Use the `SpectralMaskConfiguration` object to overlay a spectral mask on a spectrum in the Spectrum Analyzer. If the mask is green, the signal is within the mask limits. If the mask is red, the signal fails the mask limits.

You can check the status of the spectral mask from the scope toolbar, the command line, or event listeners.

- To modify a spectral mask and see its status, in the scope toolbar, click the spectral mask button . You can modify the masks in the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. Use the `getSpectralMaskStatus` function to obtain mask details, such as number of times a mask succeeded, number of times a mask failed, channels causing mask failure, and so on.
- Use the `MaskTestFailed` event to perform an action every time the mask fails. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events”.

Both the `spectrumAnalyzer` object and the `SpectrumAnalyzerConfiguration` object support the `SpectralMaskConfiguration` object in the command line.

## Creation

### Syntax

```
mask = SpectralMaskConfiguration()
```

### Description

mask = SpectralMaskConfiguration() creates a spectral mask object.

### Properties

All properties are tunable.

#### EnabledMasks — Spectral mask to enable

"none" (default) | "lower" | "upper" | "upper-and-lower"

Spectral mask to enable, specified as "none", "lower", "upper", or "upper-and-lower".

### Scope Window Use

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Views** section, select **Upper Mask**, **Lower Mask**, or both.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose either Power or Power Density.

Data Types: char | string

### UpperMask — Limit for upper spectral mask

Inf (default) | scalar | two-column matrix

Limit for the upper spectral mask, specified as a scalar or two-column matrix.

If **UpperMask** is a scalar, the upper limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If **UpperMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **ReferenceLevel** and **MaskFrequencyOffset** properties.

### Scope Window Use

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, specify **Upper Limits**.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

Data Types: double

### LowerMask — Limit for lower spectral mask

-Inf (default) | scalar | two-column matrix

Limit for the lower spectral mask, specified as a scalar or two-column matrix.

If **LowerMask** is a scalar, the lower limit mask uses the same power value for all frequencies specified in the Spectrum Analyzer.

If **LowerMask** is a matrix, the first column contains the frequency values (Hz), which correspond to the x-axis values. The second column contains the power values, which correspond to the associated y-axis values.

To apply offsets to the power and frequency values, use the **ReferenceLevel** and **MaskFrequencyOffset** property values.

**Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, specify **Lower Limits**.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

Data Types: double

**ReferenceLevel — Reference level for mask power values**

"custom" (default) | "spectrum-peak"

Reference level for mask power values, specified as either "custom" or "spectrum-peak".

When you specify ReferenceLevel as "custom", the object uses the value you specify in the CustomReferenceLevel property as the reference to the power values (in dBr) in the UpperMask and LowerMask properties.

When you specify ReferenceLevel as "spectrum-peak", the object uses the peak value of the current spectrum of the SelectedChannel as the reference power value.

**Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, set **Reference Level (dBr)** to either Spectrum peak or enter a real scalar.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

Data Types: char | string

**CustomReferenceLevel — Custom reference level**

0 (default) | real numeric scalar

Custom reference level to the power values, specified as a real numeric scalar. The reference level should have the same units as the SpectrumUnits property of the Spectrum Analyzer. The reference level is the value to which the object references the power values in the UpperMask and LowerMask properties.

**Dependency**

To enable this property, set ReferenceLevel to "custom". This property uses the same units as the SpectrumUnits property of the Spectrum Analyzer.

**Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, set **Reference Level (dBr)** to either Spectrum peak or enter a real scalar.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

Data Types: double

### **SelectedChannel** — Input channel with peak spectrum

1 (default) | integer

Input channel with peak spectrum to use as the mask reference level, specified as an integer.

#### **Dependency**

To enable this property, set `ReferenceLevel` to "spectrum-peak".

#### **Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, specify **Channel** as an integer.

To enable **Channel**, set **Reference Level (dBr)** in the **Configuration** section to Spectrum peak and display some data on the scope.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

### **MaskFrequencyOffset** — Frequency offset

0 (default) | finite numeric scalar

Frequency offset, specified as a finite numeric scalar. The object offsets the frequency values in the `UpperMask` and `LowerMask` properties by this value.

#### **Scope Window Use**

Click the **Spectral Mask** tab on the Spectrum Analyzer toolstrip. In the **Configuration** section, set **Frequency Offset (Hz)** to a real scalar.

The **Spectral Mask** tab appears when you:

- Select **Spectrum** in the **Analyzer** tab.
- In the drop-down list under **Spectrum**, choose Power or Power Density.

Data Types: double

## **Object Functions**

`getSpectralMaskStatus` Get test results of current spectral mask

## **Examples**

### **Spectral Mask with spectrumAnalyzer**

Create an upper spectral mask, set the reference level matrix, and add it to a Spectrum Analyzer object.

```

mask = SpectralMaskConfiguration();
mask.EnabledMasks = "upper";
mask.UpperMask = [...
    0 -17; ...
    90 -17; ...
    90 30; ...
    110 30; ...
    110 -17; ...
    500 -17];

scope = spectrumAnalyzer(PlotAsTwoSidedSpectrum=false,...
    ShowLegend=true);
scope.SpectralMask = mask;
scope.SpectralMask

ans =
    SpectralMaskConfiguration with properties:

        EnabledMasks: 'upper'
        UpperMask: [6x2 double]
        LowerMask: -Inf
        ReferenceLevel: 'custom'
    CustomReferenceLevel: 0
    MaskFrequencyOffset: 0

Events for class SpectralMaskConfiguration: MaskTestFailed

```

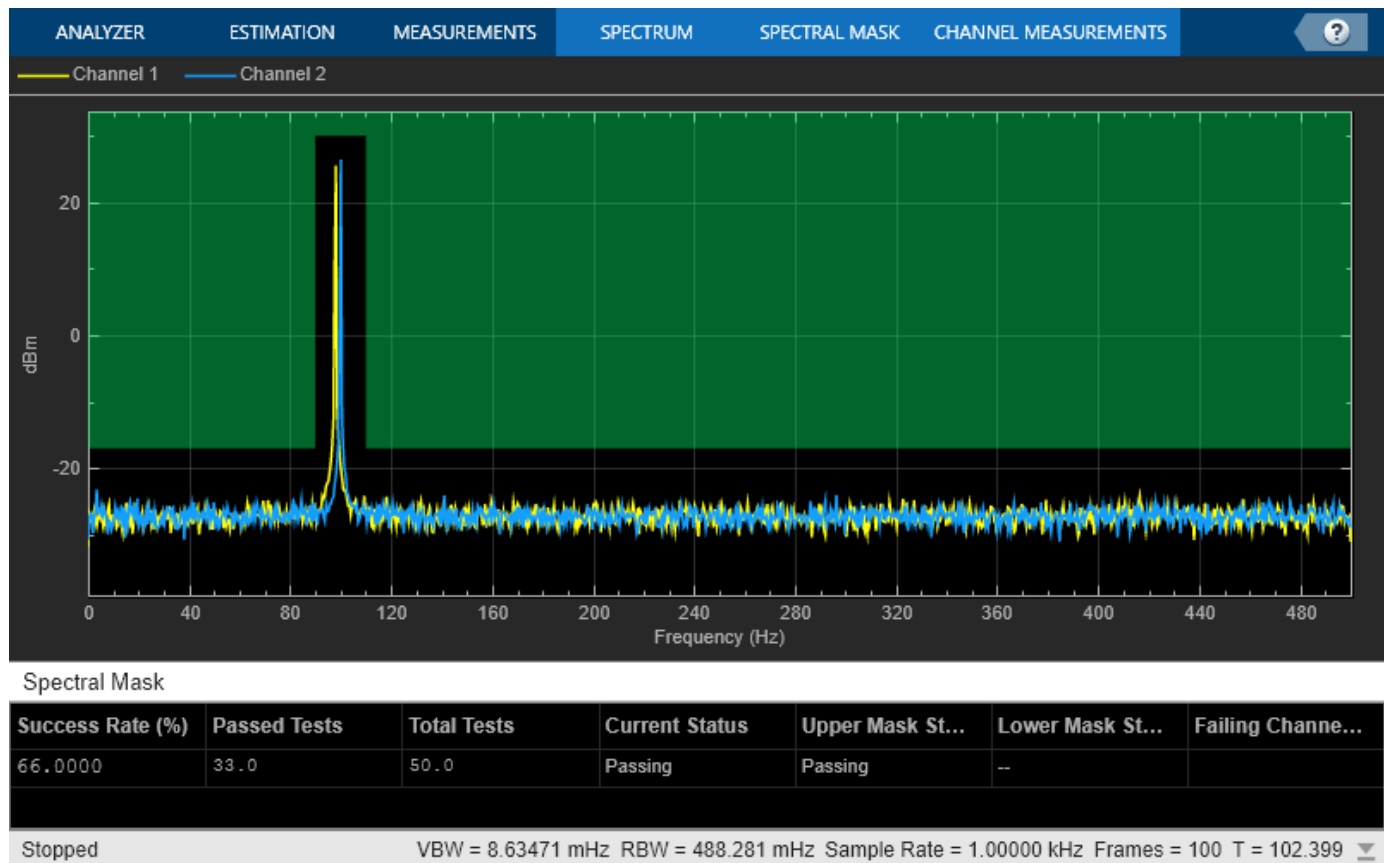

Run the spectrum analyzer using a sine wave spectrum. In the **Spectral Mask** panel at the bottom of the Spectrum Analyzer window, see how the spectrum succeeded or failed to stay within the spectral mask.

```

sine = dsp.SineWave(Frequency=[98 100],SampleRate=1000);
sine.SamplesPerFrame = 1024;
scope.SampleRate = sine.SampleRate;

for i=1:100
    scope(sine() + 0.05*randn(1024,2));
end
release(scope)

```

### Get Spectral Mask Status

Add a spectral mask to an existing spectrumAnalyzer object. Use the `getSpectralMaskStatus` function to get the spectral mask status.

```
sine = dsp.SineWave(Frequency=[98 100],SampleRate=1000);
sine.SamplesPerFrame = 1024;
scope = spectrumAnalyzer(SampleRate=sine.SampleRate,...
    PlotAsTwoSidedSpectrum=false,ShowLegend=true,YLimits=[-60 40]);
hide(scope);

scope.SpectralMask.EnabledMasks = "upper-and-lower";
upperMask = [0 -10; 90 -10; 90 30; 110 30; 110 -10; 500 -10];
set(scope.SpectralMask,UpperMask=upperMask,LowerMask=-55);

for i=1:100
    scope(sine() + 0.05*randn(1024,2));
end

res = getSpectralMaskStatus(scope)

res = struct with fields:
    IsCurrentlyPassing: 1
    NumPassedTests: 44
```

```

NumTotalTests: 50
SuccessRate: 88
FailingMasks: ''
FailingChannels: [1x0 double]
SimulationTime: 102.3990

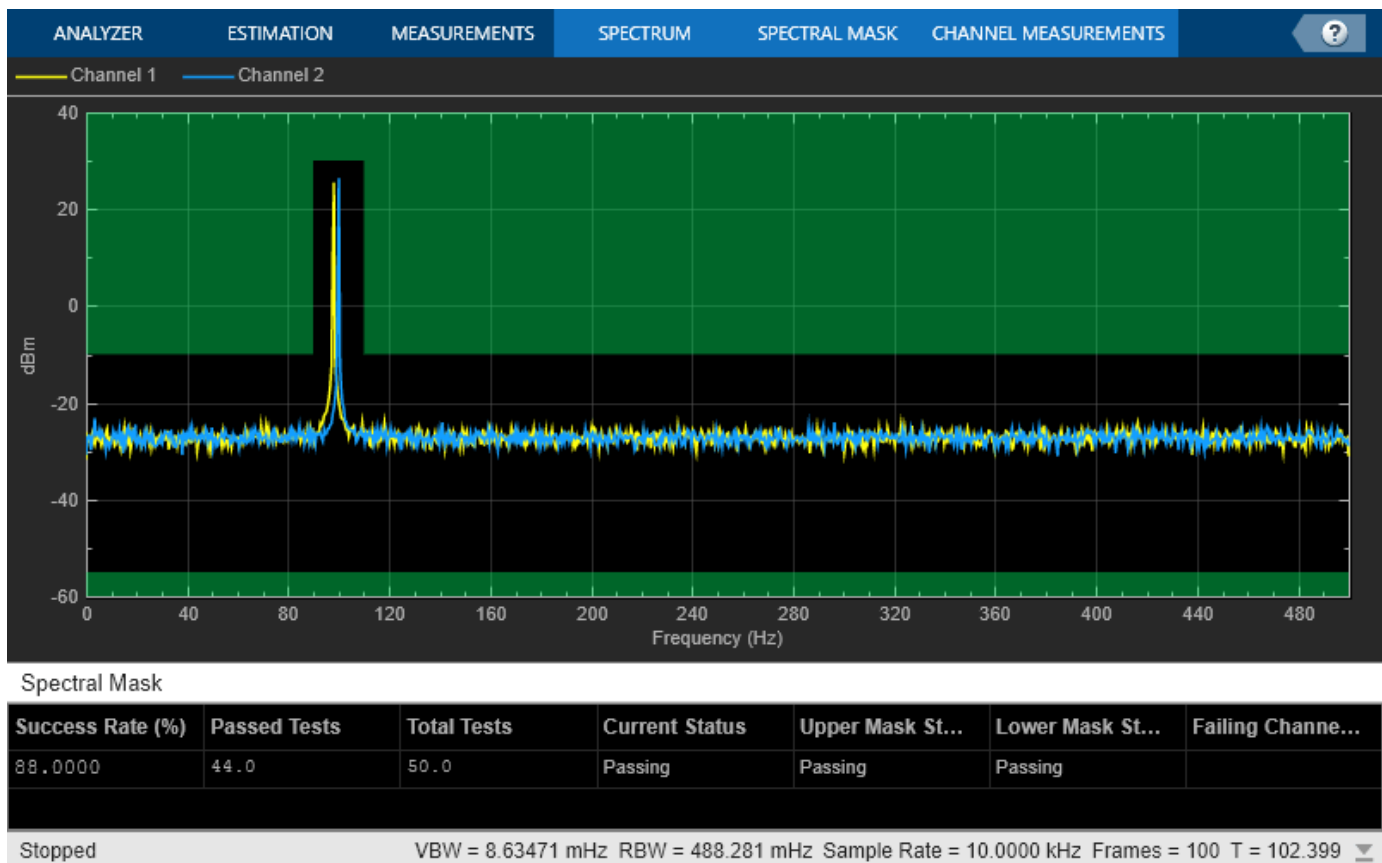

```

You can also view the status in the **Spectral Mask** tab on the Spectrum Analyzer toolstrip.

```

show(scope);
release(scope);

```

## ArrayPlotConfiguration

(Not recommended) Control Array Plot block appearance and behavior from MATLAB

---

**Note** `ArrayPlotConfiguration` is not recommended. Use `get_param` and `set_param` to modify the Array Plot block properties. For more information, see “Compatibility Considerations”.

---

### Description

Use the Array Plot Configuration object to control the appearance and behavior of an Array Plot block. Create a configuration object with `get_param`, and then change property values using the object with dot notation.

You can also modify the Array Plot block properties using `get_param` and `set_param`.

### Creation

`MyScopeConfiguration = get_param(gcbh, 'ScopeConfiguration')` creates a new Array Plot Configuration object. If you do not provide the full path to the block, you must first select the block in the model.

### Properties

#### Plot Configuration

##### **NumInputPorts** — Number of input ports

'1' (default) | character vector

Number of input ports on a scope block, specified as a character vector. The maximum number of input ports is 96.

##### **XDataMode** — Source of the x-data spacing

'Sample increment and X-offset' (default) | 'Custom'

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify 'Custom', you also must specify the `CustomXData` property values.

You can set this property only before simulation.

Data Types: `char` | `string`

##### **SampleIncrement** — x-axis spacing

'1' (default) | character vector

The spacing between samples along the x-axis, specified as a finite scalar in a character vector. The input signal is only y-axis data. x-axis data is set automatically based on the `XOffset` and `SampleIncrement` properties.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ... .

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ... .

#### Dependency

To use this property, set `XDataMode` to `'Sample increment and X-offset'`.

#### XOffset — Display offset of x-axis

`'0'` (default) | character vector

Display offset of x-axis, specified as a numeric scalar in a character vector. x-axis data is set automatically based on both the `SampleIncrement` and `XOffset` values. The x-offset represents the first value on the x-axis.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ... .

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ... .

#### Dependency

To use this property, set `XDataMode` to `'Sample increment and X-offset'`.

#### CustomXData — x-data values

`''` (default) | character vector

Specify the desired x-data values as a numeric vector in a character vector. The row or column vector must be equal to the frame length of the inputs. If you use the default (empty vector) value, the x-data is uniformly spaced and set to  $(0:L-1)$ , where  $L$  is the frame length.

Example: `scopeConfiguration.XDataMode = 'Custom';`  
`scopeConfiguration.CustomXData = 'logspace(0,log10(44100/2),1024)'`

#### Dependency

To use this property, set `XDataMode` to `'Custom'`.

#### XScale — Scale of x-axis

`"Linear"` (default) | `"Log"`

Specify whether the scale of the x-axis is `"Linear"` or `"Log"`. If `XOffset` is a negative value, you cannot set this property to `"Log"`.

#### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XScale**.

Data Types: `char` | `string`

#### YScale — Scale of y-axis

`"Linear"` (default) | `"Log"`

Specify whether the scale of the y-axis is `"Linear"` or `"Log"`.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **YScale**.

Data Types: char | string

**Visualization****PlotType — Control type of plot**

"Stem" (default) | "Line" | "Stairs"

Specify the type of plot to use for all the input signals displayed in the scope window:

- "Stem" - The scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values.
- "Line" - The scope displays the input signal as lines connecting each of the sampled values.
- "Stairs" - The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

**Scope Window Use**

Open the **Settings** and set **Plot Type**.

**AxesScaling — Axes scaling mode**

"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"

Specify when the scope scales the axes. Valid values are:

- "Auto" — The scope scales the axes as needed to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes once and only once after a specified number of updates. To specify the number of updates, use the `AxesScalingNumUpdates` property.

**AxesScalingNumUpdates — Number of updates before scaling**

"10" (default) | integer character vector | integer string scalar

Set this property to delay auto scaling the y-axis.

**Dependency**

To enable this property, set `AxesScaling` to "Updates".

**Name — Window name**

'Array Plot' (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the `Title` property.

Data Types: char | string

**Position — Scope window position and size in pixels**

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form `[left bottom width height]`. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

### MaximizeAxes — Maximize axes control

"Auto" (default) | "On" | "Off"

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

### Scope Window Use

Hover over the array plot to see the maximize axes button .

Data Types: `char` | `string`

### Title — Display title

' ' (default) | character vector | string scalar

Specify the display title as a character vector or string.

### Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Title**.

Data Types: `char` | `string`

### PlotAsMagnitudePhase — Plot signal as magnitude and phase

false (default) | true

- `true` - The scope plots the magnitude and phase of the input signal on two separate axes within the same active display.
- `false` - The scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

### Scope Window Use

On the **Plot** tab, select the **Magnitude Phase** button.

### XLabel — x-axis label

"" (default) | character vector | string scalar

Specify the text for the scope to display below the x-axis.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **XLabel**.

Data Types: char | string

**YLabel — y-axis label**

"Amplitude" (default) | character vector | string scalar

Specify the text for the scope to display to the left of the y-axis.

**Dependencies**

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values "Magnitude" and "Phase", for the magnitude plot and the phase plot, respectively.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **YLabel**.

Data Types: char | string

**YLimits — y-axis limits**

[-10,10] (default) | [ymin, ymax]

Specify the y-axis limits as a two-element numeric vector, [ymin, ymax].

If `PlotAsMagnitudePhase` is `false`, the default is [-10,10]. If `PlotAsMagnitudePhase` is `true`, the default is [0,10].

**Dependencies**

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always [-180,180].

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and set **Y-Axis Limits** as a two-element numeric vector.

**ShowGrid — Display grid**

true (default) | false

Set this property to `true` to show grid lines on the plot.

**Scope Window Use**

Open the **Plot** tab, click **Settings**, and select **Grid**.

**ShowLegend — Show legend**

false (default) | true

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the

scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

---

**Note** The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

---

### Scope Window Use

On the **Plot** tab, click **Legend**.

Data Types: `logical`

### ChannelNames — Channel names

empty cell (default) | cell array of character vectors | array of strings

Specify the input channel names as a cell array of character vectors or an array of strings. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

### Dependency

To see channel names, set `ShowLegend` to `true`.

Data Types: `char`

### OpenAtSimulationStart — Flag to open scope when simulation starts

`true` (default) | `false`

Flag to open scope when simulation starts, specified as `true` or `false`.

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening when you simulate the model.

### Scope Window Use

This parameter is available only from the **Property Inspector**. To launch the **Property Inspector**, click the **Modeling** tab of the Simulink model window that contains the Spectrum Analyzer block. In the **Design** section, click the drop-down arrow and select **Property Inspector**. The **Property Inspector** window opens on the right. If you select the Spectrum Analyzer block, the **Property Inspector** window shows the corresponding parameters. In the parameters that show up, select or clear the **Open at simulation start** parameter.

Data Types: `logical`

## Examples

### Change the Array Plot Block Title and Scaling From the Command Line

Modify an Array Plot block with a configuration object.

Create a new Simulink model with a randomly-generated name.

```
sysname='ArrayPlotExample';
new_system(sysname);
```

Add a new Array Plot block to the model.

```
add_block('built-in/ArrayPlot',[sysname,'/ArrayPlot'])
```

Call the `get_param` function to retrieve the default Array Plot block configuration properties.

```
scopeConfig = get_param([sysname,'/ArrayPlot'],'ScopeConfiguration')
```

```
scopeConfig =
```

```
ArrayPlotConfiguration with properties:
```

```
    NumInputPorts: '1'  
      XDataMode: 'Sample increment and X-offset'  
SampleIncrement: '1'  
      XOffset: '0'  
    CustomXData: '[]'  
      XScale: 'Linear'  
      YScale: 'Linear'  
    PlotType: 'Stem'  
    AxesScaling: 'OnceAtStop'  
AxesScalingNumUpdates: '100'  
    Name: 'ArrayPlot'  
    Position: [240 262 800 500]  
MaximizeAxes: 'Auto'  
PlotAsMagnitudePhase: 0  
    Title: ''  
    XLabel: ''  
    YLabel: 'Amplitude'  
    YLimits: [-10 10]  
    ShowGrid: 1  
    ShowLegend: 0  
    ChannelNames: {''}  
OpenAtSimulationStart: 1  
    Visible: 0
```

Modify the Array Plot title and axes scaling.

```
scopeConfig.Title = 'My Array Plot';  
scopeConfig.AxesScaling = 'Manual'
```

```
scopeConfig =
```

```
ArrayPlotConfiguration with properties:
```

```
    NumInputPorts: '1'  
      XDataMode: 'Sample increment and X-offset'  
SampleIncrement: '1'  
      XOffset: '0'  
    CustomXData: '[]'  
      XScale: 'Linear'  
      YScale: 'Linear'  
    PlotType: 'Stem'  
    AxesScaling: 'OnceAtStop'  
AxesScalingNumUpdates: '100'  
    Name: 'ArrayPlot'  
    Position: [240 262 800 500]  
MaximizeAxes: 'Auto'  
PlotAsMagnitudePhase: 0  
    Title: ''  
    XLabel: ''  
    YLabel: 'Amplitude'
```

```
YLimits: [-10 10]
ShowGrid: 1
ShowLegend: 0
ChannelNames: {''}
OpenAtSimulationStart: 1
Visible: 0
```

## Version History

### Introduced in R2013a

#### **R2021a: ArrayPlotConfiguration is not recommended**

*Not recommended starting in R2021a*

The ArrayPlotConfiguration object is not recommended. To view and modify the Array Plot block properties from the command-line, use `get_param` and `set_param`. For example, to change the number of input ports, use these commands.

```
modelName='ArrayPlotExample';
new_system(modelName);
add_block('built-in/ArrayPlot',[sysname,'/ArrayPlot'])
set_param([modelName,'/ArrayPlot'],'NumInputPorts','4')
```

#### **R2022b: Channel names support array of strings**

Starting in R2022b, you can specify the ChannelNames property of the ArrayPlotConfiguration object as an array of strings.

```
scopeConfig = get_param(gcbh,'ScopeConfiguration')
scopeConfig.ChannelNames=["Input", "Lowpass Output"];
```

# dsp.DynamicFilterVisualizer

Display time-varying magnitude and phase response of digital filters

## Description

The `dsp.DynamicFilterVisualizer` object displays the magnitude response and phase response of time-varying digital filters or time-varying filter coefficients. The input to this object can be a filter coefficients vector or a filter System object.

Using the dynamic filter visualizer, you can configure the plot settings, find the peak values, enable cursor measurements, and even generate script to recreate the plot with the current settings from the visualizer interface. For details, see “Configure Filter Visualizer”.

## Creation

### Syntax

```
dfv = dsp.DynamicFilterVisualizer
dfv = dsp.DynamicFilterVisualizer(nfft)
dfv = dsp.DynamicFilterVisualizer(nfft,Fs)
dfv = dsp.DynamicFilterVisualizer(nfft,Fs,range)
dfv = dsp.DynamicFilterVisualizer(Name=Value)
```

### Description

`dfv = dsp.DynamicFilterVisualizer` returns a dynamic filter visualizer object, `dfv`, that displays the magnitude response of digital filters or filter coefficients.

`dfv = dsp.DynamicFilterVisualizer(nfft)` returns a dynamic filter visualizer with the `FFTLength` property set to `nfft`.

`dfv = dsp.DynamicFilterVisualizer(nfft,Fs)` returns a dynamic filter visualizer with the `FFTLength` property set to `nfft` and the `SampleRate` property set to `Fs`.

`dfv = dsp.DynamicFilterVisualizer(nfft,Fs,range)` returns a dynamic filter visualizer with the `FFTLength` property set to `nfft`, the `SampleRate` property set to `Fs`, and the `FrequencyRange` property set to `range`.

`dfv = dsp.DynamicFilterVisualizer(Name=Value)` returns a dynamic filter visualizer with each specified property set to the specified value. You can specify name-value pair arguments in any order.

## Properties

### Frequently Used

#### **FFTLength** — FFT length

2048 (default) | positive integer

FFT length that the dynamic filter visualizer uses to compute spectral estimates, specified as a positive integer.

**Tunable:** Yes

#### Scope Window Use

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, set **FFT Length** to a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### NormalizedFrequency — Flag to display normalized frequency

`false` (default) | `true`

Flag to display normalized frequency, specified as one of these values:

- `true` -- The filter visualizer displays the frequency response in normalized frequency units (0 to 1).
- `false` -- The filter visualizer displays the frequency response in Hz. You can specify the input sample rate through the `SampleRate` property.

Data Types: `logical`

#### SampleRate — Sampling rate of input

44100 (default) | positive scalar

Sampling rate of the input signal, specified as a real positive scalar in Hz.

**Tunable:** Yes

#### Dependency

To enable this property, set `NormalizedFrequency` to `false`.

#### Scope Window Use

On the **Plot** tab, in the **Configuration** section, click **Settings**. In the Filter Visualizer Settings window, under **Data and Axes**, set **Sample Rate (Hz)** to a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### FrequencyRange — Range of frequency axis

[0 22050] (default) | two-element numeric vector

Range of the frequency axis, specified as a two-element numeric vector that is monotonically increasing and of the form [*fmin*, *fmax*].

- When you set the `NormalizedFrequency` property to `true`, *fmax* is in normalized frequency units and must be a positive scalar that is less than or equal to 1.
- When you set the `NormalizedFrequency` property to `false`, *fmax* is in Hz and must be less than or equal to  $F_s/2$ , where  $F_s$  is the value you specify in the `SampleRate` property.

**Tunable:** Yes

**Scope Window Use**

On the **Plot** tab, in the **Configuration** section, click **Settings**. In the Filter Visualizer Settings window, under **Data and Axes**, set **Frequency Range** to a two-element numeric vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**XScale — x-axis scale**

`'Log'` (default) | `'Linear'`

X-axis scale, specified as either `'Linear'` or `'Log'`.

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, set **X-Scale** to `Linear` or `Log`.

**MagnitudeDisplay — y-axis units**

`'Magnitude (dB)'` (default) | `'Magnitude'` | `'Magnitude squared'`

Y-axis units, specified as one of the following:

- `'Magnitude'`
- `'Magnitude (dB)'`
- `'Magnitude squared'`

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, set **Display Unit** to `Magnitude`, `Magnitude (dB)`, or `Magnitude Squared`.

**PlotAsMagnitudePhase — Plot magnitude and phase response of filter**

`false` (default) | `true`

- `true` - The filter visualizer plots the magnitude and phase responses of the filter on two separate axes.
- `false` - The filter visualizer plots only the magnitude response of the filter.

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click the **Magnitude Phase** button.

**PlotType — Option to control type of plot**

`"Line"` (default) | `"Stairs"` | `"Stem"`

Specify the type of plot to use in the filter visualizer window as one of these:

- "Line" - The filter visualizer connects each point on the magnitude and phase response plot with a line.
- "Stairs" - The filter visualizer displays the filter response (magnitude, phase, or both) as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the filter response over a frequency value and is connected to two vertical lines. Each vertical line represents a change in values occurring at a frequency.
- "Stem" - The filter visualizer displays the frequency response as circles with vertical lines extending down to the x-axis at each of the frequency values.

**Tunable:** Yes

#### Scope Window Use

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, set **Plot Type** to Line, Stairs, or Stem.

#### AxesScaling — Axes scaling mode

"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"

Specify the scaling mode for the axes as one of these:

- "Auto" — The filter visualizer scales the axes as needed to fit the data, both during and after simulation.
- "Manual" — The filter visualizer does not scale the axes automatically.
- "OnceAtStop" — The filter visualizer scales the axes when the simulation stops.
- "Updates" — The filter visualizer scales the axes limits once after a set number of visual updates. The number of updates is determined by the value of the AxesScalingNumUpdates property.

**Tunable:** Yes

#### Scope Window Use

Hover over the filter visualizer to see the maximize , pan , zoom , and autoscale  buttons. You can also zoom and pan using your mouse.

Data Types: char | string

#### AxesScalingNumUpdates — Number of updates before scaling

100 (default) | real positive integer

Specify the number of updates before scaling as a real, positive scalar integer.

**Tunable:** Yes

#### Dependency

To enable this property, set AxesScaling to "Updates".

Data Types: double

#### Measurements

##### MeasurementChannel — Channel for which to obtain measurements

1 (default) | positive integer

Channel for which to obtain measurements, specified as a positive integer in the range [1  $N$ ], where  $N$  is the number of input channels.

**Tunable:** Yes

### Scope Window Use

Click the **Measurements** tab on the Dynamic Filter Visualizer toolstrip. In the **Channel** section, select a **Channel**.

Data Types: double

### CursorMeasurements — Cursor measurements

CursorMeasurementsConfiguration object

Cursor measurements to display waveform cursors, specified as a CursorMeasurementsConfiguration object.

All CursorMeasurementsConfiguration properties are tunable.

**Tunable:** Yes

### Scope Window Use

Click the **Measurements** tab on the Dynamic Filter Visualizer toolstrip and modify the cursor measurements in the **Cursors** section.

### PeakFinder — Peak finder measurements

PeakFinderConfiguration object

Peak finder measurements to compute and display the largest calculated peak values, specified as a PeakFinderConfiguration object.

All PeakFinderConfiguration properties are tunable.

**Tunable:** Yes

### Scope Window Use

Click the **Measurements** tab on the Dynamic Filter Visualizer toolstrip and modify the peak finder measurements in the **Peaks** section.

### Visualization

#### Name — Caption to display on Dynamic Filter Visualizer window

'Dynamic Filter Visualizer' (default) | character vector | string scalar

Caption to display on the Dynamic Filter Visualizer window, specified as a character vector or a string scalar.

Example: 'Dynamic Filter Visualizer'

Example: "Dynamic Filter Visualizer"

**Tunable:** Yes

#### Position — Scope window position in pixels

[left bottom 800 500] (default) | four-element double vector

Scope window position in pixels, specified as a four-element double vector of the form [left bottom width height]. The default value of this property is dependent on the screen resolution, and is such that the window is positioned in the center of the screen, with a width and height of 800 and 500 pixels, respectively.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### MaximizeAxes — Maximize axes control

"Auto" (default) | "On" | "Off"

Specify whether to display the filter visualizer in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

**Tunable:** Yes

### Scope Window Use

Hover over the Dynamic Filter Visualizer window to see the maximize axes button

Data Types: `char` | `string`

### Title — Display title

' ' (default) | character vector | string scalar

Display title, specified as a character vector or a string scalar.

Example: 'Magnitude Response'

Example: "Magnitude Response"

**Tunable:** Yes

### Scope Window Use

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolstrip, click **Settings**. In the Filter Visualizer Settings window that opens, under **Display and Labels**, set **Title** to a character vector or a string scalar.

### YLimits — y-axis limits

[-25 25] (default) | two-element row vector

Y-axis limits, specified as a two-element numeric row vector with the second element greater than the first element and of the form [*ymin*, *ymax*].

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolbar, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, set **Y-Axis Limits** to a two-element numeric vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ShowLegend — Show or hide legend**

`false` (default) | `true`

When this property is set to `false`, no legend is displayed. When this property is set to `true`, a legend with automatic string labels for each input filter is displayed.

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolbar, click **Legend**.

Data Types: `logical`

**FilterNames — Names for input filters**

`{ '' }` (default) | cell array of character vectors | array of strings

Names to label the input filters in the legend, specified as a cell array of character vectors or an array of strings. The default is an empty cell array. When this property is set to an empty cell array, the filters are named by default names, such as `Filter 1`, `Filter 2`, and so on.

**Tunable:** Yes

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolbar, click **Legend**. In the legend that appears on the plot, click the filter name.

**ShowGrid — Display grid**

`true` (default) | `false`

Set this property to `true` to show grid lines on the plot.

**Scope Window Use**

In the **Configuration** section on the **Plot** tab of the Dynamic Filter Visualizer toolbar, click **Settings**. In the Filter Visualizer Settings window that opens, under **Data and Axes**, select **Grid**.

**UpperMask — Upper limit mask**

`Inf` (default) | two-column matrix

Upper limit spectral mask, specified as a two-column matrix. The first column represents the frequency values (Hz), and the second column represents the magnitude spectrum of the upper limit mask.

**Tunable:** Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**LowerMask — Lower limit mask**

-Inf (default) | two-column matrix

Lower limit spectral mask, specified as a two-column matrix. The first column represents the frequency values (Hz), and the second column represents the magnitude spectrum of the lower limit mask.

**Tunable:** Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Usage****Syntax**

```
dfv(filt)
dfv(B,A)
```

**Description**

`dfv(filt)` displays the time-varying magnitude response of the object filter, `filt`, in the Dynamic Filter Visualizer figure, as long as `filt` has a valid `freqz()` implementation.

`dfv(B,A)` displays the magnitude response for the digital filters with numerator and denominator polynomial coefficients stored in  $B_1$  and  $A_1$ ,  $B_2$  and  $A_2$ , ..., and  $B_N$  and  $A_N$ , respectively.

**Input Arguments****filt — Input filter**

filter System object

Input filter System object with a valid `freqz()` implementation.

**B — Numerator polynomial coefficients**

row vector

Numerator polynomial coefficients, specified as a row vector.

Data Types: single | double

**A — Denominator polynomial coefficients**

scalar | row vector

Denominator polynomial coefficients, specified as a:

- scalar -- The filter is an FIR filter.
- row vector -- The filter is an IIR filter.

Data Types: single | double

## Object Functions

### Specific to `dsp.DynamicFilterVisualizer`

`step` Display time-varying magnitude response

### Specific to Scopes

`show` Display scope window  
`hide` Hide scope window  
`isVisible` Determine visibility of scope  
`generateScript` Generate MATLAB script to create scope with current settings

## Examples

### Plot Time-Varying Magnitude and Phase Response of FIR Filter

Design an FIR filter with a time-varying magnitude and phase response. Plot this varying response on a dynamic filter visualizer in normalized frequency units.

Create a `dsp.DynamicFilterVisualizer` object. Set the `PlotAsMagnitudePhase` and the `NormalizedFrequency` properties to true.

```
dfv = dsp.DynamicFilterVisualizer(PlotAsMagnitudePhase=1,...  
    NormalizedFrequency=true,ShowLegend=true,...  
    Title='Magnitude and Phase Response',...  
    FilterNames="FIR Filter")
```

```
dfv =  
    dsp.DynamicFilterVisualizer with properties:
```

```
        FFTLength: 2048  
    NormalizedFrequency: 1  
        FrequencyRange: [0 1]  
            XScale: 'Linear'  
    MagnitudeDisplay: 'Magnitude (dB)'  
    PlotAsMagnitudePhase: 1  
            PlotType: 'Line'  
        AxesScaling: 'Auto'
```

Show all properties

Vary the cutoff frequency of the FIR filter  $k$  from 0.1 to 0.5 in increments of 0.001. View the varying magnitude and phase response using the dynamic filter visualizer.

```
for k = 0.1:0.001:0.5  
    b = fir1(90,k);  
    dfv(b,1);  
end
```

### Plot Time-Varying Magnitude Response of Variable Bandwidth FIR Filter

Visualize the varying magnitude response of the variable bandwidth FIR filter using the dynamic filter visualizer.

Create a `dsp.DynamicFilterVisualizer` object.

```
dfv = dsp.DynamicFilterVisualizer(YLimits=[-160 10],...
    FilterNames="Variable Bandwidth FIR Filter")
```

```
dfv =
    dsp.DynamicFilterVisualizer with properties:
```

```

        FFTLength: 2048
    NormalizedFrequency: 0
        SampleRate: 44100
    FrequencyRange: [0 22050]
        XScale: 'Linear'
    MagnitudeDisplay: 'Magnitude (dB)'
    PlotAsMagnitudePhase: 0
        PlotType: 'Line'
    AxesScaling: 'Manual'
```

Show all properties

Design a bandpass variable bandwidth FIR filter with a center frequency of 5 kHz and a bandwidth of 4 kHz.

```
Fs = 44100;
vbw = dsp.VariableBandwidthFIRFilter(FilterType='Bandpass',...
    FilterOrder=100,...
    SampleRate=Fs,...
    CenterFrequency=5e3,...
    Bandwidth=4e3);
```

Vary the center frequency of the filter. Visualize the varying magnitude response of the filter using the `dsp.DynamicFilterVisualizer` object.

```
for idx = 1:100
    dfv(vbw);
    vbw.CenterFrequency = vbw.CenterFrequency + 20;
end
```

## Version History

Introduced in R2018b

**R2022b:** Filter names support array of strings

Starting in R2022b, you can specify the `FilterNames` property of the `dsp.DynamicFilterVisualizer` object as an array of strings.

```
dfv = dsp.DynamicFilterVisualizer(FilterNames=["Filter 1", "Filter 2"]);
```

### **R2022b: Enhancements to the dsp.DynamicFilterVisualizer object and the Dynamic Filter Visualizer UI**

The `dsp.DynamicFilterVisualizer` object has the following new properties starting R2022b:

- `PlotAsMagnitudePhase` -- Split the magnitude and phase of the input signal and plot them on two separate axes within the same window
- `PlotType` -- Plot type
- `AxesScaling` -- Axes scaling mode
- `AxesScalingNumUpdates` -- Number of updates before scaling
- `MaximizeAxes` -- Maximize axes control
- `ShowGrid` -- Grid visibility

The **Dynamic Filter Visualizer** app that you launch using the object has these enhancements in R2022b:

- **Magnitude Phase** button -- This button corresponds to the `PlotAsMagnitudePhase` property in the object.
- **Generate Script** button -- Generate a script to re-create your dynamic filter visualizer plot with the same settings. When you click this button, an editor window opens with the code that you can use to re-create your `dsp.DynamicFilterVisualizer` object.

### **R2022b: Configure dsp.DynamicFilterVisualizer measurements programmatically**

You can now configure the cursor and the peak finder measurements in the `dsp.DynamicFilterVisualizer` object programmatically using these properties:

- `MeasurementChannel`
- `CursorMeasurements`
- `PeakFinder`

### **R2023a: Normalized frequency in dsp.DynamicFilterVisualizer**

When you set the `NormalizedFrequency` property to `true`, the dynamic filter visualizer shows the frequency response of the filter in normalized frequency units (0 to 1).

# dsp.FourthOrderSectionFilter

Implement cascade of fourth-order section filter

## Description

The `dsp.FourthOrderSectionFilter` implements a cascade of fourth-order section filters.

## Creation

### Syntax

```
fos = dsp.FourthOrderSectionFilter
fos = dsp.FourthOrderSectionFilter(num,den)
fos = dsp.FourthOrderSectionFilter(Name,Value)
```

### Description

`fos = dsp.FourthOrderSectionFilter` returns a `FourthOrderSectionFilter` object, `fos`, that implements a cascade of fourth order filter sections.

`fos = dsp.FourthOrderSectionFilter(num,den)` returns a `FourthOrderSectionFilter` object with the `Numerator` property set to `num` and the `Denominator` property set to `den`.

`fos = dsp.FourthOrderSectionFilter(Name,Value)` returns a `FourthOrderSectionFilter` object with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order.

Example: `fos = dsp.FourthOrderSectionFilter('Numerator',num,'Denominator',den)`

## Properties

### **num** — Numerator coefficients of filter

[1 0.1 0.2 0.3 0.4] (default) | row vector | matrix

Numerator coefficients of the filter, specified as an  $L$ -by-5 matrix, where  $L$  is the number of filter sections. The size of this property cannot change when the object is locked. However, the values can be modified.

Data Types: `single` | `double`

Complex Number Support: Yes

### **den** — Denominator coefficients of filter

[1 0.1 0.2 0.3 0.4] (default) | row vector | matrix

Denominator coefficients of the filter, specified as an  $L$ -by-5 matrix or an  $L$ -by-4 matrix, where  $L$  is the number of filter sections. The leading denominator coefficients are assumed to be 1 always. If the denominator is of size  $L$ -by-4, one(s) are appended to make the size  $L$ -by-5. If the denominator is of size  $L$ -by-5, the first column values are ignored and appended with 1s. The size of this property cannot change when the object is locked. However, the values can be modified.

Data Types: `single` | `double`  
Complex Number Support: Yes

### Usage

### Syntax

$y = \text{fos}(x)$

### Description

$y = \text{fos}(x)$  filters the input signal using the specified fourth-order section filter to produce the filtered output,  $y$ .

### Input Arguments

#### **x** — Input signal

vector | matrix

Input signal, specified as a vector or a matrix.

The input can be a variable-sized signal, that is, the frame size of each channel (number of rows) can change even after the object is locked. However, the number of channels (number of columns) cannot change.

Data Types: `single` | `double`

### Output Arguments

#### **y** — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity as the input signal.

Data Types: `single` | `double`

### Object Functions

#### Specific to `dsp.FourthOrderSectionFilter`

|                       |  |
|-----------------------|--|
| <code>fvtool</code>   | Visualize frequency response of DSP filters                  |
| <code>freqz</code>    | Frequency response of discrete-time filter System object     |
| <code>impz</code>     | Impulse response of discrete-time filter System object       |
| <code>info</code>     | Information about filter System object                       |
| <code>coeffs</code>   | Returns the filter System object coefficients in a structure |
| <code>cost</code>     | Estimate cost of implementing filter System object           |
| <code>grpdelay</code> | Group delay response of discrete-time filter System object   |

#### Common to All Objects

`step` Run System object algorithm

|          |  |
|----------|--|
| release  | Release resources and allow changes to System object property values and input characteristics |
| reset    | Reset internal states of System object   |
| clone    | Create duplicate System object   |
| isLocked | Determine if System object is in use   |

## Examples

### Filter Noisy Signal Using Fourth-Order Section (FOS) Filter

Filter a noisy sinusoidal signal using the `dsp.FourthOrderSectionFilter` object. Visualize the original and filtered signals using a spectrum analyzer.

#### Input Signal

The input signal is the sum of two sine waves with frequencies 100 Hz and 350 Hz. Add zero-mean white Gaussian noise with a standard deviation of  $1e-4$  to the sum of sine waves. The sample rate is 1000 Hz.

```
frameSize = 1024;
fs = 1000;
Sine1 = dsp.SineWave(5,100,'SamplesPerFrame',1024,'SampleRate',fs);
Sine2 = dsp.SineWave(2,350,pi/2,'SamplesPerFrame',1024,...
    'SampleRate',fs);
x = Sine1()+Sine2()+1e-4.*randn(Sine1.SamplesPerFrame,1);
```

#### Fourth-Order Section (FOS) Filter Coefficients

The numerator and denominator coefficients for the FOS filter are obtained using `designParamEq` which is part of Audio Toolbox:

```
%N = [2,4];
%gain = [5,10];
%centerFreq = [0.025,0.75];
%bandwidth = [0.025,0.35];
%mode = 'fos';
%[num,den] = designParamEQ(N,gain,centerFreq,bandwidth,mode,'Orientation','row');

num = [1.0223    -1.9368    0.9205         0         0
       1.5171    2.3980    1.4317    0.6416    0.2752];

den = [-1.9368    0.9428         0         0
       2.0136    1.9224    1.0260    0.3016];
```

#### Initialize Filter and Spectrum Analyzer

Construct the FOS IIR filter using the `num` and `den` coefficients. Construct a spectrum analyzer to visualize the original sinusoidal signal and the filtered signal.

```
fos = dsp.FourthOrderSectionFilter('Numerator',num,...
    'Denominator',den);

scope = spectrumAnalyzer(...
    'SampleRate',fs,...
    'PlotAsTwoSidedSpectrum',false,...
```

```

'FrequencyScale','linear',...
'Method','welch',...
'Title','Original and Filtered Signals',...
>ShowLegend',true,...
'ChannelNames',{'Original Signal','Filtered Signal'});

```

Filter the input signal, and visualize the original and filtered spectrums.

```

for i = 1:10000
    y = fos(x);
    scope([x,y]);
end
release(scope);

```

### Lowpass Fourth-Order Section (FOS) Filter

Design a lowpass fourth-order section (FOS) filter using the `fdesign` function. Using this filter, filter a noisy sinusoidal signal with two tones, one at 3 kHz, and the other at 12 kHz.

Design a fifth-order filter using the elliptic method in the `'df2tsos'` structure. Use L-infinity norm scaling in the frequency domain. Specify the passband frequency to be  $0.15\pi$  rad/sample and the stopband frequency to be  $0.25\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
Fp = 0.15;  
Fst = 0.25;  
Ap = 1;  
Ast = 60;
```

The filter coefficients are scaled using an `fdopts.sosscaling` object. The scaling object is defined to have no numerator constraints, and the `ScaleValueConstraint` is set to `'unit'`, specifying the scaling to be unity scaling.

```
fdo = fdopts.sosscaling;  
fdo.NumeratorConstraint='none';  
fdo.ScaleValueConstraint='unit';  
  
f = fdesign.lowpass('Fp,Fst,Ap,Ast',Fp,Fst,Ap,Ast);  
hFilter = design(f,'ellip','SystemObject',true,...  
    'FilterStructure','df2tsos','SOSScaleNorm','Linf',...  
    'SOSScaleOpts',fdo)
```

```
hFilter =  
    dsp.SOSFilter with properties:  
  
        Structure: 'Direct form II transposed'  
    CoefficientSource: 'Property'  
        Numerator: [3x3 double]  
        Denominator: [3x3 double]  
    HasScaleValues: true  
        ScaleValues: [1 1 1 1.0000]
```

Show all properties

Visualize the lowpass frequency response of the designed filter using `fvtool`.

```
fvtool(hFilter)
```

Convert the lowpass filter to a bandpass filter using the `iirlp2bp` function.

```
[num,den] = iirlp2bp(hFilter.Numerator,hFilter.Denominator,Fp,[0.25,0.75])
```

```
num = 3x5
```

```
    0.2456         0   -0.2456         0         0
    0.4175   -0.0000   -0.4206   -0.0000    0.4175
    0.4281   -0.0000   -0.6433   -0.0000    0.4281
```

```
den = 3x5
```

```
    1.0000   -0.0000    0.5088         0         0

    1.0000   -0.0000    0.5160   -0.0000    0.5283
```

Create a fourth-order section filter using these numerator and denominator coefficients.

```
fos = dsp.FourthOrderSectionFilter(num,den)
```

```
fos =
```

```
FourthOrderSectionFilter with properties:
```

```
    Numerator: [3x5 double]
    Denominator: [3x5 double]
```

Visualize the frequency response of the fourth-order section filter using `fvtool`.

```
fvtool(fos);
```

Filter a noisy input signal with the fourth-order section filter. Visualize the spectra of the original signal and the filtered signal using the spectrum analyzer.

The input is a sum of two sine waves with frequencies 3 kHz and 12 kHz, respectively. The input sample rate is 44.1 kHz, and the frame size is set to 1024 samples.

```
fs = 44100;
FrameLength = 1024;
```

```
SINE1 = dsp.SineWave('SamplesPerFrame',FrameLength,'SampleRate',fs,'Frequency',3000);
SINE2 = dsp.SineWave('SamplesPerFrame',FrameLength,'SampleRate',fs,'Frequency',12000);
```

Initialize a spectrum analyzer to visualize the signal spectra.

```
scope = spectrumAnalyzer(...
    'SampleRate',fs,...
    'PlotAsTwoSidedSpectrum',false,...
    'Title','Original and Filtered Signals',...
    'ShowLegend',true,...
    'YLimits',[-180 50],...
    'ChannelNames',{'Original Signal','Filtered Signal'});
for index = 1:1000
    x = SINE1() + SINE2() + 0.001*randn(FrameLength,1);
    y = fos(x);
```

```
scope([x,y]);  
end
```

# dsp.ISTFT

Inverse short-time FFT

## Description

The `dsp.ISTFT` object computes the inverse short-time Fourier transform (ISTFT) of the frequency-domain input signal and returns the time-domain output. The object accepts frames of Fourier-transformed data, converts these frames into the time domain using the IFFT operation, and performs overlap-add to reconstruct the data. The output of the object is the reconstructed signal normalized by a factor that depends on the hop length and `sum(window)`. For more details, see “Algorithms” on page 4-1483.

## Creation

### Syntax

```
istf = dsp.ISTFT
istf = dsp.ISTFT(window)
istf = dsp.ISTFT(window,overlap)
istf = dsp.ISTFT(window,overlap,isconjsym)
istf = dsp.ISTFT(window,overlap,isconjsym,woa)
istf = dsp.ISTFT(Name,Value)
```

### Description

`istf = dsp.ISTFT` returns an object, `istf`, that implements inverse short-time FFT. The object processes the data independently across each input channel over time.

`istf = dsp.ISTFT(window)` returns an inverse short-time FFT object with the `Window` property set to `window`.

`istf = dsp.ISTFT(window,overlap)` returns an inverse short-time FFT object with the `Window` property set to `window` and the `OverlapLength` property set to `overlap`.

`istf = dsp.ISTFT(window,overlap,isconjsym)` returns an inverse short-time FFT object with the `Window` property set to `window`, `OverlapLength` property set to `overlap`, and the `ConjugateSymmetricInput` property set to `isconjsym`.

`istf = dsp.ISTFT(window,overlap,isconjsym,woa)` returns an inverse short-time FFT object with the `Window` property set to `window`, with the `OverlapLength` property set to `overlap`, the `ConjugateSymmetricInput` property set to `isconjsym`, and the `WeightedOverlapAdd` property set to `woa`.

`istf = dsp.ISTFT(Name,Value)` returns an inverse short-time FFT object with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order.

## Properties

### Window — Synthesis window

`sqrt(hann(512, 'periodic'))` (default) | vector

Synthesis window, specified as a vector of real elements.

**Tunable:** Yes

Data Types: `single` | `double`

### OverlapLength — Overlap length

256 (default) | positive integer

Number of samples by which consecutive windows overlap, specified as a positive integer. The windows overlap to reduce the artifacts at the data boundaries.

Hop length is the difference between the window length and the overlap length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### ConjugateSymmetricInput — Input is conjugate symmetric

`true` (default) | `false`

Set this property to `true` if the input is conjugate symmetric, which yields real-valued outputs. The FFT of a real-valued signal is conjugate symmetric, and setting this property to `true` optimizes the IFFT computation method. Setting this property to `false` for conjugate symmetric inputs results in complex output values with small imaginary parts. Setting this property to `true` for non-conjugate symmetric inputs results in invalid outputs.

Data Types: `logical`

### WeightedOverlapAdd — Apply weighted overlap-add

`true` (default) | `false`

Set this property to `true` to apply weighted overlap-add. In weighted overlap-add, the IFFT output is multiplied by the window before overlap-add. Set this property to `false` to skip multiplication by the window.

Data Types: `logical`

### FrequencyRange — Frequency range

`'twosided'` (default) | `'onesided'`

Specify the frequency range as 'onesided' or 'twosided'. If you set the FrequencyRange property to:

- 'twosided' -- The inverse short-time FFT is computed for a two-sided short-time FFT. The FFT length used is equal to the input frame length.
- 'onesided' -- The one-sided inverse short-time FFT is computed for a one-sided short-time FFT. If the input frame length is odd, the FFT length used is  $(\text{frame length} - 1) \times 2$ . If the input frame length is even, the FFT length used is  $(\text{frame length} \times 2) - 1$ .

## Usage

### Syntax

```
y = istft(x)
```

### Description

`y = istft(x)` applies inverse short-time FFT on the input `x`, and returns the time-domain output `y`.

### Input Arguments

#### **x** — Input signal

vector | matrix

Frequency-domain input signal, specified as a vector or a matrix. If the input is a matrix, the object treats each column as an independent channel. The FFT length is equal to the number of rows of `x`. The FFT length, hence the number of input rows must be greater than or equal to the window length.

Data Types: `single` | `double`

### Output Arguments

#### **y** — ISTFT output

vector | matrix

Inverse short-time FFT output, returned as a vector or a matrix. The output frame length (number of rows in `y`) is equal to  $WL - OL$ , where  $WL$  is the window length and  $OL$  is the overlap length.

The output is complex with small imaginary parts when the input `x` is conjugate symmetric and the `ConjugateSymmetricInput` property is set to `false`. The data type of the output matches the data type of the input signal.

Data Types: `single` | `double`

## Object Functions

|                       |  |
|-----------------------|--|
| <code>step</code>     | Run System object algorithm  |
| <code>release</code>  | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>    | Reset internal states of System object   |
| <code>clone</code>    | Create duplicate System object   |
| <code>isLocked</code> | Determine if System object is in use   |

## Examples

### Short-Time Spectral Attenuation

Short-time spectral attenuation is achieved by applying a time-varying attenuation to the short-time spectrum of a noisy signal. The gain of the attenuation is determined by the estimate of the noise power in each subband of the spectrum. This gain, when applied to the noisy spectrum, attenuates the subbands with higher noise power and lifts the subbands with lesser noise power.

Here are the steps involved in performing the short-time spectral attenuation:

- 1 Analyze the noisy input signal by computing the short-time Fourier transform (STFT).
- 2 Multiply each subband of the transformed signal with a real positive gain less than 1.
- 3 Synthesize the denoised subbands by taking the inverse short-time Fourier transform (ISTFT). The reconstructed signal is the denoised input signal.

Use the `dsp.STFT` and `dsp.ISTFT` objects to compute the short-time and the inverse short-time Fourier transforms, respectively.

### Noisy Input Signal

The input is an audio signal sampled at the 22,050 Hz. The `dsp.AudioFileReader` object reads this signal in frames of 512 samples. The audio signal is corrupted by white Gaussian noise that has a standard deviation of 0.05. Use the `audioDeviceWriter` object to play the noisy audio signal to your computer's audio device.

```
FrameLength = 512;
afr = dsp.AudioFileReader('speech_dft.wav',...
    'SamplesPerFrame',FrameLength);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);

noiseStd = 0.05;
while ~isDone(afr)
    cleanAudio = afr();
    noisyAudio = cleanAudio + noiseStd * randn(FrameLength,1);
    adw(noisyAudio);
end
reset(afr)
```

### Initialize Short-Time and Inverse Short-Time Fourier Transform Objects

Initialize the `dsp.STFT` and `dsp.ISTFT` objects. Set the window length equal to the input frame length and the hop length to 16. The overlap length is the difference between the window length and the hop length,  $OL = WL - HL$ . Set the FFT length to 1024.

```
WindowLength = FrameLength;
HopLength = 16;
numHopsPerFrame = FrameLength / 16;
FFTLength = 1024;
```

The window used to compute the STFT and ISTFT is a periodic hamming window with length 512. The `ConjugateSymmetricInput` flag of the `istf` object is set to `true`, indicating that the output of the `istf` object is a conjugate-symmetric signal.

```
win = hamming(WindowLength, 'periodic');
stf = dsp.STFT(win, WindowLength-HopLength, FFTLength);
istf = dsp.ISTFT(win, WindowLength-HopLength, 1, 0);
```

### Gain Estimator

The next step is to define the gain estimator parameters. This gain is applied to the noisy spectrum to attenuate the subbands with higher noise power and lifter the subbands with lesser noise power.

```
dec = 16;
alpha = 15;
stftNorm = (sum(win.*win) / dec).^2;
```

### Spectral Attenuation

Feed the audio signal to `stf` one hop-length at a time. Apply the estimated gain to the transformed signal. Reconstruct the denoised version of the original speech signal by performing an inverse Fourier transform on the individual frequency bands. Play the denoised audio signal to the computer's audio device.

```
while ~isDone(afr)
    cleanAudio = afr();
    noisyAudio = cleanAudio + noiseStd * randn(FrameLength,1);
    y = zeros(FrameLength,1); % y holds the denoised audio frame

    % Feed audio to stft one hop-length at a time
    for index = 1:numHopsPerFrame
        X = stf(noisyAudio((index-1)*HopLength+1:index*HopLength));
        % Gain estimator
        Z = abs(X).^2 / (noiseStd^2 * alpha) / stftNorm;
        Z(Z<=1) = 1;
        Z = 1 - 1./Z;
        Z = sign(Z) .* sqrt(abs(Z));
        X = X .* Z;
        % Convert back to time-domain
        y((index-1)*HopLength+1:index*HopLength) = istf(X);
    end
    % Listen to denoised audio:
    adw(y);
end
```

### Perfect Reconstruction

Perfect reconstruction is when the output of `dsp. ISTFT` matches the input to `dsp. STFT`. Perfect reconstruction is obtained if the analysis window,  $g(n)$ , obeys the constant overlap-add (COLA) property at hop-size  $R$ .

$$\sum_{m=-\infty}^{\infty} g(n - mR) = 1, \forall n \in \mathbb{Z} \quad (g \in \text{COLA}(R))$$

A signal is perfectly reconstructed if the output of the `dsp. ISTFT` object matches the input to the `dsp. STFT` object.

### iscola Function

The `iscola` function checks that the specified window and overlap satisfy the COLA constraint to ensure that the inverse short-time Fourier transform (ISTFT) results in perfect reconstruction for

non-modified spectra. The function returns a logical `true` if the combination of input parameters is COLA-compliant and a logical `false` if not. The `method` argument of the function is set to `'ola'` or `'wola'` depending on whether the inversion method uses weighted overlap-add (WOLA).

Check if `hann()` window of length 120 samples and an overlap length of 60 samples is COLA compliant.

```
winLen = 120;
overlapLen = 60;
win = hann(winLen,'periodic');
tf = iscola(win,overlapLen,'ola')
```

```
tf = logical
    1
```

### Initialization

Initialize the `dsp.STFT` and `dsp.ISTFT` System objects with this hann window that is COLA compliant. Set the FFT length to equal the window length.

```
frameLen = winLen-overlapLen;
stf = dsp.STFT('Window',win,'OverlapLength',overlapLen,'FFTLength',winLen);
istf = dsp.ISTFT('Window',win,'OverlapLength',overlapLen,'WeightedOverlapAdd',0);
```

### Reconstruct Data

Compute the STFT of a random signal. Set the length of the input signal to equal the hop length (window length - overlap length). Since the window is COLA compliant, the ISTFT of this non-modified spectra perfectly reconstructs the original time-domain signal.

To confirm, compare the input,  $x$  to the reconstructed output,  $y$ . Due to the latency introduced by the objects, the reconstructed output is shifted in time compared to the input. Therefore, to compare, take the norm of the difference between the reconstructed output,  $y$  and the previous input,  $x_{prev}$ . The norm is very small, indicating that the output signal is a perfectly reconstructed version of the input signal.

```
n = zeros(1,100);
xprev = 0;
for i = 1:100
    x = randn(frameLen,1);
    X = stf(x);
    y = istf(X);
    n(1,i) = norm(y-xprev);
    xprev = x;
end
max(abs(n))
```

```
ans = 1.8077e-13
```

### ISTFT with Weighted Overlap-Add (WOLA)

In WOLA, a second window called the synthesis window,  $f(n)$ , is applied after the IFFT operation and before overlap-add. The synthesis and analysis windows are typically identical and are usually obtained by taking the square root of windows satisfying COLA (thereby ensuring perfect reconstruction).

## iscola Function

Check if `sqrt(hann())` window of length 120 samples and an overlap length of 60 samples is WOLA compliant. Set the method argument of the `iscola` function to 'wola'. The output of the `iscola` function is 1 indicating that this window is WOLA compliant.

```
winWOLA = sqrt(hann(winLen,'periodic'));
tfWOLA = iscola(winWOLA,overlapLen,'wola')

tfWOLA = logical
         1
```

## Reconstruct Data with WOLA

Release the `dsp.STFT` and `dsp.ISTFT` System objects and set the window to `sqrt(hann(winLen,'periodic'))` window. To use weighted overlap-add on the ISTFT side, set the 'WeightedOverlapAdd' to true.

```
release(stf);
release(istf);
stf.Window = winWOLA;
istf.Window = winWOLA;
istf.WeightedOverlapAdd = true;

n = zeros(1,100);
xprev = 0;
for i = 1:100
    x = randn(frameLen,1);
    X = stf(x);
    y = istf(X);
    n(1,i) = norm(y-xprev);
    xprev = x;
end
max(abs(n))

ans = 3.7930e-15
```

The norm of the difference between the input signal and the reconstructed signal is very small indicating that the signal has been reconstructed perfectly.

## More About

### Inverse Short-Time Fourier Transform (ISTFT)

The inverse short-time Fourier transform of a discrete frequency-domain signal is computed by taking the IFFT of the input frequency subbands, overlap-adding the inverted signals, and normalizing the output to reconstruct the data.

The object accepts frames of Fourier-transformed data. These segments are converted into the time-domain using the IFFT operation. The inverted segments are overlapped so that the artifacts at the boundary are reduced. To reconstruct the data, the overlapped signals are added and normalized by a factor that is a ratio of the hop length and `sum(window)`.

The ISTFT is given by

$$\begin{aligned}
 y(n) &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \sum_{m=-\infty}^{\infty} Y_m(\omega) e^{j\omega n} d\omega \\
 &= \sum_{m=-\infty}^{\infty} \frac{1}{2\pi} \int_{-\pi}^{\pi} Y_m(\omega) e^{j\omega n} d\omega \\
 &= \sum_{m=-\infty}^{\infty} y_m(n)
 \end{aligned}$$

where,

- $y(n)$  -- Reconstructed signal at time  $n$ .
- $Y_m(\omega)$  -- Frequency-domain input.

### ISTFT with Weighted Overlap-Add (WOLA)

In WOLA, a second window (usually called the synthesis window) is applied after the IFFT operation and before overlap-add. WOLA is used to suppress discontinuities at frame boundaries caused by nonlinear processing of the STFT.

The analysis window (on the STFT side) and the synthesis window (on the ISTFT side) are typically identical, and are usually obtained by taking the square root of windows satisfying the constant overlap-add (COLA) property, thereby ensuring perfect reconstruction. For details on the COLA property, see the More About on page 4-1494 section in dsp . STFT page.

The inverse FFT of frequency-domain input  $Y_m(\omega)$  produces the output  $y_m(n)$ , where  $n = 0$  to  $N - 1$ ,

and is given by  $y_m(n) = \frac{1}{2\pi} \int_{-\pi}^{\pi} Y_m(\omega) e^{j\omega n} d\omega$ .

The synthesis window,  $f(n)$ , applied to  $y_m(n)$  yields the weighted output frame:

$$y_m^f(n) = y_m(n) \cdot f(n), \quad \forall n = 0, \dots, N - 1.$$

Translate the  $m^{\text{th}}$  output frame to time  $mR$ :

$$y_m^f(n) = y_m^f(n - mR).$$

Add the translated signal to the accumulated output signal,  $y(n)$ :

$$y(n) = y(n - 1) + y_m^f(n).$$

To obtain perfect reconstruction in the absence of spectral modifications, then the following condition must be true:

$$\begin{aligned}
 y(n) &= \sum_{m=-\infty}^{\infty} x(n)g(n - mR)f(n - mR) \\
 &= x(n) \sum_{m=-\infty}^{\infty} g(n - mR)f(n - mR), \\
 &= x(n),
 \end{aligned}$$

which is true if and only if

$$\sum_m g(n - mR)f(n - mR) = 1, \quad \forall n \in \mathbb{Z}.$$

where,

- $g(n)$  -- Analysis window on the STFT side.
- $f(n)$  -- Synthesis window on the ISTFT side.

## Algorithms

Here is a sketch of how the algorithm is implemented without weighted overlap-add (WOLA):

The frequency-domain input is inverted using IFFT, and then overlap-add is performed. Note that each run of the algorithm generates  $R$  new output time-domain samples, where  $R$  is the hop length. The hop length is defined as  $WL - OL$ , where  $WL$  is the window length and  $OL$  is the overlap length. The normalization stage multiplies the output by  $R/\text{sum}(win)$ , where  $win$  is the window vector specified in the Window property.

Here is a sketch of how the algorithm is implemented with Weighted Overlap-Add (WOLA):

In WOLA, a second window (usually called the synthesis window) is applied after the IFFT operation and before overlap-add. WOLA is used to suppress discontinuities at frame boundaries caused by nonlinear processing of the STFT. For more details, see More About on page 4-1481.

Here is an illustration of how the input frequency subbands look when inverted with IFFT and overlap-added together to reconstruct a time-domain signal.

The analysis window (on the STFT side) and the synthesis window (on the ISTFT side) are typically identical. To ensure perfect reconstruction, the windows are usually obtained by taking the square root of windows satisfying the constant overlap-add (COLA) property. For details on the COLA property and how perfect reconstruction is defined, see the More About on page 4-1494 in `dsp.STFT` page.

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

When the FFT length, which is determined by the number of rows in the input signal, is not a power of two, the executable generated from this object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

This limitation does not apply when the FFT length is a power of two.

Inverse Short-Time FFT

# dsp.STFT

Short-time FFT

## Description

The `dsp.STFT` object computes the short-time Fourier transform (STFT) of the time-domain input signal. The object accepts frames of time-domain data, buffers them to the desired window length and overlap length, multiplies the samples by the window, and then performs FFT on the buffered windows. For more details, see “Algorithms” on page 4-1495.

Use the STFT to analyze the frequency content of a signal that varies with time.

## Creation

### Syntax

```
stf = dsp.STFT
stf = dsp.STFT(window)
stf = dsp.STFT(window,overlap)
stf = dsp.STFT(window,overlap,nfft)
stf = dsp.STFT(Name,Value)
```

### Description

`stf = dsp.STFT` returns an object, `stf`, that implements the short-time FFT. The object processes the data independently across each input channel over time.

`stf = dsp.STFT(window)` returns a short-time FFT object with the `Window` property set to `window`.

`stf = dsp.STFT(window,overlap)` returns a short-time FFT object with the `Window` property set to `window` and the `OverlapLength` property set to `overlap`.

`stf = dsp.STFT(window,overlap,nfft)` returns a short-time FFT object with the `Window` property set to `window`, the `OverlapLength` property set to `overlap`, and the `FFTLength` property set to `nfft`.

`stf = dsp.STFT(Name,Value)` returns a short-time FFT object with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order.

## Properties

### Window — Analysis window

`sqrt(hann(512,'periodic'))` (default) | vector

Analysis window, specified as a vector of real elements.

The object buffers the input into overlapping window segments using the specified window length and overlap length, and then multiplies each overlapped segment by the window.

**Tunable:** Yes

Data Types: single | double

**OverlapLength — Overlap length**

256 (default) | positive integer

Number of samples by which consecutive windows overlap, specified as a positive integer. The window overlap reduces the artifacts at the data boundaries.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### FFTLength — FFT length

512 (default) | positive integer

FFT length, specified as a positive integer. This property determines the length of the STFT output (number of rows). The FFT length must be greater than or equal to the window length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### FrequencyRange — Frequency range

'twosided' (default) | 'onesided'

Frequency range over which the short-time FFT is computed, specified as:

- 'twosided' --The short-time FFT is computed for complex or real inputs signals. The length of the short-time FFT is equal to the value you specify in the `FFTLength` property.
- 'onesided' -- The one-sided short-time FFT is computed for real input signals only. When the FFT length is even, the short-time FFT length is  $\text{FFTLength}/2+1$ . If FFT length is odd, the length of the short-time FFT is equal to  $(\text{FFTLength}+1)/2$ .

## Usage

### Syntax

```
y = stf(x)
```

### Description

`y = stf(x)` applies short-time FFT on the input `x` and returns the frequency-domain output `y`.

### Input Arguments

#### **x** — Input signal

vector | matrix

Time-domain input signal, specified as a vector or a matrix. If the input is a matrix, the object treats each column as an independent channel. The frame size (number of rows in `x`) must be equal to or less than the hop length (window length – overlap length).

The input can be a variable-sized signal. That is, the frame size of the signal can change in between calls to the object algorithm without calling the `release` function. The number of channels must remain the same.

If the `FrequencyRange` property is set to `'onesided'`, the input must be real. If the `FrequencyRange` property is set to `'twosided'`, the input can be real or complex.

Data Types: `single` | `double`

### Output Arguments

#### **y** — STFT output

vector | matrix

Short-time FFT output, returned as a vector or a matrix.

If there are enough samples (equal to hop length) to form an STFT output, `y` is an `FFTLength`-by-`N` matrix, where `N` is the number of input channels. If there are not enough samples to form an STFT output, `y` is empty.

The data type of the output matches that of the input signal.

Data Types: `single` | `double`

### Object Functions

|                                 |  |
|---------------------------------|--|
| <code>step</code>               | Run System object algorithm  |
| <code>release</code>            | Release resources and allow changes to System object property values and input characteristics |
| <code>reset</code>              | Reset internal states of System object   |
| <code>clone</code>              | Create duplicate System object   |
| <code>isLocked</code>           | Determine if System object is in use   |
| <code>getFrequencyVector</code> | Get the vector of frequencies at which the short-time FFT is computed                          |

### Examples

#### Short-Time Spectral Attenuation

Short-time spectral attenuation is achieved by applying a time-varying attenuation to the short-time spectrum of a noisy signal. The gain of the attenuation is determined by the estimate of the noise power in each subband of the spectrum. This gain, when applied to the noisy spectrum, attenuates the subbands with higher noise power and lifts the subbands with lesser noise power.

Here are the steps involved in performing the short-time spectral attenuation:

- 1 Analyze the noisy input signal by computing the short-time Fourier transform (STFT).
- 2 Multiply each subband of the transformed signal with a real positive gain less than 1.
- 3 Synthesize the denoised subbands by taking the inverse short-time Fourier transform (ISTFT). The reconstructed signal is the denoised input signal.

Use the `dsp.STFT` and `dsp.ISTFT` objects to compute the short-time and the inverse short-time Fourier transforms, respectively.

#### Noisy Input Signal

The input is an audio signal sampled at the 22,050 Hz. The `dsp.AudioFileReader` object reads this signal in frames of 512 samples. The audio signal is corrupted by white Gaussian noise that has a

standard deviation of 0.05. Use the `audioDeviceWriter` object to play the noisy audio signal to your computer's audio device.

```
FrameLength = 512;
afr = dsp.AudioFileReader('speech_dft.wav',...
    'SamplesPerFrame',FrameLength);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);

noiseStd = 0.05;
while ~isDone(afr)
    cleanAudio = afr();
    noisyAudio = cleanAudio + noiseStd * randn(FrameLength,1);
    adw(noisyAudio);
end
reset(afr)
```

### Initialize Short-Time and Inverse Short-Time Fourier Transform Objects

Initialize the `dsp.STFT` and `dsp.ISTFT` objects. Set the window length equal to the input frame length and the hop length to 16. The overlap length is the difference between the window length and the hop length,  $OL = WL - HL$ . Set the FFT length to 1024.

```
WindowLength = FrameLength;
HopLength = 16;
numHopsPerFrame = FrameLength / 16;
FFTLength = 1024;
```

The window used to compute the STFT and ISTFT is a periodic hamming window with length 512. The `ConjugateSymmetricInput` flag of the `istft` object is set to `true`, indicating that the output of the `istft` object is a conjugate-symmetric signal.

```
win = hamming(WindowLength,'periodic');
stf = dsp.STFT(win,WindowLength-HopLength,FFTLength);
istf = dsp.ISTFT(win,WindowLength-HopLength,1,0);
```

### Gain Estimator

The next step is to define the gain estimator parameters. This gain is applied to the noisy spectrum to attenuate the subbands with higher noise power and lifter the subbands with lesser noise power.

```
dec = 16;
alpha = 15;
stftNorm = (sum(win.*win) / dec).^2;
```

### Spectral Attenuation

Feed the audio signal to `stf` one hop-length at a time. Apply the estimated gain to the transformed signal. Reconstruct the denoised version of the original speech signal by performing an inverse Fourier transform on the individual frequency bands. Play the denoised audio signal to the computer's audio device.

```
while ~isDone(afr)
    cleanAudio = afr();
    noisyAudio = cleanAudio + noiseStd * randn(FrameLength,1);
    y = zeros(FrameLength,1); % y holds the denoised audio frame

    % Feed audio to stft one hop-length at a time
    for index = 1:numHopsPerFrame
```

```

X = stf(noisyAudio((index-1)*HopLength+1:index*HopLength));
% Gain estimator
Z = abs(X).^2 / (noiseStd^2 * alpha) / stftNorm;
Z(Z<=1) = 1;
Z = 1 - 1./Z;
Z = sign(Z) .* sqrt(abs(Z));
X = X .* Z;
% Convert back to time-domain
y((index-1)*HopLength+1:index*HopLength) = istf(X);
end
% Listen to denoised audio:
adw(y);
end

```

### Perfect Reconstruction

Perfect reconstruction is when the output of `dsp.ISTFT` matches the input to `dsp.STFT`. Perfect reconstruction is obtained if the analysis window,  $g(n)$ , obeys the constant overlap-add (COLA) property at hop-size  $R$ .

$$\sum_{m=-\infty}^{\infty} g(n - mR) = 1, \quad \forall n \in \mathbb{Z} \quad (g \in \text{COLA}(R))$$

A signal is perfectly reconstructed if the output of the `dsp.ISTFT` object matches the input to the `dsp.STFT` object.

### iscola Function

The `iscola` function checks that the specified window and overlap satisfy the COLA constraint to ensure that the inverse short-time Fourier transform (ISTFT) results in perfect reconstruction for non-modified spectra. The function returns a logical `true` if the combination of input parameters is COLA-compliant and a logical `false` if not. The `method` argument of the function is set to `'ola'` or `'wola'` depending on whether the inversion method uses weighted overlap-add (WOLA).

Check if `hann()` window of length 120 samples and an overlap length of 60 samples is COLA compliant.

```

winLen = 120;
overlapLen = 60;
win = hann(winLen,'periodic');
tf = iscola(win,overlapLen,'ola')

```

```

tf = logical
     1

```

### Initialization

Initialize the `dsp.STFT` and `dsp.ISTFT` System objects with this hann window that is COLA compliant. Set the FFT length to equal the window length.

```

frameLen = winLen-overlapLen;
stf = dsp.STFT('Window',win,'OverlapLength',overlapLen,'FFTLength',winLen);
istf = dsp.ISTFT('Window',win,'OverlapLength',overlapLen,'WeightedOverlapAdd',0);

```

## Reconstruct Data

Compute the STFT of a random signal. Set the length of the input signal to equal the hop length (window length - overlap length). Since the window is COLA compliant, the ISTFT of this non-modified spectra perfectly reconstructs the original time-domain signal.

To confirm, compare the input,  $x$  to the reconstructed output,  $y$ . Due to the latency introduced by the objects, the reconstructed output is shifted in time compared to the input. Therefore, to compare, take the norm of the difference between the reconstructed output,  $y$  and the previous input,  $x_{prev}$ . The norm is very small, indicating that the output signal is a perfectly reconstructed version of the input signal.

```
n = zeros(1,100);
xprev = 0;
for i = 1:100
    x = randn(frameLen,1);
    X = stf(x);
    y = istf(X);
    n(1,i) = norm(y-xprev);
    xprev = x;
end
max(abs(n))
```

```
ans = 1.8077e-13
```

## ISTFT with Weighted Overlap-Add (WOLA)

In WOLA, a second window called the synthesis window,  $f(n)$ , is applied after the IFFT operation and before overlap-add. The synthesis and analysis windows are typically identical and are usually obtained by taking the square root of windows satisfying COLA (thereby ensuring perfect reconstruction).

### iscola Function

Check if `sqrt(hann())` window of length 120 samples and an overlap length of 60 samples is WOLA compliant. Set the method argument of the `iscola` function to `'wola'`. The output of the `iscola` function is 1 indicating that this window is WOLA compliant.

```
winWOLA = sqrt(hann(winLen,'periodic'));
tfWOLA = iscola(winWOLA,overlapLen,'wola')
```

```
tfWOLA = logical
        1
```

## Reconstruct Data with WOLA

Release the `dsp.STFT` and `dsp.ISTFT` System objects and set the window to `sqrt(hann(winLen,'periodic'))` window. To use weighted overlap-add on the ISTFT side, set the `'WeightedOverlapAdd'` to `true`.

```
release(stf);
release(istf);
stf.Window = winWOLA;
istf.Window = winWOLA;
istf.WeightedOverlapAdd = true;
```

```
n = zeros(1,100);
xprev = 0;
for i = 1:100
    x = randn(frameLen,1);
    X = stf(x);
    y = istf(X);
    n(1,i) = norm(y-xprev);
    xprev = x;
end
max(abs(n))

ans = 3.7930e-15
```

The norm of the difference between the input signal and the reconstructed signal is very small indicating that the signal has been reconstructed perfectly.

## More About

### Short-Time Fourier Transform

The short-time Fourier transform of a discrete time-domain signal is computed by taking the Fourier transform of short windowed segments of the time-domain data.

The discrete-time domain signal to be transformed is broken up into short segments. These segments usually overlap each other so that the artifacts at the boundaries are reduced. Each segment is Fourier transformed, and the complex result is added to a matrix, which records the magnitude and phase for each point in time and frequency.

The STFT is given by

$$X_m(\omega) = \sum_{n=-\infty}^{\infty} x(n)g(n-mR)e^{j\omega n}$$

where,

- $x(n)$  -- Input signal at time  $n$ .
- $g(n)$  -- Length  $M$  window function.
- $X_m(\omega)$  -- DTFT of windowed data centered about time  $mR$ .
- $R$  -- Hop size, in samples, between successive DTFTs.

If the window  $g(n)$  has the constant overlap-add (COLA) property at hop-size  $R$ , that is, if

$$\sum_{m=-\infty}^{\infty} g(n-mR) = 1, \forall n \in Z \quad (g \in COLA(R)),$$

then the sum of the successive DTFTs over time equals the DTFT of the whole signal  $X(\omega)$ :

$$\begin{aligned}
\sum_{m=-\infty}^{\infty} X_m(\omega) &\triangleq \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} x(n)g(n-mR)e^{j\omega n}, \\
&= \sum_{n=-\infty}^{\infty} x(n)e^{j\omega n} \cdot \sum_{m=-\infty}^{\infty} g(n-mR), \\
&= \sum_{n=-\infty}^{\infty} x(n)e^{j\omega n} \cdot 1, \\
&\triangleq \text{DTFT}_{\omega}(x) = X(\omega).
\end{aligned}$$

Taking the inverse short-time Fourier transform of this DTFT reconstructs the original time-domain signal.

The magnitude squared of the STFT yields the spectrogram representation of the Power Spectral Density of the function.

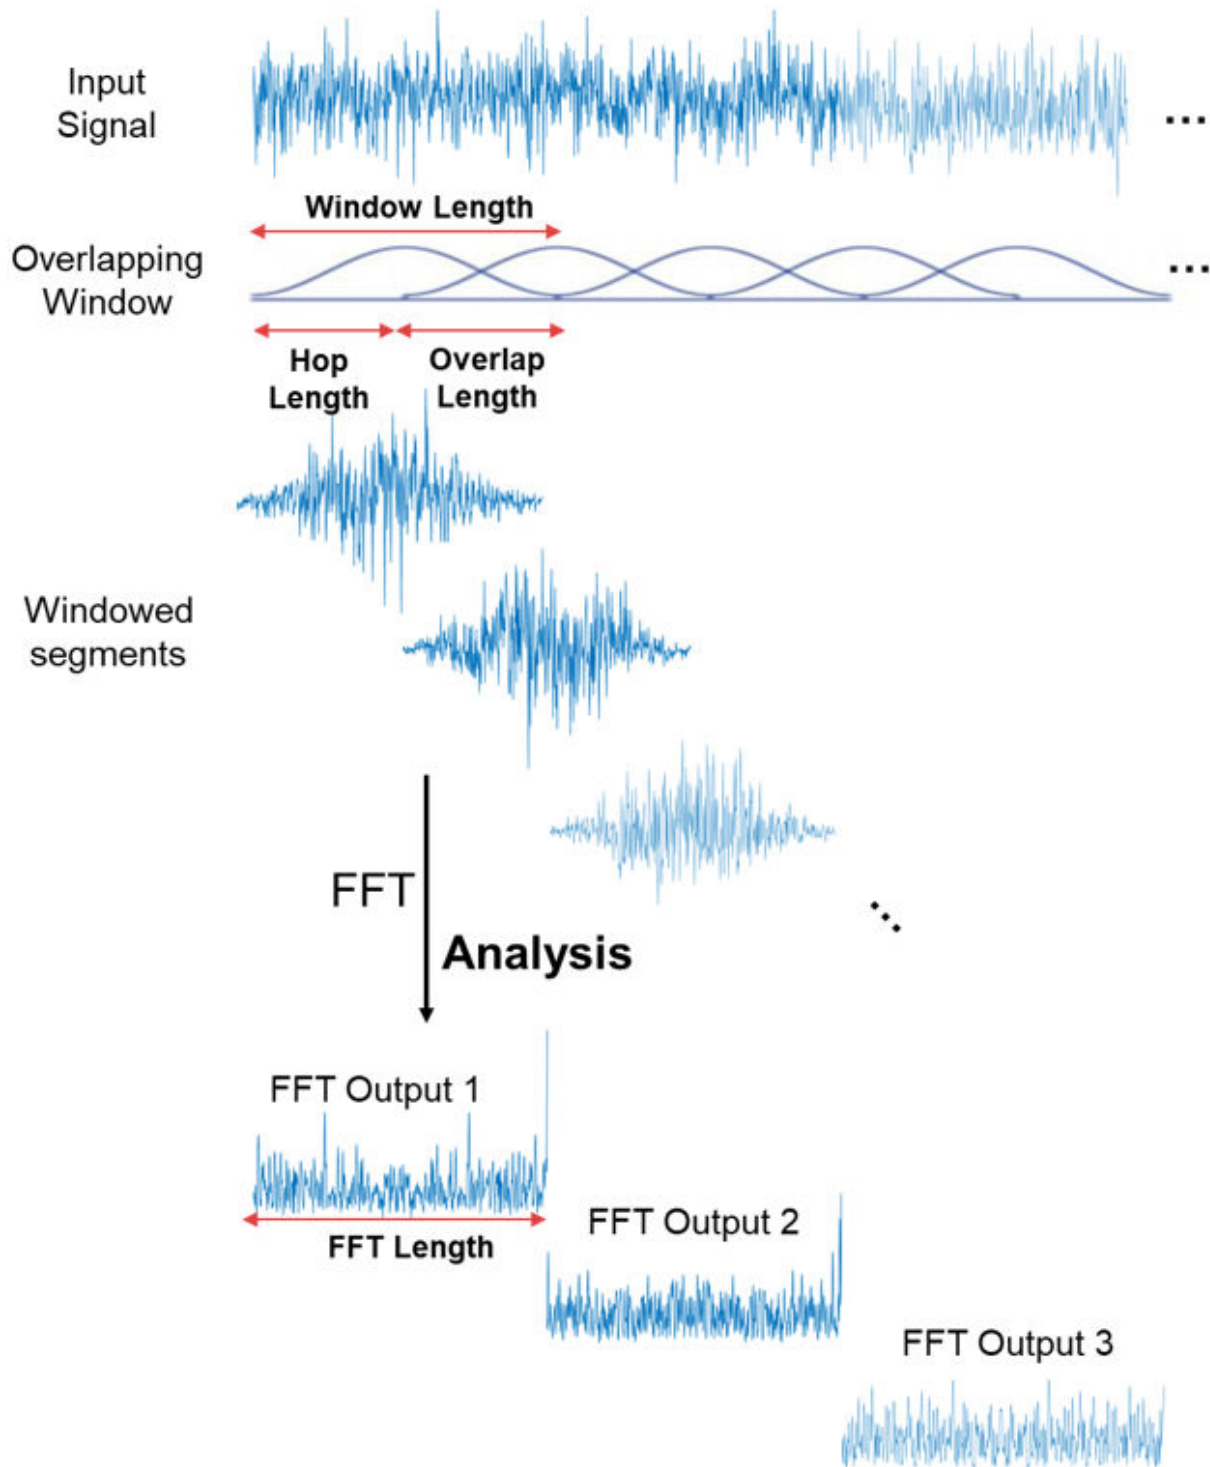

## Algorithms

Here is a sketch of how the algorithm is implemented:

The time-domain input signal is buffered based on a user-specified window length ( $WL$ ) and overlap length ( $OL$ ). The hop size,  $R$ , is defined as  $R = WL - OL$ . Buffered windows are multiplied by a user-specified window of length  $WL$ . The STFT output is the FFT of this product. The number of time-domain samples required to form a new FFT output is  $R$ .

Here is an illustration of how a random signal looks like in the original time-domain, after multiplying with the overlapping windows, and after applying FFT on the multiplied windows:

# addCursor

**Package:** dsp

Add cursor to Logic Analyzer

## Syntax

```
cursorTag = addCursor(scope)
cursorTag = addCursor(scope,Name,Value)
```

## Description

`cursorTag = addCursor(scope)` adds in a cursor to the display. A tag value is returned, which can be used to modify and delete the cursor.

`cursorTag = addCursor(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);
for ii = 1:20
    scope(ii,10*ii,20*ii);
end
```

### Add Cursor

Add a cursor at 15 seconds and show the cursor information.

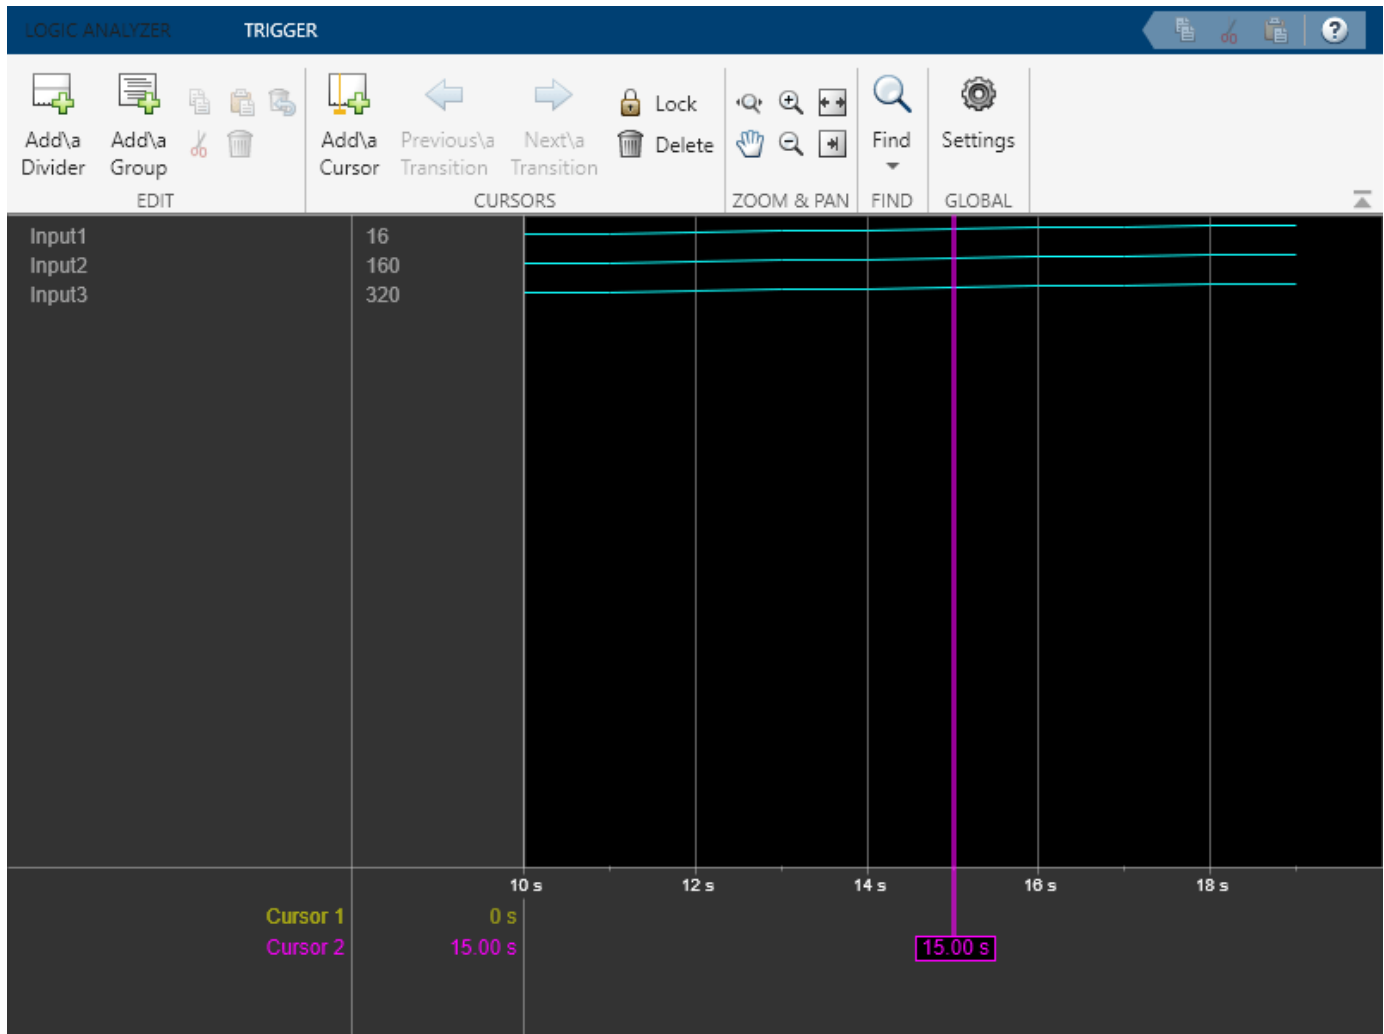

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
    Location: 15
    Color: [0 1 1]
    Locked: 0
    Tag: 'C2'
```

### Modify Cursor

Change the cursor color to magenta.

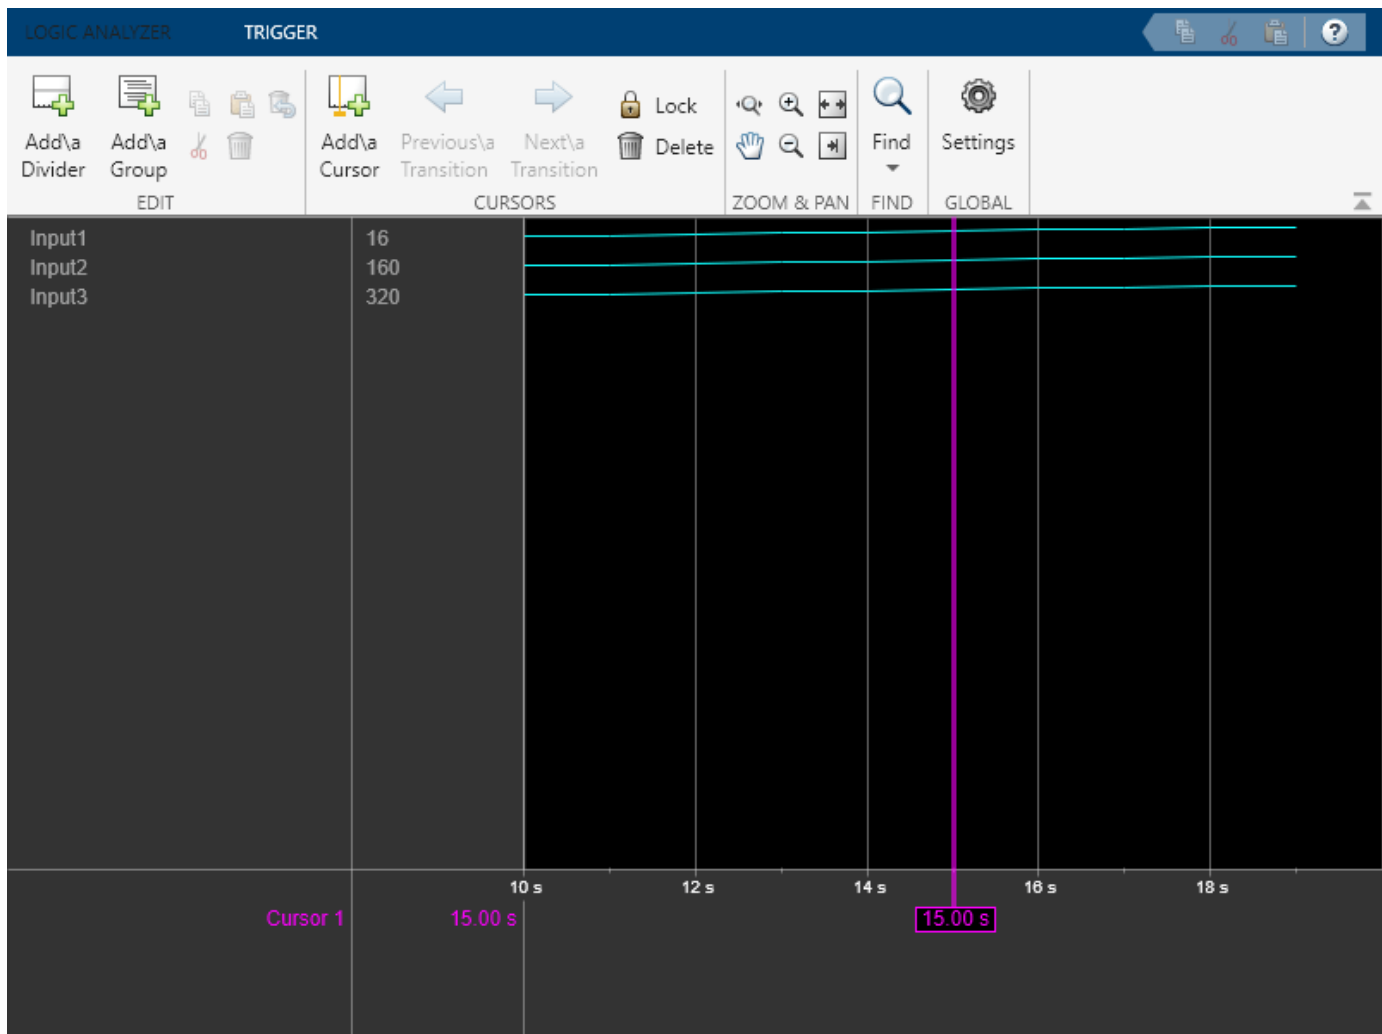

```
hide(scope)
modifyCursor(scope, cursor, 'Color', 'Magenta')
show(scope)
```

### Remove Cursor

Delete the yellow cursor at 0 seconds.

```
hide(scope)
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
show(scope)
```

## Input Arguments

**scope** – The Logic Analyzer object to which you want to add a cursor

`dsp.LogicAnalyzer` object

Example: `addCursor(scope)` adds a cursor with the default characteristics.

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

### Color – Color of the cursor

'Yellow' (default) | character vector | three element numeric vector | string scalar

Color of the cursor, specified as a [R G B] number value, color name, or color short name:

| Color Name | Short Name | RGB Triplet | Appearance  |
|------------|------------|-------------|---|
| "red"      | "r"        | [1 0 0]     |  |
| "green"    | "g"        | [0 1 0]     |  |
| "blue"     | "b"        | [0 0 1]     |  |
| "cyan"     | "c"        | [0 1 1]     |  |
| "magenta"  | "m"        | [1 0 1]     |  |
| "yellow"   | "y"        | [1 1 0]     |  |
| "black"    | "k"        | [0 0 0]     |  |
| "white"    | "w"        | [1 1 1]     |  |

Example: 'Color', 'blue'

Example: 'Color', [0,0,1]

Data Types: char | string | double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

### Location — Location of the cursor

0 (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: 'Location', 1

Data Types: double

### Locked — Locked status of the cursor

false (default) | true

Locked status of the cursor, specified as false or true.

- `true` — the cursor location cannot be changed. Logic Analyzer denotes the locked cursor by assigning a default color of gray. This color cannot be changed.
- `false` — the cursor location can be changed. Logic Analyzer denotes the unlocked cursor by assigning a default color of yellow.

Example: 'Locked', true

# addDivider

**Package:** dsp

Add divider to Logic Analyzer

## Syntax

```
dividerTag = addDivider(scope)
dividerTag = addDivider(scope,Name,Value)
```

## Description

`dividerTag = addDivider(scope)` adds a divider to the display. A tag value is returned, which can be used to modify and delete the divider.

`dividerTag = addDivider(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Manipulate Logic Analyzer Programatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

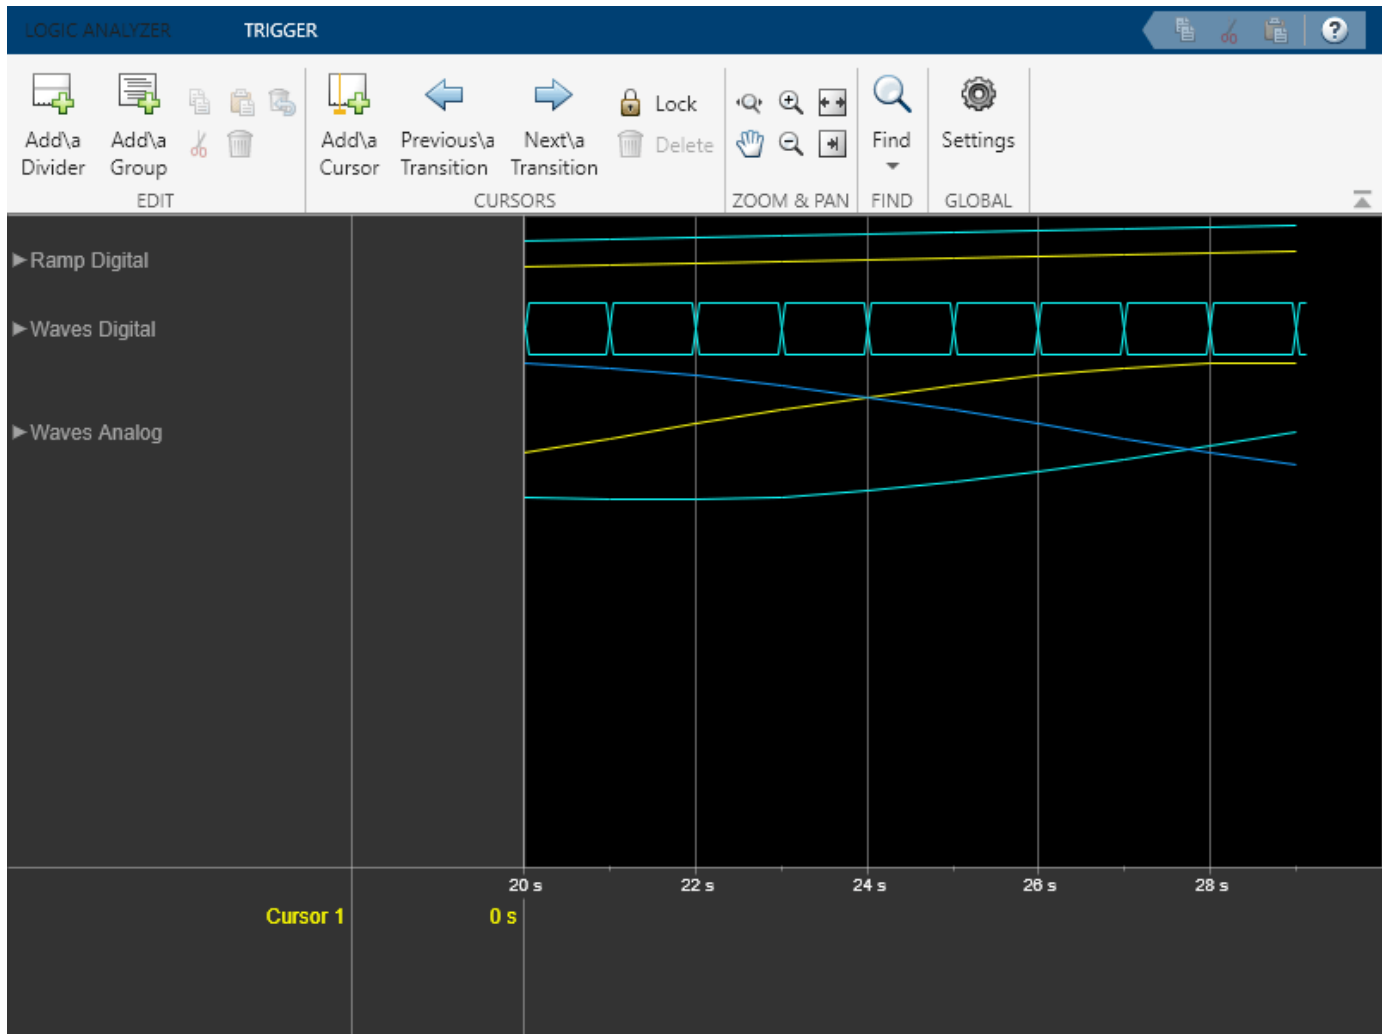

### Duplicate Wave and Check Information

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

dsp.LogicAnalyzer object to which you want to add a divider.

Example: `addDivider(scope)` adds a divider with the default characteristics.

### Divider Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'DisplayChannel',2,'Name','MyDivider' specifies that a divider should be added to display channel 2 and named "MyDivider".

**DisplayChannel — Channel on the display that shows this divider**

NumInputPorts (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: 'DisplayChannel',2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Height — Height of the divider**

0 (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8-200. If you choose 0, the value of the DisplayChannelHeight property in the Logic Analyzer is used.

Example: 'Height',2

Data Types: double

**Name — The name or label for the divider**

' ' (default) | character vector | string scalar

Specify the name that you would like to set for the new divider.

Example: 'Name','MyDivider'

Data Types: char | string

**Output Arguments****dividerTag — tag for new divider**

random character vector

A tag for the newly added divider. Use the tag name to modify and delete the divider.

**Version History**

Introduced in R2013a

# addWave

**Package:** dsp

Add wave to Logic Analyzer

## Syntax

```
waveTag = addWave(scope)
waveTag = addWave(scope,Name,Value)
```

## Description

`waveTag = addWave(scope)` adds a wave to the display. A tag value is returned, which can be used to modify and delete the wave.

`waveTag = addWave(scope,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Manipulate Logic Analyzer Programatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

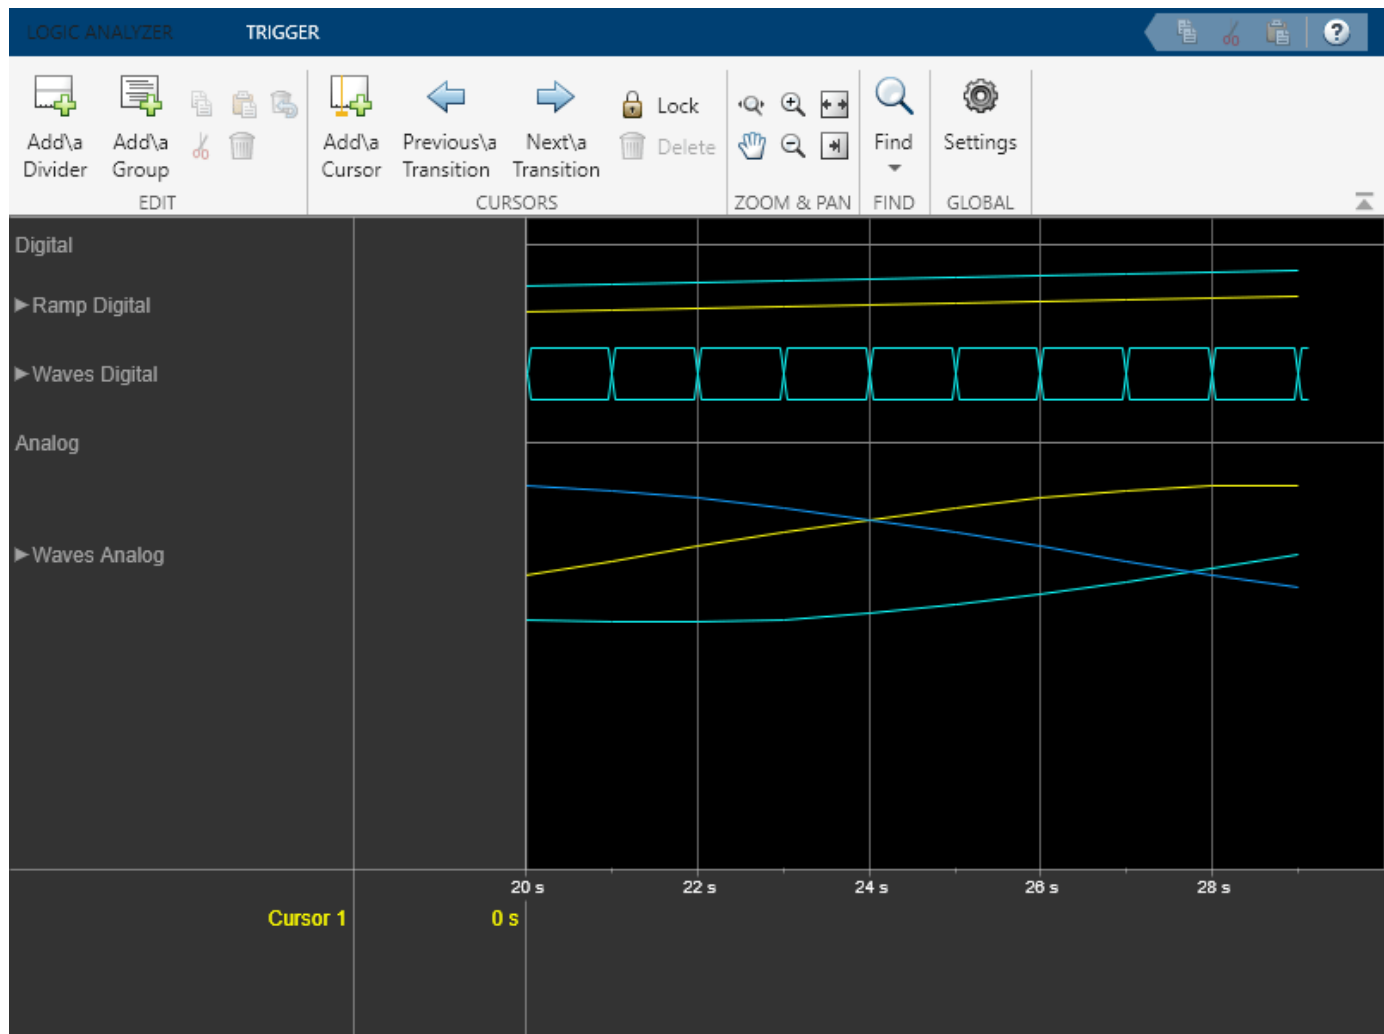

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

**scope** — The Logic Analyzer object to which you want to add a wave

`dsp.LogicAnalyzer` object

Example: 'addWave(scope)' adds a wave with the default characteristics.

### Wave Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: 'InputChannel',2,'Color','Blue' specifies that a wave should be added to input channel 1 and colored blue.

**Color — Color of the wave**

'Default' (default) | character vector | three element numeric vector | string scalar

Color of the wave, specified as an [R G B] value or one of the following:

- 'Black'
- 'Blue'
- 'Cyan'
- 'Default'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

When you choose 'Default', the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: 'Color', 'Blue'

Example: 'Color', [0,0,1]

Data Types: char | string | double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**DisplayChannel — Channel on the display that shows this wave**

NumInputPorts (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: 'DisplayChannel', 2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**FontSize — Font size for values in the wave**

0 (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: 'FontSize', 8

Data Types: double

**Format — Display format for the wave**

'Default' (default) | 'Analog' | 'Digital'

When you choose 'Default', the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: 'Format', 'Digital'

Data Types: char | string

**Height — Height of the wave**

0 (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: double

**InputChannel — Input channel that corresponds to this wave**

1 (default) | scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

**Name — Name or label for the wave**

' ' (default) | character vector | string scalar

Specify the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types: char | string

**Radix — Radix for the wave**

'Default' (default) | 'Binary' | 'Hexadecimal' | 'Octal' | 'Signed decimal' | 'Unsigned decimal'

When the input signals are of class double, single, or logical, you should not set this property. When you choose 'Default', the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Data Types: char | string

**Output Arguments****waveTag — tag for new wave**

random character vector

A tag for the newly added wave. Use the tag name to modify and delete the wave.

**Version History**

Introduced in R2013a

## allpass2wdf

Allpass to Wave Digital Filter coefficient transformation

### Syntax

```
w = allpass2wdf(a)
W = allpass2wdf(A)
```

### Description

`w = allpass2wdf(a)` accepts a vector of real allpass polynomial filter coefficients `a`, and returns the transformed coefficient `w`. `w` can be used with allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with `Structure` set to 'Wave Digital Filter'.

`W = allpass2wdf(A)` accepts the cell array of allpass polynomial coefficient vectors `A`. Each cell of `A` holds the coefficients of a section of a cascade allpass filter. `W` is also a cell array, and each cell of `W` contains the transformed version of the coefficients in the corresponding cell of `A`. `W` can be used with allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with `structure` set to 'Wave Digital Filter'.

### Examples

#### Convert Allpass coefficients to Wave Digital Filter Coefficients

Create a second order allpass filter with coefficients `a = [0 0.5]`. Convert these coefficients into wave digital filter form using `allpass2wdf`. Assign the transformed coefficients to an allpass filter using the wave digital filter structure. Pass a random input to both these filters and compare the outputs.

```
a = [0 0.5];
allpass = dsp.AllpassFilter('AllpassCoefficients', a);
w = allpass2wdf(a);
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter', ...
    'WDFCoefficients', w);
in = randn(512, 1);
outputAllpass = allpass(in);
outputAllpasswdf = allpasswdf(in);
plot(outputAllpass-outputAllpasswdf)
```

The difference between the two outputs is very small.

## Input Arguments

### **a** — allpass filter coefficients

vector of real numbers

Numeric vector of allpass filter coefficients, specified as real numbers. **a** can have length only equal to 1, 2, and 4. When the length is 4, the first and third components must both be zero. **a** can be a row or a column vector.

Example: 0.7

Data Types: double | single

### **A** — allpass filter coefficients

vector of cells

Cascade of allpass filter coefficients, specified as a cell vector. Every cell of **A** must contain a real vector of length 1, 2, or 4. When the length is 4, the first and third components must both be zero. **A** can be a row or column vector of cells.

Example: {0.7, [0.1, 0.2]}

Data Types: double | single

## Output Arguments

### **w** — transformed version of the coefficients **a**

vector of real numbers

Numeric vector of transformed coefficients, determined as a real number, to use with single-section allpass filter objects having `Structure` set to 'Wave Digital Filter'. `w` is always returned as a numeric row vector.

Example: `0.7`

Data Types: `double` | `single`

### **W** — transformed version of the coefficients cell array **A**

vector of cell

Cascade of transformed allpass filter coefficients, determined as a cell array, to use with multi-section allpass filter objects having `Structure` set to 'Wave Digital Filter'. `W` is always returned as a column of cells.

Example: `{0.7; [0.2, -0.0833]}`

Data Types: `double` | `single`

## Algorithms

In the more general case, the input coefficients `A` define a cascade or multisection allpass filter. `allpass2wdf` applies separately to each section of the same transformation used in the single-section case. In the single-section case, the numeric coefficients vector `a` contains a standard polynomial representation of an allpass filter of order 1, 2, or 4. For example, in the first order case,

$$a = [a_1]$$

represents the first order transfer function:

$$H_1(z) = \frac{z^{-1} + a_1}{1 + a_1 z^{-1}}$$

and in the second order case,

$$a = [a_1, a_2]$$

represents the second order transfer function:

$$H_2(z) = \frac{z^{-2} + a_1 z^{-1} + a_2}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

.

The allpass transfer functions  $H_1$  and  $H_2$  can also have the following alternative representations, using decoupled coefficients in vector  $w_1$  or  $w_2$  respectively.

$$\tilde{H}_1(z) = \frac{z^{-1} + w_1}{1 + w_1 z^{-1}}$$

$$\tilde{H}_2(z) = \frac{z^{-2} + w_2(1 + w_1)z^{-1} + w_1}{1 + w_2(1 + w_1)z^{-1} + w_1z^{-2}}$$

For allpass coefficients,  $w$  is often used to derive adaptor multipliers for Wave Digital Filter structures, and it is required by a number of allpass based filters in DSP System Toolbox when Structure is set to 'Wave Digital Filter' (e.g. `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`).

For a given vector of section coefficients  $a$ , `allpass2wdf` computes the corresponding vector  $w$  such that

when  $i = 1, 2$  or  $4$

$$\tilde{H}_i(z) = H_i(z)$$

This results in using the following formulas:

for order 1:

$$w_1 = a_1$$

for order 2:

$$w_1 = a_2$$

$$w_2 = \frac{a_1}{1 + a_2}$$

for order 4:

$$w_1 = a_4$$

$$w_3 = \frac{a_2}{1 + a_4}$$

$$w_2 = w_4 = 0$$

## allpassbpc2bpc

Allpass filter for complex bandpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)
```

### Description

[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. For more information, see “Complex Bandpass to Complex Bandpass Frequency Transformation” on page 5-26.

### Examples

#### Design of the allpass mapping filter

This example shows how to design allpass mapping filter, changing the complex bandpass filter with the band edges at  $W_{o1} = 0.2$  and  $W_{o2} = 0.4$  to the new band edges of  $W_{t1} = 0.3$  and  $W_{t2} = 0.6$ . Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];  
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);  
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');  
plot(f/pi, -angle(ha)/pi, Wt, Wo, 'ro')  
title('Mapping Function Wo(Wt)');  
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Input Arguments

### **$W_o$ — Frequency values to be transformed from prototype filter**

real vector with values in the range  $(-1, 1)$

Frequency values to be transformed from the prototype filter, specified as a real vector with values in the range  $(-1, 1)$ .

Data Types: single | double

### **$W_t$ — Desired frequency locations in target filter**

real vector with values in the range  $(-1, 1)$

Desired frequency locations in the transformed target filter, specified as a real vector with values in the range  $(-1, 1)$ .

Data Types: single | double

## Output Arguments

### **AllpassNum — Numerator of mapping filter**

complex-valued vector

Numerator of the mapping filter, returned as a complex-valued vector.

Data Types: double  
Complex Number Support: Yes

### **AllpassDen — Denominator of mapping filter**

complex-valued vector

Denominator of the mapping filter, returned as a complex-valued vector.

Data Types: double  
Complex Number Support: Yes

## **More About**

### **Complex Bandpass to Complex Bandpass Frequency Transformation**

Complex bandpass to complex bandpass frequency transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations  $W_{t1}$  and  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

## allpasslp2bp

Allpass filter for lowpass to bandpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. For more information, see “Real Lowpass to Real Bandpass Frequency Transformation” on page 5-29.

### Examples

#### Design Allpass Mapping Filter from Lowpass Filter

Design the allpass mapping filter changing the lowpass filter with cutoff frequency  $W_o$  at 0.5 to the real-valued bandpass filter with cutoff frequencies  $W_{t1}$  and  $W_{t2}$  at 0.25 and 0.375, respectively.

Compute the frequency response and plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies.

```
Wo = 0.5;
Wt = [0.25 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo,Wt);
[h,f] = freqz(AllpassNum,AllpassDen,'whole');
plot(f/pi,abs(angle(h))/pi,Wt,Wo,'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

## Input Arguments

### **Wo** — Frequency value to be transformed from prototype filter

real scalar in the range  $(0, 1)$

Frequency value to be transformed from the prototype filter, specified as a real scalar in the range  $(0, 1)$ .

Data Types: single | double

### **Wt** — Desired frequency locations in target filter

real vector with values in the range  $(0, 1)$

Desired frequency locations in the transformed target filter, specified as a real vector with values in the range  $(0, 1)$ .

Data Types: single | double

## Output Arguments

### **AllpassNum** — Numerator of mapping filter

real-valued vector

Numerator of the mapping filter, returned as a real-valued vector.

Data Types: double

### AllpassDen — Denominator of mapping filter

real-valued vector

Denominator of the mapping filter, returned as a real-valued vector.

Data Types: double

## More About

### Real Lowpass to Real Bandpass Frequency Transformation

Real lowpass to real bandpass frequency transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the DC mobility, which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other features.

Lowpass to bandpass transformation can also be used for transforming other types of filters, for example, real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

## allpasslp2bpc

Allpass filter for lowpass to complex bandpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to complex bandpass frequency transformation. For more information, see “Real Lowpass to Complex Bandpass Frequency Transformation” on page 5-33.

### Examples

#### Design Allpass Matching Filter

Design the allpass mapping filter changing the real lowpass filter with the cutoff frequency  $W_o$  at 0.5 into a complex bandpass filter with band edges  $W_{t1}$  and  $W_{t2}$  precisely defined at 0.2 and 0.4, respectively. Calculate the frequency response of the mapping filter in the full range.

```
Wo = 0.5;
Wt = [0.2 0.4];
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt);
[h,f] = freqz(AllpassNum,AllpassDen,'whole');
plot(f/pi,abs(angle(h))/pi,Wt,Wo,'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

## Input Arguments

### Wo — Frequency value to be transformed from prototype filter

real scalar in the range  $(0, 1)$

Frequency value to be transformed from the prototype filter, specified as a real scalar in the range  $(0, 1)$  with 1 corresponding to half the sample rate.

Data Types: single | double

### Wt — Desired frequency locations in target filter

real vector with values in the range  $(-1, 1)$

Desired frequency locations in the transformed target filter, specified as a real vector with values in the range  $(-1, 1)$  with 1 corresponding to half the sample rate.

Data Types: single | double

## Output Arguments

### AllpassNum — Numerator of mapping filter

complex-valued vector

Numerator of the mapping filter, returned as a complex-valued vector.

Data Types: double

### AllpassDen — Denominator of mapping filter

complex-valued vector

Denominator of the mapping filter, returned as a complex-valued vector.

Data Types: double

## More About

### Real Lowpass to Complex Bandpass Frequency Transformation

Real lowpass to complex bandpass frequency transformation effectively places one feature of the original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters, for example, real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

## allpasslp2bs

Allpass filter for lowpass to bandstop transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

### Examples

Design the allpass filter changing the lowpass filter with cutoff frequency at  $W_o=0.5$  to the real bandstop filter with cutoff frequencies at  $W_{t1}=0.25$  and  $W_{t2}=0.375$ :

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to  $\pi$ :

## Arguments

| Variable          | Description  |
|-------------------|--|
| $W_o$             | Frequency value to be transformed from the prototype filter  |
| $W_t$             | Desired frequency locations in the transformed target filter |
| <i>AllpassNum</i> | Numerator of the mapping filter                              |
| <i>AllpassDen</i> | Denominator of the mapping filter                            |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Version History

Introduced in R2011a

## allpasslp2bsc

Allpass filter for lowpass to complex bandstop transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the first-order allpass mapping filter for performing a real lowpass to complex bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

### Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex bandstop filter with band edges of  $W_{t1}=0.2$  and  $W_{t2}=0.4$  precisely defined:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

### Arguments

| Variable  | Description   |
|-----------|---|
| <i>Wo</i> | Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate. |

| <b>Variable</b>   | <b>Description</b>  |
|-------------------|---|
| <i>Wt</i>         | Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. |
| <i>AllpassNum</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter   |

## allpasslp2hp

Allpass filter for lowpass to highpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency,  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

### Examples

Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from  $W_o = 0.5$  to  $W_t = 0.25$ .

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

## Arguments

| Variable     | Description   |
|--------------|---|
| $W_o$        | Frequency value to be transformed from the prototype filter |
| $W_t$        | Desired frequency location in the transformed target filter |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Version History

Introduced in R2011a

## allpasslp2lp

Allpass filter for lowpass to lowpass transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency  $W_o$ , at the required target frequency location,  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

### Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at  $W_o=0.5$  to  $W_t=0.25$ . Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

## Arguments

| Variable                | Description   |
|-------------------------|---|
| $W_o$                   | Frequency value to be transformed from the prototype filter |
| $W_t$                   | Desired frequency location in the transformed target filter |
| <code>AllpassNum</code> | Numerator of the mapping filter                             |
| <code>AllpassDen</code> | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Version History

Introduced in R2011a

## allpasslp2mb

Allpass filter for lowpass to M-band transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the  $M$ th-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter  $M$  is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ . By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a real multiband filter with band edges of  $W_t=[1:2:9]/10$  precisely defined. Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

| Variable          | Description   |
|-------------------|---|
| $W_o$             | Frequency value to be transformed from the prototype filter                           |
| $W_t$             | Desired frequency locations in the transformed target filter                          |
| <i>Pass</i>       | Choice ( ' pass ' / ' stop ' ) of passband/stopband at DC, ' pass ' being the default |
| <i>AllpassNum</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter   |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# allpasslp2mbc

Allpass filter for lowpass to complex M-band transformation

## Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)
```

## Description

`[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the  $M$ th-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter  $M$  is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of  $W_o=0.5$  into a complex multiband filter with band edges of  $W_t=[-3+1:2:9]/10$  precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.

## Arguments

| Variable          | Description   |
|-------------------|---|
| $w_0$             | Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.     |
| $w_t$             | Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. |
| <i>AllpassNum</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter   |

## allpasslp2xc

Allpass filter for lowpass to complex N-point transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the Nth-order allpass mapping filter, where N is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of the, original filter located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design the allpass filter moving four features of an original complex filter given in  $W_o$  to the new independent frequency locations  $W_t$ . Please note that the transformation creates N replicas of an original filter around the unit circle, where N is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

### Arguments

| Variable | Description  |
|----------|--|
| $W_o$    | Frequency values to be transformed from the prototype filter |

| <b>Variable</b>   | <b>Description</b>   |
|-------------------|--|
| <i>Wt</i>         | Desired frequency locations in the transformed target filter |
| <i>AllpassNum</i> | Numerator of the mapping filter                              |
| <i>AllpassDen</i> | Denominator of the mapping filter                            |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## allpasslp2xn

Allpass filter for lowpass to N-point transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)
```

### Description

[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt) returns the numerator, AllpassNum, and the denominator, AllpassDen, of the Nth-order allpass mapping filter, where N is the allpass filter order, for performing a real lowpass to real multipoint frequency transformation. Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ . By default the DC feature is kept at its original location.

[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass) allows you to specify an additional parameter, Pass, which chooses between using the “DC Mobility” and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Arguments

| Variable | Description  |
|----------|--|
| $W_o$    | Frequency values to be transformed from the prototype filter |
| $W_t$    | Desired frequency locations in the transformed target filter |

| <b>Variable</b>   | <b>Description</b>   |
|-------------------|--|
| <i>Pass</i>       | Choice ( 'pass ' / 'stop ' ) of passband/stopband at DC, 'pass ' being the default |
| <i>AllpassNum</i> | Numerator of the mapping filter  |
| <i>AllpassDen</i> | Denominator of the mapping filter  |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

# allpassrateup

Allpass filter for integer upsample transformation

## Syntax

```
[AllpassNum,AllpassDen] = allpassrateup(N)
```

## Description

`[AllpassNum,AllpassDen] = allpassrateup(N)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the  $N$ th-order allpass mapping filter for performing the rateup frequency transformation, which creates  $N$  equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

## Examples

Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at  $W_o=0.2$ :

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

## Arguments

| Variable          | Description                                    |
|-------------------|--|
| $N$               | Frequency replication ratio (upsampling ratio) |
| <i>AllpassNum</i> | Numerator of the mapping filter                |
| <i>AllpassDen</i> | Denominator of the mapping filter              |

## allpassshift

Allpass filter for real shift transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)
```

### Description

`[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ . This transformation implements the “DC mobility,” which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be moved to a different frequency by applying a shift transformation. In such a way you can avoid designing the filter from the beginning.

### Examples

Design the allpass filter precisely shifting one feature of the lowpass filter originally at  $W_o=0.5$  to the new frequencies of  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshift(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to  $\pi$ , which is in effect the mapping function  $W_o(W_t)$ . Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

## Arguments

| Variable          | Description   |
|-------------------|---|
| $W_o$             | Frequency value to be transformed from the prototype filter |
| $W_t$             | Desired frequency location in the transformed target filter |
| <i>AllpassNum</i> | Numerator of the mapping filter                             |
| <i>AllpassDen</i> | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Version History

Introduced in R2011a

## allpassshiftc

Allpass filter for complex shift transformation

### Syntax

```
[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt)
[AllpassNum,AllpassDen] = allpassshiftc(0,0.5)
[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5)
```

### Description

[AllpassNum,AllpassDen] = allpassshiftc(Wo,Wt) returns the numerator, AllpassNum, and denominator, AllpassDen, vectors of the allpass mapping filter for performing a complex frequency shift of the frequency response of the digital filter by an arbitrary amount.

[AllpassNum,AllpassDen] = allpassshiftc(0,0.5) calculates the allpass filter for doing the Hilbert transformation, a 90 degree counterclockwise rotation of an original filter in the frequency domain.

[AllpassNum,AllpassDen] = allpassshiftc(0,-0.5) calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

### Examples

Design the allpass filter precisely rotating the whole filter by the amount defined by the location of the selected feature from an original filter,  $W_o=0.5$ , and its required position in the target filter,  $W_t=0.25$ :

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpassshiftc(Wo, Wt);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

### Arguments

| Variable          | Description   |
|-------------------|---|
| <i>Wo</i>         | Frequency value to be transformed from the prototype filter |
| <i>Wt</i>         | Desired frequency location in the transformed target filter |
| <i>AllpassNum</i> | Numerator of the mapping filter                             |
| <i>AllpassDen</i> | Denominator of the mapping filter                           |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## autoscale

Automatic dynamic range scaling

### Syntax

```
autoscale(hd,x)  
hnew = autoscale(hd,x)
```

### Description

`autoscale(hd,x)` provides dynamic range scaling for each node of the filter `hd`. This method runs signal `x` through `hd` in floating-point to simulate filtering. `autoscale` uses the maximum and minimum data obtained from that simulation at each filter node to set fraction lengths to cover the simulation full range and maximize the precision. Word lengths are not changed during autoscaling.

`hnew = autoscale(hd,x)` If you request an output, `autoscale` returns a new filter with the scaled fraction lengths. The original filter is not changed.

For an introductory example of the automatic scale process, see “Floating-Point to Fixed-Point Conversion of IIR Filters”.

### Examples

#### Dynamic Range Scaling in a Lattice ARMA Filter

```
hd = design(fdesign.bandpass,'ellip');  
hd = convert(hd,'latticearma');  
hd.arithmetic = 'fixed';  
rng(4); x = rand(100,10); % Training input data.  
hd(2) = autoscale(hd,x);  
hfvt = fvtool(hd,'Analysis','magestimate','ShowReference','off');  
legend(hfvt, 'Before Autoscaling', 'After Autoscaling')
```

## Version History

Introduced in R2011a

## bandedgeFrequencies

**Package:** dsp

Compute the bandedge frequencies

### Syntax

```
w = bandedgeFrequencies(obj)
f = bandedgeFrequencies(obj, Fs)
```

### Description

`w = bandedgeFrequencies(obj)` returns a vector of normalized frequencies, `w`, containing the bandedge frequencies between adjacent bandpass filters in the `dsp.Channelizer` System object.

`f = bandedgeFrequencies(obj, Fs)` returns a vector of bandedge frequencies in Hz, using the sample rate `Fs`.

### Examples

#### Bandedge Frequencies of Channelizer

Compute the normalized bandedge frequencies of the bandpass filters in a channelizer using the `bandedgeFrequencies` function.

```
channelizer = dsp.Channelizer;
w = bandedgeFrequencies(channelizer)
```

```
w = 1×8
```

```
    -2.7489    -1.9635    -1.1781    -0.3927     0.3927     1.1781     1.9635     2.7489
```

To compute the frequencies in Hz, pass a sampling frequency, `Fs`.

$$f = (\omega/2\pi) \times Fs$$

where:

- $f$  is frequency in Hz.
- $\omega$  is frequency in radians.

Here, the sampling frequency is 44,100 Hz.

```
f = bandedgeFrequencies(channelizer, 44100)
```

```
f = 1×8
    104 ×
```

```
    -1.9294    -1.3781    -0.8269    -0.2756     0.2756     0.8269     1.3781     1.9294
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

### **Fs** — Sample rate

positive scalar

Sample rate used to compute the bandedge frequencies in Hz, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **w** — Normalized bandedge frequencies

row vector

Normalized frequencies containing the bandedge frequencies between adjacent bandpass filters in the channelizer, returned as a row vector. The length of the vector equals the number of frequency bands.

Data Types: `double`

### **f** — Bandedge frequencies in Hz

row vector

Bandedge frequencies in Hz, returned as a row vector. The length of the vector equals the number of frequency bands. To return the frequencies in Hz, input the sample rate,  $F_s$ . Frequency in Hz is given by  $[w/(2\pi)] \times F_s$ , where  $w$  is the normalized frequency in rad/sample, and  $F_s$  is the sampling rate in Hz.

Data Types: `double`

## block

Generate block from a digital filter

### Syntax

```
block(hd)
block(hd,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)
```

### Description

`block(hd)` generates a DSP System Toolbox block equivalent to the digital filter, `hd`.

`block(hd,'propertyname1',propertyvalue1,'propertyname2',propertyvalue2,...)` generates a DSP System Toolbox block using the options specified in the property name/property value pairs. The valid properties and their values are

| Property Name  | Property Values                                       | Description and Values  |
|----------------|---|---|
| Destination    | 'current' (default), 'new', or <i>Subsystemname</i> . | Determine which Simulink model gets the block. Enter 'current', 'new', or specify the name of an existing subsystem with <i>subsystemname</i> . 'current' adds the block to your current Simulink model. Specifying 'new' opens a new model and adds the block. If you provide the name of a subsystem in <i>subsystemname</i> , <code>block</code> adds the new block to your specified subsystem. |
| Blockname      | 'filter' (default)                                    | Specify the name of the generated block. The name appears below the block in the model. When you do not specify a block name, the default is <code>filter</code> .  |
| OverwriteBlock | 'off' (default), or 'on'.                             | Tell <code>block</code> whether to overwrite an existing block of the same name, or create a new block. 'off' is the default setting— <code>block</code> does not overwrite existing blocks with matching names. Switching from 'off' to 'on' directs <code>block</code> to overwrite existing blocks.  |
| MapStates      | 'off' (default), or 'on'.                             | Specify whether to apply the current filter states to the new block. This lets you save states from a filter object you may have used or configured in a specific way. The default setting of 'off' means the states are not transferred to the block. Choosing 'on' preserves the current filter states in the block.  |

| Property Name    | Property Values   | Description and Values   |
|------------------|---|--|
| Link2Obj         | 'off' (default), or 'on'.   | Specify how to set the <b>Coefficient source</b> in the block mask. The default setting is 'off' and the <b>Coefficient source</b> is set to <b>Dialog parameters</b> . Setting Link2Obj to 'on' sets the <b>Coefficient source</b> to <b>Discrete-time filter object (DFILT)</b> . The Link2Obj and MapCoeffstoPorts cannot be simultaneously 'on'. |
| MapCoeffstoPorts | 'off' (default) or 'on'   | Specify whether to map the coefficients of the filter to the ports of the block. The Link2Obj and MapCoeffstoPorts cannot be simultaneously 'on'.  |
| CoeffNames       | { 'Num' } (default FIR)<br>{ 'Num', 'Den' } (default direct form IIR)<br>{ 'Num', 'Den', 'g' } (default IIR SOS),<br>{ 'K' } (default form lattice) | Specify the coefficient variable names as a cell array of character vectors.<br><br>MapCoeffstoPorts must be set to 'on' for this property to apply.   |
| InputProcessing  | 'columns as channels' (default), 'elements as channels'   | Specify sample-based (elements as channels) or frame-based (columns as channels) processing.   |
| RateOption       | 'enforce single rate' (default) or 'allow multirate'  | Specify how the block adjusts the rate at the output to accommodate the reduced number of samples. This parameter applies only when InputProcessing is 'columns as channels'.  |

### Using block to Realize a Fixed-Point Digital Filter

When the source filter `hd` is fixed-point, the input word and fraction lengths for the block are derived from the block input signal. The realization process issues a warning and ignores the input word and input fraction lengths that are part of the source filter object, choosing to inherit the settings from the input data. Other fixed-point properties map directly to settings for word and fraction length in the realized block.

## Examples

### Create a Block from a Lowpass Filter

Create a lowpass filter specification object. Specify the passband frequency to be  $0.15\pi$  rad/sample and the stopband frequency to be  $0.25\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

In the first example, use `block` with the default syntax, letting the function determine the block name and configuration.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
hd = design(d);
```

Now use the default syntax to create a block.

```
block(hd);
```

In this second example, define the block name to meet your needs by using the property name/property value pair input arguments.

```
block(hd, 'blockname', 'FIR Filter');
```

The figure shows the blocks in a Simulink model. When you try these examples, you see that the second block writes over the first block location. You can avoid this by moving the first block before you generate the second, always naming your block with the blockname property, or setting the Destination property to new which puts the filter block in a new Simulink model.

# butter

Butterworth IIR digital filter design

## Syntax

```
butterFilter = butter(designSpecs,SystemObject=true)
butterFilter = butter(designSpecs,designoption=value,... SystemObject=true)
butterFilter = design(designSpecs,'butter',SystemObject=true)
```

## Description

`butterFilter = butter(designSpecs,SystemObject=true)` designs a butterworth IIR digital filter using specifications in the object `designSpecs`.

Depending on the filter specification object `designSpecs`, the `butter` design method might not be valid. Use `designmethods` with the filter specification object to determine if a butterworth IIR digital filter design is possible.

```
designmethods(designSpecs,SystemObject=true)
```

`butterFilter = butter(designSpecs,designoption=value,... SystemObject=true)` returns a butterworth IIR filter with one or more specified designed options and the corresponding values.

To view a list of available design options, run the `designoptions` function on the specification object. The function also lists the default design options the filter uses.

```
designoptions(designSpecs,'butter')
```

`butterFilter = design(designSpecs,'butter',SystemObject=true)` is an alternative syntax for designing the butterworth IIR digital filter.

For complete help about using the `butter` design method for a specification object, `designSpecs`, enter the following at the MATLAB command prompt.

```
help(designSpecs,'butter')
```

## Examples

### Design Butterworth Filter

Design a butterworth filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

## Lowpass Filter

Construct a default lowpass filter design specification object using `fdesign.lowpass`.

```
designSpecs = fdesign.lowpass

designSpecs =
    lowpass with properties:

        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
            Fpass: 0.4500
            Fstop: 0.5500
            Apass: 1
            Astop: 60
```

Determine the available design methods using the `designmethods` function. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)

Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'butter',SystemObject=true)

ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascade...
        SOSScaleNorm: 'ustring'
        SOSScaleOpts: 'fdopts.sosscaling'
        MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

Use the `design` function to design the filter. Pass `'butter'` and the specifications given by variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'`.

```
lpFilter = design(designSpecs,'butter',matchexactly='passband',SystemObject=true);
```

Visualize the frequency response of the designed filter.

```
fvtool(lpFilter)
```

## Highpass Filter

Construct a highpass filter design specification object using `fdesign.highpass`. Specify the order to be 7 and the 3 dB frequency to be  $0.6\pi$  radians/sample.

```
designSpecs = fdesign.highpass('N,F3dB',7,.6);
```

Determine the available design methods. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass(N,F3dB)`:

```
butter
maxflat
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'butter',SystemObject=true)
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
```

```
DefaultFilterStructure: 'df2sos'  
DefaultSOSScaleNorm: ''  
DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

To design the butterworth filter, use the design function and specify 'butter' as an input. Set 'FilterStructure' to 'cascadeallpass'.

```
hpFilter = design(designSpecs, 'butter', FilterStructure='cascadeallpass', SystemObject=true);
```

Visualize the highpass frequency response.

```
fvtool(hpFilter)
```

## Input Arguments

### **designSpecs** — Filter specification object

object

Filter specification object, specified as one of the following:

- `fdesign.bandpass`
- `fdesign.bandstop`
- `fdesign.comb`
- `fdesign.decimator`

- `fdesign.halfband`
- `fdesign.highpass`
- `fdesign.interpolator`
- `fdesign.lowpass`
- `fdesign.notch`
- `fdesign.nyquist`
- `fdesign.peak`

## Output Arguments

### **butterFilter** — Butterworth IIR filter

System object

Butterworth IIR filter, returned as a filter System object. The System object and the values of its properties depend on the input `designSpecs` object and the other design options specified to the function.

## Version History

### Introduced in R2011a

### **R2022b: Designs `dsp.SOSFilter` object instead of `dsp.BiquadFilter` object**

*Behavior changed in R2022b*

The `butter` design method now generates a `dsp.SOSFilter` object instead of the `dsp.BiquadFilter` object.

Initialize the default `fdesign.lowpass` filter specification object. Use the design function with the `SystemObject=true` flag to design a `dsp.SOSFilter` filter object.

```
designSpecs = fdesign.lowpass;
filtObj = design(designSpecs, 'butter', SystemObject=true)
```

```
filtObj =
```

```
  dsp.SOSFilter with properties:
```

```
      Structure: 'Direct form II'
CoefficientSource: 'Property'
      Numerator: [13×3 double]
      Denominator: [13×3 double]
HasScaleValues: true
      ScaleValues: [0.4151 0.3718 0.3374 0.3099 0.2878 0.2701 0.2558 ... ]
```

```
Show all properties
```

To design a `dsp.BiquadFilter` object instead of the `dsp.SOSFilter` object, you can use the `UseLegacyBiquadFilter` flag and set it to `true`.

```
filtObj = design(designSpecs, 'butter', SystemObject=true, ...
UseLegacyBiquadFilter=true)
```

```
filtObj =
```

```
  dsp.BiquadFilter with properties:
```

```
        Structure: 'Direct form II'  
    SOSMatrixSource: 'Property'  
        SOSMatrix: [13×6 double]  
        ScaleValues: [14×1 double]  
    InitialConditions: 0  
    OptimizeUnityScaleValues: true
```

Show all properties

### Functions

design | designmethods | designoptions | fdesign | cheby1 | cheby2 | ellip | equiripple | kaiserwin

## ca2tf

Convert coupled allpass filter to transfer function form

### Syntax

```
[b,a] = ca2tf(d1,d2)
[b,a] = ca2tf(d1,d2,beta)
[b,a,bp] = ca2tf(d1,d2)
[b,a,bp] = ca2tf(d1,d2,beta)
```

### Description

`[b,a] = ca2tf(d1,d2)` returns the vector of coefficients of **b** and **a**. **b** and **a** corresponds to the numerator and the denominator of the transfer function  $H(z)$ , respectively, where **d1** and **d2** are real vectors corresponding to the denominators of the allpass filters  $H1(z)$  and  $H2(z)$ .

$$H(z) = B(z)/A(z) = \frac{1}{2}[H1(z) + H2(z)]$$

`[b,a] = ca2tf(d1,d2,beta)` returns the vector of coefficients **b** and the vector of coefficients **a** corresponding to the numerator and the denominator of the transfer function  $H(z)$ , respectively, where **d1** and **d2** are complex vectors and **beta** is a complex scalar.

$$H(z) = B(z)/A(z) = \frac{1}{2}[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)]$$

`[b,a,bp] = ca2tf(d1,d2)` also returns the vector **bp** of real coefficients corresponding to the numerator of the power-complementary filter  $G(z)$ , where **d1** and **d2** are real vectors.

$$G(z) = Bp(z)/A(z) = \frac{1}{2}[H1(z) - H2(z)]$$

`[b,a,bp] = ca2tf(d1,d2,beta)` also returns the vector of coefficients **bp** of real or complex coefficients that correspond to the numerator of the power-complementary filter  $G(z)$ , where **d1** and **d2** are complex vectors and **beta** is a complex scalar.

$$G(z) = Bp(z)/A(z) = \frac{1}{2j}[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)]$$

### Examples

#### Convert Coupled Allpass Filter to Transfer Function Form

Create a coupled allpass filter.

```
[b,a] = cheby1(10,.5,.4);
```

The `tf2ca` function returns the denominators of the coupled allpass filter.

```
[d1,d2,beta] = tf2ca(b,a);
```

Reconstruct the original and the power-complementary filters using the `ca2tf` function.

```
[num,den,numpc] = ca2tf(d1,d2,beta);
```

Plot the magnitude response of the original filter and the power-complementary one.

```
fvtool(num,den,numpc,den,'Analysis','magnitude','MagnitudeDisplay',...
        'Magnitude Squared')
```

## Input Arguments

### **d1 — Denominator of allpass filter $H1(z)$**

vector

Denominator of the allpass filter  $H1(z)$ , specified as a real- or complex-valued vector.

Data Types: `single` | `double`

### **d2 — Denominator of allpass filter $H2(z)$**

vector

Denominator of the allpass filter  $H2(z)$ , specified as a real- or complex-valued vector.

Data Types: `single` | `double`

### **beta — Complex scalar of magnitude 1**

complex scalar

Complex scalar of magnitude 1.

Data Types: `single` | `double`

## Output Arguments

### **b** — Numerator coefficients of transfer function

vector

Numerator coefficients of the transfer function  $H(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

### **a** — Denominator coefficients of transfer function

vector

Denominator coefficients of the transfer function  $H(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

### **bp** — Numerator coefficients of power-complementary filter $G(z)$

vector

Numerator coefficients of the power-complementary filter  $G(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

## cascade

Cascade of filter system objects

### Syntax

```
FC = cascade(obj1,obj2,...objn)
```

### Description

`FC = cascade(obj1,obj2,...objn)` returns an object, `FC`, of type `dsp.FilterCascade`. `FC` is a cascaded version of the input System objects `obj1`, `obj2`, ..., `objn`. You can input multiple System objects to the function. The input System objects must be supported by the cascade method. For the list of supported System objects, see “Input Arguments” on page 5-75.

### Examples

#### Design Two-Stage Decimator

Design a two-stage decimator by cascading `dsp.CICDecimator` and `dsp.CICCompensationDecimator` System objects.

#### Construct the objects

```
CICDecim = dsp.CICDecimator('DecimationFactor', 6, ...
                           'NumSections', 6);
fs = 16e3;    % Sampling frequency of input of compensation decimator
fPass = 4e3;  % Passband frequency
fStop = 4.5e3; % Stopband frequency
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
                                             'DecimationFactor', 2, ...
                                             'PassbandFrequency', fPass, ...
                                             'StopbandFrequency', fStop, ...
                                             'SampleRate', fs);
```

#### Create a cascade of the two objects using the cascade method

```
FC = cascade(CICDecim, CICCompDecim);
```

#### Visualize the frequency response of the cascade

```
f = fvtool(CICDecim, CICCompDecim, FC, 'Fs', [fs*6, fs, fs*6], ...
           'Arithmetic', 'fixed');
set(f, 'NormalizeMagnitudeto1', 'on');
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...
       'Overall Response');
```

## Input Arguments

### obj1 — Filter to be cascaded

filter System object

obj1, obj2, . . . objn are filters to be cascaded. To see the list of System objects you can pass to the cascade method, type

```
dsp.FilterCascade.helpSupportedSystemObjects
```

in the MATLAB command prompt.

## Output Arguments

### FC — cascaded filter

dsp.FilterCascade System object

Cascaded filter, returned as a System object of type `dsp.FilterCascade`. For information on the properties of the filter in each stage, type `info(FC)` in the MATLAB command prompt.

## Version History

Introduced in R2016a

**See Also**

`dsp.FilterCascade`

# centerFrequencies

**Package:** dsp

Compute center frequencies

## Syntax

```
w = centerFrequencies(obj)
f = centerFrequencies(obj, Fs)
```

## Description

`w = centerFrequencies(obj)` returns a vector of normalized frequencies,  $w$ , containing the center frequencies of all the bandpass filters in the `dsp.Channelizer` System object.

`f = centerFrequencies(obj, Fs)` returns a vector of center frequencies in Hz, using the sample rate  $F_s$ .

## Examples

### Center Frequencies of Channelizer

Compute the normalized center frequencies of the bandpass filters in a channelizer using the `centerFrequencies` function.

```
channelizer = dsp.Channelizer;
w = centerFrequencies(channelizer)
```

$w = 1 \times 8$

```
-3.1416  -2.3562  -1.5708  -0.7854      0   0.7854   1.5708   2.3562
```

To compute the frequencies in Hz, pass a sampling frequency. Frequency in Hz,  $f$ , equals  $f = (\omega/2\pi) \times F_s$ , where  $w$  is frequency in radians, and  $F_s$  is the sampling rate.

```
f = centerFrequencies(channelizer, 44100)
```

$f = 1 \times 8$   
 $10^4 \times$

```
-2.2050  -1.6538  -1.1025  -0.5513      0   0.5513   1.1025   1.6538
```

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

**Fs — Sample rate**

positive scalar

Sample rate used to compute the center frequencies in Hz, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Output Arguments****w — Normalized center frequencies**

row vector

Normalized frequencies containing the center frequencies of all the bandpass filters in the channelizer, returned as a row vector. The length of the vector equals the number of frequency bands.

Data Types: double

**f — Center frequencies in Hz**

row vector

Center frequencies in Hz, returned as a row vector. The length of the vector equals the number of frequency bands. To return the frequencies in Hz, input the sample rate,  $F_s$ . Frequency in Hz is given by  $[w/(2\pi)] \times F_s$ , where  $w$  is the normalized frequency in rad/sample, and  $F_s$  is the sampling rate in Hz.

Data Types: double

# cheby1

Chebyshev Type I filter using specification object

## Syntax

```
chebOneFilter = cheby1(designSpecs,SystemObject=true)
chebOneFilter = cheby1(designSpecs,designoption=value,... SystemObject=true)
chebOneFilter = design(designSpecs,'cheby1',SystemObject=true)
```

## Description

`chebOneFilter = cheby1(designSpecs,SystemObject=true)` designs a type I Chebyshev IIR digital filter using specifications in the `designSpecs` object.

For help about using the `cheby1` design method for a filter specification object, enter the following at the MATLAB command prompt.

```
help(designSpecs,'cheby1')
```

You cannot use the `cheby1` design method for certain filter specification objects. Use the `designmethods` function with the filter specification object to determine if the `cheby1` design method is valid for your filter specifications.

```
designmethods(designSpecs,SystemObject=true)
```

`cheby1` returns filters that use second-order sections (SOS). SOS filters are particularly well-suited for most fixed-point applications.

`chebOneFilter = cheby1(designSpecs,designoption=value,... SystemObject=true)` returns a type I Chebyshev IIR digital filter with the specified design options. You can specify one or more design options and their corresponding values.

To view a list of available design options, run the `designoptions` function on the filter specification object. The function also lists the default design options that the filter uses.

```
designoptions(designSpecs,'cheby1')
```

`chebOneFilter = design(designSpecs,'cheby1',SystemObject=true)` is an alternative syntax for designing a type I Chebyshev IIR digital filter.

## Examples

### Design Chebyshev Type I Filter

Design a type 1 Chebyshev IIR filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.

- 3 To determine the available design options, use the `designoptions` function.
- 4 Design the filter using the `design` function.

### Lowpass Filter

Create a default lowpass filter specification object using the `fdesign.lowpass` function.

```
designSpecs = fdesign.lowpass;
```

Determine the available design methods using the `designmethods` function. To design a type 1 Chebyshev filter, pick `cheby1`.

```
designmethods(designSpecs, SystemObject=true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

While designing the filter, you can specify additional design options. View the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs, 'cheby1', SystemObject=true)
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'passband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

Use the `design` function to design the filter. Pass `'cheby1'` and the `designSpecs` object containing the filter design specifications as input arguments. Set the filter structure to `'df1sos'` to design a filter with a direct form I SOS structure.

```
LowpassCheb1 = design(designSpecs, 'cheby1', FilterStructure='df1sos', ...
    SystemObject=true)
```

```
LowpassCheb1 =
    dsp.SOSFilter with properties:
```

```
    Structure: 'Direct form I'
    CoefficientSource: 'Property'
    Numerator: [5x3 double]
    Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [0.4117 0.3484 0.2445 0.1195 0.0258 0.8913]
```

Show all properties

Use `fvtool` to view the frequency response of the designed filter.

```
fvtool(LowpassCheb1)
```

## Highpass Filter

Create a highpass filter design specification object using the `fdesign.highpass` function. Specify the filter order, passband edge frequency, and the passband ripple.

```
designSpecs = fdesign.highpass('n,fp,ap',7,20,.4,50);
```

Determine the available design methods.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass(N,Fp,Ap)`:

```
cheby1
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
HighpassCheb1 = design(designSpecs,'cheby1',SystemObject=true)
```

```
HighpassCheb1 =  
  dsp.SOSFilter with properties:  
  
    Structure: 'Direct form II'  
    CoefficientSource: 'Property'  
    Numerator: [4x3 double]  
    Denominator: [4x3 double]  
    HasScaleValues: true  
    ScaleValues: [0.0943 0.0612 0.0233 0.0814 1]
```

Show all properties

Use `fvtool` to visualize the highpass frequency response.

```
fvtool(HighpassCheb1)
```

## Input Arguments

### **designSpecs** — Filter specification object

object

Filter specification object, specified as one of the following:

- `fdesign.bandpass`
- `fdesign.bandstop`

- `fdesign.highpass`
- `fdesign.lowpass`

## Output Arguments

### **chebOneFilter** — Type I Chebyshev IIR digital filter

System object

Type I Chebyshev IIR digital filter, returned as a System object. The System object and the values of its properties depend on the input `designSpecs` object and the other design options that you specify as inputs to the function.

## Version History

Introduced in R2011a

### **R2022b: Designs `dsp.SOSFilter` object instead of `dsp.BiquadFilter` object**

*Behavior changed in R2022b*

The `cheby1` design method now generates a `dsp.SOSFilter` object instead of the `dsp.BiquadFilter` object.

Initialize the default `fdesign.lowpass` filter specification object. Use the design function with the `SystemObject=true` flag to design a `dsp.SOSFilter` filter object.

```
designSpecs = fdesign.lowpass;
filtObj = design(designSpecs, 'cheby1', SystemObject=true)

filtObj =

    dsp.SOSFilter with properties:

        Structure: 'Direct form II'
    CoefficientSource: 'Property'
        Numerator: [5×3 double]
        Denominator: [5×3 double]
    HasScaleValues: true
        ScaleValues: [0.4117 0.3484 0.2445 0.1195 0.0258 0.8913]
```

Show all properties

To design a `dsp.BiquadFilter` object instead of the `dsp.SOSFilter` object, you can use the `UseLegacyBiquadFilter` flag and set it to `true`.

```
filtObj = design(designSpecs, 'cheby1', SystemObject=true, ...
    UseLegacyBiquadFilter=true)

filtObj =

    dsp.BiquadFilter with properties:

        Structure: 'Direct form II'
    SOSMatrixSource: 'Property'
        SOSMatrix: [5×6 double]
        ScaleValues: [6×1 double]
```

```
InitialConditions: 0  
OptimizeUnityScaleValues: true
```

Show all properties

## cheby2

Chebyshev Type II filter using specification object

### Syntax

```
chebTwoFilter = cheby2(designSpecs,SystemObject=true)
chebTwoFilter = cheby2(designSpecs,designoption=value,... SystemObject=true)
chebTwoFilter = design(designSpecs,'cheby2',SystemObject=true)
```

### Description

`chebTwoFilter = cheby2(designSpecs,SystemObject=true)` designs a type II Chebyshev IIR digital filter using specifications in the object `designSpecs`.

Depending on the filter specification object `designSpecs`, the `cheby2` design method might not be valid. Use `designmethods` with the filter specification object to determine if a Chebyshev type II filter design is possible.

```
designmethods(designSpecs,SystemObject=true)
```

`chebTwoFilter = cheby2(designSpecs,designoption=value,... SystemObject=true)` returns a type II Chebyshev IIR digital filter with one or more specified designed options and the corresponding values.

To view a list of available design options, run the `designoptions` function on the specification object. The function also lists the default design options the filter uses.

```
designoptions(designSpecs,'cheby2')
```

`chebTwoFilter = design(designSpecs,'cheby2',SystemObject=true)` is an alternative syntax for designing the type II Chebyshev IIR digital filter.

For complete help about using the `cheby2` design method for a specification object, `designSpecs`, enter the following at the MATLAB command prompt.

```
help(designSpecs,'cheby2')
```

### Examples

#### Design a Chebyshev Type II Filter

Design a type II Chebyshev IIR filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

## Lowpass Filter

Construct a default lowpass filter specification object using `fdesign.lowpass`.

```
designSpecs = fdesign.lowpass

designSpecs =
    lowpass with properties:

        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
            Fpass: 0.4500
            Fstop: 0.5500
            Apass: 1
            Astop: 60
```

Determine the available design methods using the `designmethods` function. To design a type II Chebyshev filter, pick `cheby2`.

```
designmethods(designSpecs,SystemObject=true)

Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'cheby2',SystemObject=true)

ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascade...
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

Use the `design` function to design the filter. Pass `'cheby2'` and the specifications given by the variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'` to ensure the performance of the filter in the passband.

```
LowpassCheb2 = design(designSpecs,'cheby2',matchexactly='passband',...
    SystemObject=true);
```

Use `fvtool` to view the frequency response of the designed filter.

```
fvtool(LowpassCheb2)
```

## Highpass Filter

Construct a highpass filter specification object using `fdesign.highpass`. Specify the filter order, stopband edge frequency, and the stopband attenuation to get the filter exactly as required.

```
designSpecs = fdesign.highpass('n,fst,ast',5,20,55,50);
```

Determine the available design methods. To design a type II Chebyshev IIR filter, pick `cheby2`.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass(N,Fst,Ast)`:

```
cheby2
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
HighpassCheb2 = design(designSpecs,'cheby2',SystemObject=true)
```

```
HighpassCheb2 =  
  dsp.SOSFilter with properties:
```

```

Structure: 'Direct form II'
CoefficientSource: 'Property'
Numerator: [3x3 double]
Denominator: [3x3 double]
HasScaleValues: true
ScaleValues: [0.1995 0.0880 0.1450 1]

```

Show all properties

Use `fvtool` to visualize the highpass frequency response.

```
fvtool(HighpassCheb2)
```

By design, `cheby2` returns filters that use second-order sections (SOS). For many applications, and for most fixed-point applications, SOS filters are particularly well-suited.

## Input Arguments

**designSpecs** — Filter specification object

object

Filter specification object, specified as one of the following:

- `fdesign.bandpass`
- `fdesign.bandstop`

- `fdesign.highpass`
- `fdesign.lowpass`

## Output Arguments

### **chebTwoFilter** — Type II Chebyshev IIR digital filter

System object

Type II Chebyshev IIR digital filter, returned as a filter System object. The System object and the values of its properties depend on the input `designSpecs` object and the other design options specified to the function.

## Version History

Introduced in R2011a

### **R2022b: Designs `dsp.SOSFilter` object instead of `dsp.BiquadFilter` object**

*Behavior changed in R2022b*

The `cheby2` design method now generates a `dsp.SOSFilter` object instead of the `dsp.BiquadFilter` object.

Initialize the default `fdesign.lowpass` filter specification object. Use the design function with the `SystemObject=true` flag to design a `dsp.SOSFilter` filter object.

```
designSpecs = fdesign.lowpass;
filtObj = design(designSpecs, 'cheby2', SystemObject=true)

filtObj =

    dsp.SOSFilter with properties:

        Structure: 'Direct form II'
    CoefficientSource: 'Property'
        Numerator: [5×3 double]
        Denominator: [5×3 double]
    HasScaleValues: true
        ScaleValues: [0.7003 0.5771 0.4734 0.3925 0.3466 1]

    Show all properties
```

To design a `dsp.BiquadFilter` object instead of the `dsp.SOSFilter` object, you can use the `UseLegacyBiquadFilter` flag and set it to `true`.

```
filtObj = design(designSpecs, 'cheby2', SystemObject=true, ...
    UseLegacyBiquadFilter=true)

filtObj =

    dsp.BiquadFilter with properties:

        Structure: 'Direct form II'
    SOSMatrixSource: 'Property'
        SOSMatrix: [5×6 double]
        ScaleValues: [6×1 double]
```

```
InitialConditions: 0  
OptimizeUnityScaleValues: true
```

Show all properties

### **See Also**

## cl2tf

Convert coupled allpass lattice to transfer function form

### Syntax

```
[b,a] = cl2tf(k1,k2)
[b,a] = cl2tf(k1,k2,beta)
[b,a,bp] = cl2tf(k1,k2)
[b,a,bp] = cl2tf(k1,k2,beta)
```

### Description

`[b,a] = cl2tf(k1,k2)` returns vectors of coefficients `b` and `a` when `k1` and `k2` are real vectors. `b` is the vector of coefficients corresponding to the numerator of the transfer function  $H(z)$ . `a` is the vector of coefficients corresponding to the denominator of the transfer function  $H(z)$ . `k1` and `k2` are real vectors corresponding to denominators of the allpass filters  $H1(z)$  and  $H2(z)$ . This is provided in the transfer function:

$$H(z) = B(z)/A(z) = \frac{1}{2}[H1(z) + H2(z)]$$

`[b,a] = cl2tf(k1,k2,beta)` returns the vectors of coefficients `b` and `a` corresponding to the numerator and denominator, respectively, of the transfer function  $H(z)$ , where `k1`, `k2`, and `beta` are complex vectors.

$$H(z) = B(z)/A(z) = \frac{1}{2}[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)]$$

`[b,a,bp] = cl2tf(k1,k2)` also returns the vector `bp` of real coefficients corresponding to the numerator of the power-complementary filter  $G(z)$ , where `k1` and `k2` are real vectors.

$$G(z) = Bp(z)/A(z) = \frac{1}{2}[H1(z) - H2(z)]$$

`[b,a,bp] = cl2tf(k1,k2,beta)` also returns the vector of coefficients `bp` of possibly complex coefficients corresponding to the numerator of the power complementary filter  $G(z)$ , where `k1`, `k2`, and `beta` are complex.

$$G(z) = Bp(z)/A(z) = \frac{1}{2j}[-(\bar{\beta}) \cdot H1(z) + \beta \cdot H2(z)]$$

### Examples

#### Convert Coupled Allpass Filter Lattice to Transfer Function

Compute the reflection coefficient using `tf2cl` function.

```
[b,a] = cheby1(10,.5,.4);
[k1,k2,beta] = tf2cl(b,a);
```

Construct the original and the power-complementary filters.

```
[num,den,numpc] = cl2tf(k1,k2,beta);
[h,w] = freqz(num,den);
hpc = freqz(numpc,den);
```

Plot the frequency response.

```
subplot(211)
plot(w./pi,20*log10(abs(h)), 'k')
hold on;
grid on;
plot(w./pi,20*log10(abs(hpc)), 'b')
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('dB');
legend('Original Filter', 'Power Complementary Filter', ...
'Location', 'best');
subplot(212)
plot(w./pi,unwrap(angle(h)), 'k')
hold on;
grid on;
plot(w./pi,unwrap(angle(hpc)), 'b')
xlabel('Normalized Frequency (x \pi radians/sample)');
ylabel('Phase (radians)');
```

## Input Arguments

### **k1 — Reflection coefficients corresponding to allpass lattice structure of H1(z)**

vector

Reflection coefficients corresponding to allpass lattice structure of  $H1(z)$ , specified as a real- or complex-valued vector.

Data Types: `single` | `double`

### **k2 — Reflection coefficients corresponding to allpass lattice structure of H2(z)**

vector

Reflection coefficients corresponding to allpass lattice structure of  $H2(z)$ , specified as a real- or complex-valued vector.

Data Types: `single` | `double`

### **beta — Complex scalar of magnitude 1**

complex scalar

Complex scalar of magnitude 1.

Data Types: `single` | `double`

## Output Arguments

### **b — Numerator coefficients of transfer function**

vector

Coefficients of the numerator of the transfer function  $H(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

### **a — Denominator coefficients of transfer function**

vector

Coefficients of the denominator of the transfer function  $H(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

### **bp — Numerator coefficients of power-complementary filter G(z)**

vector

Coefficients of the numerator of the power-complementary filter  $G(z)$ , returned as a real- or complex-valued vector.

Data Types: `double`

## Version History

# coeffs

**Package:** dsp

Returns the filter System object coefficients in a structure

## Syntax

```
s = coeffs(sysobj)
s = coeffs(sysobj, 'Arithmetic', arithType)
```

## Description

`s = coeffs(sysobj)` returns the coefficients of filter System object, `sysobj`, in the structure `s`.

`s = coeffs(sysobj, 'Arithmetic', arithType)` returns filter coefficients for the filter System object `sysobj` with the arithmetic specified in `arithType`.

## Examples

### Coefficients of an FIR Halfband Interpolator

```
FIRHalfbandInterp = dsp.FIRHalfbandInterpolator('Specification', ...
    'Filter order and transition width', 'FilterOrder', 26);
C = coeffs(FIRHalfbandInterp);
C.Numerator
```

```
ans = 1×27
```

```
    0.0525         0   -0.0379         0    0.0537         0   -0.0771         0    0.1172
```

```
% Impulse response of the filter
fvtool(FIRHalfbandInterp, 'impulse')
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`

- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## **Output Arguments**

### **s — Structure**

struct

Structure with a single field, `Numerator`, containing filter coefficients.

## **Version History**

**Introduced in R2011a**

# coeffs

**Package:** dsp

Coefficients of prototype lowpass filter

## Syntax

```
c = coeffs(obj)
```

## Description

`c = coeffs(obj)` returns the coefficients of the prototype lowpass filter in `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects.

## Examples

### Coefficients Of Channelizer

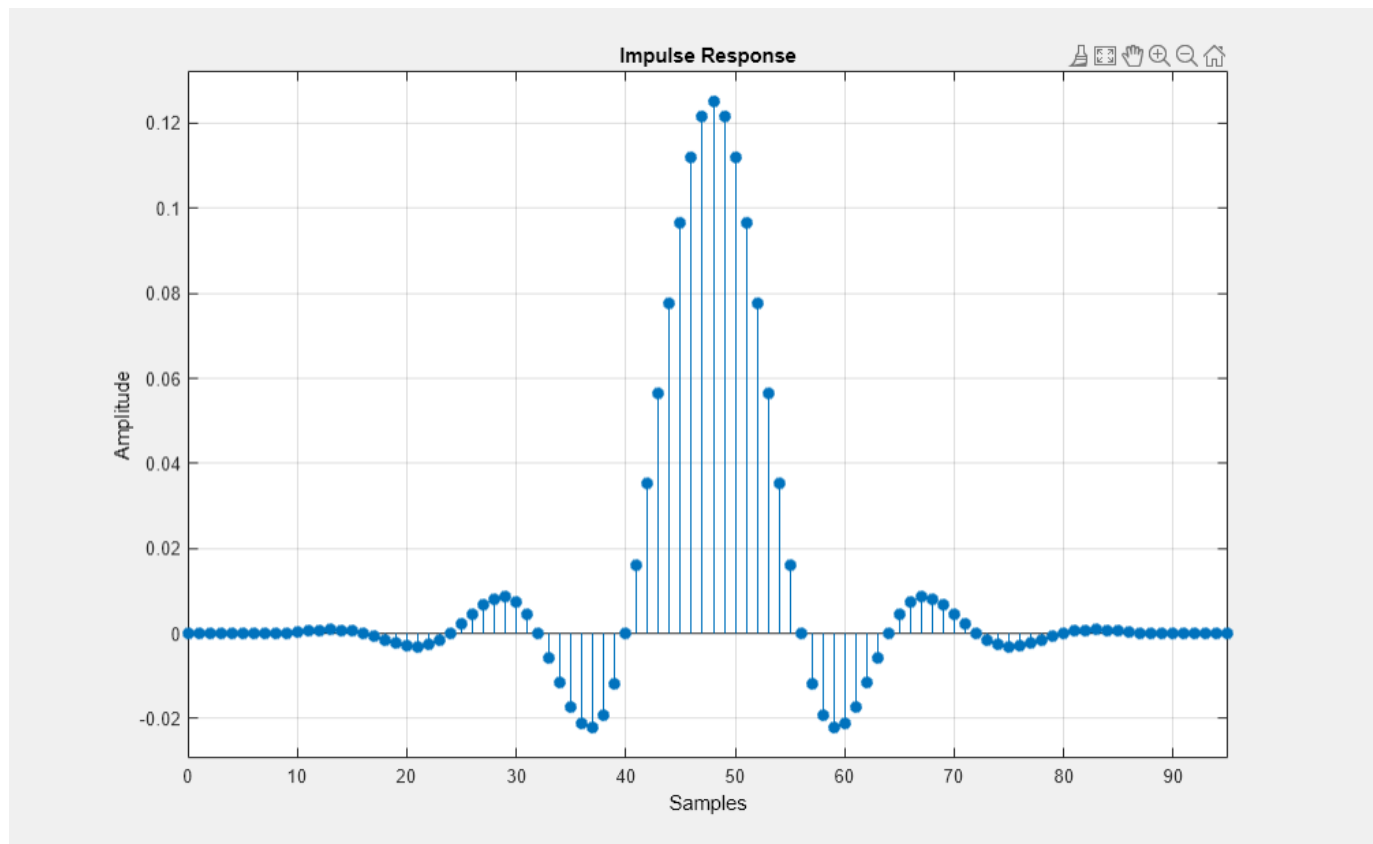

Determine the coefficients of the prototype lowpass filter in the `dsp.Channelizer` object using the `coeffs` function.

The `coeffs` function returns a structure, `c`. The structure field `Numerator` contains the coefficients as a row vector. The number of elements in the row vector, given by `c.Numerator`, equals the number of frequency bands times the number of coefficients per band. These values are given by the `NumFrequencyBands` and `NumTapsPerBand` properties of the `dsp.Channelizer` object.

```
channelizer = dsp.Channelizer;  
c = coeffs(channelizer);
```

Visualize the impulse response of the filter using `fvtool`.

```
fvtool(c.Numerator, 'impulse');
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or a `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer`

## Output Arguments

### **c** — Lowpass filter coefficients

structure

Lowpass filter coefficients, returned as a structure. The structure field `Numerator` contains the coefficients as a row vector.

## Version History

**Introduced in R2016b**

## **coeread**

Read Xilinx COE file

### **Syntax**

```
hd = coeread(filename)
```

### **Description**

`hd = coeread(filename)` extracts the Distributed Arithmetic FIR filter coefficients defined in the XILINX CORE Generator .COE file specified by `filename`. It returns a `dfilt` object, the fixed-point filter `hd`. If you do not provide the file type extension `.coe` with the `filename`, the function assumes the `.coe` extension.

### **Version History**

**Introduced in R2011a**

# coewrite

Write Xilinx COE file

## Syntax

```
coewrite(hd)
coewrite(hd,radix)
coewrite(...,filename)
```

## Description

`coewrite(hd)` writes a XILINX Distributed Arithmetic FIR filter coefficient .COE file which can be loaded into the XILINX CORE Generator. The coefficients are extracted from the fixed-point `dfilt` object `hd`. Your fixed-point filter must be a direct form FIR structure `dfilt` object with one section and whose Arithmetic property is set to `fixed`. You cannot export single-precision, double-precision, or floating-point filters as .coe files, nor multiple-section filters. To enable you to provide a name for the file, `coewrite` displays a dialog box where you fill in the file name. If you do not specify the name of the output file, the default file name is `untitled.coe`.

`coewrite(hd,radix)` indicates the radix (number base) used to specify the FIR filter coefficients. Valid radix values are 2 for binary, 10 for decimal, and 16 for hexadecimal (default).

`coewrite(...,filename)` writes a XILINX.COE file to `filename`. If you omit the file extension, `coewrite` adds the .coe extension to the name of the file.

The `coewrite` function always generates the XILINX.COE file in your current folder. To use this function, you must have write permission in your current folder.

## Examples

`coewrite` generates an ASCII text file that contains the filter coefficients in a format the XILINX CORE Generator can read and load. In this example, you create a 30th-order fixed-point filter and generate the .coe file that includes the filter coefficients as well as associated information about the filter.

```
b = firceqrip(30,0.4,[0.05 0.03]); hq = dfilt.dffir(b);
set(hq,'arithmetic','fixed'); coewrite(hq,10,'mycoefile');
```

The `coewrite` function generates the output file, `mycoefile.coe`, in your current folder. The .coe file contains the radix, coefficient width, and filter coefficients. The file reports the filter coefficients in column-major order. The radix, coefficient width, and filter coefficients are the minimum set of data needed in a .coe file.

## Version History

Introduced in R2011a

## constraincoeffwl

Constrain coefficient word length

### Syntax

```
Hq = constraincoeffwl(Hd,wordlength)
Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)
Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)
Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)
Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)
```

### Description

`Hq = constraincoeffwl(Hd,wordlength)` returns a fixed-point filter `Hq` meeting the design specifications of the single-stage or multistage FIR filter object `Hd` with a wordlength of at most `wordlength` bits. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same word length is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `Hd` must be generated using `fdesign` and `design`. `constraincoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = constraincoeffwl(Hd,wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use. `Hq` is first filter among the trials to meet the specifications in `Hd` with a wordlength of at most `wordlength`.

`Hq = constraincoeffwl(Hd,wordlength,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the constraint of the word length. By default `NSFlag` is `true`. Setting `NSFlag` to `false` constrains the word length without using noise-shaping.

`Hq = constraincoeffwl(Hd,wordlength,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = constraincoeffwl(Hd,wordlength,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`

You must have the Fixed-Point Designer software installed to use this function.

### Examples

#### Design Fixed-Point Filter

Design fixed-point filter with a word length of at most 11 bits using `constraincoeffwl`.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',.4,.5,1,60);
Hd = design(Hf,'equiripple'); % 43 coefficients
Hq = constraincoeffwl(Hd,11); % 45 11-bit coefficients
hfvt = fvtool(Hd,Hq);
legend(hfvt,'Floating-point Filter','Fixed-point Filter');
```

## convert

Convert filter structure of discrete-time filter

### Syntax

```
hq = convert(hq,newstruct)
```

### Description

#### Discrete-Time Filters

`hq = convert(hq,newstruct)` returns a quantized filter whose structure has been transformed to the filter structure specified by `newstruct`. You can enter any one of the following quantized filter structures:

- 'antisymmetricfir': Antisymmetric finite impulse response (FIR)
- 'df1': Direct form I
- 'df1t': Direct form I transposed
- 'df1sos': Direct-Form I, Second-Order Sections
- 'df1tsos': Direct-Form I Transposed, Second-Order Sections
- 'df2': Direct form II
- 'df2t': Direct form II transposed. Default filter structure
- 'df2sos': Direct-Form II, Second-Order Sections
- 'df2tsos': Direct-Form II Transposed, Second-Order Sections
- 'dffir': FIR
- 'dffirt': Direct form FIR transposed
- 'latcallpass': Lattice allpass
- 'latticeca': Lattice coupled-allpass
- 'latticecapc': Lattice coupled-allpass power-complementary
- 'latticear': Lattice autoregressive (AR)
- 'latticemax': Lattice moving average (MA) maximum phase
- 'latticemin': Lattice moving average (MA) minimum phase
- 'latticearma': Lattice ARMA
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

All filters can be converted to the following structures:

- 'df1': Direct form I
- 'df1t': Direct form I transposed
- 'df1sos': Direct-Form I, Second-Order Sections
- 'df1tsos': Direct-Form I Transposed, Second-Order Sections

- 'df2': Direct form II
- 'df2t': Direct form II transposed. Default filter structure
- 'df2sos': Direct-Form II, Second-Order Sections
- 'df2tsos': Direct-Form II Transposed, Second-Order Sections
- 'statespace': Single-input/single-output state-space
- 'symmetricfir': Symmetric FIR. Even and odd forms

For the following filter classes, you can specify other conversions as well:

- Minimum phase FIR filters can be converted to `lattice` `mamin`
- Maximum phase FIR filters can be converted to `lattice` `mamax`
- Allpass filters can be converted to `latcallpass`

`convert` generates an error when you specify a conversion that is not possible.

## Examples

### Convert Direct-Form II Transposed Structure to Direct-Form I

```
[b,a]=ellip(5,3,40,.7); hq = dfilt.df2t(b,a)
```

```
hq =
  FilterStructure: 'Direct-Form II Transposed'
  Arithmetic: 'double'
  Numerator: [1x6 double]
  Denominator: [1x6 double]
  PersistentMemory: false
```

```
hq2 = convert(hq,'df1')
```

```
hq2 =
  FilterStructure: 'Direct-Form I'
  Arithmetic: 'double'
  Numerator: [1x6 double]
  Denominator: [1x6 double]
  PersistentMemory: false
```

## Version History

Introduced in R2011a

## cost

**Package:** dsp

Estimate cost of implementing filter System object

### Syntax

```
c = cost(sysobj)
c = cost(sysobj, 'Arithmetic', arithType)
```

### Description

`c = cost(sysobj)` returns a structure, `c`, whose fields contain information about the computational cost of implementing the filter System object, `sysobj`.

`c = cost(sysobj, 'Arithmetic', arithType)` returns a cost estimate `c` for the filter System object `sysobj` in the arithmetic specified by `arithType`.

### Examples

#### Cost of FIR Filter

This example shows how to compute the cost of implementing an FIR Filter created using `dsp.FIRFilter` object.

```
Fs = 8000; Fcutoff = 2000;
firFilt = dsp.FIRFilter('Numerator', fir1(130, Fcutoff/(Fs/2)));
cost(firFilt)
```

```
ans = struct with fields:
    NumCoefficients: 131
    NumStates: 130
    MultiplicationsPerInputSample: 131
    AdditionsPerInputSample: 130
```

### Input Arguments

#### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`

- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

#### **arithType — Arithmetic type**

`'double'` (default) | `'single'` | `'Fixed'`

Arithmetic used in the filter analysis, specified as `'double'`, `'single'`, or `'Fixed'`. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Fixed'` value applies to filter System objects with fixed-point properties only.

When the `'Arithmetic'` input argument is specified as `'Fixed'` and the filter object has the data type of the coefficients set to `'Same word length as input'`, the arithmetic analysis depends on whether the System object is unlocked or locked.

- `unlocked` -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **c** — cost estimate

struct

Cost estimate, `c` contains the following fields:

| Estimated Value               | Description   |
|-------------------------------|---|
| NumCoefficients               | Number of filter coefficients (excluding coefficients with values 0, 1 or -1) |
| NumStates                     | Number of filter states   |
| MultiplicationsPerInputSample | Number of multiplication operations performed for each input sample           |
| AdditionsPerInputSample       | Number of addition operations performed for each input sample                 |

# cost

**Package:** dsp

Implementation cost of the complex bandpass decimator

## Syntax

```
c = cost(cbd)
```

## Description

`c = cost(cbd)` returns a structure, `c`, whose fields contain information about the computation cost of implementing the complex bandpass decimator object, `cbd`.

## Examples

### Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =
  dsp.ComplexBandpassDecimator with properties:
      CenterFrequency: 5000
      Specification: 'Decimation factor'
      DecimationFactor: 12
      StopbandAttenuation: 80
      TransitionWidth: 100
      MinimizeComplexCoefficients: true
      SampleRate: 44100
```

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)

c = struct with fields:
      NumCoefficients: 201
      NumStates: 379
      RealMultiplicationsPerInputSample: 44.3333
      RealAdditionsPerInputSample: 43.8333
```

## Input Arguments

### **cbd** — Filter System object

`dsp.ComplexBandpassDecimator`

Filter System object, specified as a `dsp.ComplexBandpassDecimator` System object.

## Output Arguments

### **c** — Cost estimate

structure

Cost estimate containing these fields:

| Estimated Value                   | Description   |
|-----------------------------------|---|
| NumCoefficients                   | Number of filter coefficients (excluding coefficients with values 0, 1 or -1) |
| NumStates                         | Number of filter states   |
| RealMultiplicationsPerInputSample | Number of real multiplication operations performed for each input sample      |
| RealAdditionsPerInputSample       | Number of real addition operations performed for each input sample            |

The function assumes that a complex-by-complex multiplication requires 3 real multiplications and 5 real additions.

# cost

**Package:** dsp

Implementation cost of the sample rate converter

## Syntax

```
c = cost(src)
```

## Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a multistage sample rate converter, `src`.

## Examples

### Computational Cost of Sample Rate Converter

Create `src`, a multistage sample rate converter with default values. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its computational cost: the number of coefficients, the number of states, the number of multiplications per unit sample, and the number of additions per unit sample.

```
src = dsp.SampleRateConverter;  
cst = cost(src)  
  
cst = struct with fields:  
    NumCoefficients: 8631  
    NumStates: 138  
    MultiplicationsPerInputSample: 27.6672  
    AdditionsPerInputSample: 26.6875
```

Repeat the computation allowing a tolerance of 10% in the output sample rate.

```
src.OutputRateTolerance = 0.1;  
ctl = cost(src)  
  
ctl = struct with fields:  
    NumCoefficients: 44  
    NumStates: 80  
    MultiplicationsPerInputSample: 14.2500  
    AdditionsPerInputSample: 13.5000
```

## Input Arguments

**src** — Multistage sample rate converter

SampleRateConverter System object

Multistage sample rate converter, specified as a `dsp.SampleRateConverter` System object.

## Output Arguments

### c — Output structure

structure

Output structure with information about the computational cost of `src`:

| Estimated Value               | Description   |
|-------------------------------|---|
| NumCoefficients               | Number of filter coefficients (excluding coefficients with values 0, 1 or -1) |
| NumStates                     | Number of filter states   |
| MultiplicationsPerInputSample | Number of multiplication operations performed for each input sample           |
| AdditionsPerInputSample       | Number of addition operations performed for each input sample                 |

# getFilters

**Package:** dsp

Obtain single-stage filters

## Syntax

```
c = getFilters(src)
```

## Description

`c = getFilters(src)` returns the multirate filters cascaded together in `src` to perform the overall sample rate conversion. The result is a `FilterCascade` structure, `c`. Each field of `c` holds the filter used at a particular stage and gives access to its coefficients and rate-change factors.

## Examples

### Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;  
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;  
  
[h,w] = freqz(m);  
plot(w/pi,20*log10(abs(h)))  
xlabel('\omega / \pi')  
ylabel('Magnitude (dB)')
```

## Input Arguments

**src** — Multistage sample rate converter

`dsp.SampleRateConverter` System object

Multistage sample rate converter, specified as a `dsp.SampleRateConverter` System object.

## Output Arguments

**c** — Single-stage filters

`FilterCascade` structure

Single-stage filters, returned as a `FilterCascade` structure.

Display information about sample rate converter

### Syntax

```
s = info(src)
```

### Description

`s = info(src)` displays information about the multistage `SampleRateConverter` System object, `src`.

### Examples

#### Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz.

```
src = dsp.SampleRateConverter

src =
  dsp.SampleRateConverter with properties:

      InputSampleRate: 192000
      OutputSampleRate: 44100
      OutputRateTolerance: 0
      Bandwidth: 40000
      StopbandAttenuation: 80
```

Display information about the design.

```
info(src)

ans =
  'Overall Interpolation Factor    : 147
  Overall Decimation Factor      : 640
  Number of Filters              : 3
  Multiplications per Input Sample: 27.667188
  Number of Coefficients         : 8631
  Filters:
    Filter 1:
      dsp.FIRDecimator - Decimation Factor : 2
    Filter 2:
      dsp.FIRDecimator - Decimation Factor : 2
    Filter 3:
      dsp.FIRRateConverter - Interpolation Factor: 147
                          - Decimation Factor   : 160
```

## Input Arguments

### **src** — Multistage sample rate converter

`dsp.SampleRateConverter` System object

Multistage sample rate converter, specified as a `dsp.SampleRateConverter` System object.

## Output Arguments

### **s** — Store filter information

character array

Filter information, returned as a character array with the following fields.

- Overall Interpolation Factor
- Overall Decimation Factor
- Number of Filters
- Multiplications Per Input Sample
- Number of Coefficients
- Filters

## cumsec

**Package:** dsp

Cumulative second-order section of the biquadratic filter

### Syntax

```
sect = cumsec(sysobj)
sect = cumsec(sysobj,indices)
sect = cumsec(sysobj,indices,secondary)
cumsec(sysobj,...)
sect = cumsec(sysobj,'Arithmetic',arithType)
```

### Description

`sect = cumsec(sysobj)` returns a cell array, `sect`, which contains cumulative sections of the biquadratic filter System object, `sysobj`. Each element in `sect` is a filter with the structure of the original filter. The first element is the first filter section of the biquadratic filter. The second element of `sect` is a filter that represents the combination of the first and second sections of the biquadratic filter. The third element of `sect` is a filter which combines sections 1, 2, and 3 of the biquadratic filter. This pattern continues until the final element of `sect` contains all the sections of the biquadratic filter and should be identical to the biquadratic filter.

`sect = cumsec(sysobj,indices)` returns the cumulative sections of the biquadratic filter object whose indices in the original filter are in the vector `indices`.

`sect = cumsec(sysobj,indices,secondary)` uses the secondary scaling points `secondary` in the sections to determine where the sections should be split when `secondary` is true. `secondary` is false by default. This option only applies for biquadratic filter objects with 'Direct form II' and 'Direct form I transposed' structures. For these structures, the secondary scaling points refer to the location between the recursive and the nonrecursive part, that is the 'middle' of the section.

`cumsec(sysobj,...)` plots the magnitude response of the cumulative sections using `fvtool`.

`sect = cumsec(sysobj,'Arithmetic',arithType)` returns the cumulative sections of the biquadratic filter object with the arithmetic specified in `arithType`.

### Examples

#### Frequency Response of SOS Filter

This example plots the relative responses of the sections of a sixth-order filter with three sections. Each curve adds one more section to form the filter response.

```
Lowpass = fdesign.lowpass('n,fc',6,.4); ButterLowpass = butter(Lowpass,'SystemObject',true);
CumSections = cumsec(ButterLowpass); hfvt = fvtool(CumSections{1},CumSections{2},CumSections{3})
legend(hfvt,'First Section','First Two Sections','Overall Filter');
```

## Input Arguments

### **sysobj** — Input filter object

`dsp.BiquadFilter` System object | `dsp.SOSFilter` System object

Input filter, specified as one of the following System objects:

- `dsp.BiquadFilter`
- `dsp.SOSFilter`

### **indices** — Filter indices

scalar | row vector

Filter indices. Use `indices` to specify the filter sections `cumsec` uses to compute the cumulative responses.

### **secondary** — Flag to use secondary scaling points

`false` (default) | `true`

This option applies only when `sysobj` has the `df2sos` and `df1tsos` structures. For these second-order section structures, the secondary scaling points refer to the scaling locations between the recursive and the nonrecursive parts of the section (the "middle" of the section). Argument `secondary` accepts either `true` or `false`. By default, `secondary` is `false`.

**arithType – Arithmetic type**`'double' (default) | 'single' | 'Fixed'`

Arithmetic used in the filter analysis, specified as `'double'`, `'single'`, or `'Fixed'`. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Fixed'` value applies to filter System objects with fixed-point properties only.

When the `'Arithmetic'` input argument is specified as `'Fixed'` and the filter object has the data type of the coefficients set to `'Same word length as input'`, the arithmetic analysis depends on whether the System object is unlocked or locked.

- `unlocked` -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

# deleteCursor

**Package:** dsp

Delete Logic Analyzer cursor

## Syntax

```
deleteCursor(scope, tag)
```

## Description

`deleteCursor(scope, tag)` deletes the Logic Analyzer cursor specified by the input tag.

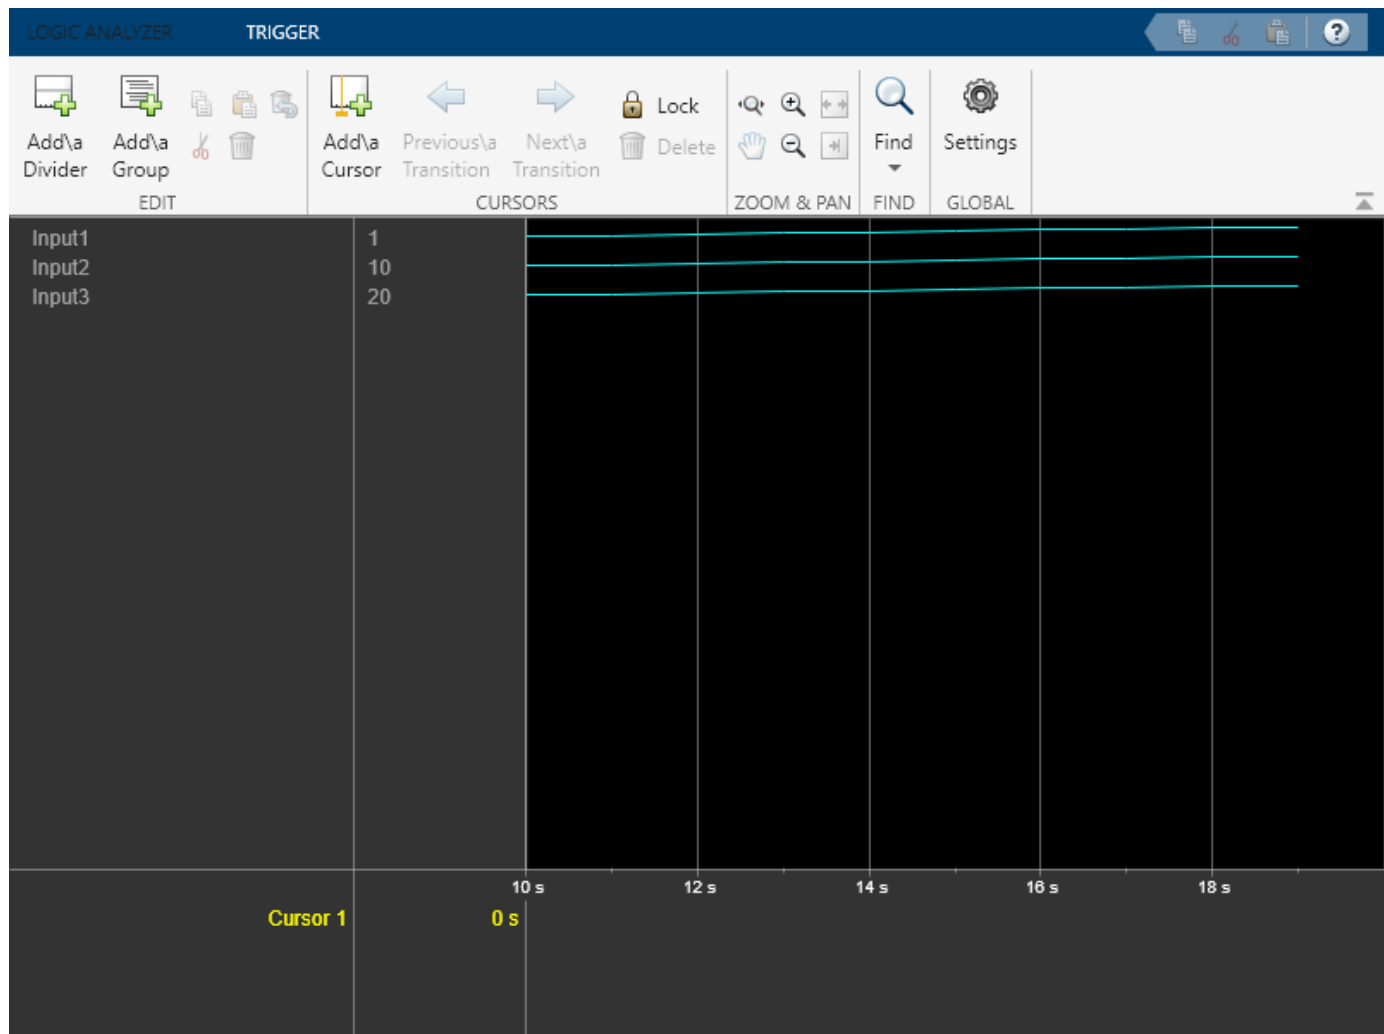

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

Add a cursor at 15 seconds and show the cursor information.

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
    Location: 15
    Color: [0 1 1]
    Locked: 0
    Tag: 'C2'
```

### Modify Cursor

Change the cursor color to magenta.

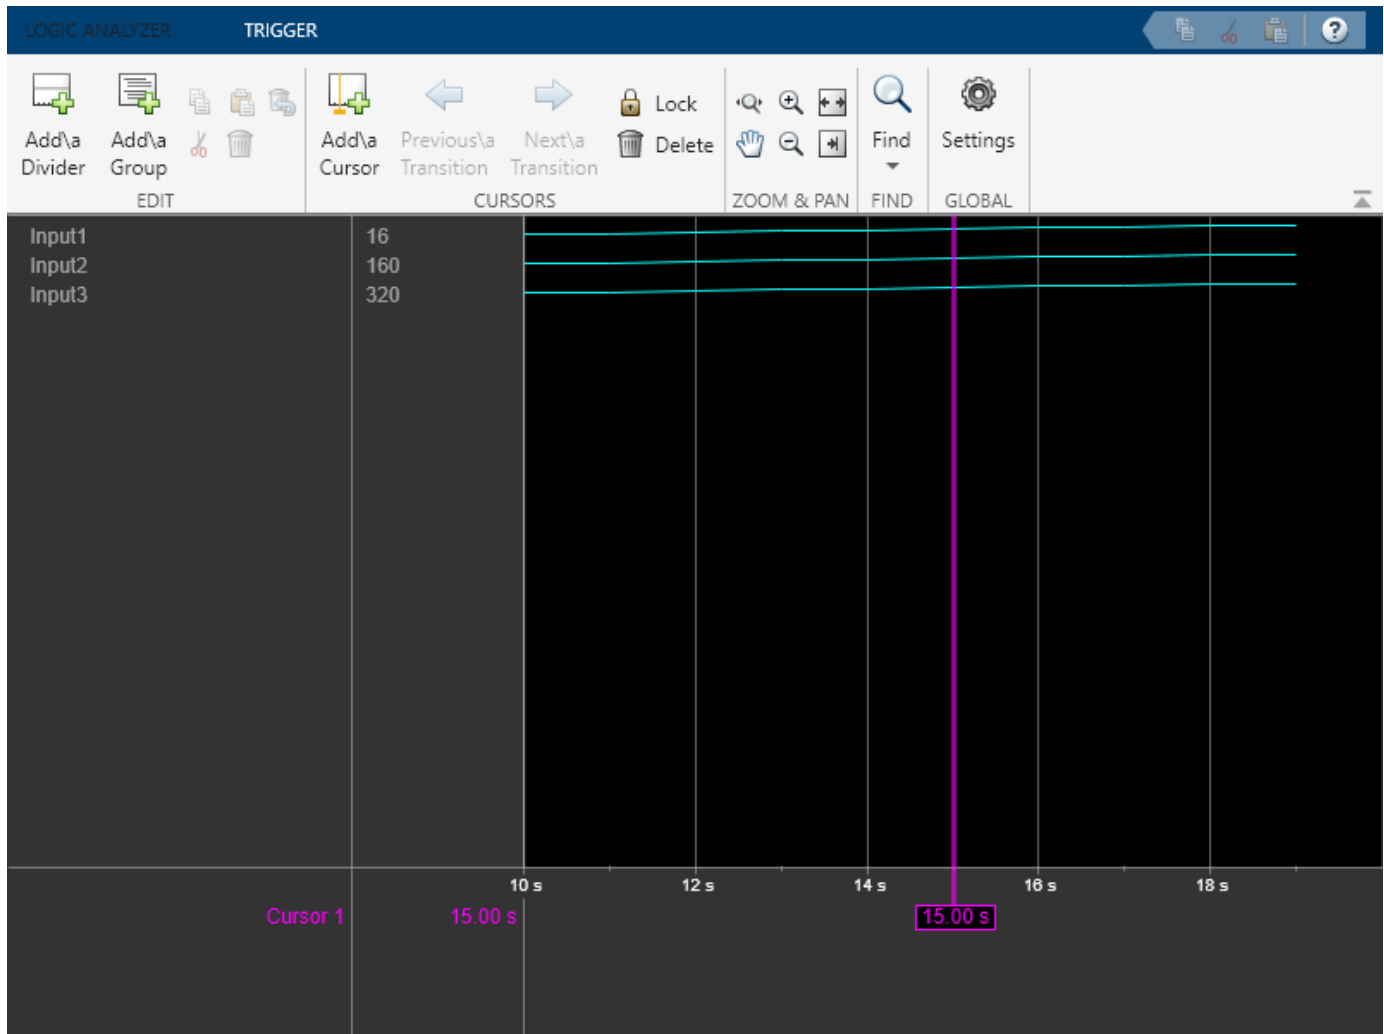

```
hide(scope)
modifyCursor(scope, cursor, 'Color', 'Magenta')
show(scope)
```

### Remove Cursor

Delete the yellow cursor at 0 seconds.

```
hide(scope)
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
show(scope)
```

## Input Arguments

**scope** — Logic Analyzer object from which you want to delete a cursor

`dsp.LogicAnalyzer` object handle

The Logic Analyzer object from which you want to delete a cursor, specified as a handle to the `dsp.LogicAnalyzer` object.

**tag** — Tag identifying which cursor to delete

randomly assigned character vector

The tag identifying which cursor to delete, specified as a randomly assigned character vector.

Example: `deleteCursor(scope, tag)` deletes a cursor from Logic Analyzer.

Data Types: `char` | `string`

## Version History

Introduced in R2013a

**See Also**

`dsp.LogicAnalyzer` | `addCursor` | `getCursorTags` | `getCursorInfo` | `modifyCursor` | `deleteDisplayChannel`

## deleteDisplayChannel

**Package:** dsp

Delete Logic Analyzer channel

### Syntax

```
deleteDisplayChannel(scope, tag)
```

### Description

`deleteDisplayChannel(scope, tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

### Examples

#### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

## Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

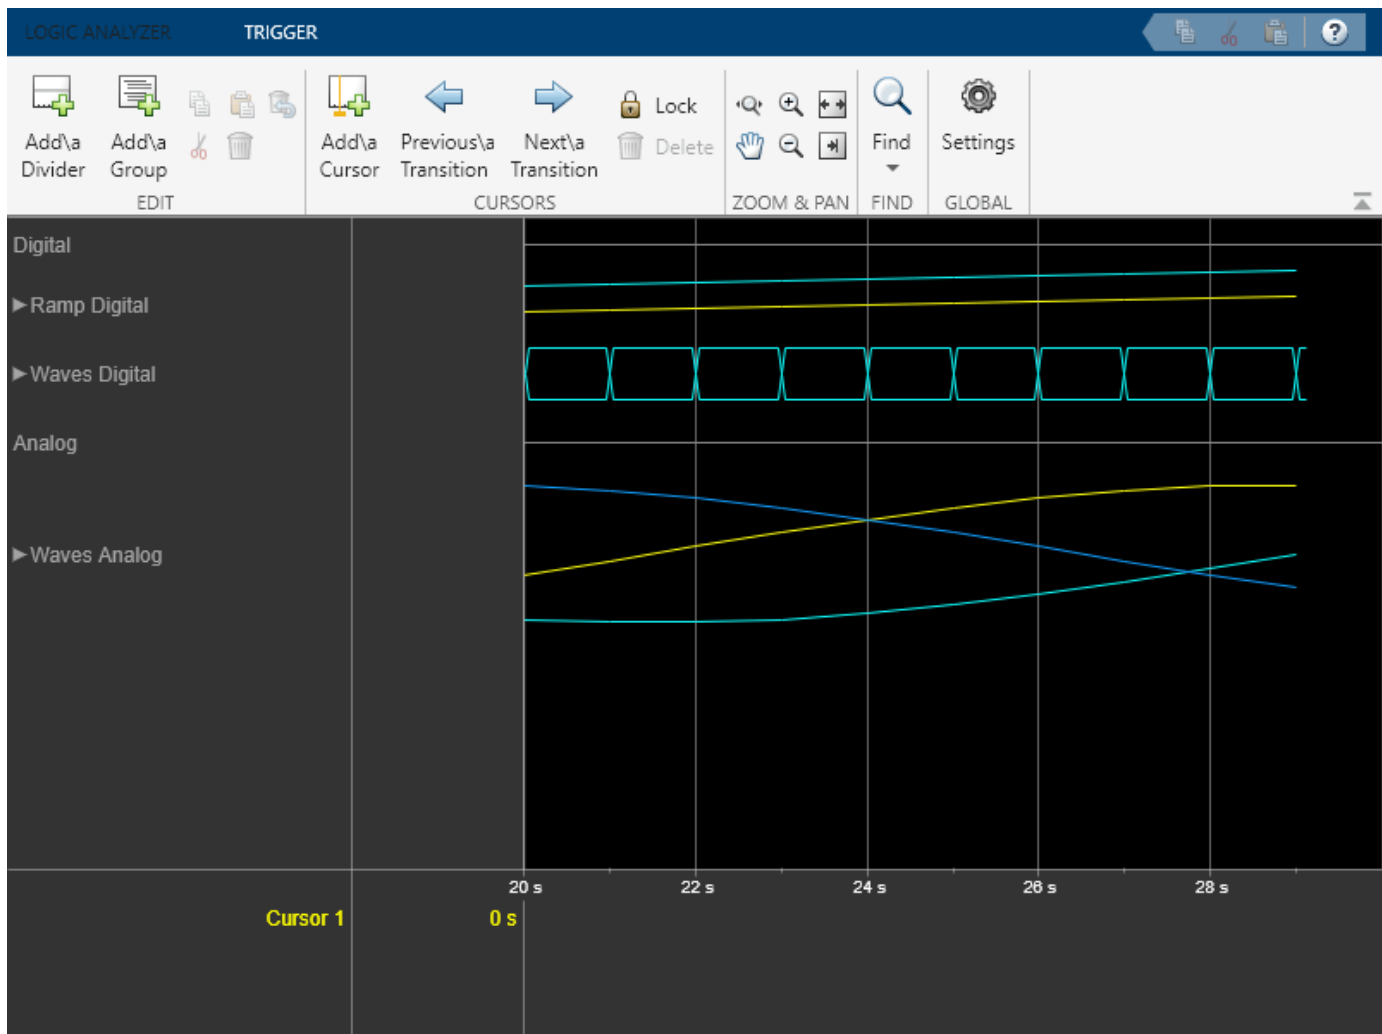

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

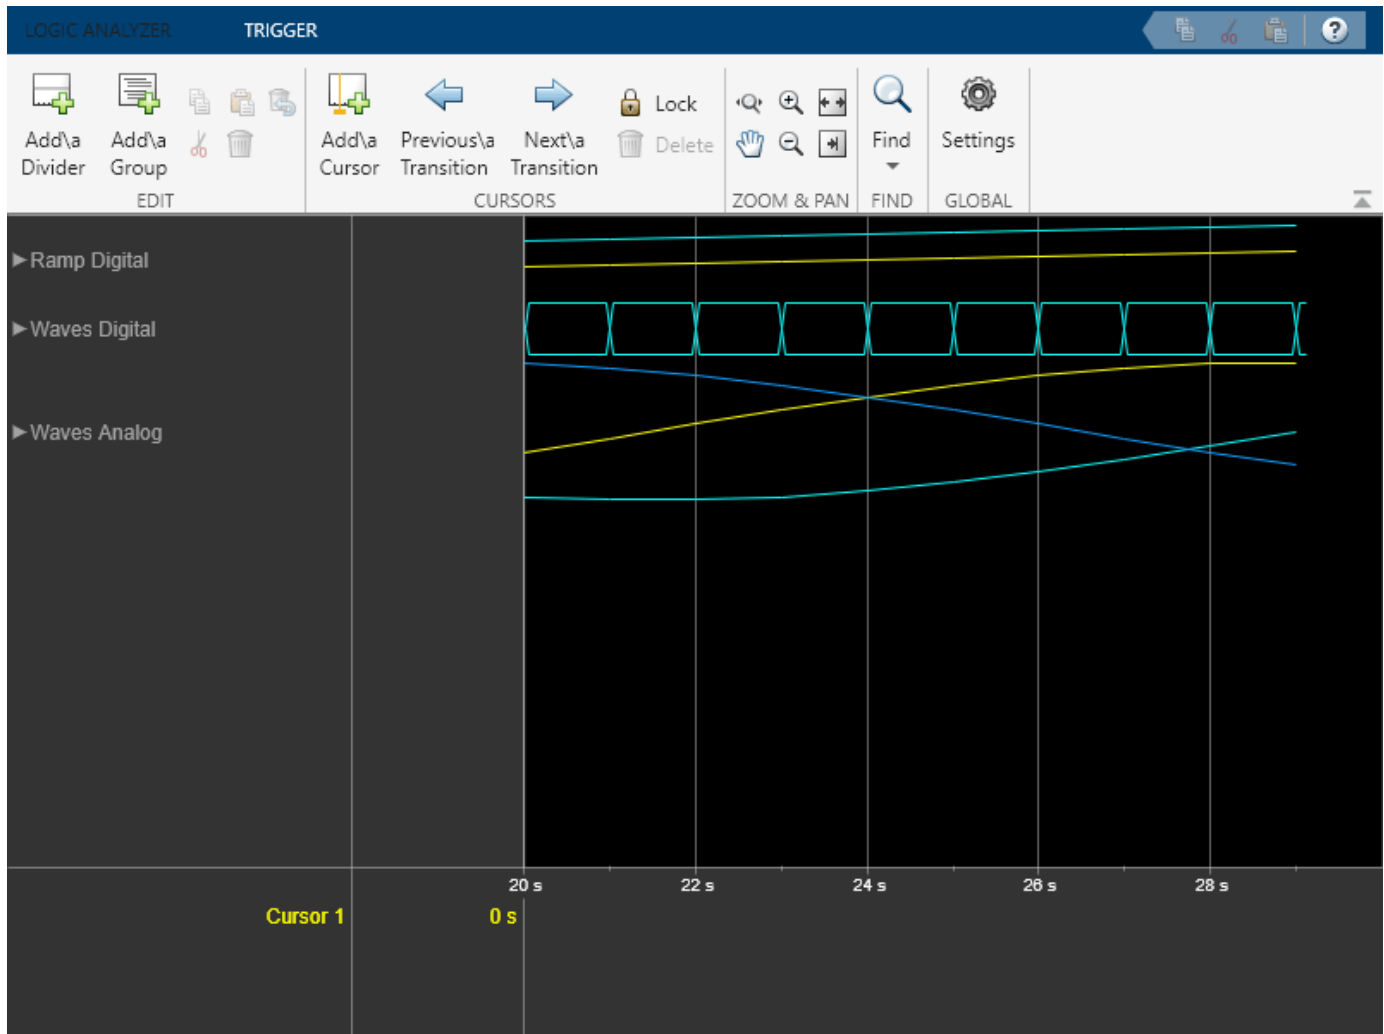

### Duplicate Wave and Check Information

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
    'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to delete a display channel, specified as a handle to the dsp.LogicAnalyzer object.

### tag — tag identifier

randomly assigned character vector

The tag identifying which display channel to delete, specified as the randomly assigned character vector.

Example: 'deleteDisplayChannel(scope,tag)' deletes a display channel from Logic Analyzer.

Data Types: char | string

## **Version History**

## getFilter

**Package:** dsp

Get underlying FIR filter

### Syntax

```
filter = getFilter(DF)
```

### Description

`filter = getFilter(DF)` returns the underlying FIR filter, `filter`, used to implement the differentiator, `DF`.

### Examples

#### Get the Underlying FIR Filter of the Differentiator

Create a `dsp.Differentiator System` object with default properties.

```
DF = dsp.Differentiator;
```

Use `getFilter` to get the underlying FIR filter, `filter`, which implements the differentiator, `DF`.

```
filter = getFilter(DF)
```

```
filter =
```

```
    dsp.FIRFilter with properties:
```

```
        Structure: 'Direct form'
```

```
    NumeratorSource: 'Property'
```

```
        Numerator: [-0.0019 0.0024 -8.7640e-04 6.6377e-04 -6.2364e-04 6.3164e-04 -6.6022e-04
```

```
    InitialConditions: 0
```

```
    Show all properties
```

### Input Arguments

#### **DF** — Differentiator filter

`dsp.Differentiator System` object

Differentiator filter, specified as a `dsp.Differentiator System` object.

### Output Arguments

#### **filter** — Underlying filter

system object

Underlying filter used to implement the differentiator, returned as a filter System object.

## **Version History**

**Introduced in R2016a**

## **See Also**

### **Objects**

`dsp.Differentiator`

## fvtool

**Package:** dsp

Visualize frequency response of digital down converter or digital up converter filter cascade

### Syntax

```
fvtool(Conv)
fvtool(Conv, 'Arithmetic', arithType)
```

### Description

`fvtool(Conv)` plots the magnitude response of a digital down converter or digital up converter, `Conv`. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). To use this syntax, the object `Conv` must be locked.

`fvtool(Conv, 'Arithmetic', arithType)` specifies the arithmetic type of the filters inside the converter. Set the 'Arithmetic' input to 'double', 'single', or 'fixed-point'. When the `Conv` object is in an unlocked state, you must specify the arithmetic type. When the `Conv` object is in a locked state, it ignores the arithmetic input argument.

For example, to plot the magnitude response of a digital down converter in an unlocked state, set the 'Arithmetic' input.

```
dwnConv = dsp.DigitalDownConverter
fvtool(dwnConv, 'Arithmetic', 'fixed-point')
```

### Examples

#### Magnitude Response of Digital Down Converter

Plot the magnitude response of the digital down converter using the `fvtool` function and the `visualizeFilterStages` function.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `fvtool` function, plot the magnitude response of the overall filter cascade. The `visualizeFilterStages` function in addition plots the magnitude response of the individual filters stages.

```
dwnConv = dsp.DigitalDownConverter

dwnConv =
    dsp.DigitalDownConverter with properties:

        DecimationFactor: 100
        MinimumOrderDesign: true
        Bandwidth: 200000
        StopbandFrequencySource: 'Auto'
        PassbandRipple: 0.1000
        StopbandAttenuation: 60
        Oscillator: 'Sine wave'
```

CenterFrequency: 14000000  
 SampleRate: 30000000

Show all properties

## Using fvtool

If the System object is unlocked, you must specify the filter arithmetic through the 'Arithmetic' input of the fvtool function. If the System object is locked, the arithmetic input is ignored.

```
fvtool(dwnConv, 'Arithmetic', 'fixed-point')
```

## Using visualizeFilterStages

To view the magnitude response of the individual filter stages, call the visualizeFilterStages function.

```
visualizeFilterStages(dwnConv, 'Arithmetic', 'fixed-point')
```

## Input Arguments

### Conv — Digital down converter or digital up converter

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

Digital down converter or digital up converter, specified as a `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` System object.

### arithType — Arithmetic type

'double' (default) | 'single' | 'fixed-point'

When the Conv object is in an unlocked state, you must specify the arithmetic type. When the Conv object is in a locked state, it ignores the arithmetic input argument.

## denormalize

Undo filter coefficient and gain changes caused by `normalize`

### Syntax

```
denormalize(hq)
```

### Description

`denormalize(hq)` reverses the coefficient changes you make when you use `normalize` with `hq`. The filter coefficients do not change if you call `denormalize(hq)` before you use `normalize(hq)`. Calling `denormalize` more than once on a filter does not change the coefficients after the first `denormalize` call.

### Examples

#### Denormalize Filter Coefficients

Construct a quantized filter `hd`.

```
d=fdesign.highpass('n,F3dB',14,0.45);  
hd =design(d,'butter');  
hd.arithmetic='fixed';
```

Normalize the filter coefficients

```
normalize(hd)  
NormSOSMatrix = hd.sosMatrix;
```

After normalizing the filter coefficients, restore them to their original values by reversing the effects of the `normalize` function.

```
denormalize(hd)  
eqSOSMatrices = isequal(NormSOSMatrix,hd.sosMatrix)
```

```
eqSOSMatrices = logical  
0
```

## Version History

Introduced in R2011a

# design

Apply design method to filter specification object

## Syntax

```
filt = design(designSpecs,'Systemobject',true)
filt = design(designSpecs,method,'Systemobject',true)
filt = design(designSpecs,method,PARAM,VALUE,...,'Systemobject',true)
filt = design(designSpecs,method,opts,'Systemobject',true)
```

## Description

`filt = design(designSpecs,'Systemobject',true)` uses the filter specification object, `designSpecs`, to generate a filter System object, `filt`. When you do not provide a design method as an input argument, `design` uses the default design method. Use `designmethods(designSpecs,'default')` to see the default design method for your filter design specification object. For more information on filter design specifications, see “Design a Filter in Fdesign — Process Overview”.

`filt = design(designSpecs,method,'Systemobject',true)` uses the design method specified by `method`. `method` must be one of the options returned by `designmethods`.

`filt = design(designSpecs,method,PARAM,VALUE,...,'Systemobject',true)` specifies design method options. Use `designoptions(designSpecs,method)` to see a list of available design method options to choose from. For detailed help on each of these options, type `help(designSpecs,method)` in the MATLAB command prompt.

`filt = design(designSpecs,method,opts,'Systemobject',true)` specifies design method options using the structure `opts`. `opts` is usually obtained from the `designopts` function and then specified as an input to the `design` function. Use `help(designSpecs,method)` for more information on optional inputs.

## Examples

### Design FIR Equiripple Lowpass Filters

Design an FIR equiripple lowpass filter. Specify a passband edge frequency of  $0.2\pi$  rad/sample and a stopband edge frequency of  $0.25\pi$  rad/sample. Set the passband ripple to 0.5 dB and the stopband attenuation to 40 dB..

```
designSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,0.5,40)
```

```
designSpecs =
    lowpass with properties:
        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
```

```

Fpass: 0.2000
Fstop: 0.2500
Apass: 0.5000
Astop: 40

```

Use the default Equiripple method to design the filter.

```
filt = design(designSpecs, 'SystemObject', true)
```

```

filt =
  dsp.FIRFilter with properties:

    Structure: 'Direct form'
    NumeratorSource: 'Property'

## Input Arguments

### designSpecs — Filter design specification object

`fdesign.response` object

`fdesign` returns a filter design specification object. Every filter design specification object has these properties.

| Property Name | Default Value                         | Description  |
|---------------|---------------------------------------|--|
| Response      | Depends on the chosen type            | Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.   |
| Specification | Depends on the chosen type            | Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency $F_c$ or the filter order $N$ .   |
| Description   | Depends on the filter type you choose | Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value. |

| Property Name       | Default Value | Description  |
|---------------------|---------------|--|
| NormalizedFrequency | Logical true  | Determines whether the filter calculation uses a normalized frequency from 0 to 1, or the frequency band from 0 to $F_s/2$ , the sampling frequency. Accepts either <code>true</code> or <code>false</code> without single quotation marks. Audio weighting filters do not support normalized frequency. |

In addition to these properties, filter design specification objects may have other properties as well, depending on whether they design single-rate filters or multirate filters.

| Added Properties for Multirate Filters | Description   |
|--|---|
| DecimationFactor                       | Specifies the amount to decrease the sampling rate. Always a positive integer.  |
| InterpolationFactor                    | Specifies the amount to increase the sampling rate. Always a positive integer.  |
| PolyphaseLength                        | Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change factor filters. Total filter length is the product of <code>pl</code> and the rate change factors. <code>pl</code> must be an even integer. |

### method — Design method

character vector

Design method, specified as a character vector. The design method you provide as the input argument must be one of the methods returned by:

```
designmethods(designSpecs, 'Systemobject', true)
```

The table lists all the design methods. A subset of these become available depending on the filter design specification object, `designSpecs`.

| Design methods           | Description                          |
|--------------------------|--------------------------------------|
| <code>butter</code>      | Butterworth filter                   |
| <code>cheby1</code>      | Chebyshev Type I filter              |
| <code>cheby2</code>      | Chebyshev Type II filter             |
| <code>ellip</code>       | Elliptic filter                      |
| <code>equiripple</code>  | Equiripple FIR filter                |
| <code>firls</code>       | Least-square linear-phase FIR filter |
| <code>freqsamp</code>    | Frequency-sampled FIR filter         |
| <code>ifir</code>        | Interpolated FIR filter              |
| <code>iirlinphase</code> | Quasi-linear phase IIR filter        |
| <code>iirlpnorm</code>   | Least P-norm optimal IIR filter      |

| Design methods | Description                                |
|----------------|--|
| iirls          | Least-squares IIR filter                   |
| fircls         | FIR constrained least squares filter       |
| kaiserwin      | Kaiser window filter                       |
| maxflat        | Maxflat FIR filter                         |
| multistage     | Multistage filter                          |
| window         | FIR filter using windowed impulse response |

To help you design filters more quickly, the input argument `method` accepts a variety of special keywords that force `design` to behave in different ways. This table presents the keywords you can use for `method` and how `design` responds to the keyword:

| Design Method Keyword | Description of the Design Response  |
|-----------------------|---|
| 'FIR'                 | Forces <code>design</code> to produce an FIR filter. When no FIR design method exists for object <code>d</code> , <code>design</code> returns an error.   |
| 'IIR'                 | Forces <code>design</code> to produce an IIR filter. When no IIR design method exists for object <code>d</code> , <code>design</code> returns an error.   |
| 'ALLFIR'              | Produces filters from every applicable FIR design method for the specifications in <code>d</code> , one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.  |
| 'ALLIIR'              | Produces filters from every applicable IIR design method for the specifications in <code>d</code> , one filter for each design method. As a result, <code>design</code> returns multiple filters in the output object.  |
| 'ALL'                 | Designs filters using all applicable design methods for the specifications object <code>d</code> . As a result, <code>design</code> returns multiple filters, one for each design method. <code>design</code> uses the design methods in the order that <code>designmethods(D, 'SystemObject', true)</code> returns them. |

Keywords are not case sensitive.

When `design` returns multiple filters in the output object, use indexing to see the individual filters. For example, to see the third filter in `filt`, enter:

```
filt(3)
```

```
Example: filt = design(designSpecs, 'butter', 'SystemObject', true)
```

```
Example: filt = design(designSpecs, 'ALLFIR', 'SystemObject', true)
```

### opts — Specify design options

structure

Specify design options by passing `opts` structure as an input to the `design` function. The `opts` structure is obtained by running `designopts(designSpecs, method)`.

```
designSpecs = fdesign.notch
opts = designopts(designSpecs, 'butter')
opts.FilterStructure = 'df1sos'
filt = design(designSpecs, 'butter', opts, 'SystemObject', true)
```

## **Version History**

# designFracDelayFIR

Design band-limited fractional delay FIR filter

## Syntax

```
h = designFracDelayFIR(fd)
h = designFracDelayFIR(fd,N)
h = designFracDelayFIR(fd,TBW)
[h,i0] = designFracDelayFIR(____)
[h,i0,MBW] = designFracDelayFIR(____)
```

## Description

`h = designFracDelayFIR(fd)` designs a fractional delay FIR filter of delay `fd`, default length of 50, approximate bandwidth of 0.9.

`h = designFracDelayFIR(fd,N)` designs a fractional delay FIR filter of delay `fd` and length `N > 1`. The function designs the filter to achieve the specified FIR length.

`h = designFracDelayFIR(fd,TBW)` designs a fractional delay FIR filter of delay `fd` and a combined bandwidth of at least `TBW`, where `TBW < 0.999` and is specified in normalized frequency units. The function automatically determines the appropriate FIR length `N` for which the combined bandwidth is at least `TBW`.

`[h,i0] = designFracDelayFIR(____)` returns the integer latency of the FIR filter. This value is approximately `N/2`. The nominal group delay of the filter is `i0+fd`.

`[h,i0,MBW] = designFracDelayFIR(____)` returns the measured combined bandwidth of the filter `h`.

## Examples

### Design Fractional Delay FIR Filter with Specified Delay and Filter Length

Design a fractional delay FIR filter using the `designFracDelayFIR` function. Pass the delay and the filter length as the input arguments to the function. Vary the filter length and observe the effect on the measured combined bandwidth and the nominal group delay.

#### Vary Filter Length

##### Filter Length Set to 8

Specify the delay to be 0.25 and the filter length to be 8 and design the fractional delay FIR filter.

```
fd = 0.25;
len = [8 32 64];
[h1,i10,bw1] = designFracDelayFIR(fd,len(1))
```

```
h1 = 1×8
```

```
-0.0086  0.0417  -0.1355  0.8793  0.2931  -0.0968  0.0341  -0.0074
```

```
i10 = 3
```

```
bw1 = 0.5810
```

The nominal group delay of the filter `i10+fd` equals 3.25 samples. The measured combined bandwidth of the filter is 0.5810 in normalized frequency units.

### Filter Length Set to 32

Repeat the process with a filter length of 32 taps.

```
[h2,i20,bw2] = designFracDelayFIR(fd,len(2))
```

```
h2 = 1×32
```

```
-0.0001  0.0004  -0.0009  0.0017  -0.0029  0.0046  -0.0071  0.0104  -0.0148  0.0
```

```
i20 = 15
```

```
bw2 = 0.8571
```

The nominal group delay of the filter now equals 15.25 samples. By increasing the filter length, the integer latency `i0` also increases, resulting in an increase in the nominal group delay. The combined bandwidth of the filter has increased to 0.8571 in normalized frequency units.

### Filter Length Set to 64

Increase the filter length to 64 taps. The group delay increases to 31.25 samples, and the integer latency is 31 samples. The measured combined bandwidth of the filter further increases to 0.9219. That is a bandwidth coverage of 92.19% of the overall bandwidth. As the filter length continues to increase, the combined bandwidth tends closer towards 1.

```
[h3,i30,bw3] = designFracDelayFIR(fd,len(3))
```

```
h3 = 1×64
```

```
-0.0000  0.0001  -0.0001  0.0002  -0.0003  0.0004  -0.0006  0.0008  -0.0010  0.
```

```
i30 = 31
```

```
bw3 = 0.9219
```

### Plot Magnitude Response

Plot the resulting magnitude response of the three filters. Mark the measured combined bandwidth of the three filters. By increasing the filter length, you can see that the measured combined bandwidth increases.

```
[H1,w] = freqz(h1,1);
H2 = freqz(h2,1);
H3 = freqz(h3,1);
figure;
plot(w/pi,mag2db(abs([H1 H2 H3])))
hold on
```

```

hline = lines;
xline(bw1, LineStyle = '--', LineWidth = 2, Color = hline(1,:))
xline(bw2, LineStyle = '--', LineWidth = 2, Color = hline(2,:))
xline(bw3, LineStyle = '--', LineWidth = 2, Color = hline(3,:))
hold off
title('Magnitude Responses in dB', FontSize = 12)
xlabel("Normalized Frequency (\times\pi rad/sample)")
ylabel("Magnitude (dB)")
grid
legend('Gain Response (N = 8)', 'Gain Response (N = 32)', 'Gain Response (N = 64)', ...
       'Measured Combined Bandwidth (N = 8)', ...
       'Measured Combined Bandwidth (N = 32)', ...
       'Measured Combined Bandwidth (N = 64)', Location = 'Southwest')

```

### Plot Group Delay Response

Plot the group delay response of the three filters. Mark the nominal group delay  $i0 + fd$  of the three filters. By increasing the filter length, you can see that the nominal group delay increases.

```

[g1,w] = grpdelay(h1,1);
g2 = grpdelay(h2,1);
g3 = grpdelay(h3,1);

```

```

figure;
plot(w/pi,[g1 g2 g3])

```

```

hline = lines;
yline(i10+fd, LineStyle = '--', LineWidth = 2, Color = hline(1,:))
yline(i20+fd, LineStyle = '--', LineWidth = 2, Color = hline(2,:))
yline(i30+fd, LineStyle = '--', LineWidth = 2, Color = hline(3,:))

title('Group Delay Responses',FontSize = 12)

xlabel("Normalized Frequency (\times\pi rad/sample)")
ylabel("Group Delay")
grid

legend('Group Delay Response (N = 8)', 'Group Delay Response (N = 32)', 'Group Delay Response (N = 64)', ...
       'Nominal Group Delay (N = 8)', ...
       'Nominal Group Delay (N = 32)', ...
       'Nominal Group Delay (N = 64)', Location = 'west', FontSize = 10);
ylim([-10,40]);

```

### Design Fractional Delay FIR Filter with Specified Delay and Combined Bandwidth

Design a fractional delay FIR filter using the `designFracDelayFIR` function. Pass the delay and the combined bandwidth as input arguments to the function.

Specify the delay to be 0.786 and the target combined bandwidth to be 0.8. The function designs a filter that has a length of 22 taps, an integer latency  $i0$  of 10 samples, and a combined bandwidth

$mbw$  of 0.8044 in normalized frequency units. This  $mbw$  value makes the combined bandwidth coverage to be 80.44% of the frequency domain and exceeds the specified target combined bandwidth. The nominal group delay of the filter  $i\theta + fd$  equals 10.786.

```
fd = 0.786;
tbw = 0.8;
[h,i0,mbw] = designFracDelayFIR(fd, tbw)
```

```
h = 1×22
```

```
    0.0003   -0.0011    0.0026   -0.0052    0.0094   -0.0156    0.0248   -0.0386    0.0611   -0.1
```

```
i0 = 10
```

```
mbw = 0.8044
```

Plot the impulse response of the FIR.

```
stem((0:length(h)-1),h);
xlabel('h'); ylabel('h[n]');
title('Impulse Response of the Fractional Delay FIR')
```

Plot the resulting magnitude response and the group delay response. Mark the nominal group delay and the combined bandwidth of the filter.

```
[H1,w] = freqz(h,1);
G1 = grpdelay(h,1);
```

```

figure;
yyaxis left
plot(w/pi,mag2db(abs(H1)))
ylabel("Magnitude (dB)")

hold on
yyaxis right
plot(w/pi,G1)
ylabel("Group Delay (in samples)")

hline = lines;
xline(mbw,LineStyle=':',Color='b',LineWidth=2)
xline(tbw,LineStyle='--',Color='m',LineWidth=2)
yline(i0+fd,LineStyle=':',Color='r',LineWidth=1)
yticks([i0,i0+fd,i0+1:i0+9]);

hold off
title('Magnitude Responses (dB) and Group Delay',FontSize=10)
xlabel("Normalized Frequency (\times\pi rad/sample)")

legend('Gain Response','Group Delay Response','Measured Combined Bandwidth',...
       'Target Combined Bandwidth','Nominal Group Delay',...
       Location='west',FontSize=10)

```

## Design Fractional Delay FIR Filter and Compare with Shifted Input

Design a fractional delay FIR filter using the `designFracDelayFIR` function. Determine the group delay of the designed filter. Create a `dsp.FIRFilter` object that uses these designed coefficients and hence has the same group delay. Alternately, create a sampled sequence of a known function. Pass the sampled sequence to the FIR filter. Compare the output of the FIR filter to the shifted samples of the known function. Specify this shift to be equal to the group delay of the FIR filter. Verify that the two sequences match.

Specify the delay of the fractional delay FIR filter to be  $1/3$  and the length to be 6 taps.

```
fd = 1/3;  
len = 6;
```

Design the filter using the `designFracDelayFIR` function and determine the center index  $i0$  and the combined bandwidth  $bw$  of the filter. The group delay of the filter you have designed is  $i0 + fd$  or approximately 2.33 for the bandwidth of  $bw$ .

```
[h,i0,bw] = designFracDelayFIR(fd,len)  
  
h = 1×6  
    0.0293    -0.1360    0.7932    0.3966   -0.1088    0.0257
```

```
i0 = 2
```

```
bw = 0.5158
```

Create a `dsp.FIRFilter` object and set its numerator to the filter coefficients  $h$ . This filter is now effectively a fractional delay FIR filter. Verify that the group delay response of this filter is approximately 2.33 for the duration of the bandwidth  $bw$ .

```
fdf = dsp.FIRFilter(h);  
grpdelay(fdf)
```

### Compare with Shifted Function

Define a sequence  $x$  as samples of a known function.

```
f = @(t) (0.1*t.^2+cos(0.9*t)).*exp(-0.1*(t-5).^2);
n = (0:19)'; t = linspace(0,19,512);
x = f(n); % Samples
```

Plot the sampled values  $x$  against the original known function  $f(t)$ .

```
scatter(n,x,20,'k','filled');
hold on;
plot(t,f(t),'color',[0.5 0.5 0.5],'LineWidth',0.5)
hold off;
xlabel('Time')
legend(["Input Samples", "f(t)"])
title('Input Sequence with Known Underlying Analog Signal')
ax = gca; ax.XGrid='on';
```

Pass the sampled sequence  $x$  through the FIR filter. Plot the input sequence and output sequence.

```
y = fdf(x);
```

```
subplot(2,1,1);  
stem(x);  
title('Input Sequence');  
xlabel('n')  
subplot(2,1,2)  
stem(y);  
title('FIR Output Sequence');  
xlabel('n')
```

Shift the input sequence horizontally by  $i0 + fd$ , which is equal to the group delay of the FIR filter. Plot the function  $f(t-i0-FD)$ . Verify that the input and output sequences fall roughly on the shifted function.

```
figure
scatter(n,y,20,'red','filled')
hold on;
scatter(n+i0+fd,x,20,'black','filled')

## Input Arguments

### **fd** — Fractional delay of filter

positive scalar in the range [0,1]

Fractional delay of the filter, specified as a positive scalar in the range [0,1]. The fractional delay value that you specify determines the measured combined bandwidth MBW of the filter. When `fd` is set to 0 or 1, the designed filter has a full bandwidth.

Data Types: `single` | `double`

### **N** — Length of FIR filter

integer greater than 1

Length of the fractional delay FIR filter, specified as an integer greater than 1. In order to specify the length of the filter, you must specify the second input argument of the function to be an integer that is greater than 1. The function treats this value as the desired filter length and returns a filter that is  $N$  taps long.

Data Types: `single` | `double`

### **TBW** — Target combined bandwidth

positive scalar less than 0.999

Target combined bandwidth, specified as a positive scalar less than 0.999. This is the value of the combined bandwidth that the function must satisfy. Combined bandwidth is defined as the minimum of the gain bandwidth on page 5-164 and the group delay bandwidth on page 5-164.

In order to specify the target combined bandwidth, you must specify the second input argument of the function to be a real scalar that is less than 0.999. The function then treats this value as the target combined bandwidth, determines the corresponding filter length, and designs the filter accordingly.

Specify a higher target combined bandwidth for a longer filter. For example TBW set to 0.9 yields a filter of length of 52. For TBW that is set to 0.99, the length is 724. This value is more than 10 times longer. As TBW tends towards 1, the filter length theoretically tends towards infinity.

Data Types: `single` | `double`

## Output Arguments

### **h** — Coefficients of fractional delay FIR filter

row vector

Coefficients of the fractional delay FIR filter, returned as a real-valued N-length row vector. When fractional delay is the only input to the function, the function designs a filter of length 50. The bandwidth for this default filter is approximately 0.9. When the second input argument is specified, the function designs the filter according to the following:

- When the second input argument to the function is specified to be a value greater than 1, the function treats this value as the desired filter length and returns a filter that is N taps long.
- When the second input argument to the function is specified to be a value less than 0.999, the function treats this value as the desired combined bandwidth TBW, determines the corresponding filter length, and designs the filter accordingly.

Data Types: `single` | `double`

### **i0** — Integer latency

integer

Integer latency of the designed FIR filter, returned as an integer value. Integer latency is the smallest integer shift required to make the symmetric Kaiser window causal. This value is approximately equal to half the filter length,  $N/2$ . For more details, see “Integer latency,  $i_0$ ” on page 5-162.

The nominal group delay of the filter is given by  $i_0 + fd$ .

Data Types: `single` | `double`

### **MBW** — Measured combined bandwidth

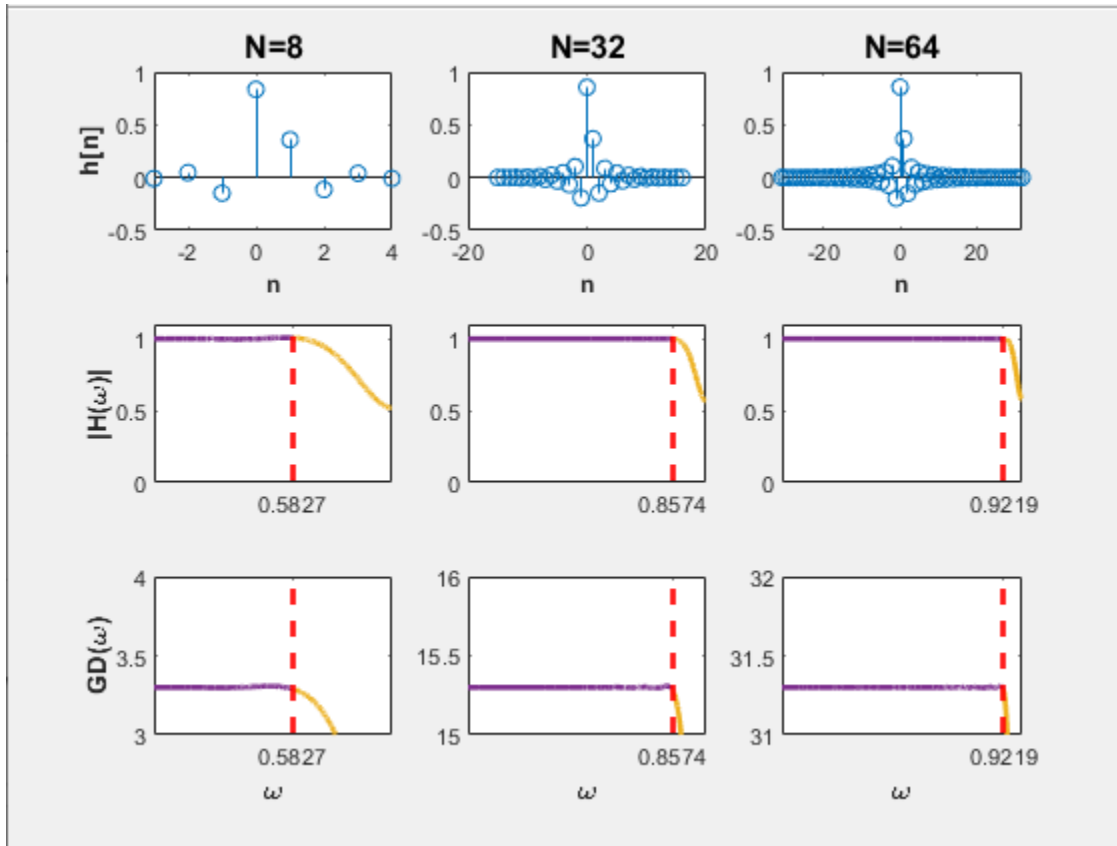

positive scalar less than 0.999

Measured combined bandwidth, returned as a real positive scalar that is less than 0.999. This is the value of the combined bandwidth of the designed filter. Combined bandwidth is defined as the minimum of the gain bandwidth on page 5-164 and the group delay bandwidth on page 5-164.

When you specify the second input argument and the value is less than 0.999, the function treats this value as the target combined bandwidth TBW. The function designs the filter such that the measured combined bandwidth MBW meets or exceeds the target combined bandwidth TBW. The filter length is determined such that this bandwidth constraint is met.

When you specify the second input argument and the value is an integer greater than 1, the function treats this value as the desired length  $N$  of the filter. The measured combined bandwidth in this case varies with the length you specify. Larger the value of  $N$ , higher is the measured combined bandwidth MBW. See the plot below that shows this variation. As the filter length grows, the combined bandwidth of the filter moves closer towards 1. The red dashed vertical line marks the combined bandwidth for each length. The fractional delay value for each of these filters is set to 0.3

Data Types: single | double

## More About

### Fractional Delay FIR Filter

The fractional delay FIR filter is an FIR approximation of an ideal sinc shift filter with a specified fractional (non-integer) delay value  $fd$  within  $[0,1]$ .

The ideal shift filter models a band-limited D/A interpolator followed by shifted A/D uniform sampling. Assuming uniform sampling rate and shift invariant interpolation, the resulting overall system can be expressed as a convolution filter, approximated by an FIR filter. In other words,  $y[n] = h_{fd}[n] * x[n]$ , which encapsulates the D/A interpolation, shift, and A/D sampling chain as depicted in the figure.

where,

$$\begin{aligned}
 h_{fd}[n] &= \text{sinc}(n - fd), \\
 \hat{x}(t) &= \sum_k x[k] \text{sinc}(t - k) \\
 \Rightarrow \hat{x}(t + fd) &= \sum_k x[k] \text{sinc}(t + fd - k)
 \end{aligned}$$

The frequency response of the ideal shift filter is given by the following equation:

$$H_{fd}(\omega) = e^{-j\omega fd}$$

The ideal shift filter has a flat unity gain response, and a constant group delay of  $fd$ , where  $fd$  is the fractional delay value you specify.

The FIR approximation is obtained by truncating the ideal filter and weighting the truncated filter by a Kaiser window.

$$\hat{x}(n + fd) \approx y[n] = (h * x)[n], \quad \text{where } h[m] = \text{sinc}(m + fd) \cdot K_{N,\beta}[m]$$

where,  $K_{N,\beta}[m]$  is a Kaiser window of length  $N$  and has a shape parameter  $\beta$ . The Kaiser window is designed to optimize the FIR frequency response, maximizing the combined bandwidths of both gain response and group delay response.

To make the FIR approximation causal, an additional shift of  $i_0$  is introduced, making the nominal group delay of the filter equal to  $i_0 + fd$ . The frequency response of the truncated filter is given by,  $H(\omega) = e^{-j\omega(fd + i_0)}$ .

For more details, see "Integer latency,  $i_0$ " on page 5-162.

### Integer latency, $i_0$

Integer latency,  $i_0$ , is the smallest integer shift that is required to make the symmetric Kaiser window causal.

The ideal sinc shift filter is an allpass filter, which has an infinite and non-causal impulse response. To approximate this filter, the function uses a finite index Kaiser window of length  $N$  that is symmetric around the origin and captures the main lobe of the sinc function.

Due to the symmetric nature of the window (approximately equal to  $N/2$ ) is on the negative side of the origin making the truncated filter anti-causal. To make the truncated filter causal, shift the anti-causal (negative indices) part of the FIR window by an integer latency,  $i_0$ , that is approximately equal to  $N/2$ .

The overall delay of the causal FIR filter is  $i_0 + fd$ , where  $fd$  is the fractional delay value you specify.

For more details on FIR approximation, see the Causal FIR Approximations of an Ideal sinc Shift Filter section in “Design of Fractional Delay FIR Filters”.

### Gain Bandwidth

Given an FIR frequency response  $H(\omega)$ , the gain bandwidth is the largest interval  $[0 B_a]$  over which the gain response  $|H(\omega)|$  is close to 1 up to a given tolerance value,  $tol$ .

$$B_a = \max_{\omega} \{ | |H(\nu)| - 1 | < tol \ \forall \ 0 \leq \nu \leq \omega \}$$

### Group Delay Bandwidth

Given a tolerance  $tol$  and a group delay response  $G$ , the group delay bandwidth is the largest interval  $[0 B_g]$  such that the group delay is close to the nominal value,  $fd$ .

$$B_g = \max_{\omega} \{ |G(\nu) - fd - i_0| < tol \ \forall \ 0 \leq \nu \leq \omega \}$$

### Combined Bandwidth

Combined bandwidth is defined as the minimum between the gain bandwidth and the group delay bandwidth.

$$B_c = \min(B_a, B_g)$$

Combined bandwidth depends on the fractional delay  $f_d$  and the length of the FIR filter  $N$ .

## designMultirateFIR

Multirate FIR filter design

### Syntax

```
B = designMultirateFIR(L,M)
B = designMultirateFIR(L,M,P)
B = designMultirateFIR(L,M,TW)
B = designMultirateFIR(L,M,P,Astop)
B = designMultirateFIR(L,M,TW,Astop)
B = designMultirateFIR( __ , 'SystemObject', flag)
```

### Description

`B = designMultirateFIR(L,M)` designs a multirate FIR filter with interpolation factor  $L$  and decimation factor  $M$ . The output  $B$  is the vector of designed FIR coefficients. To design a pure interpolator, set  $M$  to 1. To design a pure decimator, set  $L$  to 1.

`B = designMultirateFIR(L,M,P)` designs a multirate FIR filter with half-polyphase length  $P$ . By default, the half-polyphase length is 12.

`B = designMultirateFIR(L,M,TW)` designs a multirate FIR filter with interpolation factor  $L$ , decimation factor  $M$ , and normalized transition width  $TW$ .

`B = designMultirateFIR(L,M,P,Astop)` designs a multirate FIR filter with stopband attenuation  $Astop$ . By default, the stopband attenuation is 80 dB.

`B = designMultirateFIR(L,M,TW,Astop)` designs a multirate FIR filter with interpolation factor  $L$ , decimation factor  $M$ , normalized transition width  $TW$ , and stopband attenuation  $Astop$ , specified in dB.

`B = designMultirateFIR( __ , 'SystemObject', flag)` returns a vector of filter coefficients  $B$  if the flag is set to `false`, or a multirate filter System object if the flag is set to `true`.

### Examples

#### Design an FIR Interpolator

To design an FIR Interpolator using the `designMultirateFIR` function, you must specify the interpolation factor of interest (usually greater than 1) and a decimation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values.

Design an FIR interpolator with interpolation factor set to 5. Use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(5,1);
fvtool(b,'impulse')
```

### Design an FIR Decimator

To design an FIR Decimator using the `designMultirateFIR` function, you must specify the decimation factor of interest (usually greater than 1) and an interpolation factor equal to 1. You can use the default half-polyphase length of 12 and the default stopband attenuation of 80 dB. Alternately, you can also specify the half-polyphase length and stopband attenuation values. Design an FIR decimator with decimation factor set to 3, and half-polyphase length set to 14. Use the default stopband attenuation of 80 dB.

```
b = designMultirateFIR(1,3,14);
fvtool(b,'impulse');
```

### Design an FIR Rate Converter

To design an FIR Rate Converter using the `designMultirateFIR` function, you must specify the interpolation and decimation factors of interest (usually greater than 1). In addition, you can specify either the half-polyphase length and stopband attenuation values, or the normalized transition width and stopband attenuation values.

Design an FIR rate converter with interpolation factor set to 3, decimation factor set to 4, half-polyphase length set to 14, and stopband attenuation set to 90 dB.

```
b = designMultirateFIR(3,4,14,90);  
impz(b,1)
```

Design an FIR rate converter with interpolation factor set to 3, decimation factor set to 4, normalized transition width set to 0.2, and stopband attenuation set to 90 dB.

```
bTW = designMultirateFIR(3,4,0.2,90);  
impz(bTW,1)
```

### Design a `dsp.FIRInterpolator` System object

Set the `'SystemObject'` flag to `true` in the `designMultirateFIR` function to design a multirate filter object. The design parameters specified in the function determine the type of System object the function designs.

In this example, the function designs a polyphase FIR interpolator System object™. For more details, see `dsp.FIRInterpolator`.

Create a `dsp.FIRInterpolator` object with the interpolation factor equal to 5, transition width equal to 0.01, and stopband attenuation equal to 60 dB. Set the `'SystemObject'` flag to `true` to design a multirate filter object.

```
firInterp = designMultirateFIR(5,1,0.01,60,'SystemObject',true);  
fvtool(firInterp)
```

Compute the cost of implementing the filter.

```
cost(firInterp)
```

```
ans = struct with fields:
    NumCoefficients: 582
    NumStates: 145
    MultiplicationsPerInputSample: 582
    AdditionsPerInputSample: 578
```

Measure the frequency response characteristics of the filter object.

```
measure(firInterp)
```

```
ans =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.195
3-dB Point       : 0.19884
6-dB Point       : 0.2
Stopband Edge    : 0.205
Passband Ripple  : 0.016474 dB
Stopband Atten.  : 60.1827 dB
Transition Width  : 0.01
```

## Input Arguments

### **L — Interpolation factor**

positive scalar integer

Interpolation factor, specified as a positive scalar integer. To design a decimator only, set  $L$  to 1.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **M — Decimation factor**

positive scalar integer

Decimation factor, specified as a positive scalar integer. To design an interpolator only, set  $M$  to 1.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **P — Half-polyphase length**

12 (default) | positive scalar integer

Half-polyphase length, specified as a positive scalar integer that is greater than or equal to 1.

Example: 12

Example: 20

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **TW — Normalized transition width**

real scalar in the range (0 1)

Normalized transition width of the multirate FIR filter, specified as a real scalar in the range (0 1).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Astop — Stopband attenuation**

90 (default) | nonnegative scalar

Stopband attenuation in dB, specified as a nonnegative real scalar greater than or equal to 0.

Example: 0.0

Example: 80.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **flag — System object flag**

false (default) | true

System object flag set to:

- `false` -- Function returns a vector of filter coefficients.
- `true` -- Function returns one of the following multirate filter System objects:
  - `dsp.FIRInterpolator` -- When  $L > 1$  and  $M = 1$ .
  - `dsp.FIRDecimator` -- When  $L = 1$  and  $M > 1$ .

- `dsp.FIRRateConverter` -- When  $L > 1$  and  $M > 1$ .

Data Types: `logical`

## Output Arguments

### B — Coefficients

real-valued vector

Multirate FIR filter coefficients, returned as a real-valued  $N$ -length vector.

If both  $L$  and  $M$  are equal to 1, then  $N$  equals 1.

If  $L > 1$  or  $M > 1$ , then  $N$  is given by  $N = \begin{cases} 2PR + 1 & M > L > 1 \text{ and } \text{mod}(PL, M) \neq 0 \\ 2PR & \text{otherwise} \end{cases}$ , where  $P$  is the half-polyphase length and  $R$  is defined by the following equations:

- If  $L > 1$ ,  $R = L$ .
- If  $L = 1$ ,  $R = M$ .

For more details, see the “Algorithms” on page 5-173 section.

When the 'SystemObject' flag is set to `true`, the function returns one of the following multirate filter System objects:

- `dsp.FIRInterpolator` -- When  $L > 1$  and  $M = 1$ .
- `dsp.FIRDecimator` -- When  $L = 1$  and  $M > 1$ .
- `dsp.FIRRateConverter` -- When  $L > 1$  and  $M > 1$ .

Data Types: `double`

## Algorithms

`designMultirateFIR` designs an  $R^{\text{th}}$  band Nyquist FIR filter using a Kaiser window vector to window the truncated impulse response of the FIR filter.

The filter length  $N$  is defined as one of the following:

$$N = \begin{cases} 2PR + 1 & M > L > 1 \text{ and } \text{mod}(PL, M) \neq 0 \\ 2PR & \text{otherwise} \end{cases}$$

$P$  is the half-polyphase length and  $R$  is defined as explained in “B” on page 5-0 .

The truncated impulse response  $d(n)$  is delayed by  $N/2$  samples to make it causal. The truncated and delayed impulse response is given by:

$$d(n - N/2) = \frac{\sin(w_c(n - N/2))}{\pi(n - N/2)}, \quad n = 0, \dots, \frac{N}{2}, \dots, N$$

where  $w_c = \pi/R$ .

For every  $R^{\text{th}}$  band, the impulse response of the Nyquist filters is exactly zero. Because of this property, when Nyquist filters are used for pure interpolation, the input samples remain unaltered after interpolating.

A Kaiser window is used because of its near-optimum performance while providing a robust way of designing a Nyquist filter. The window depends on two parameters: length  $N + 1$  and shape parameter  $\beta$ .

The Kaiser window is defined by:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

The shape parameter  $\beta$  is calculated from:

$$\beta = \begin{cases} 0.1102(A_{\text{stop}} - 8.7) & \text{if } A_{\text{stop}} \geq 50 \\ 0.5842(A_{\text{stop}} - 21)^{0.4} + 0.07886(A_{\text{stop}} - 21) & \text{if } 21 < A_{\text{stop}} < 50 \\ 0 & \text{if } A_{\text{stop}} \leq 21, \end{cases}$$

where  $A_{\text{stop}}$  is the stopband attenuation in dB.

The windowed impulse response is given by

$$h(n) = w(n)d(n - N/2) = w(n)\frac{\sin(w_c(n - N/2))}{\pi(n - N/2)}, \quad n = 0, \dots, \frac{N}{2}, \dots, N$$

$h(n)$  for  $n = 0, \dots, N/2, \dots, N$  are the coefficients of the multirate filter. These coefficients are defined by the interpolation factor,  $L$ , and decimation factor,  $M$ .

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The function must return a vector of coefficients. Setting the 'SystemObject' flag to true is not supported for code generation.

- The inputs to the function must be constants when generating code for transition width-based filter design. In this design, you cannot specify the polyphase length (and therefore the filter length) and the function determines this value iteratively.

While generating code from the `designMultirateFIR` function, if you specify the inputs to the function as:

- Constants -- The third argument (if specified) is either treated as the transition width or the half polyphase length. If the value of the third argument is less than 1, then it is treated as the transition width. Otherwise, the third argument is treated as the half-polyphase length. This behavior is consistent with the behavior of the function.

```
% Transition width equals 0.1
codegen designMultirateFIR -args {coder.Constant(5),coder.Constant(4),coder.Constant(0.1)}
designMultirateFIR_mex(5,4,.1)
```

```
% Half-polyphase length equals 10
codegen designMultirateFIR -args {coder.Constant(5),coder.Constant(4),coder.Constant(10)}
designMultirateFIR_mex(5,4,10)
```

- Nonconstants -- The third argument (if specified) is always treated as the half-polyphase length, irrespective of its value.

For example, specify the third argument as 0.1 while generating the code. Even though the function treats a value less than 1 as the transition width, the generated code treats this value as the half-polyphase length.

```
codegen designMultirateFIR -args {5,4,0.1}
```

While running the generated code, specify the third argument as a positive integer since the half-polyphase length input must be a positive integer.

```
designMultirateFIR_mex(5,4,1)
```

However, if you specify the third argument as a scalar less than 1, the function displays the following error message.

```
designMultirateFIR_mex(5,4,0.1)
```

Expected P to be a scalar with value  $\geq 1$ .

## designMultistageDecimator

Multistage decimator design

### Syntax

```
C = designMultistageDecimator(M)
C = designMultistageDecimator(M,Fs,TW)
C = designMultistageDecimator(M,Fs,TW,Astop)
C = designMultistageDecimator( ____,Name,Value)
```

### Description

`C = designMultistageDecimator(M)` designs a multistage decimator that has an overall decimation factor of  $M$ . In order for  $C$  to be multistage,  $M$  must not be a prime number. For details, see “Algorithms” on page 5-186. The design process can take a while if  $M$  has many factors.

`C = designMultistageDecimator(M,Fs,TW)` designs a multistage decimator with a sampling rate of  $F_s$  and a transition width of  $TW$ . Sampling rate in this case refers to the input sampling rate of the signal before the multistage decimator.

The multistage decimator has a cutoff frequency of  $F_s/(2M)$ .

`C = designMultistageDecimator(M,Fs,TW,Astop)` specifies a minimum attenuation of  $A_{stop}$  dB for the resulting design.

`C = designMultistageDecimator( ____,Name,Value)` specifies additional design parameters using one or more name-value pair arguments.

Example: `C = designMultistageDecimator(48,48000,200,80,'NumStages','auto')` designs a multistage decimator with the least number of multiplications per input sample (MPIS).

### Examples

#### Design Efficient Decimator

Design a single-stage decimator using the `designMultirateFIR` function and a multistage decimator using the `designMultistageDecimator` function. Determine the efficiency of the two designs using the `cost` function. The implementation efficiency is characterized by two cost metrics - `NumCoefficients` and `MultiplicationsPerInputSample`.

Compute the cost of implementing both designs, and determine which design is more efficient. To make a comparison, design the filters such that their transition width is the same.

#### Initialization

Choose a decimation factor of 48, input sample rate of  $30.72 \times 48$  MHz, one-sided bandwidth of 10 MHz, and a stopband attenuation of 90 dB.

```
M = 48;
Fin = 30.72e6*M;
```

```
Astop = 90;
BW = 1e7;
```

### Using the designMultirateFIR Function

Designing the decimation filter using the `designMultirateFIR` function yields a single-stage design. Set the half-polyphase length to a finite integer, in this case 8.

```
HalfPolyLength = 8;
b = designMultirateFIR(1,M,HalfPolyLength,Astop);
d = dsp.FIRDecimator(M,b)
```

```
d =
dsp.FIRDecimator with properties:

    Main
    DecimationFactor: 48
    NumeratorSource: 'Property'
        Numerator: [0 -5.7242e-08 -1.2617e-07 -2.0736e-07 -3.0130e-07 -4.0841e-07 -5.2899e-07]
        Structure: 'Direct form'

    Show all properties
```

Compute the cost of implementing the decimator. The decimation filter requires 753 coefficients and 720 states. The number of multiplications per input sample and additions per input sample are 15.6875 and 15.6667, respectively.

```
cost(d)

ans = struct with fields:
    NumCoefficients: 753
    NumStates: 720
    MultiplicationsPerInputSample: 15.6875
    AdditionsPerInputSample: 15.6667
```

### Using the designMultistageDecimator Function

Design a multistage decimator with the same filter specifications as the single-stage design. Compute the transition width using the following relationship:

```
Fc = Fin/(2*M);
TW = 2*(Fc-BW);
```

By default, the number of stages given by the `NumStages` argument is set to 'Auto', yielding an optimal design that tries to minimize the number of multiplications per input sample.

```
c = designMultistageDecimator(M,Fin,TW,Astop)
```

```
c =
dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    Stage3: [1x1 dsp.FIRDecimator]
    Stage4: [1x1 dsp.FIRDecimator]
    CloneStages: false
```

Calling the `info` function on `c` shows that the filter is implemented as a cascade of four `dsp.FIRDecimator` objects, with decimation factors of 3, 2, 2, and 4, respectively.

Compute the cost of implementing the decimator.

```
cost(c)
```

```
ans = struct with fields:
    NumCoefficients: 78
    NumStates: 99
    MultiplicationsPerInputSample: 7.2708
    AdditionsPerInputSample: 6.6667
```

The `NumCoefficients` and the `MultiplicationsPerInputSample` parameters are lower for the four-stage filter designed by the `designMultistageDecimator` function, making it more efficient.

Compare the magnitude response of both the designs.

```
hvft = fvtool(b,c);
legend(hvft, 'Single-stage', 'Multistage')
```

The magnitude response shows that the transition width of both the filters is the same, making the filters comparable. The `cost` function shows that implementing the multistage design is more efficient compared to implementing the single-stage design.

## Using the 'design' Option in the designMultistageDecimator Function

The filter can be made even more efficient by setting the 'CostMethod' argument of the designMultistageDecimator function to 'design'. By default, this argument is set to 'estimate'.

In the 'design' mode, the function designs each stage and computes the filter order. This yields an optimal design compared to the 'estimate' mode, where the function estimates the filter order for each stage and designs the filter based on the estimate.

Note that the 'design' option can take much longer compared to the 'estimate' option.

```
cOptimal = designMultistageDecimator(M,Fin,TW,Astop,'CostMethod','design')
```

```
cOptimal =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    Stage3: [1x1 dsp.FIRDecimator]
    Stage4: [1x1 dsp.FIRDecimator]
    CloneStages: false
```

```
cost(cOptimal)
```

```
ans = struct with fields:
    NumCoefficients: 70
    NumStates: 93
    MultiplicationsPerInputSample: 7
    AdditionsPerInputSample: 6.5417
```

## Compare Multistage Decimator Designs

Design a decimator with an overall decimation factor of 24 using the designMultistageDecimator function. Design the filter in two configurations:

- Two-stage configuration - NumStages is set to 2.
- Auto configuration - NumStages is set to 'Auto'. This configuration designs a filter with the lowest number of multiplications per input sample.

Compare the cost of implementing both the configurations.

### Initialization

Choose a decimation factor of 24, input sample rate of 6 kHz, stopband attenuation of 90 dB, and a transition width of  $0.03 \times \frac{6000}{2}$ .

```
M = 24;
Fs = 6000;
Astop = 90;
TW = 0.03*Fs/2;
```

## Design the Filter

Design the two filters using the `designMultistageDecimator` function.

```
cAuto = designMultistageDecimator(M,Fs,TW,Astop,'NumStages','Auto')
```

```
cAuto =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    Stage3: [1x1 dsp.FIRDecimator]
    CloneStages: false
```

```
cTwo = designMultistageDecimator(M,Fs,TW,Astop,'NumStages',2)
```

```
cTwo =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRDecimator]
    Stage2: [1x1 dsp.FIRDecimator]
    CloneStages: false
```

View the filter information using the `info` function. The 'Auto' configuration designs a cascade of three FIR decimators with decimation factors 2, 3, and 4, respectively. The two-stage configuration designs a cascade of two FIR decimators with decimation factors 4 and 6, respectively.

## Compare the Cost

Compare the cost of implementing the two designs using the `cost` function.

```
cost(cAuto)
ans = struct with fields:
    NumCoefficients: 73
    NumStates: 94
    MultiplicationsPerInputSample: 8.6250
    AdditionsPerInputSample: 7.9167
```

```
cost(cTwo)
ans = struct with fields:
    NumCoefficients: 100
    NumStates: 118
    MultiplicationsPerInputSample: 8.9583
    AdditionsPerInputSample: 8.6667
```

The 'Auto' configuration decimation filter yields a three-stage design that out-performs the two-stage design on all cost metrics.

## Compare the Magnitude Response

Comparing the magnitude response of the two filters, both the filters have the same transition-band behavior and follow the design specifications.

```
hfvt = fvtool(cAuto,cTwo,Analysis="magnitude");
legend(hfvt,"Auto multistage","Two-stage")
```

However, to understand where the computational savings are coming from in the three-stage design, look at the magnitude response of the three stages individually.

```
autoSt1 = cAuto.Stage1;
autoSt2 = cAuto.Stage2;
autoSt3 = cAuto.Stage3;
hfvt = fvtool(autoSt1, autoSt2, autoSt3,Analysis="magnitude");
legend(hfvt,"Stage 1","Stage 2","Stage 3")
```

The third stage provides the narrow transition width required for the overall design ( $0.03 \times F_s/2$ ). However, the third stage operates at 1.5 kHz and has spectral replicas centered at that frequency and its harmonics.

The first stage removes such replicas. This first and second stages operate at a faster rate but can afford a wide transition width. The result is a decimate-by-2 first-stage filter with only 7 nonzero coefficients and a decimate-by-3 second-stage filter with only 19 nonzero coefficients. The third stage requires 47 coefficients. Overall, there are 73 nonzero coefficients for the three-stage design and 100 nonzero coefficients for the two-stage design.

### Determining Best Multistage Decimator Design

The filters in the multistage design satisfy the following conditions:

- The combined response must meet or exceed the given design specifications.
- The combined decimation must equal the overall decimation required.

For an overall decimation factor of 48, there are several combinations of individual stages.

To obtain a design with the least number of total coefficients, set the 'MinTotalCoeffs' argument to true.

```
Astop = 80;
M = 48;
```

```

Fs = 6000;
TW = 0.03*Fs/2;
cMinCoeffs = designMultistageDecimator(M,Fs,TW,Astop,'MinTotalCoeffs',true)

```

```

cMinCoeffs =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRDecimator]
        Stage2: [1x1 dsp.FIRDecimator]
        Stage3: [1x1 dsp.FIRDecimator]
        Stage4: [1x1 dsp.FIRDecimator]
    CloneStages: false

```

```
cost(cMinCoeffs)
```

```

ans = struct with fields:
    NumCoefficients: 48
    NumStates: 59
    MultiplicationsPerInputSample: 5.8542
    AdditionsPerInputSample: 5.0833

```

To obtain the design with the least number of multiplications per input sample, set 'NumStages' to 'auto'.

```
cMinMulti = designMultistageDecimator(M,Fs,TW,Astop,'NumStages','auto')
```

```

cMinMulti =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRDecimator]
        Stage2: [1x1 dsp.FIRDecimator]
    CloneStages: false

```

```
cost(cMinMulti)
```

```

ans = struct with fields:
    NumCoefficients: 158
    NumStates: 150
    MultiplicationsPerInputSample: 5.6875
    AdditionsPerInputSample: 5.1667

```

Compare the magnitude response of both filters using `fvtool`. Both filters have the same transition-band behavior and a stopband attenuation that is below 80 dB.

```
hvft = fvtool(cMinCoeffs,cMinMulti)
```

```

hvft =
    Figure (filtervisualizationtool) with properties:
        Number: []
        Name: 'Figure 1: Magnitude Response (dB)'
        Color: [0.9400 0.9400 0.9400]
        Position: [360 402 560 420]
        Units: 'pixels'

```

Use `get` to show all properties

```
legend(hvft, 'Minimize total coefficients', 'Minimize number of multiplications per input sample')
```

## Input Arguments

### M — Overall decimation factor

positive integer

Overall decimation factor, specified as a positive integer greater than one. In order for `C` to be multistage, `M` must not be a prime number. For details, see “Algorithms” on page 5-186.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Fs — Input sampling rate

48000 (default) | positive real scalar

Input sampling rate prior to the multistage decimator, specified as a positive real scalar. If not specified, `Fs` defaults to 48,000 Hz. The multistage decimator has a cutoff frequency of  $F_s/(2M)$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### TW — Transition width

$0.2 \times F_s/M$  (default) | positive real scalar

Transition width, specified as a positive real scalar less than  $F_s/M$ . If not specified,  $TW$  defaults to  $0.2 \times F_s/M$ . Transition width must be less than  $F_s/M$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Astop** — Minimum stopband attenuation

positive real scalar

Minimum stopband attenuation for the resulting design, specified as a positive real scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `C = designMultistageDecimator(48,48000,200,80,'NumStages','auto')` designs a multistage decimator with the lowest number of multiplications per input sample.

### **NumStages** — Number of decimator stages

'auto' (default) | positive integer

Number of decimator stages, specified as a positive integer. If set to 'auto', the design algorithm determines the number of stages that result in the lowest number of multiplications per input sample. If specified as a positive integer,  $N$ , the overall decimation factor,  $M$ , must be able to factor into at least  $N$  factors, not counting 1 or  $M$  as factors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **MinTotalCoeffs** — Minimize total number of coefficients

false (default) | true

When false, the design algorithm minimizes the number of multiplications per input sample. When true, the design algorithm minimizes the total number of coefficients.

Data Types: `logical`

### **CostMethod** — Cost computation method

'estimate' (default) | 'design'

Cost computation method, specified as either:

- 'estimate' -- The function estimates the filter order required for each stage and designs the filter based on the estimate. This method is faster than 'design', but can lead to suboptimal designs.
- 'design' -- The function designs each stage and computes the filter order. This method leads to an optimal overall design.

Data Types: `char`

### **CostTolerance** — Tolerance

1e-6 (default) | positive scalar

Tolerance, specified as a positive scalar. The tolerance is used to determine the multistage configuration with the least MPIS. When multiple configurations result in the same lowest MPIS within the tolerance specified, the configuration that yields the lowest number of coefficients overall is chosen. To view the total number of coefficients and MPIS for a specific filter, use the `cost` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### C — Designed filter

`dsp.FilterCascade`

Designed filter, returned as a `dsp.FilterCascade` System object. The filter is a cascade of the multiple stages designed by the function. The number of stages is determined by the `'NumStages'` argument.

To get information about each filter stage, call the `info` function on the C argument.

## Algorithms

The overall decimation factor is split into smaller factors with each factor being the decimation factor of the corresponding individual stage. The combined decimation of all the individual stages must equal the overall decimation. The combined response must meet or exceed the given design specifications.

The function determines the number of decimator stages through the `'NumStages'` argument. The sequence of stages is determined based on the implementation cost. By default, `'NumStages'` is set to `'auto'`, resulting in a sequence that gives the lowest number of MPIS. When multiple configurations result in the same lowest MPIS within the tolerance specified, the configuration that yields the lowest number of coefficients overall is chosen. If `'MinTotalCoeffs'` is set to `true`, the function determines the sequence that requires the lowest number of total coefficients.

By default, the `'CostMethod'` is set to `'estimate'`. In this mode, the function estimates the filter order required for each stage and designs the filter based on the estimate. This method is faster than `'design'`, but can lead to suboptimal designs. For an optimal design, set `'CostMethod'` to `'design'`. In this mode, the function designs each stage and computes the filter order.

## designMultistageInterpolator

Multistage interpolator design

### Syntax

```
C = designMultistageInterpolator(L)
C = designMultistageInterpolator(L,Fs,TW)
C = designMultistageInterpolator(L,Fs,TW,Astop)
C = designMultistageInterpolator( ___,Name,Value)
```

### Description

`C = designMultistageInterpolator(L)` designs a multistage interpolator that has an overall interpolation factor of  $L$ . In order for  $C$  to be multistage,  $L$  must not be a prime number. For details, see “Algorithms” on page 5-196. The design process can take a while if  $L$  has many factors.

`C = designMultistageInterpolator(L,Fs,TW)` designs a multistage interpolator with a sampling rate of  $F_s$  and a transition width of  $TW$ . Sampling rate in this case refers to the output sampling rate of the signal after the multistage interpolator.

The multistage interpolator has a cutoff frequency of  $F_s/(2L)$ .

`C = designMultistageInterpolator(L,Fs,TW,Astop)` specifies a minimum attenuation of  $A_{stop}$  dB for the resulting design.

`C = designMultistageInterpolator( ___,Name,Value)` specifies additional design parameters using one or more name-value pair arguments.

Example: `C = designMultistageInterpolator(48,48000,200,80,'NumStages','auto')` designs a multistage interpolator with the least number of multiplications per input sample (MPIS).

### Examples

#### Design Efficient Interpolator

Design a single-stage interpolator using the `designMultirateFIR` function and a multistage interpolator using the `designMultistageInterpolator` function. Determine the efficiency of the two designs using the `cost` function. The implementation efficiency is characterized by two cost metrics: `NumCoefficients` and `MultiplicationsPerInputSample`.

Compute the cost of implementing both designs, and determine which design is more efficient. To make a comparison, design the filters such that their transition width is the same.

#### Initialization

Choose an interpolation factor of 48, input sample rate of 30.72 MHz, one-sided bandwidth of 100 kHz, and a stopband attenuation of 90 dB.

```
L = 48;
Fin = 30.72e6;
```

```
Astop = 90;
BW = 1e5;
```

### Using the designMultirateFIR Function

Designing the interpolation filter using the `designMultirateFIR` function yields a single-stage design. Set the half-polyphase length to a finite integer, in this case 4.

```
HalfPolyLength = 4;
b = designMultirateFIR(L,1,HalfPolyLength,Astop);
d = dsp.FIRInterpolator(L,b)
```

```
d =
dsp.FIRInterpolator with properties:
```

```
InterpolationFactor: 48
  NumeratorSource: 'Property'
      Numerator: [0 -6.0692e-06 -1.4587e-05 -2.5889e-05 -4.0313e-05 -5.8200e-05 -7.9886e-05]
```

```
Show all properties
```

Compute the cost of implementing the interpolator. The interpolation filter requires 376 coefficients and 7 states. The number of multiplications per input sample and additions per input sample are 376 and 329, respectively.

```
cost(d)
```

```
ans = struct with fields:
      NumCoefficients: 376
      NumStates: 7
  MultiplicationsPerInputSample: 376
    AdditionsPerInputSample: 329
```

### Using the designMultistageInterpolator Function

Design a multistage interpolator with the same filter specifications as the single-stage design. Compute the transition width using the following relationship:

```
Fc = Fin/(2*L);
TW = 2*(Fc-BW);
```

By default, the number of stages given by the `NumStages` argument is set to 'Auto', yielding an optimal design that tries to minimize the number of multiplications per input sample.

```
c = designMultistageInterpolator(L,Fin,TW,Astop)
```

```
c =
dsp.FilterCascade with properties:
```

```
Stage1: [1x1 dsp.FIRInterpolator]
Stage2: [1x1 dsp.FIRInterpolator]
CloneStages: false
```

Calling the `info` function on `c` shows that the filter is implemented as a cascade of two `dsp.FIRInterpolator` objects with interpolation factors of 24 and 2, respectively.

Compute the cost of implementing the interpolator.

```
cost(c)
```

```
ans = struct with fields:
    NumCoefficients: 184
    NumStates: 12
    MultiplicationsPerInputSample: 322
    AdditionsPerInputSample: 275
```

The `NumCoefficients` and the `MultiplicationsPerInputSample` parameters are lower for the two-stage filter designed by the `designMultistageInterpolator` function, making it more efficient.

Compare the magnitude response of both designs.

```
hvft = fvtool(b,c);
legend(hvft, 'Single-stage', 'Multistage')
```

The magnitude response shows that the transition width of both the filters is the same, making the filters comparable. The `cost` function shows that implementing the multistage design is more efficient compared to implementing the single-stage design.

## Using the 'design' Option in the designMultistageInterpolator Function

The filter can be made even more efficient by setting the 'CostMethod' argument of the designMultistageInterpolator function to 'design'. By default, this argument is set to 'estimate'.

In the 'design' mode, the function designs each stage and computes the filter order. This yields an optimal design compared to the 'estimate' mode, where the function estimates the filter order for each stage and designs the filter based on the estimate.

Note that the 'design' option can take much longer compared to the 'estimate' option.

```
cOptimal = designMultistageInterpolator(L,Fin,TW,Astop,'CostMethod','design')
```

```
cOptimal =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    Stage3: [1x1 dsp.FIRInterpolator]
  CloneStages: false
```

```
cost(cOptimal)
```

```
ans = struct with fields:
    NumCoefficients: 74
    NumStates: 17
  MultiplicationsPerInputSample: 296
    AdditionsPerInputSample: 249
```

## Compare Multistage Interpolator Designs

Design an interpolator with an overall interpolation factor of 24 using the designMultistageInterpolator function. Design the filter in two configurations:

- Two-stage configuration - NumStages is set to 2.
- Auto configuration - NumStages is set to 'Auto'. This configuration designs a filter with the lowest number of multiplications per input sample.

Compare the cost of implementing both the configurations.

### Initialization

Choose an interpolation factor of 24, input sample rate of 6 kHz, stopband attenuation of 90 dB, and a transition width of  $0.03 \times 6000/2$ .

```
L = 24;
Fs = 6000;
Astop = 90;
TW = 0.03*Fs/2;
```

### Design the Filter

Design the two filters using the designMultistageInterpolator function.

```
cAuto = designMultistageInterpolator(L,Fs,TW,Astop,'NumStages','Auto')
```

```
cAuto =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    Stage3: [1x1 dsp.FIRInterpolator]
  CloneStages: false
```

```
cTwo = designMultistageInterpolator(L,Fs,TW,Astop,'NumStages',2)
```

```
cTwo =
  dsp.FilterCascade with properties:

    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
  CloneStages: false
```

View the filter information using the `info` function. The 'Auto' configuration designs a cascade of three FIR interpolators with interpolation factors 4, 3, and 2, respectively. The two-stage configuration designs a cascade of two FIR interpolators with interpolation factors 6 and 4, respectively.

### Compare the Cost

Compare the cost of implementing the two designs using the `cost` function.

```
cost(cAuto)
```

```
ans = struct with fields:
    NumCoefficients: 70
    NumStates: 28
  MultiplicationsPerInputSample: 190
  AdditionsPerInputSample: 167
```

```
cost(cTwo)
```

```
ans = struct with fields:
    NumCoefficients: 98
    NumStates: 22
  MultiplicationsPerInputSample: 208
  AdditionsPerInputSample: 185
```

The 'Auto' configuration interpolation filter yields a three-stage design that out-performs the two-stage design in terms of `NumCoefficients` and `MultiplicationsPerInputSample` metrics.

### Determining Best Multistage Interpolator Design

The filters in the multistage design satisfy the following conditions:

- The combined response must meet or exceed the given design specifications.

- The combined interpolation must equal the overall interpolation required.

For an overall interpolation factor of 50, there are several combinations of individual stages.

To obtain a design with the least number of total coefficients, set the 'MinTotalCoeffs' argument to true.

```
Astop = 80;
L = 50;
Fs = 6000;
TW = 0.03*Fs/2;
cMinCoeffs = designMultistageInterpolator(L,Fs,TW,Astop,'MinTotalCoeffs',true)
```

```
cMinCoeffs =
  dsp.FilterCascade with properties:

      Stage1: [1x1 dsp.FIRInterpolator]
      Stage2: [1x1 dsp.FIRInterpolator]
      Stage3: [1x1 dsp.FIRInterpolator]
  CloneStages: false
```

```
cost(cMinCoeffs)
```

```
ans = struct with fields:
      NumCoefficients: 58
      NumStates: 18
  MultiplicationsPerInputSample: 306
  AdditionsPerInputSample: 257
```

To obtain the design with the lowest number of multiplications per input sample, set 'NumStages' to 'auto'.

```
cMinMulti = designMultistageInterpolator(L,Fs,TW,Astop,'NumStages','auto')
```

```
cMinMulti =
  dsp.FilterCascade with properties:

      Stage1: [1x1 dsp.FIRInterpolator]
      Stage2: [1x1 dsp.FIRInterpolator]
  CloneStages: false
```

```
cost(cMinMulti)
```

```
ans = struct with fields:
      NumCoefficients: 156
      NumStates: 9
  MultiplicationsPerInputSample: 252
  AdditionsPerInputSample: 203
```

Compare the magnitude response of both the filters using `fvtool`. Both filters have the same transition-band behavior and a stopband attenuation that is below 80 dB.

```
hvft = fvtool(cMinCoeffs,cMinMulti);
legend(hvft,'Minimize total coefficients','Minimize number of multiplications per input sample')
```

## Input Arguments

### L — Overall interpolation factor

positive integer

Overall interpolation factor, specified as a positive integer greater than one. In order for C to be multistage, L must not be a prime number. For details, see “Algorithms” on page 5-196.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### Fs — Input sampling rate

48000 (default) | positive real scalar

Sampling rate of the output signal after the multistage interpolator, specified as a positive real scalar. If not specified, Fs defaults to 48,000 Hz. The multistage interpolator has a cutoff frequency of  $F_s/(2L)$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### TW — Transition width

$0.2 \times F_s/L$  (default) | positive real scalar

Transition width, specified as a positive real scalar less than  $F_s/L$ . If not specified, TW defaults to  $0.2 \times F_s/L$ . Transition width must be less than  $F_s/L$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Astop — Minimum stopband attenuation**

positive real scalar

Minimum stopband attenuation for the resulting design, specified as a positive real scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `C = designMultistageInterpolator(48,48000,200,80,'NumStages','auto')` designs a multistage interpolator with the lowest number of multiplications per input sample.

**NumStages — Number of interpolator stages**`'auto'` (default) | positive integer

Number of interpolator stages, specified as a positive integer. If set to `'auto'`, the design algorithm determines the number of stages that result in the lowest number of multiplications per input sample. If specified as a positive integer,  $N$ , the overall interpolation factor,  $L$ , must be able to factor into at least  $N$  factors, not counting 1 or  $L$  as factors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**MinTotalCoeffs — Minimize total number of coefficients**`false` (default) | `true`

When `false`, the design algorithm minimizes the number of multiplications per input sample. When `true`, the design algorithm minimizes the total number of coefficients.

Data Types: `logical`

**CostMethod — Cost computation method**`'estimate'` (default) | `'design'`

Cost computation method, specified as either:

- `'estimate'` -- The function estimates the filter order required for each stage and designs the filter based on the estimate. This method is faster than `'design'`, but can lead to suboptimal designs.
- `'design'` -- The function designs each stage and computes the filter order.

Data Types: `char`

**CostTolerance — Tolerance**`1e-6` (default) | positive scalar

Tolerance, specified as a positive scalar. The tolerance is used to determine the multistage configuration with the least number of MPIS. When multiple configurations result in the same lowest MPIS within the tolerance specified, the configuration that yields the lowest number of coefficients overall is chosen. To view the total number of coefficients and MPIS for a specific filter, use the `cost` function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### C — Designed filter

`dsp.FilterCascade`

Designed filter, returned as a `dsp.FilterCascade` System object. The filter is a cascade of the multiple stages designed by the function. The number of stages is determined by the `'NumStages'` argument.

To get information about each filter stage, call the `info` function on the C argument.

## Algorithms

The overall interpolation factor is split into smaller factors with each factor being the interpolation factor of the corresponding individual stage. The combined interpolation of all the individual stages must equal the overall interpolation. The combined response must meet or exceed the given design specifications.

The function determines the number of interpolator stages through the `'NumStages'` argument. The sequence of stages is determined based on the implementation cost. By default, `'NumStages'` is set to `'auto'`, resulting in a sequence that gives the lowest number of MPIS. When multiple configurations result in the same lowest MPIS within the tolerance specified, the configuration that yields the lowest number of coefficients overall is chosen. If `'MinTotalCoeffs'` is set to `true`, the function determines the sequence that requires the lowest number of total coefficients.

By default, the `'CostMethod'` is set to `'estimate'`. In this mode, the function estimates the filter order required for each stage and designs the filter based on the estimate. This method is faster but can lead to suboptimal designs. For an optimal design, set `'CostMethod'` to `'design'`. In this mode, the function designs each stage and computes the filter order.

# designmethods

Methods available for designing filter from specification object

## Syntax

```
methods = designmethods(designSpecs, 'SystemObject', true)
methods = designmethods(designSpecs, 'default')
methods = designmethods(designSpecs, TYPE, 'SystemObject', true)
methods = designmethods(designSpecs, 'full', 'SystemObject', true)
```

## Description

`methods = designmethods(designSpecs, 'SystemObject', true)` returns the available design methods for designing filter System objects for the filter specification object, `designSpecs`.

`methods = designmethods(designSpecs, 'default')` returns the default design method for the filter specification object `designSpecs`.

`methods = designmethods(designSpecs, TYPE, 'SystemObject', true)` returns the TYPE design methods for the filter specification object, `designSpecs`. TYPE can be either 'FIR' or 'IIR'.

`methods = designmethods(designSpecs, 'full', 'SystemObject', true)` returns the full name for each of the available design methods. For example, `designmethods` with the 'full' argument returns Butterworth for the `butter` method.

## Examples

### Valid Design Methods for Lowpass Filter

Construct a lowpass filter design specification object and determine the valid design methods.

```
designSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',500,600,0.5,60,1e4);
methods = designmethods(designSpecs, 'SystemObject', true)
```

```
methods = 8x1 cell
    {'butter'    }
    {'cheby1'   }
    {'cheby2'   }
    {'ellip'    }
    {'equiripple'}
    {'ifir'     }
    {'kaiserwin' }
    {'multistage'}
```

Use `help` to get more information on the Chebyshev type I design method.

```
help(designSpecs, methods{2})
```

DESIGN Design a Chebyshev type I iir filter.

HD = DESIGN(D, 'cheby1') designs a Chebyshev type I filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'df2sos' by default and can be any of the following:

```
'df1sos'
'df2sos'
'dfltsos'
'df2tsos'
'cascadeallpass'
'cascadewdfallpass'
```

Some of the listed structures may not be supported by System object filters. Type validstructures(D, 'cheby1', 'SystemObject', true) to get a list of structures supported by System objects.

HD = DESIGN(..., 'MatchExactly', MATCH) designs a Chebyshev type I filter and matches the frequency and magnitude specification for the band MATCH exactly. The other band will exceed the specification. MATCH can be 'stopband' or 'passband' and is 'passband' by default.

HD = DESIGN(..., 'SOSScaleNorm', NORM) designs an SOS filter and scales the coefficients using the P-Norm NORM. NORM can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'. Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting SOSScaleNorm = ''.

HD = DESIGN(..., 'SOSScaleOpts', OPTS) designs an SOS filter and scales the coefficients using an FDOPTS.SOSSCALING object OPTS. Scaling options are:

| Property               | Default    | Description/Valid values   |
|------------------------|------------|--|
| 'sosReorder'           | 'auto'     | Reorder section prior to scaling.<br>{'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'} |
| 'MaxNumerator'         | 2          | Maximum value for numerator coefficients   |
| 'NumeratorConstraint'  | 'none'     | {'none', 'unit', 'normalize', 'po2'}   |
| 'OverflowMode'         | 'wrap'     | {'wrap', 'saturate'}   |
| 'ScaleValueConstraint' | 'unit'     | {'unit', 'none', 'po2'}  |
| 'MaxScaleValue'        | 'Not used' | Maximum value for scale values   |

When sosReorder is set to 'auto', the sections will be automatically

reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint' is set to something other than 'unit'. If 'MaxScaleValue' is set to a number, the 'ScaleValueConstraint' will be changed to 'none'. Further, if SOSScaleNorm is off (as it is by default), then all the SOSScaleOpts will be ignored.

For more information about P-Norm and scaling options see help for DFILT\SCALE.

```
% Example #1 - Compare passband and stopband MatchExactly.
h      = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd     = design(h, 'cheby1', 'MatchExactly', 'passband');
Hd(2) = design(h, 'cheby1', 'MatchExactly', 'stopband');

% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);
```

## Input Arguments

### **designSpecs** — Filter specification object

object

Filter specification object, specified as one of the `fdesign` functions.

### **TYPE** — Filter impulse response type

'FIR' | 'IIR'

Impulse response of the designed filter, specified as 'FIR' or 'IIR'. When not specified, the function outputs design methods which support both 'FIR' and 'IIR' response types.

Example: `designmethods(designSpecs, 'FIR', 'SystemObject', true)`

## Output Arguments

### **methods** — Available design methods

cell array

Available design methods, returned as a cell array. Each cell contains the name of the method and is determined by the arguments input to the function.

## Version History

**Introduced in R2009a**

## See Also

`design` | `designopts` | `fdesign` | `designoptions`

## designoptions

Show all options available for specified design

### Syntax

```
options = designoptions(designSpecs,method)
```

### Description

`options = designoptions(designSpecs,method)` returns all design options available for a specification object, `designSpecs`, using a particular design method, `method`.

### Examples

#### Design Butterworth Filter

Design a butterworth filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

#### Lowpass Filter

Construct a default lowpass filter design specification object using `fdesign.lowpass`.

```
designSpecs = fdesign.lowpass
designSpecs =
    lowpass with properties:
        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
            Fpass: 0.4500
            Fstop: 0.5500
            Apass: 1
            Astop: 60
```

Determine the available design methods using the `designmethods` function. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage

```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs, 'butter', SystemObject=true)
```

```
ans = struct with fields:
```

```

    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascadeallpass'}
    SOSScaleNorm: 'ustring'
    SOSScale0pts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScale0pts: [1x1 fdopts.sosscaling]

```

Use the `design` function to design the filter. Pass `'butter'` and the specifications given by variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'`.

```
lpFilter = design(designSpecs, 'butter', matchexactly='passband', SystemObject=true);
```

Visualize the frequency response of the designed filter.

```
fvtool(lpFilter)
```

## Highpass Filter

Construct a highpass filter design specification object using `fdesign.highpass`. Specify the order to be 7 and the 3 dB frequency to be  $0.6\pi$  radians/sample.

```
designSpecs = fdesign.highpass('N,F3dB',7,.6);
```

Determine the available design methods. To design a butterworth filter, pick `butter`.

```
designMethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass(N,F3dB)`:

```
butter
maxflat
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'butter',SystemObject=true)
```

```
ans = struct with fields:
```

```
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascadeallpass'}
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    DefaultFilterStructure: 'df2sos'
    DefaultSOSScaleNorm: ''
```

```
DefaultSOSScale0pts: [1x1 fdopts.sosscaling]
```

To design the butterworth filter, use the design function and specify 'butter' as an input. Set 'FilterStructure' to 'cascadeallpass'.

```
hpFilter = design(designSpecs, 'butter', FilterStructure='cascadeallpass', SystemObject=true);
```

Visualize the highpass frequency response.

```
fvtool(hpFilter)
```

## Design Notch Filter

Design a direct-form I notching filter that has a filter order of 6, center frequency of 0.5, quality factor of 10, and a passband ripple of 1 dB.

Create a notch filter design specification object using the `fdesign.notch` function and specify these design parameters.

```
notchSpecs = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
```

Design the notch filter using the `design` function. The resulting filter is a `dsp.SOSFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.SOSFilter`.

```
notchFilt = design(notchSpecs, SystemObject=true)
```

```
notchFilt =  
  dsp.SOSFilter with properties:  
  
    Structure: 'Direct form II'  
  CoefficientSource: 'Property'  
    Numerator: [3x3 double]  
    Denominator: [3x3 double]  
  HasScaleValues: true  
    ScaleValues: [0.7722 0.7722 1.3597 1]  
  
  Show all properties
```

Visualize the frequency response of the designed filter using `fvtool`.

```
fvtool(notchFilt)
```

## Input Arguments

**designSpecs** — Filter specification object

object

Filter specification object, specified as one of the `fdesign` functions.

**method** — Design method

character vector

Design method, specified as a character vector. You can pick a design method from the available methods given by the `designmethods` function.

## Output Arguments

### **options** — Available design options

structure

Available design options, returned as a structure with the fields determined by the input filter specification object, `designSpecs`, and the design method chosen.

## Version History

Introduced in R2007b

## See Also

### Functions

`fdesign` | `designmethods` | `design`

## designopts

Valid input arguments and values for specification object and method

### Syntax

```
OPTS = designopts(D,METHOD)
```

### Description

`OPTS = designopts(D,METHOD)` returns a structure array with the default design parameters used by the design method `METHOD`. `METHOD` must be one of the options returned by `designmethods`.

Use `help(D,METHOD)` to get a description of the design parameters.

If you have DSP System Toolbox software installed, `OPTS` has the `SystemObject` property if at least one of the structures available for that design method is supported by System objects. However, not all structures for that design method are supported by System objects.

### Examples

#### Butterworth Filter Design Options

Create a lowpass filter with a numerator and denominator order of 10 and a 3-dB frequency of  $0.2\pi$  rad/sample. Obtain the default design parameters for a Butterworth design. Test whether the filter structure is a direct-form II biquad.

```
D = fdesign.lowpass('Nb,Na,F3dB',10,10,0.2);  
OPTS = designopts(D,'butter')
```

```
OPTS = struct with fields:  
  FilterStructure: 'df2sos'  
  SOSScaleNorm: ''  
  SOSScaleOpts: [1x1 fdopts.sosscaling]  
  SystemObject: 0
```

```
if isequal(OPTS.FilterStructure,'df2sos')  
    fprintf('The default filter structure is Direct-Form II\n');  
    fprintf('with second-order sections.\n');  
end
```

The default filter structure is Direct-Form II  
with second-order sections.

## dfilt

Discrete-time filter

### Syntax

```
hd = dfilt.structure(input1,...)
hd = design(d,'designmethod')
```

### Description

`hd = dfilt.structure(input1,...)` returns a discrete-time filter, `hd`, of type *structure*. Each structure takes one or more inputs. When you specify a `dfilt.structure` with no inputs, a default filter is created.

You must use a *structure* with `dfilt`.

You can get a vector of `dfilt` filters by concatenating `dfilt.structure(input1,...)` as an array.

```
hd = [dfilt.dffir, dfilt.df1, dfilt.df2]
```

```
hd =
```

```
dfilt.dffir
dfilt.df1
dfilt.df2
```

### Structures

Structures for `dfilt.structure` specify the type of filter structure. Available types of structures for `dfilt` are shown below.

| <b>dfilt.structure</b>               | <b>Description</b>                              | <b>Coefficient Mapping Support in <code>realizemdl</code></b> |
|--------------------------------------|---|---|
| <code>dfilt.allpass</code>           | Allpass filter                                  | Supported   |
| <code>dfilt.cascadeallpass</code>    | Cascade of allpass filter sections              | Supported   |
| <code>dfilt.cascadewdfallpass</code> | Cascade of allpass wave digital filters         | Supported   |
| <code>dfilt.delay</code>             | Delay   | Not supported   |
| <code>dfilt.df1</code>               | Direct-form I                                   | Supported   |
| <code>dfilt.df1sos</code>            | Direct-form I, second-order sections            | Supported   |
| <code>dfilt.df1t</code>              | Direct-form I transposed                        | Supported   |
| <code>dfilt.df1tsos</code>           | Direct-form I transposed, second-order sections | Supported   |
| <code>dfilt.df2</code>               | Direct-form II                                  | Supported   |
| <code>dfilt.df2sos</code>            | Direct-form II, second-order sections           | Supported   |

| <b>dfilt.structure</b> | <b>Description</b>                                       | <b>Coefficient Mapping Support in realizedl</b> |
|------------------------|--|---|
| dfilt.df2t             | Direct-form II transposed                                | Supported                                       |
| dfilt.df2tsos          | Direct-form II transposed, second-order sections         | Supported                                       |
| dfilt.dffir            | Direct-form FIR  | Supported                                       |
| dfilt.dffirt           | Direct-form FIR transposed                               | Supported                                       |
| dfilt.dfsymfir         | Direct-form symmetric FIR                                | Supported                                       |
| dfilt.dfasymfir        | Direct-form antisymmetric FIR                            | Supported                                       |
| dfilt.farrowfd         | Generic fractional delay Farrow filter                   | Supported                                       |
| dfilt.farrowlinearfd   | Linear fractional delay Farrow filter                    | Not supported                                   |
| dfilt.fftir            | Overlap-add FIR  | Not supported                                   |
| dfilt.latticeallpass   | Lattice allpass  | Supported                                       |
| dfilt.latticear        | Lattice autoregressive (AR)                              | Supported                                       |
| dfilt.latticearma      | Lattice autoregressive moving- average (ARMA)            | Supported                                       |
| dfilt.latticemamax     | Lattice moving-average (MA) for maximum phase            | Supported                                       |
| dfilt.latticemamin     | Lattice moving-average (MA) for minimum phase            | Supported                                       |
| dfilt.calattice        | Coupled, allpass lattice                                 | Supported                                       |
| dfilt.calatticepc      | Coupled, allpass lattice with power complementary output | Supported                                       |
| dfilt.statespace       | State-space  | Supported                                       |
| dfilt.scalar           | Scalar gain object                                       | Supported                                       |
| dfilt.wdfallpass       | Allpass wave digital filter object                       | Supported                                       |
| dfilt.cascade          | Filters arranged in series                               | Supported                                       |
| dfilt.parallel         | Filters arranged in parallel                             | Supported                                       |

For more information on each structure, refer to its reference page.

`hd = design(d, 'designmethod')` returns the `dfilt` object `hd` resulting from the filter specification object `d` and the design method you specify in *designmethod*. When you omit the `designmethod` argument, `design` uses the default design method to construct a filter from the object `d`.

With this syntax, you design filters by:

- 1 Specifying the filter specifications, such as the response shape (perhaps highpass) and details (passband edges and attenuation).
- 2 Selecting a method (such as `equiripple`) to design the filter.
- 3 Applying the method to the specifications object with `design(d, 'designmethod')`.

Using the specification-based technique can be more effective than the coefficient-based filter design techniques.

## Design Methods for Design Syntax

When you use the `hd = design(d, 'designmethod')` syntax, you have a range of design methods available depending on `d`, the filter specification object. The next table lists all of the design methods in the toolbox.

| Design Method           | Filter Design Result                                      |
|-------------------------|---|
| <code>butter</code>     | Butterworth IIR   |
| <code>cheby1</code>     | Chebyshev Type I IIR                                      |
| <code>cheby2</code>     | Chebyshev Type II IIR                                     |
| <code>ellip</code>      | Elliptic IIR  |
| <code>equiripple</code> | Equiripple with the same ripple in the pass and stopbands |
| <code>firls</code>      | Least-squares FIR   |
| <code>fregsamp</code>   | Frequency-Sampled FIR                                     |
| <code>ifir</code>       | Interpolated FIR  |
| <code>iirlpnorm</code>  | Least Pth norm IIR  |
| <code>iirls</code>      | Least-Squares IIR   |
| <code>kaiserwin</code>  | Kaiser-windowed FIR                                       |
| <code>lagrange</code>   | Fractional delay filter                                   |
| <code>multistage</code> | Multistage FIR  |
| <code>window</code>     | Windowed FIR  |

As the specifications object `d` changes, the available methods for designing filters from `d` also change. For instance, if `d` is a lowpass filter with the default specification `'Fp,Fst,Ap,Ast'`, the applicable methods are:

```
% Create an object to design a lowpass filter.
d=fdesign.lowpass;
designmethods(d) % What design methods apply to object d?
```

If you change the specification to `'N,F3dB'`, the available design methods change:

```
d=fdesign.lowpass('N,F3dB');
designmethods(d)
```

## Analysis Methods

Methods provide ways of performing functions directly on your `dfilt` object without having to specify the filter parameters again. You can apply these methods directly on the variable you assigned to your `dfilt` object.

For example, if you create a `dfilt` object, `hd`, you can check whether it has linear phase with `islinphase(hd)`, view its frequency response plot with `fvtool(hd)`, or obtain its frequency response values with `h = freqz(hd)`. You can use all of the methods described here in this way.

---

**Note** If your variable `hd` is a 1-D array of `dfilt` filters, the method is applied to each object in the array. Only `freqz`, `grpdelay`, `impz`, `is*`, `order`, and `stepz` methods can be applied to arrays. The `zplane` method can be applied to an array only if `zplane` is used without outputs.

---

Some of the methods listed here have the same name as functions in Signal Processing Toolbox software. They behave similarly.

| Method                 | Description   |
|------------------------|---|
| <code>addstage</code>  | Adds a stage to a <code>cascade</code> or <code>parallel</code> object, where a stage is a separate, modular filter. Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .  |
| <code>block</code>     | <p><code>block(hd)</code> creates a block of the <code>dfilt</code> object. The <code>block</code> method can specify these properties and values:</p> <p>'Destination' indicates where to place the block. 'Current' places the block in the current Simulink model. 'New' creates a new model. Default value is 'Current'.</p> <p>'Blockname' assigns the entered character vector to the block name. Default name is 'Filter'.</p> <p>'OverwriteBlock' indicates whether to overwrite the block generated by the <code>block</code> method ('on') and defined by <code>Blockname</code>. Default is 'off'.</p> <p>'MapStates' specifies initial conditions in the block ('on'). Default is 'off'. Refer to "Using Filter States" in Signal Processing Toolbox documentation.</p> |
| <code>cascade</code>   | Returns the series combination of two <code>dfilt</code> objects. Refer to <code>dfilt.cascade</code> .   |
| <code>coeffs</code>    | Returns the filter coefficients in a structure containing fields that use the same property names as those in the original <code>dfilt</code> .   |
| <code>convert</code>   | Converts a <code>dfilt</code> object from one filter structure, to another filter structure.  |
| <code>fcfwrite</code>  | <p>Writes a filter coefficient ASCII file. The file can contain a single filter or a vector of objects. The default file name is <code>untitled.fcf</code>.</p> <p><code>fcfwrite(hd, filename)</code> writes to a disk file named <code>filename</code> in the current working folder. The <code>.fcf</code> extension is added automatically.</p> <p><code>fcfwrite(..., fmt)</code> writes the coefficients in the format <code>fmt</code>, where valid <code>fmt</code> character vectors are:</p> <p>'hex' for hexadecimal</p> <p>'dec' for decimal</p> <p>'bin' for binary representation</p>   |
| <code>fftcoeffs</code> | Returns the frequency-domain coefficients used when filtering with a <code>dfilt.fftir</code>   |
| <code>filter</code>    | Performs filtering using the <code>dfilt</code> object.   |
| <code>firtype</code>   | Returns the type (1-4) of a linear phase FIR filter.  |

| Method                  | Description  |
|-------------------------|--|
| <code>freqz</code>      | Plots the frequency response in <b>FVTool</b> . Unlike the <code>freqz</code> function, this <code>dfilt freqz</code> method has a default length of 8192.   |
| <code>grpdelay</code>   | Plots the group delay in <b>FVTool</b> .   |
| <code>impz</code>       | Plots the impulse response in <b>FVTool</b> .  |
| <code>impzlength</code> | Returns the length of the impulse response.  |
| <code>info</code>       | Displays <code>dfilt</code> information, such as filter structure, length, stability, linear phase, and, when appropriate, lattice and ladder length.  |
| <code>isallpass</code>  | Returns a logical 1 (i.e., true) if the <code>dfilt</code> object is an allpass filter or a logical 0 (i.e., false) if it is not.  |
| <code>iscascade</code>  | Returns a logical 1 if the <code>dfilt</code> object is cascaded or a logical 0 if it is not.  |
| <code>isfir</code>      | Returns a logical 1 if the <code>dfilt</code> object has finite impulse response (FIR) or a logical 0 if it does not.  |
| <code>islinphase</code> | Returns a logical 1 if the <code>dfilt</code> object is linear phase or a logical 0 if it is not.  |
| <code>ismaxphase</code> | Returns a logical 1 if the <code>dfilt</code> object is maximum-phase or a logical 0 if it is not.   |
| <code>isminphase</code> | Returns a logical 1 if the <code>dfilt</code> object is minimum-phase or a logical 0 if it is not.   |
| <code>isparallel</code> | Returns a logical 1 if the <code>dfilt</code> object has parallel stages or a logical 0 if it does not.  |
| <code>isreal</code>     | Returns a logical 1 if the <code>dfilt</code> object has real-valued coefficients or a logical 0 if it does not.   |
| <code>isscalar</code>   | Returns a logical 1 if the <code>dfilt</code> object is a scalar or a logical 0 if it is not scalar.   |
| <code>issos</code>      | Returns a logical 1 if the <code>dfilt</code> object has second-order sections or a logical 0 if it does not.  |
| <code>isstable</code>   | Returns a logical 1 if the <code>dfilt</code> object is stable or a logical 0 if it are not.   |
| <code>nsections</code>  | Returns the number of sections in a second-order sections filter. If a multistage filter contains stages with multiple sections, using <code>nsections</code> returns the total number of sections in all the stages (a stage with a single section returns 1).  |
| <code>nstages</code>    | Returns the number of stages of the filter, where a stage is a separate, modular filter.   |
| <code>nstates</code>    | Returns the number of states for an object.  |
| <code>order</code>      | Returns the filter order. If <code>hd</code> is a single-stage filter, the order is given by the number of delays needed for a minimum realization of the filter. If <code>hd</code> has multiple stages, the order is given by the number of delays needed for a minimum realization of the overall filter. |

| Method      | Description  |
|-------------|--|
| parallel    | Returns the parallel combination of two <code>dfilt</code> filters. Refer to <code>dfilt.parallel</code> .   |
| phasez      | Plots the phase response in <b>FVTool</b> .  |
| realizemdl  | <p>(Available only with Simulink.)</p> <p><code>realizemdl(hd)</code> creates a Simulink model containing a subsystem block realization of your <code>dfilt</code>.</p> <p><code>realizemdl(hd,p1,v1,p2,v2,...)</code> creates the block using the properties <code>p1, p2,...</code> and values <code>v1, v2,...</code> specified.</p> <p>The following properties are available:</p> <p>'Blockname' specifies the name of the block. The default value is 'Filter'.</p> <p>'Destination' specifies whether to add the block to a current Simulink model or create a new model. Valid values are 'Current' and 'New'.</p> <p>'OverwriteBlock' specifies whether to overwrite an existing block that was created by <code>realizemdl</code> or create a new block. Valid values are 'on' and 'off'. Only blocks created by <code>realizemdl</code> are overwritten.</p> <p>The following properties optimize the block structure. Specifying 'on' turns the optimization on and 'off' creates the block without optimization. The default for each block is 'off'.</p> <p>'OptimizeZeros' removes zero-gain blocks.</p> <p>'OptimizeOnes' replaces unity-gain blocks with a direct connection.</p> <p>'OptimizeNegOnes' replaces negative unity-gain blocks with a sign change at the nearest summation block.</p> <p>'OptimizeDelayChains' replaces delay chains made up of <math>n</math> unit delays with a single delay by <math>n</math>.</p> |
| removestage | Removes a stage from a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .  |
| setstage    | Overwrites a stage of a cascade or parallel <code>dfilt</code> . Refer to <code>dfilt.cascade</code> and <code>dfilt.parallel</code> .   |

| Method    | Description  |
|-----------|--|
| sos       | <p>Converts the <code>dfilt</code> to a second-order sections <code>dfilt</code>. If <code>hd</code> has a single section, the returned filter has the same class.</p> <p><code>sos(hd, flag)</code> specifies the ordering of the second-order sections. If <code>flag='UP'</code>, the first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle. If <code>flag='down'</code>, the sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.</p> <p><code>sos(hd, flag, scale)</code> specifies the scaling of the gain and the numerator coefficients of all second-order sections. <code>scale</code> can be <code>'none'</code>, <code>'inf'</code> (infinity-norm), or <code>'two'</code> (2-norm). Using infinity-norm scaling with <code>up</code> ordering minimizes the probability of overflow in the realization. Using 2-norm scaling with <code>down</code> ordering minimizes the peak roundoff noise.</p> |
| ss        | Converts the <code>dfilt</code> to state-space. To see the separate <code>A, B, C, D</code> matrices for the state-space model, use <code>[A, B, C, D]=ss(hd)</code> .   |
| stepz     | <p>Plots the step response in <b>FVTool</b>.</p> <p><code>stepz(hd, n)</code> computes the first <code>n</code> samples of the step response.</p> <p><code>stepz(hd, n, Fs)</code> separates the time samples by <math>T = 1/Fs</math>, where <code>Fs</code> is assumed to be in hertz.</p>   |
| sysobj    | Converts the <code>dfilt</code> to a filter System object. See the reference page for a list of supported objects.   |
| tf        | Converts the <code>dfilt</code> to a transfer function.  |
| zerophase | Plots the zero-phase response in <b>FVTool</b> .   |
| zpk       | Converts the <code>dfilt</code> to zeros-pole-gain form.   |
| zplane    | Plots a pole-zero plot in <b>FVTool</b> .  |

### Viewing Properties

As with any object, use `get` to view a `dfilt` properties. To see a specific property, use

```
get(hd, 'property')
```

To see all properties for an object, use

```
get(hd)
```

---

**Note** `dfilt` objects include an `arithmetic` property. You can change the internal arithmetic of the filter from double-precision to single-precision using: `hd.arithmetic = 'single'`.

If you have Fixed-Point Designer software, you can change the `arithmetic` property to fixed-point using: `hd.arithmetic = 'fixed'`

---

### Changing Properties

To set specific properties, use

```
set(hd, 'property1', value, 'property2', value, ...)
```

You must use single quotation marks around the property name. Use single quotation marks around the `value` argument when the value is a character vector, such as `specifyall` or `fixed`.

### Copying an Object

To create a copy of an object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** Using the syntax `H2 = hd` copies only the object handle and does not create a new, independent object.

---

### Converting Between Filter Structures

To change the filter structure of a `dfilt` object `hd`, use

```
hd2 = convert(hd, 'structure_charactervector');
```

where `structure_charactervector` is any valid structure name in single quotation marks. If `hd` is a `cascade` or `parallel` structure, each stage is converted to the new structure.

### Using Filter States

Two properties control the filter states:

- `states` — Stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions. For `df1`, `df1t`, `df1sos` and `df1tsos` structures, `states` returns a `filtstates` object.
- `PersistentMemory` — Controls whether filter states are saved. The default value is `'false'`, which causes the initial conditions to be reset to zero before filtering and turns off the display of states information. Setting `PersistentMemory` to `'true'` allows the filter to use your initial conditions or to reuse the final conditions from a previous filtering operation as the initial conditions of the next filtering operation. The `true` setting also displays information about the filter states.

---

**Note** If you set the `states` and want to use them for filtering, you must set `PersistentMemory` to `'true'` before you use the filter.

---

## Examples

Create a direct-form I filter, and use a method to see if it is stable.

```
[b,a] = butter(8,0.25);  
hd = dfilt.df1(b,a);  
isstable(hd)
```

If a `dfilt`'s numerator values do not fit on a single line, a description of the vector is displayed. To see the specific numerator values for this example, use

```
B = get(hd, 'numerator');  
% or  
B1 = hd.numerator;
```

Create an array containing two `dfilt` objects, apply a method and verify that the method acts on both objects. Use a method to test whether the objects are FIR objects.

```
b = fir1(5, .5);  
hd = dfilt.dffir(b);           % Create an FIR filter object  
[b,a] = butter(5, .5);       % Create IIR filter  
hd(2) = dfilt.df2t(b,a);     % Create DF2T object and place  
                             % in the second column of hd.  
  
[h,w] = freqz(hd);  
test_fir = isfir(hd)  
% hd(1) is FIR and hd(2) is not.
```

Refer to the reference pages for each structure for more examples.

## dfilt.allpass

Allpass filter

### Syntax

```
hd = dfilt.allpass(c)
```

### Description

`hd = dfilt.allpass(c)` constructs an allpass filter with the minimum number of multipliers from the elements in vector `c`. To be valid, `c` must contain one, two, three, or four real elements. The number of elements in `c` determines the order of the filter. For example, `c` with two elements creates a second-order filter and `c` with four elements creates a fourth-order filter.

The transfer function for the allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

given the coefficients in `c`.

To construct a cascade of allpass filter objects, use `dfilt.cascadeallpass`.

### Properties

The following table provides a list of all the properties associated with an allpass `dfilt` object.

| Property Name       | Brief Description  |
|---------------------|--|
| AllpassCoefficients | Contains the coefficients for the allpass filter object  |
| FilterStructure     | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| PersistentMemory    | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.   |
| States              | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system. |

## Examples

This example constructs and displays the information about a second-order allpass filter that uses the minimum number of multipliers.

```
c = [1.5, 0.7];  
% Create a second-order dfilt object.  
hd = dfilt.allpass(c);
```

# dfilt.calattice

Coupled-allpass, lattice filter

## Syntax

```
hd = dfilt.calattice(k1,k2,beta)
hd = dfilt.calattice
```

## Description

`hd = dfilt.calattice(k1,k2,beta)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, which is two allpass, lattice filter structures coupled together. The lattice coefficients for each structure are vectors `k1` and `k2`. Input argument `beta` is shown in the diagram below.

`hd = dfilt.calattice` returns a default, discrete-time coupled-allpass, lattice filter object, `hd`. The default values are `k1 = k2 = []`, and `beta = 1`. This filter passes the input through to the output unchanged.

## Examples

Specify a third-order lattice coupled-allpass filter structure for a `dfilt` filter, `hd` with the following code.

```
k1 = [0.9511 + 1j*0.3088; 0.7511 + 1j*0.1158];
k2 = 0.7502 - 1j*0.1218;
```

```
beta = 0.1385 + 1j*0.9904;  
hd = dfilt.calattice(k1,k2,beta);
```

The Allpass1 and Allpass2 properties store vectors of coefficients.

`dsp.CoupledAllpassFilter`

# dfilt.calatticepc

Coupled-allpass, power-complementary lattice filter

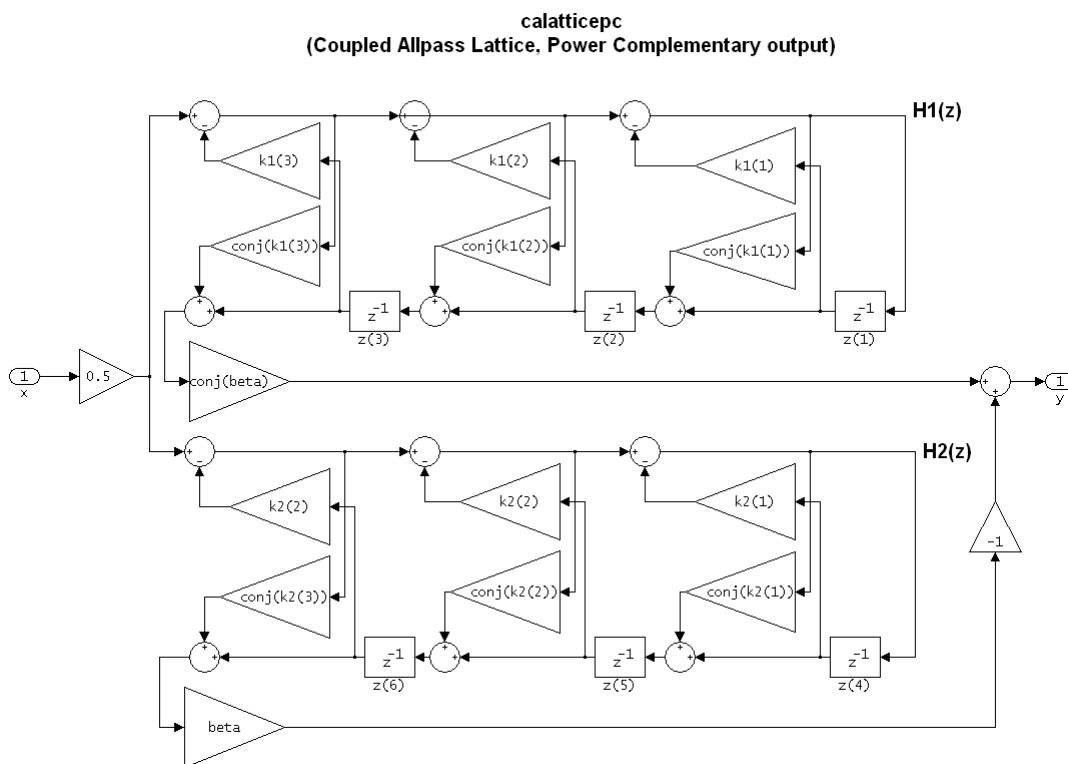

## Syntax

```
hd = dfilt.calatticepc(k1,k2)
hd = dfilt.calatticepc
```

## Description

`hd = dfilt.calatticepc(k1,k2)` returns a discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. This object is two allpass lattice filter structures coupled together to produce complementary output. The lattice coefficients for each structure are vectors, `k1` and `k2`, respectively. `beta` is shown in the following diagram.

`hd = dfilt.calatticepc` returns a default, discrete-time, coupled-allpass, lattice filter object `hd`, with power-complementary output. The default values are `k1 = k2 = []`, which is the default value for the `dfilt.latticeallpass`. The default for `beta = 1`. This filter passes the input through to the output unchanged.

## Examples

Specify a third-order lattice coupled-allpass power complementary filter structure for a filter `hd` with the following code. You see from the returned properties that `Allpass1` and `Allpass2` contain vectors of coefficients for the constituent filters.

```
k1 = [0.9511 + 0.3088i; 0.7511 + 0.1158i];  
k2 = 0.7502 - 0.1218i;  
beta = 0.1385 + 0.9904i;  
hd = dfilt.calatticepc(k1,k2,beta);
```

To see the coefficients for `Allpass1`, check the property values.

```
get(hd, 'Allpass1')
```

`dsp.CoupledAllpassFilter`

# dfilt.cascade

Cascade of discrete-time filters

## Syntax

```
hd = dfilt.cascade(filterobject1,filterobject2,...)
```

## Description

`hd = dfilt.cascade(filterobject1,filterobject2,...)` returns a discrete-time filter object `hd` of type `cascade`, which is a serial interconnection of two or more filter objects `filterobject1`, `filterobject2`, and so on. `dfilt.cascade` accepts any combination of `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

You can use the standard notation to cascade one or more filters:

```
cascade(hd1,hd2,...)
```

where `hd1`, `hd2`, and so on can be mixed types, such as `dfilt` objects and other filtering objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the cascade must be the same arithmetic format — `double`, `single`, or `fixed`. `hd`, the filter object returned, inherits the format of the cascaded filters.

## Examples

Cascade a lowpass filter and a highpass filter to produce a bandpass filter.

```
[b1,a1]=butter(8,0.6);           % Lowpass
[b2,a2]=butter(8,0.4,'high');    % Highpass
h1=dfilt.df2t(b1,a1);
h2=dfilt.df2t(b2,a2);
hcas=dfilt.cascade(h1,h2);      % Bandpass with passband 0.4-0.6
% View stage 1 with hcas.Stage(1)
```

## Version History

`dsp.FilterCascade`

## dfilt.cascadeallpass

Cascade of allpass discrete-time filters

### Syntax

```
hd = dfilt.cascadeallpass(c1,c2,...)
```

### Description

`hd = dfilt.cascadeallpass(c1,c2,...)` constructs a cascade of allpass filters, each of which uses the minimum number of multipliers, given the filter coefficients provided in `c1`, `c2`, and so on.

Each vector `c` represents one section in the cascade filter. `c` vectors must contain one, two, three, or four elements as the filter coefficients for each section. As a result of the design algorithm, each section is a `dfilt.allpass` structure whose coefficients are given in the matching `c` vector, such as the `c1` vector contains the coefficients for the first stage.

States for each section are shared between sections.

Vectors `c` do not have to be the same length. You can combine various length vectors in the input arguments. For example, you can cascade fourth-order sections with second-order sections, or first-order sections.

For more information about the vectors `ci` and about the transfer function of each section, refer to `dfilt.allpass`.

Generally, you do not construct these allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadeallpass` to design an IIR filter.

### Properties

In the next table, the row entries are the filter properties and a brief description of each property.

| Property Name       | Brief Description  |
|---------------------|--|
| AllpassCoefficients | Contains the coefficients for the allpass filter object  |
| FilterStructure     | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.                                    |
| PersistentMemory    | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting. |

| Property Name | Brief Description  |
|---------------|--|
| States        | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system. |

## Examples

Two examples show how `dfilt.cascadeallpass` works in very different applications — designing a halfband IIR filter and constructing an allpass cascade of `dfilt` objects.

First, design the IIR halfband filter using cascaded allpass filters. Each branch of the parallel cascade construction is a `cascadeallpass` filter object.

```
tw = 100; % Transition width of filter to be designed, 100 Hz.
ast = 80; % Stopband attenuation of filter to be designed, 80dB.
fs = 2000; % Sampling frequency of signal to be filtered.
% Store halfband design specs in the specifications object d.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual filter design. `hd` contains two `dfilt.cascadeallpass` objects.

```
hd = design(d,'ellip','filterstructure','cascadeallpass');
% Get summary information about one dfilt.cascadeallpass stage.
StageInfo = hd.Stage(1).Stage(1);
```

This second example constructs a `dfilt.cascadeallpass` filter object directly given allpass coefficients for the input vectors.

```
section1 = 0.8;
section2 = [1.2,0.7];
section3 = [1.3,0.9];
hd = dfilt.cascadeallpass(section1,section2,section3);
% Get information about the filter
% return informatio in character array
S = info(hd);
```

## dfilt.cascadewdfallpass

Cascade allpass WDF filters to construct allpass WDF

### Syntax

```
hd = dfilt.cascadewdfallpass(c1,c2,...)
```

### Description

`hd = dfilt.cascadewdfallpass(c1,c2,...)` constructs a cascade of allpass wave digital filters given the allpass coefficients in the vectors `c1`, `c2`, and so on.

Each `c` vector contains the coefficients for one section of the cascaded filter. `C` vectors must have one, two, or four elements (coefficients). Three element vectors are not supported.

When the `c` vector has four elements, the first and third elements of the vector must be 0. Each section of the cascade is an allpass wave digital filter, from `dfilt.wdfallpass`, with the coefficients given by the corresponding `c` vector. That is, the first section has coefficients from vector `c1`, the second section coefficients come from `c2`, and on until all of the `c` vectors are used.

You can mix the lengths of the `c` vectors. They do not need to be the same length. For example, you can cascade several fourth-order sections (`length(c) = 4`) with first or second-order sections.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

Generally, you do not construct these WDF allpass cascade filters directly. Instead, they result from the design process for an IIR filter. Refer to the first example in Examples for more about using `dfilt.cascadewdfallpass` to design an IIR filter.

For more information about the `c` vectors and the transfer function for the allpass filters, refer to `dfilt.wdfallpass`.

### Properties

In the next table, the row entries are the filter properties and a brief description of each property.

| Property Name       | Brief Description  |
|---------------------|--|
| AllpassCoefficients | Contains the coefficients for the allpass wave digital filter object   |
| FilterStructure     | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.                                    |
| PersistentMemory    | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting. |

| Property Name | Brief Description  |
|---------------|--|
| States        | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system. |

## Examples

To demonstrate two approaches to using `dfilt.cascadewdfallpass` to design a filter, these examples show both direct construction and construction as part of another filter.

The first design shown creates an IIR halfband filter that uses lattice wave digital filters. Each branch of the parallel connection in the lattice is an allpass cascade wave digital filter.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency of signal to filter.
% Store halfband specs.
d = fdesign.halfband('tw,ast',tw,ast,fs);
```

Now perform the actual halfband design process. `hd` contains two `dfilt.cascadewdfallpass` filters.

```
hd = design(d,'ellip','filterstructure','cascadewdfallpass');
% Summary info on dfilt.cascadewdfallpass.
StageSummary = hd.stage(1).stage(2);
```

This example demonstrates direct construction of a `dfilt.cascadewdfallpass` filter with allpass coefficients.

```
section1 = 0.8;
section2 = [1.5,0.7];
section3 = [1.8,0.9];
hd = dfilt.cascadewdfallpass(section1,section2,section3);
```

## Version History

Introduced in R2011a

## dfilt.delay

Delay filter

### Syntax

```
Hd = dfilt.delay  
Hd = dfilt.delay(latency)
```

### Description

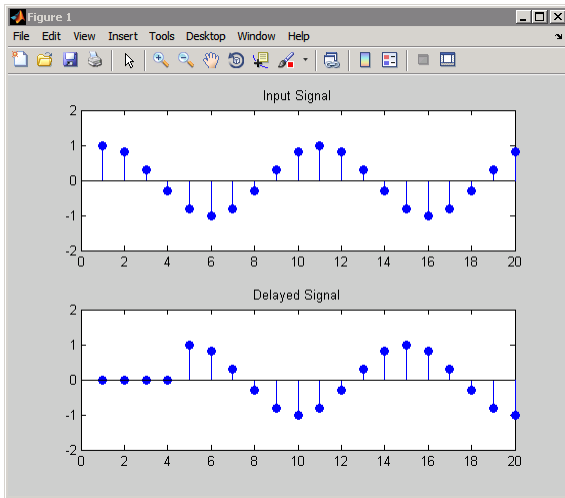

`Hd = dfilt.delay` returns a discrete-time filter, `Hd`, of type `delay`, which adds a single delay to any signal filtered with `Hd`. The filtered signal has its values shifted by one sample.

`Hd = dfilt.delay(latency)` returns a discrete-time filter, `Hd`, of type `delay`, which adds the number of delay units specified in `latency` to any signal filtered with `Hd`. The filtered signal has its values shifted by the `latency` number of samples. The values that appear before the shifted signal are the filter states.

### Examples

Create a delay filter with a latency of 4 and filter a simple signal to view the impact of applying a delay.

```
h = dfilt.delay(4);  
Fs = 1000;  
t = 0:1/Fs:1;  
sig = cos(2*pi*100*t);  
y = filter(h,sig);  
subplot(211);  
stem(sig,'markerfacecolor',[0 0 1]);  
axis([0 20 -2 2]);  
title('Input Signal');  
subplot(212);  
stem(y,'markerfacecolor',[0 0 1]);  
axis([0 20 -2 2]);  
title('Delayed Signal');
```

## Version History

Introduced in R2011a

## dfilt.df1

Discrete-time, direct-form I filter

### Syntax

```
hd = dfilt.df1
```

### Description

`hd = dfilt.df1` returns a default discrete-time, direct-form I filter object that uses double-precision arithmetic. By default, the numerator and denominator coefficients `b` and `a` are set to 1. With these coefficients the filter passes the input to the output without changes.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

---

**Note** `a(1)`, the leading denominator coefficient, cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented by `dfilt.df1`. To help you see how the filter processes the coefficients, input, output, and states of the filter, as well as numerical operations, the figure includes the locations of the arithmetic and data type format elements within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| DenAccumFormat    | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum          |
| DenFormat         | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, SignedDenominator |
| DenProdFormat     | CoeffWordLength                    | DenProdFracLength                      | ProductMode, ProductWordLength    |
| InputFormat       | InputWordLength                    | InputFracLength                        | None                              |
| NumAccumFormat    | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum          |
| NumFormat         | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator |
| NumProdFormat     | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode    |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | OutputMode         |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFormat, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFormat refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with df1 implementations of dfilt objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use `get(hd)` where `hd` is a filter.

| Property Name   | Brief Description   |
|-----------------|---|
| AccumMode       | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic      | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum   | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |
| CoeffAutoScale  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.   |
| CoeffWordLength | Specifies the word length to apply to filter coefficients.  |

| Property Name      | Brief Description  |
|--------------------|--|
| DenAccumFracLength | Specifies the fraction length the filter algorithm uses to interpret the results of product operations involving denominator coefficients. You can change the value for this property when you set AccumMode to SpecifyPrecision.  |
| DenFracLength      | Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.   |
| Denominator        | Stores the denominator coefficients for the IIR filter.  |
| DenProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.   |
| FilterStructure    | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| InputFracLength    | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength    | Specifies the word length applied to interpret input data.   |
| NumAccumFracLength | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.  |
| Numerator          | Holds the numerator coefficient values for the filter.   |
| NumFracLength      | Sets the fraction length used to interpret the value of numerator coefficients.  |
| NumProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.  |
| OutputFracLength   | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.   |
| OutputWordLength   | Determines the word length used for the output data.   |
| OverflowMode       | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision. |

| Property Name     | Brief Description   |
|-------------------|---|
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li><code>ceil</code> - Round toward positive infinity.</li> <li><code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li><code>fix</code> - Round toward zero.</li> <li><code>floor</code> - Round toward negative infinity.</li> <li><code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li><code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States            | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.  |

## Examples

Specify a second-order direct-form I structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1(b,a);
```

```
% Convert hd to fixed-point filter  
set(hd, 'arithmetic', 'fixed')
```

## **Version History**

**Introduced in R2011a**

### **See Also**

dsp.IIRFilter

## dfilt.df1sos

Discrete-time, SOS direct-form I filter

### Syntax

```
hd = dfilt.df1sos(s)
hd = dfilt.df1sos(b1,a1,b2,a2,...)
hd = dfilt.df1sos(...,g)
hd = dfilt.df1sos
```

### Description

`hd = dfilt.df1sos(s)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df1sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, and so on.

`hd = dfilt.df1sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. When you do not specify `g`, all gains default to one.

`hd = dfilt.df1sos` returns a default, discrete-time, second-order section, direct-form I filter object, `hd`. This filter passes the input through to the output unchanged.

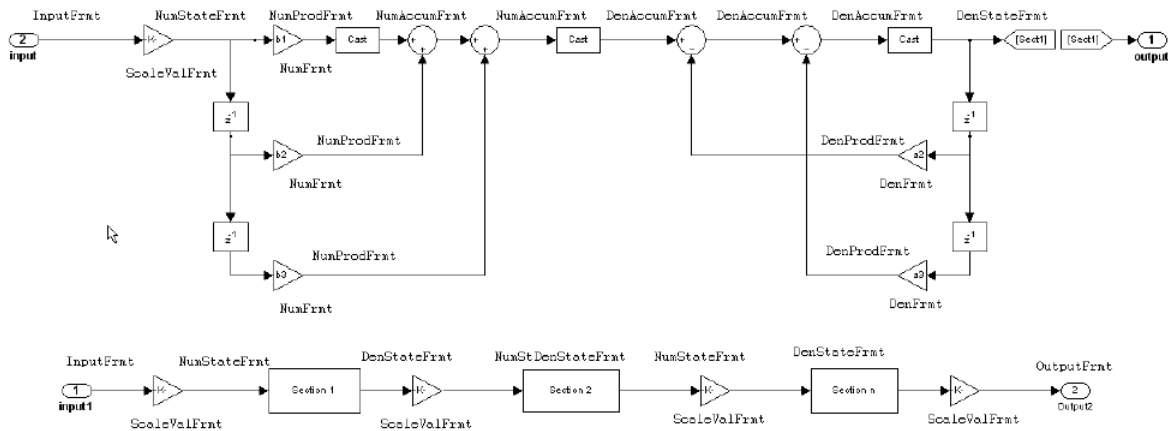

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I filter implemented in second-order sections by `dfilt.df1sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

**Notes About the Signal Flow Diagram**

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Similarly consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum            |
| DenFrmt           | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, Signed, Denominator |
| DenProdFrmt       | ProductWordLength                  | DenProdFracLength                      | ProductMode                         |
| DenStateFrmt      | DenStateWordLength                 | DenStateFracLength                     | CastBeforeSum, States               |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                                |
| NumAccumFrmt      | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum            |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator   |
| NumProdFrmt       | ProductWordLength                  | NumProdFracLength                      | ProductMode                         |
| NumStateFrmt      | NumStateWordLength                 | NumStateFracLength                     | States                              |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | OutputMode                          |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties          |
|-------------------|------------------------------------|--|-----------------------------|
| ScaleValueFrmt    | CoeffWordLength                    | ScaleValueFracLength                   | CoeffAutoScale, ScaleValues |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProductWordLength, DenProdFracLength and ProductMode that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of direct-form I `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name   | Brief Description   |
|-----------------|---|
| AccumMode       | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic      | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum   | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |
| CoeffAutoScale  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.   |

| Property Name       | Brief Description  |
|---------------------|--|
| CoeffWordLength     | Specifies the word length to apply to filter coefficients.   |
| DenAccumFracLength  | Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set AccumMode to SpecifyPrecision. |
| DenFracLength       | Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.                               |
| DenProdFracLength   | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.       |
| DenStateFracLength  | Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.   |
| DenStateWordLength  | Specifies the word length used to represent the states associated with denominator coefficients in the filter.   |
| FilterStructure     | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.                            |
| InputFracLength     | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength     | Specifies the word length applied to interpret input data.   |
| NumAccumFracLength  | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.  |
| NumFracLength       | Sets the fraction length used to interpret the value of numerator coefficients.  |
| NumStateFracLength  | Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.   |
| NumWordFracLength   | Specifies the word length used to interpret the states associated with numerator coefficient operations in the filter.   |
| OptimizeScaleValues | When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.  |
| OutputFracLength    | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.   |

| Property Name     | Brief Description   |
|-------------------|---|
| OutputMode        | <p>Sets the mode the filter uses to scale the filtered data for output. You have the following choices:</p> <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength  | Determines the word length applied for the output data.   |
| OverflowMode      | <p>Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.</p>   |
| ProductMode       | <p>Determines how the filter handles the output of product operations. Choose from full precision (<b>FullPrecision</b>), or whether to keep the most significant bit (<b>KeepMSB</b>) or least significant bit (<b>KeepLSB</b>) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>  |
| ProductWordLength | <p>Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <b>ProductMode</b> to <b>SpecifyPrecision</b>.</p>   |
| PersistentMemory  | <p>Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <b>False</b> is the default setting.</p>   |

| Property Name        | Brief Description   |
|----------------------|---|
| RoundMode            | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li><code>ceil</code> - Round toward positive infinity.</li> <li><code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li><code>fix</code> - Round toward zero.</li> <li><code>floor</code> - Round toward negative infinity.</li> <li><code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li><code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| ScaleValueFracLength | Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code> .   |
| ScaleValues          | Scaling for the filter objects in SOS filters.  |
| Signed               | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| SosMatrix            | Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.  |
| States               | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.  |
| StateWordLength      | Sets the word length used to represent the filter states.   |

## Examples

Specify a fixed-point, second-order section, direct-form I `dfilt` object with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.df1sos(b,a);
% Convert to fixed-point filter
hd.arithmetic = 'fixed';
```

## **Version History**

Introduced in R2011a

### **See Also**

`dsp.BiquadFilter`

## dfilt.df1t

Discrete-time, direct-form I transposed filter

### Syntax

```
hd = dfilt.df1t(b,a)
hd = dfilt.df1t
```

### Description

`hd = dfilt.df1t(b,a)` returns a discrete-time, direct-form I transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df1t` returns a default, discrete-time, direct-form I transposed filter object `hd`, with `b=1` and `a=1`. This filter passes the input through to the output unchanged.

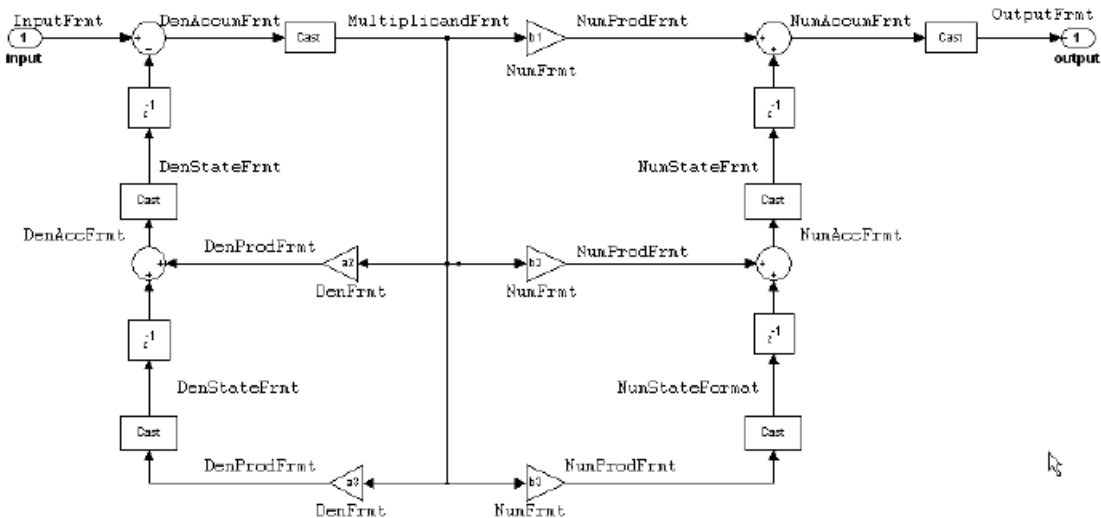

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form I filter implemented by `dfilt.df1t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                   |
|-------------------|------------------------------------|--|--------------------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df1t` implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name   | Brief Description   |
|-----------------|---|
| AccumMode       | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic      | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum   | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |

| Property Name          | Brief Description   |
|------------------------|---|
| CoeffAutoScale         | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used. |
| CoeffWordLength        | Specifies the word length to apply to filter coefficients.  |
| DenAccumFracLength     | Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .   |
| DenFracLength          | Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .  |
| Denominator            | Holds the denominator coefficients for the filter.  |
| DenProdFracLength      | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| DenStateFracLength     | Specifies the fraction length used to interpret the states associated with denominator coefficients in the filter.  |
| FilterStructure        | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.   |
| InputFracLength        | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength        | Specifies the word length applied to interpret input data.  |
| MultiplicandFracLength | Sets the fraction length for values (multiplicands) used in multiply operations in the filter.  |
| MultiplicandWordLength | Sets the word length applied to the values input to a multiply operation (the multiplicands).   |
| NumAccumFracLength     | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .  |
| Numerator              | Holds the numerator coefficient values for the filter.  |
| NumFracLength          | Sets the fraction length used to interpret the value of numerator coefficients.   |
| NumProdFracLength      | Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |

| Property Name      | Brief Description  |
|--------------------|--|
| NumStateFracLength | For IIR filters, this defines the binary point location applied to the numerator states of the filter. Specifies the fraction length used to interpret the states associated with numerator coefficient operations in the filter.  |
| OutputFracLength   | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .   |
| OutputMode         | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength   | Determines the word length used for the output data.   |
| OverflowMode       | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.   |
| ProductMode        | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| ProductWordLength  | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| PersistentMemory   | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.   |

| Property Name   | Brief Description   |
|-----------------|---|
| RoundMode       | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li><code>ceil</code> - Round toward positive infinity.</li> <li><code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li><code>fix</code> - Round toward zero.</li> <li><code>floor</code> - Round toward negative infinity.</li> <li><code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li><code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed          | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| StateAutoScale  | Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.  |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.   |
| StateWordLength | Sets the word length used to represent the filter states.   |

## Examples

Specify a second-order direct-form I transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd = dfilt.dflt(b,a);
% Convert filter to single-precision arithmetic
set(hd,'arithmetic','single')
```

## Version History

Introduced in R2011a

**See Also**

`dsp.IIRFilter`

## dfilt.df1tsos

Discrete-time, SOS direct-form I transposed filter

### Syntax

```
hd = dfilt.df1tsos(s)
hd = dfilt.df1tsos(b1,a1,b2,a2,...)
hd = dfilt.df1tsos(...,g)
hd = dfilt.df1tsos
```

### Description

`hd = dfilt.df1tsos(s)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

For more information about the property `Arithmetic`, refer to .

`hd = dfilt.df1tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form I, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df1tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df1tsos` returns a default, discrete-time, second-order section, direct-form I, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

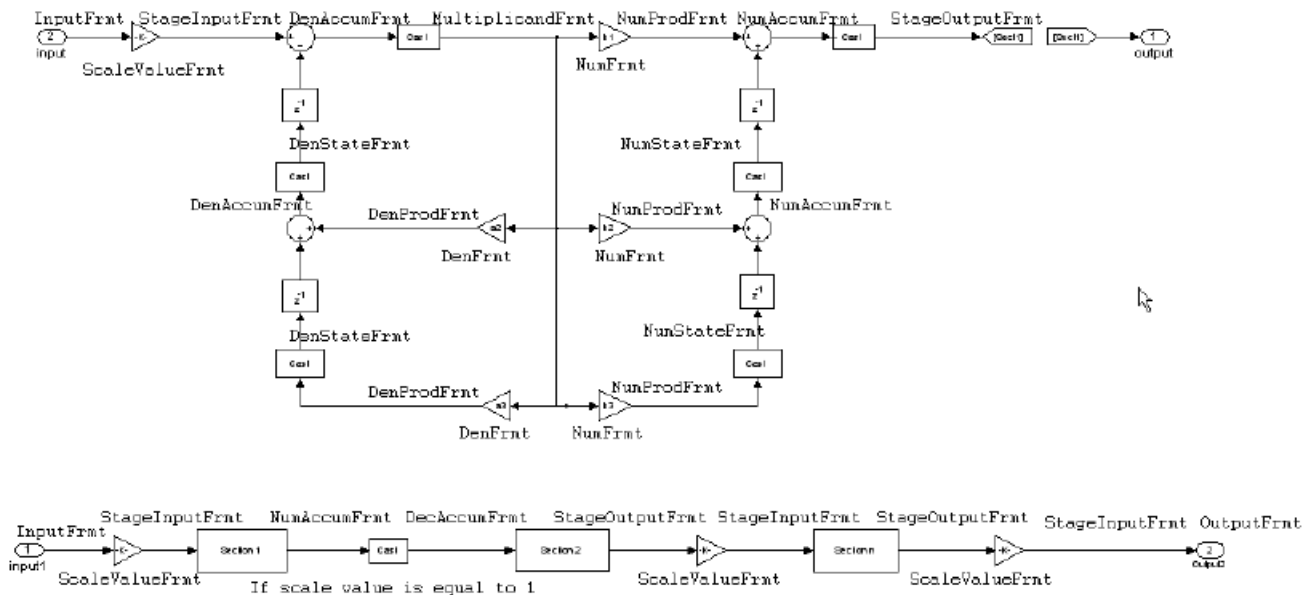

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form I transposed filter implemented using second-order sections by `dfilt.df1tsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum            |
| DenFrmt           | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, Signed, Denominator |
| DenProdFrmt       | CoeffWordLength                    | DenProdFracLength                      | ProductMode, ProductWordLength      |
| DenStateFrmt      | DenStateWordLength                 | DenStateFracLength                     | CastBeforeSum, States               |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                                |
| MultiplicandFrmt  | Multiplicand-WordLength            | Multiplicand-FracLength                | CastBeforeSum                       |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| NumAccumFrmt      | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum          |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator |
| NumProdFrmt       | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode    |
| NumStateFrmt      | NumStateWordLength                 | NumStateFracLength                     | States                            |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | OutputMode                        |
| ScaleValueFrmt    | CoeffWordLength                    | ScaleValueFracLength                   | CoeffAutoScale, ScaleValues       |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with SOS implementation of transposed direct-form I `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name   | Brief Description   |

| Property Name   | Brief Description   |
|-----------------|---|
| StateWordLength | Sets the word length used to represent the filter states. |

## Examples

With the following code, this example specifies a second-order section, direct-form I transposed `dfilt` object for a filter. Then convert the filter to fixed-point operation.

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df1tsos(b,a);  
set(hd,'arithmetic','fixed')
```

## Version History

Introduced in R2011a

## See Also

`dsp.BiquadFilter`

## dfilt.df2

Discrete-time, direct-form II filter

### Syntax

```
hd = dfilt.df2(b,a)
hd = dfilt.df2
```

### Description

`hd = dfilt.df2(b,a)` returns a discrete-time, direct-form II filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df2` returns a default, discrete-time, direct-form II filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

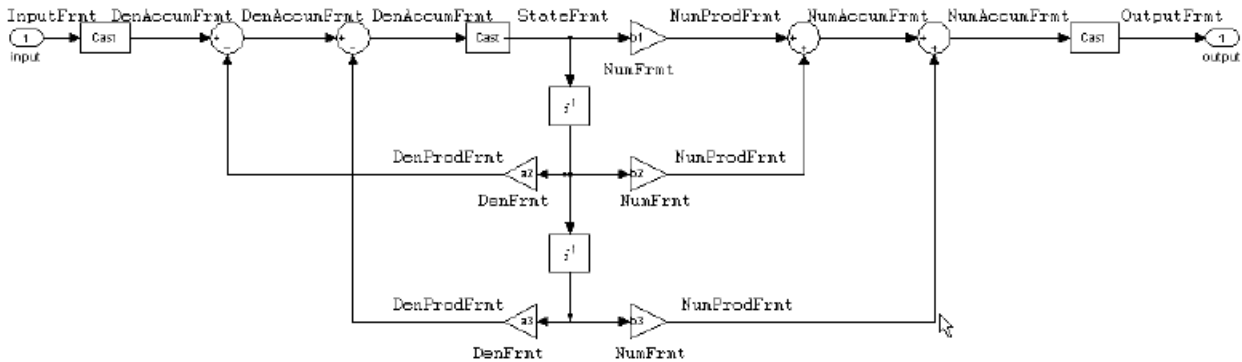

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II filter implemented by `dfilt.df2`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum            |
| DenFrmt           | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, Signed, Denominator |
| DenProdFrmt       | CoeffWordLength                    | DenProdFracLength                      | ProductMode, ProductWordLength      |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                                |
| NumAccumFrmt      | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum            |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator   |
| NumProdFrmt       | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode      |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | OutputMode                          |
| StateFrmt         | StateWordLength                    | StateFracLength                        | States                              |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the df2 implementation of dfilt objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name      | Brief Description   |
|--------------------|---|
| AccumMode          | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength    | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic         | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum      | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |
| CoeffAutoScale     | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.   |
| CoeffWordLength    | Specifies the word length to apply to filter coefficients.  |
| DenAccumFracLength | Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .   |

| Property Name      | Brief Description  |
|--------------------|--|
| DenFracLength      | Set the fraction length the filter uses to interpret denominator coefficients. DenFracLength is always available, but it is read-only until you set CoeffAutoScale to false.   |
| Denominator        | Holds the denominator coefficients for IIR filters.  |
| DenProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set ProductMode to SpecifyPrecision.   |
| FilterStructure    | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| InputFracLength    | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength    | Specifies the word length applied to interpret input data.   |
| NumAccumFracLength | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set AccumMode to SpecifyPrecision.  |
| Numerator          | Holds the numerator coefficient values for the filter.   |
| NumFracLength      | Sets the fraction length used to interpret the value of numerator coefficients.  |
| NumProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set ProductMode to SpecifyPrecision.  |
| OutputFracLength   | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.   |
| OutputMode         | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength   | Determines the word length used for the output data.   |

| Property Name    | Brief Description   |
|------------------|---|
| OverflowMode     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.  |
| ProductMode      | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| PersistentMemory | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode        | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed           | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| StateFracLength  | When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.   |
| States           | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.   |

| Property Name   | Brief Description   |
|-----------------|---|
| StateWordLength | Sets the word length used to represent the filter states. |

## Examples

Specify a second-order direct-form II filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2(b,a);  
% Change filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## Version History

Introduced in R2011a

## See Also

`dsp.IIRFilter`

## dfilt.df2sos

Discrete-time, SOS, direct-form II filter

### Syntax

```
hd = dfilt.df2sos(s)
hd = dfilt.df2sos(b1,a1,b2,a2,...)
hd = dfilt.df2sos(...,g)
hd = dfilt.df2sos
```

### Description

`hd = dfilt.df2sos(s)` returns a discrete-time, second-order section, direct-form II filter object `hd`, with coefficients given in the `s` matrix.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df2sos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II object, `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2sos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2sos` returns a default, discrete-time, second-order section, direct-form II filter object, `hd`. This filter passes the input through to the output unchanged.

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The figure below shows the signal flow for the direct-form II filter implemented with second-order sections by `dfilt.df2sos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The frmt properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                        |
|-------------------|------------------------------------|--|---|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum                  |
| DenFrmt           | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, Signed, sosMatrix         |
| DenProdFrmt       | CoeffWordLength                    | DenProdFracLength                      | ProductMode, ProductWordLength, sosMatrix |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                                      |
| NumAccumFrmt      | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum                  |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, sosMatrix |
| NumProdFrmt       | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode    |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | OutputMode                        |
| ScaleValueFrmt    | CoeffWordLength                    | ScaleValueFracLength                   | CoeffAutoScale, ScaleValues       |
| SectionInputFrmt  | SectionInput-WordLength            | SectionInput-FracLength                | SectionInput-AutoScale            |
| SectionOutputFrmt | SectionOutput-WordLength           | SectionOutput-FracLength               | SectionOutput-AutoScale           |
| StateFrmt         | StateWordLength                    | StateFracLength                        | CastBeforeSum, States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with second-order section implementation of direct-form II dfilt objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name | Brief Description   |
|---------------|---|
| AccumMode     | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |

Choose from full precision ( <b>FullPrecision</b> ), or whether to keep the most significant bit ( <b>KeepMSB</b> ) or least significant bit ( <b>KeepLSB</b> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set ProductMode to SpecifyPrecision.  |
| ProductWordLength   | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set ProductMode to SpecifyPrecision.   |
| PersistentMemory    | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <b>False</b> is the default setting.   |

| Property Name           | Brief Description   |
|-------------------------|---|
| RoundMode               | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| ScaleValueFracLength    | <p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length.</p> <p><code>ScaleValueFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code>.</p>  |
| ScaleValues             | Scaling for the filter objects in SOS filters.  |
| SectionInputAutoScale   | Tells the filter whether to set the stage input data format to minimize the occurrence of overflow conditions.  |
| SectionInputFracLength  | Lets you set the fraction length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code> .   |
| SectionInputWordLength  | Lets you set the word length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code> .   |
| SectionOutputAutoScale  | Tells the filter whether to set the section output data format to minimize the occurrence of overflow conditions.   |
| SectionOutputFracLength | Lets you set the fraction length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>off</code> .   |
| SectionOutputWordLength | Lets you set the word length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>false</code> .   |
| Signed                  | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| SosMatrix               | Holds the filter coefficients as property values. Displays the matrix in the format [sections x coefficients/section datatype]. A [15x6 double] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.  |

| Property Name   | Brief Description   |
|-----------------|---|
| StateFracLength | StateFracLength property that lets you set the fraction length applied to interpret the filter states.  |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. |
| StateWordLength | Sets the word length used to represent the filter states.   |

## Examples

Specify a second-order section, direct-form II `dfilt` object for a Butterworth filter converted to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);
[s,g] = zp2sos(z,p,k);
hd = dfilt.df2sos(s,g);
% Convert filter to fixed-point
hd.arithmetic='fixed';
```

## Version History

Introduced in R2011a

## See Also

`dsp.BiquadFilter`

## dfilt.df2t

Discrete-time, direct-form II transposed filter

### Syntax

```
hd = dfilt.df2t(b,a)
hd = dfilt.df2t
```

### Description

`hd = dfilt.df2t(b,a)` returns a discrete-time, direct-form II transposed filter object `hd`, with numerator coefficients `b` and denominator coefficients `a`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df2t` returns a default, discrete-time, direct-form II transposed filter object `hd`, with `b = 1` and `a = 1`. This filter passes the input through to the output unchanged.

---

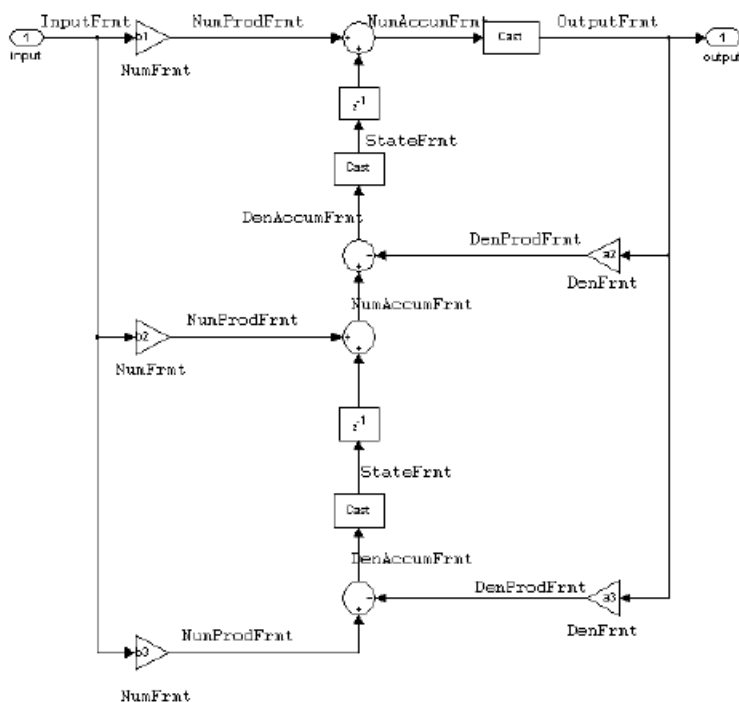

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form II transposed filter implemented by `dfilt.df2t`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt.” In this use, “frmt” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum            |

| NumProdFrmt       | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode    |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | None                              |
| StateFrmt         | StateWordLength                    | StateFracLength                        | States                            |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with `df2t` implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name   | Brief Description   |
|-----------------|---|
| AccumMode       | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic      | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum   | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |

| Property Name      | Brief Description  |
|--------------------|--|
| CoeffAutoScale     | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.  |
| CoeffWordLength    | Specifies the word length to apply to filter coefficients.   |
| DenAccumFracLength | Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .  |
| DenFracLength      | Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .   |
| Denominator        | Holds the denominator coefficients for IIR filters.  |
| DenProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| FilterStructure    | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.  |
| InputFracLength    | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength    | Specifies the word length applied to interpret input data.   |
| NumAccumFracLength | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .   |
| Numerator          | Holds the numerator coefficient values for the filter.   |
| NumFracLength      | Sets the fraction length used to interpret the value of numerator coefficients.  |
| NumProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| OutputFracLength   | Determines how the filter interprets the filter output data.   |
| OutputWordLength   | Determines the word length used for the output data.   |
| OverflowMode       | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision. |

| Property Name     | Brief Description   |
|-------------------|---|
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li><code>ceil</code> - Round toward positive infinity.</li> <li><code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li><code>fix</code> - Round toward zero.</li> <li><code>floor</code> - Round toward negative infinity.</li> <li><code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li><code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| StateAutoScale    | Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code> , <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.  |
| StateFracLength   | When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.   |
| States            | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.   |
| StateWordLength   | Sets the word length used to represent the filter states.   |

## Examples

Create a fixed-point filter by specifying a second-order direct-form II transposed filter structure for a `dfilt` object, and then converting the double-precision arithmetic setting to fixed-point.

```
b = [0.3 0.6 0.3];  
a = [1 0 0.2];  
hd = dfilt.df2t(b,a);  
% Convert filter to fixed-point  
set(hd,'arithmetic','fixed')
```

## Version History

**Introduced in R2011a**

### See Also

`dsp.IIRFilter`

## dfilt.df2tsos

Discrete-time, SOS direct-form II transposed filter

### Syntax

```
hd = dfilt.df2tsos(s)
hd = dfilt.df2tsos(b1,a1,b2,a2,...)
hd = dfilt.df2tsos(...,g)
hd = dfilt.df2tsos
```

### Description

`hd = dfilt.df2tsos(s)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients given in the matrix `s`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.df2tsos(b1,a1,b2,a2,...)` returns a discrete-time, second-order section, direct-form II, transposed filter object `hd`, with coefficients for the first section given in the `b1` and `a1` vectors, for the second section given in the `b2` and `a2` vectors, etc.

`hd = dfilt.df2tsos(...,g)` includes a gain vector `g`. The elements of `g` are the gains for each section. The maximum length of `g` is the number of sections plus one. If `g` is not specified, all gains default to one.

`hd = dfilt.df2tsos` returns a default, discrete-time, second-order section, direct-form II, transposed filter object, `hd`. This filter passes the input through to the output unchanged.

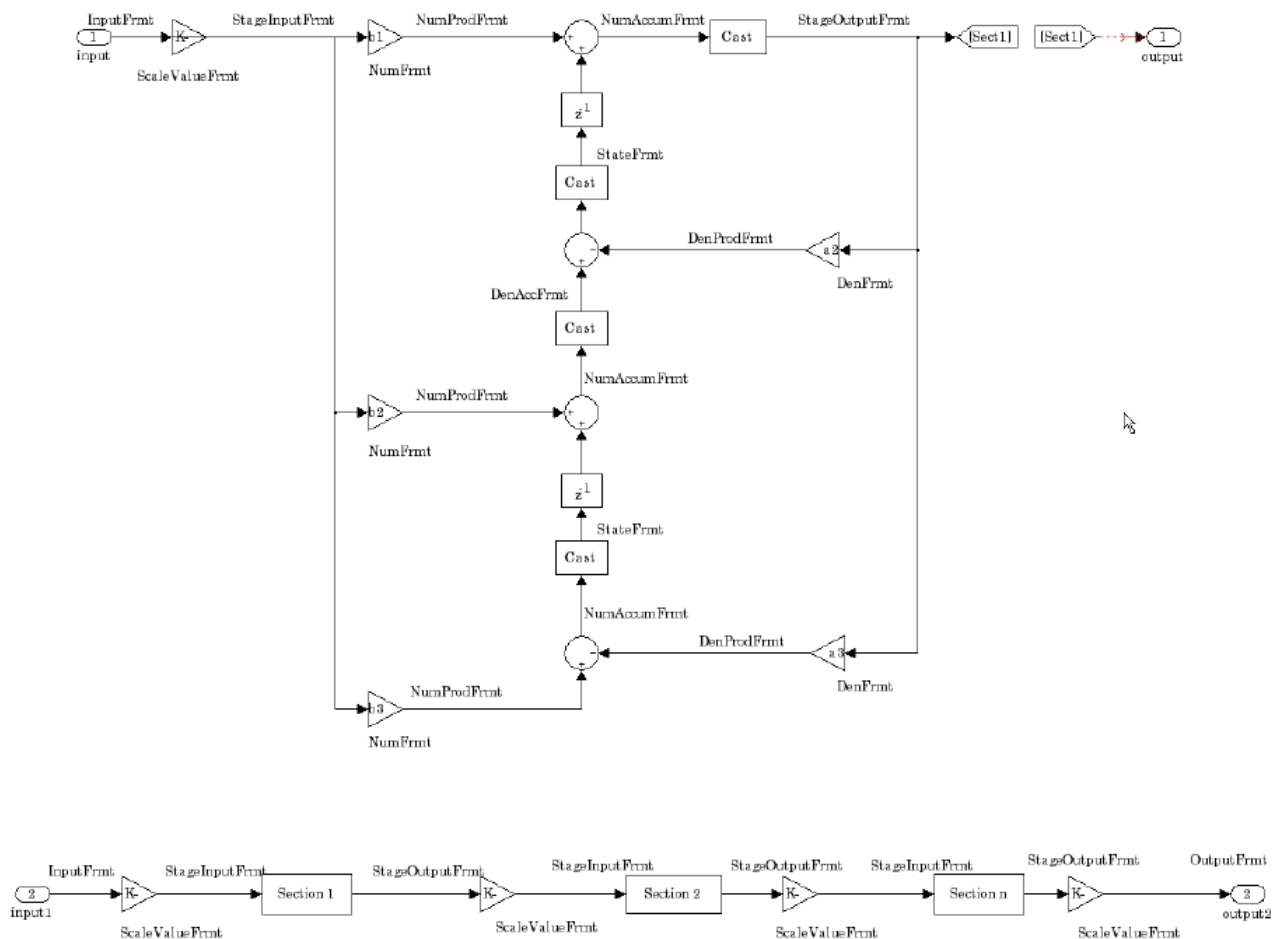

---

**Note** The leading coefficient of the denominator `a(1)` cannot be 0. To allow you to change the arithmetic setting to `fixed` or `single`, `a(1)` must be equal to 1.

---

### Fixed-Point Filter Structure

The figure below shows the signal flow for the second-order section transposed direct-form II filter implemented by `dfilt.dftsos`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties       |
|-------------------|------------------------------------|--|--------------------------|
| DenAccumFrmt      | AccumWordLength                    | DenAccumFracLength                     | AccumMode, CastBeforeSum |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| DenFrmt           | CoeffWordLength                    | DenFracLength                          | CoeffAutoScale, Signed, Denominator |
| DenProdFrmt       | CoeffWordLength                    | DenProdFracLength                      | ProductMode, ProductWordLength      |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                                |
| NumAccumFrmt      | AccumWordLength                    | NumAccumFracLength                     | AccumMode, CastBeforeSum            |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, SignedNumerator     |
| NumProdFrmt       | CoeffWordLength                    | NumProdFracLength                      | ProductWordLength, ProductMode      |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | OutputMode                          |
| ScaleValueFrmt    | CoeffWordLength                    | ScaleValueFracLength                   | CoeffAutoScale, ScaleValues         |
| SectionInputFrmt  | SectionInput-WordLength            | SectionInput-FracLength                |                                     |
| SectionOutputFrmt | SectionOutput-WordLength           | SectionOutput-FracLength               |                                     |
| StateFrmt         | StateWordLength                    | StateFracLength                        | States                              |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label DenProdFrmt, which always follows a denominator coefficient multiplication element in the signal flow. The label indicates that denominator coefficients leave the multiplication element with the word length and fraction length associated with product operations that include denominator coefficients. From reviewing the table, you see that the DenProdFrmt refers to the properties ProdWordLength, ProductMode and DenProdFracLength that fully define the denominator format after multiply (or product) operations.

## Properties

In this table you see the properties associated with second-order section implementation of transposed direct-form II `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

| Property Name      | Brief Description   |
|--------------------|---|
| AccumMode          | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| AccumWordLength    | Sets the word length used to store data in the accumulator/buffer.  |
| Arithmetic         | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| CastBeforeSum      | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |
| CoeffAutoScale     | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> and <code>DenFracLength</code> properties to specify the precision used.   |
| CoeffWordLength    | Specifies the word length to apply to filter coefficients.  |
| DenAccumFracLength | Specifies the fraction length used to interpret data in the accumulator used to hold the results of sum operations. You can change the value for this property when you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .   |
| DenFracLength      | Set the fraction length the filter uses to interpret denominator coefficients. <code>DenFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .  |
| DenProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving denominator coefficients. You can change this property value when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| FilterStructure    | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.   |
| InputFracLength    | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength    | Specifies the word length applied to interpret input data.  |
| NumAccumFracLength | Specifies how the filter algorithm interprets the results of addition operations involving numerator coefficients. You can change the value of this property after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .  |
| NumFracLength      | Sets the fraction length used to interpret the value of numerator coefficients.   |
| NumProdFracLength  | Specifies how the filter algorithm interprets the results of product operations involving numerator coefficients. Available to be changed when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |

| Property Name       | Brief Description  |
|---------------------|--|
| OptimizeScaleValues | When true, the filter skips multiplication-by-one scaling. When false, the filter performs multiplication-by-one scaling.  |
| OutputFracLength    | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .   |
| OutputMode          | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength    | Determines the word length used for the output data.   |
| OverflowMode        | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.   |
| ProductMode         | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| ProductWordLength   | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| PersistentMemory    | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.   |

| Property Name           | Brief Description   |
|-------------------------|---|
| RoundMode               | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| ScaleValueFracLength    | <p>Scale values work with SOS filters. Setting this property controls how your filter interprets the scale values by setting the fraction length. Only available when you disable <code>AutoScaleMode</code> by setting it to <code>false</code>.</p>   |
| ScaleValues             | <p>Scaling for the filter objects in SOS filters.</p>   |
| Signed                  | <p>Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.</p>  |
| SosMatrix               | <p>Holds the filter coefficients as property values — you use <code>set</code> and <code>get</code> to modify them. Displays the matrix in the format [sections x coefficients/section data type]. A [15x6 <code>double</code>] SOS matrix represents a filter with 6 coefficients per section and 15 sections, using data type <code>double</code> to represent the coefficients.</p>  |
| SectionInputFracLength  | <p>Lets you set the fraction length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code>.</p>   |
| SectionInputWordLength  | <p>Lets you set the word length for section inputs in SOS filters, if you set <code>SectionInputAutoScale</code> to <code>false</code>.</p>   |
| SectionOutputFracLength | <p>Lets you set the fraction length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>off</code>.</p>   |
| SectionOutputWordLength | <p>Lets you set the word length for section outputs in SOS filters, if you set <code>SectionOutputAutoScale</code> to <code>false</code>.</p>   |
| StateAutoScale          | <p>Setting autoscaling for filter states to <code>true</code> reduces the possibility of overflows occurring during fixed-point operations. Set to <code>false</code>, <code>StateAutoScale</code> lets the filter select the fraction length to limit the overflow potential.</p>  |

| Property Name   | Brief Description   |
|-----------------|---|
| StateFracLength | When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states. |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.   |
| StateWordLength | Sets the word length used to represent the filter states.   |

## Examples

Construct a second-order section Butterworth filter for fixed-point filtering. Start by specifying a Butterworth filter, and then convert the filter to second-order sections, with the following code:

```
[z,p,k] = butter(30,0.5);  
[s,g] = zp2sos(z,p,k);  
hd = dfilt.df2tsos(s,g);  
% convert filter to fixed-point  
hd.arithmetic='fixed';
```

## Version History

Introduced in R2011a

## See Also

`dsp.BiquadFilter`

## dfilt.dfasymfir

Discrete-time, direct-form antisymmetric FIR filter

### Syntax

```
hd = dfilt.dfasymfir(b)
hd = dfilt.dfasymfir
```

### Description

`hd = dfilt.dfasymfir(b)` returns a discrete-time, direct-form, antisymmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  
`set(hd,'arithmetic','single');`
- To change to fixed-point filtering, enter  
`set(hd,'arithmetic','fixed');`

`hd = dfilt.dfasymfir` returns a default, discrete-time, direct-form, antisymmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

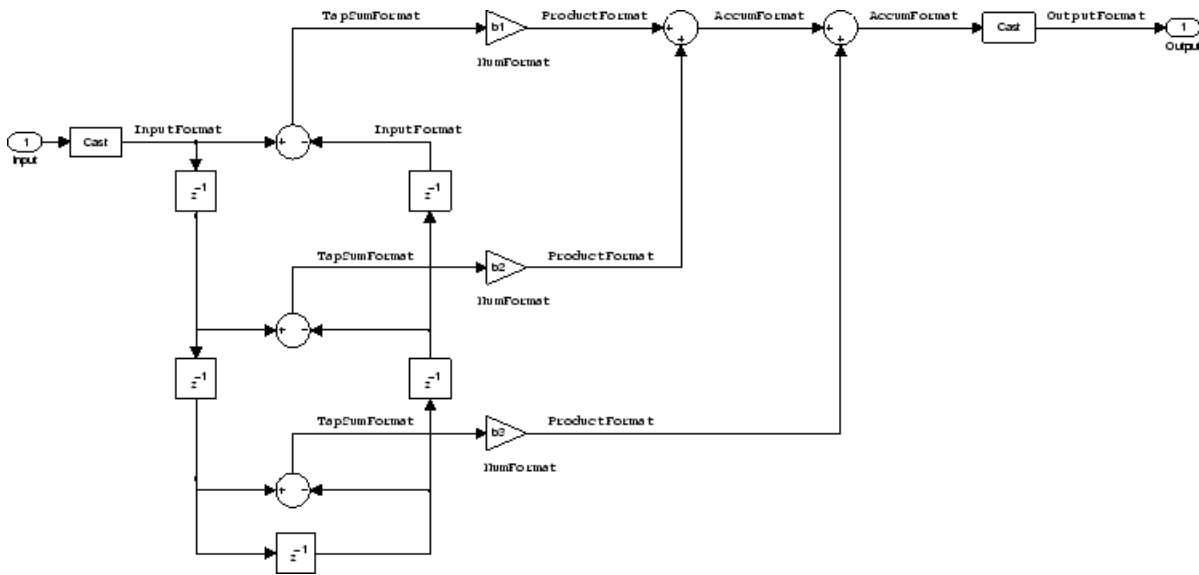

---

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfasymfir` assumes the coefficients in the second half are antisymmetric to those in the first half. For example, in the figure coefficients,  $b(4) = -b(3)$ ,  $b(5) = -b(2)$ , and  $b(6) = -b(1)$ .

---

### Fixed-Point Filter Structure

The following figure shows the signal flow for the odd-order antisymmetric FIR filter implemented by `dfilt.dfasymfir`. The even-order filter uses similar flow. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                  |
|-------------------|------------------------------------|--|-------------------------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | None                                |
| InputFormat       | InputWordLength                    | InputFracLength                        | None                                |
| NumFormat         | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, , Signed, Numerator |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | None                                |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | None                                |
| TapSumFormat      | InputWordLength                    | InputFracLength                        | InputFormat                         |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties

ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with an antisymmetric FIR implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Name            | Values   | Description   |
|-----------------|--|---|
| AccumFracLength | Any positive or negative integer number of bits [27] | Specifies the fraction length used to interpret data output by the accumulator.   |
| AccumWordLength | Any integer number of bits[33]                       | Sets the word length used to store data in the accumulator.   |
| Arithmetic      | fixed for fixed-point filters                        | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale  | [true], false  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.  |
| CoeffWordLength | Any integer number of bits [16]                      | Specifies the word length to apply to filter coefficients.  |
| FilterInternals | [FullPrecision], SpecifyPrecision                    | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data. Also controls <code>TapSumFracLength</code> .  |
| InputWordLength | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data. Also determines <code>TapSumWordLength</code> .  |

| Name              | Values   | Description  |
|-------------------|--|--|
| NumFracLength     | Any positive or negative integer number of bits [14] | Sets the fraction length used to interpret the numerator coefficients.   |
| OutputFracLength  | Any positive or negative integer number of bits [29] | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .  |
| OutputWordLength  | Any integer number of bits [33]                      | Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .  |
| OverflowMode      | saturate, [wrap]                                     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision. |
| ProductFracLength | Any positive or negative integer number of bits [27] | Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Any integer number of bits [33]                      | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |

| Name      | Values   | Description   |
|-----------|--|---|
| RoundMode | [convergent], ceil, fix, floor, nearest, round   | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> <li>• <b>floor</b> - Round toward negative infinity.</li> <li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed    | [true], false                                    | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States    | fi object to match the filter arithmetic setting | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.  |

## Examples

Specify a fifth-order direct-form antisymmetric FIR filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [-0.008 0.06 -0.44 0.44 -0.06 0.008];
hd = dfilt.dfasymfir(b);
```

## Version History

Introduced in R2011a

## See Also

`dsp.FIRFilter`

## dfilt.dffir

Discrete-time, direct-form FIR filter

### Syntax

```
hd = dfilt.dffir(b)
hd = dfilt.dffir
```

### Description

`hd = dfilt.dffir(b)` returns a discrete-time, direct-form finite impulse response (FIR) filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  
`set(hd,'arithmetic','single');`
- To change to fixed-point filtering, enter  
`set(hd,'arithmetic','fixed');`

`hd = dfilt.dffir` returns a default, discrete-time, direct-form FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the direct-form FIR filter implemented by `dfilt.dffir`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following

table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| AccumFrmt         | AccumWordLength                    | AccumFracLength                        | None                              |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                              |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | None                              |
| ProductFrmt       | ProductWordLength                  | ProductFracLength                      | None                              |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with direct-form FIR implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Name            | Values   | Description   |
|-----------------|--|---|

For details, refer to fixed-point objects in Fixed-Point Designer documentation.  |

## Examples

Specify a second-order direct-form FIR filter structure for a `dfilt` object `hd`, with the following code that constructs the filter in double-precision format and then converts the filter to fixed-point operation:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffir(b);
% Create fixed-point filter
hd.arithmetic='fixed';
% Change FilterInternals property to
% SpecifyPrecision enabling other properties
hd.FilterInternals='SpecifyPrecision';
```

## **Version History**

**Introduced in R2011a**

### **See Also**

`dsp.FIRFilter`

## dfilt.dffirt

Discrete-time, direct-form FIR transposed filter

### Syntax

```
hd = dfilt.dffirt(b)
hd = dfilt.dffirt
```

### Description

`hd = dfilt.dffirt(b)` returns a discrete-time, direct-form FIR transposed filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.dffirt` returns a default, discrete-time, direct-form FIR transposed filter object `hd`, with `b = 1`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the transposed direct-form FIR filter implemented by `dfilt.dffirt`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

**Notes About the Signal Flow Diagram**

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | None               |
| InputFormat       | InputWordLength                    | InputFracLength                        | None               |

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| NumFormat         | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | None                              |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | None                              |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the transposed direct-form FIR implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Name            | Values   | Description  |

| Signed    | [true], false   | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States    | <code>fi</code> object to match the filter arithmetic setting | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.   |

## Examples

Specify a second-order direct-form FIR transposed filter structure for a `dfilt` object, `hd`, with the following code:

```
b = [0.05 0.9 0.05];
hd = dfilt.dffirt(b);
set(hd, 'arithmetic', 'fixed')
```

## Version History

Introduced in R2011a

## See Also

`dsp.FIRFilter`

## dfilt.dfsymfir

Discrete-time, direct-form symmetric FIR filter

### Syntax

```
hd = dfilt.dfsymfir(b)
hd = dfilt.dfsymfir
```

### Description

`hd = dfilt.dfsymfir(b)` returns a discrete-time, direct-form symmetric FIR filter object `hd`, with numerator coefficients `b`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.dfsymfir` returns a default, discrete-time, direct-form symmetric FIR filter object `hd`, with `b=1`. This filter passes the input through to the output unchanged.

---

**Note** Only the coefficients in the first half of vector `b` are used because `dfilt.dfsymfir` assumes the coefficients in the second half are symmetric to those in the first half. In the following figure, for example,  $b(3) = 0$ ,  $b(4) = b(2)$  and  $b(5) = b(1)$ .

---

### Fixed-Point Filter Structure

In the following figure you see the signal flow diagram for the symmetric FIR filter that `dfilt.dfsymfir` implements.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the letters “frmt” (format). In this use, “frmt” indicates the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFrmt label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFrmt, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties                |
|-------------------|------------------------------------|--|-----------------------------------|
| AccumFrmt         | AccumWordLength                    | AccumFracLength                        | None                              |
| InputFrmt         | InputWordLength                    | InputFracLength                        | None                              |
| NumFrmt           | CoeffWordLength                    | NumFracLength                          | CoeffAutoScale, Signed, Numerator |
| OutputFrmt        | OutputWordLength                   | OutputFracLength                       | None                              |
| ProductFrmt       | ProductWordLength                  | ProductFracLength                      | None                              |
| TapSumFrmt        | InputWordLength                    | InputFracLength                        | None                              |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFrmt, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFrmt refers to the properties

ProductFracLength and ProductWordLength that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the symmetric FIR implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Name            | Values   | Description   |
|-----------------|--|---|
| AccumFracLength | Any positive or negative integer number of bits [27] | Specifies the fraction length used to interpret data output by the accumulator.   |
| AccumWordLength | Any integer number of bits[33]                       | Sets the word length used to store data in the accumulator.   |
| Arithmetic      | fixed for fixed-point filters                        | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale  | [true], false  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.  |
| CoeffWordLength | Any integer number of bits [16]                      | Specifies the word length to apply to filter coefficients.  |
| FilterInternals | [FullPrecision], SpecifyPrecision                    | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data.  |

| Name              | Values   | Description  |
|-------------------|--|--|
| NumFracLength     | Any positive or negative integer number of bits [14] | Sets the fraction length used to interpret the numerator coefficients.   |
| OutputFracLength  | Any positive or negative integer number of bits [29] | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .  |
| OutputWordLength  | Any integer number of bits [33]                      | Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .  |
| OverflowMode      | saturate, [wrap]                                     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision. |
| ProductFracLength | Any positive or negative integer number of bits [29] | Specifies the fraction length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Any integer number of bits [33]                      | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |

| Name      | Values  | Description   |
|-----------|---|---|
| RoundMode | [convergent], ceil, fix, floor, nearest, round                | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed    | [true], false   | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States    | <code>fi</code> object to match the filter arithmetic setting | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.   |

## Examples

Specify a fifth-order direct-form symmetric FIR filter structure for a `dfilt` object `hd`, with the following code:

```
b = [-0.008 0.06 0.44 0.44 0.06 -0.008];
hd = dfilt.dfsymfir(b);
% Create fixed-point filter
set(hd,'arithmetic','fixed')
% Change FilterInternals property to
% SpecifyPrecision
hd.FilterInternals='SpecifyPrecision';
```

## Version History

Introduced in R2011a

**See Also**

`dsp.FIRFilter`

## dfilt.farrowfd

Fractional Delay Farrow filter

### Syntax

```
Hd = dfilt.farrowfd(D, COEFFS)
```

### Description

`Hd = dfilt.farrowfd(D, COEFFS)` Constructs a discrete-time fractional delay Farrow filter with `COEFFS` coefficients and `D` delay.

### Examples

#### Design a Fractional Delay Farrow Filter

Farrow filters can be designed with the `dfilt.farrowfd` filter designer.

```
coeffs = [-1/6 1/2 -1/3 0;1/2 -1 -1/2 1;  
-1/2 1/2 1 0;1/6 0 -1/6 0];  
farrow = dfilt.farrowfd(0.5, coeffs);
```

Design a cubic fractional delay filter with the Lagrange method.

```
fdelay = .2; % Fractional delay  
d = fdesign.fracdelay(fdelay,'N',3);  
cubicfarrow = design(d, 'lagrange', 'FilterStructure', 'farrowfd');  
fvtool(cubicfarrow, 'Analysis', 'grpdelay');
```

## Version History

Introduced in R2011a

## dfilt.farrowlinearfd

Farrow Linear Fractional Delay filter

### Syntax

```
Hd = dfilt.farrowlinearfd(D)
```

### Description

`Hd = dfilt.farrowlinearfd(D)` Constructs a discrete-time linear fractional delay Farrow filter with the delay `D`.

### Examples

Farrow linear fractional delay filter with 1/2 sample delay:

```
Hd = dfilt.farrowlinearfd(0.5);  
x = cos(pi/10*(0:159));  
y = filter(Hd,x);  
stem(x(1:40));  
axis([0 40 -2 2]);  
hold on;  
stem(y(1:40), 'color',[1 0 0], 'markerfacecolor',[1 0 0]);  
legend('Original Signal', 'Filtered Signal', 'Location', 'best');
```

For more information about fractional delay filter implementations, see “Fractional Delay Filters Using Farrow Structures”.

## Version History

**Introduced in R2011a**

## dfilt.fftfir

Discrete-time, overlap-add, FIR filter

### Syntax

```
Hd = dfilt.fftfir(b, len)
Hd = dfilt.fftfir(b)
Hd = dfilt.fftfir
```

### Description

This object uses the overlap-add method of block FIR filtering, which is very efficient for streaming data.

`Hd = dfilt.fftfir(b, len)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len`. The block length is the number of input points to use for each overlap-add computation.

`Hd = dfilt.fftfir(b)` returns a discrete-time, FFT, FIR filter, `Hd`, with numerator coefficients, `b` and block length, `len=100`.

`Hd = dfilt.fftfir` returns a default, discrete-time, FFT, FIR filter, `Hd`, with the numerator `b=1` and block length, `len=100`. This filter passes the input through to the output unchanged.

---

**Note** When you use a `dfilt.fftfir` object to filter, the input signal length must be an integer multiple of the object's block length, `len`. The resulting number of FFT points = (filter length + the block length - 1). The filter is most efficient if the number of FFT points is a power of 2.

---

The `fftfir` uses an overlap-add block processing algorithm, which is represented as follows,

where  $len$  is the block length and  $M$  is the length of the numerator-1,  $(length(b) - 1)$ , which is also the number of states. The output of each convolution is a block that is longer than the input block by

a tail of  $(\text{length}(b) - 1)$  samples. These tails overlap the next block and are added to it. The states reported by `dfilt.fftfilter` are the tails of the final convolution.

## Examples

Create an FFT FIR discrete-time filter with coefficients from a 30<sup>th</sup> order lowpass equiripple design:

```
b = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);  
Hd = dfilt.fftfilter(b);  
% To obtain frequency domain coefficients  
% used in filtering  
Coeffs = fftcoeffs(Hd);
```

## Version History

Introduced in R2011a

# dfilt.latticeallpass

Discrete-time, lattice allpass filter

## Syntax

```
hd = dfilt.latticeallpass(k)
hd = dfilt.latticeallpass
```

## Description

`hd = dfilt.latticeallpass(k)` returns a discrete-time, lattice allpass filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter
 

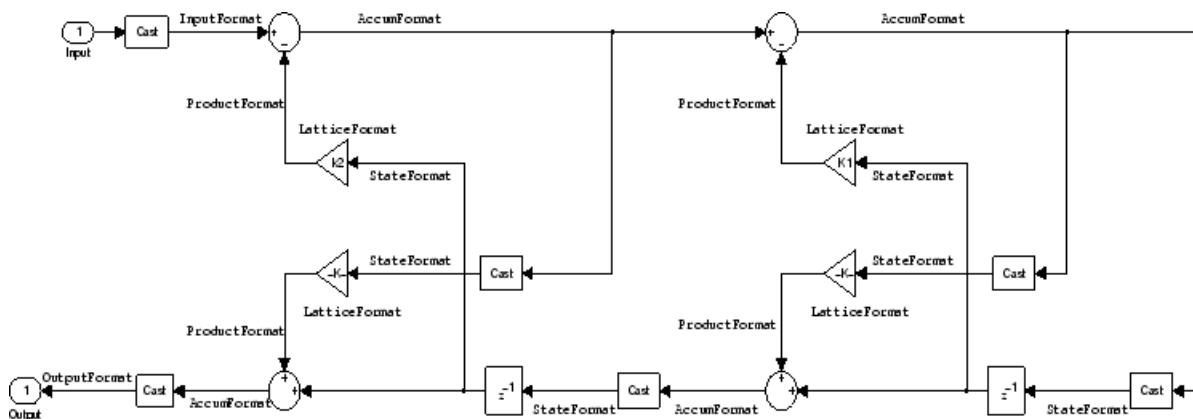

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.latticeallpass` returns a default, discrete-time, lattice allpass filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the allpass lattice filter implemented by `dfilt.latticeallpass`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | AccumMode          |
| InputFormat       | InputWordLength                    | InputFracLength                        | None               |
| LatticeFormat     | CoeffWordLength                    | LatticeFracLength                      | CoeffAutoScale     |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | OutputMode         |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | ProductMode        |
| StateFormat       | StateWordLength                    | StateFracLength                        | States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the allpass lattice implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name     | Brief Description  |
|-------------------|--|
| AccumFracLength   | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties —DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.  |
| AccumMode         | Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.  |
| AccumWordLength   | Sets the word length used to store data in the accumulator/buffer.   |
| Arithmetic        | Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.   |
| CastBeforeSum     | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.  |
| CoeffAutoScale    | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property value to specify the precision used.   |
| CoeffWordLength   | Specifies the word length to apply to filter coefficients.   |
| FilterStructure   | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| InputFracLength   | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength   | Specifies the word length applied to interpret input data.   |
| Lattice           | Any lattice structure coefficients. No default value.  |
| LatticeFracLength | Sets the fraction length applied to the lattice coefficients.  |
| OutputFracLength  | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.   |
| OutputMode        | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |

| Property Name     | Brief Description   |
|-------------------|---|
| OutputWordLength  | Determines the word length used for the output data.  |
| OverflowMode      | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.  |
| ProductFracLength | For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |

| Property Name   | Brief Description  |
|-----------------|--|
| StateFracLength | When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.  |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system. |
| StateWordLength | Sets the word length used to represent the filter states.  |

## Examples

Specify a third-order lattice allpass filter structure for a dfilt object hd, with the following code:

```
k = [.66 .7 .44];
hd=dfilt.latticeallpass(k);
% convert to fixed-point arithmetic
hd.arithmetic = 'fixed';
```

## Version History

Introduced in R2011a

## dfilt.latticear

Discrete-time, lattice, autoregressive filter

### Syntax

```
hd = dfilt.latticear(k)
hd = dfilt.latticear
```

### Description

`hd = dfilt.latticear(k)` returns a discrete-time, lattice autoregressive filter object `hd`, with lattice coefficients, `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter  

```
set(hd,'arithmetic','fixed');
```

`hd = dfilt.latticear` returns a default, discrete-time, lattice autoregressive filter object `hd`, with `k=[]`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticear`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

### Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following

table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | AccumMode          |
| InputFormat       | InputWordLength                    | InputFracLength                        | None               |
| LatticeFormat     | CoeffWordLength                    | LatticeFracLength                      | CoeffAutoScale     |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | OutputMode         |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | ProductMode        |
| StateFormat       | StateWordLength                    | StateFracLength                        | States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive lattice implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

| AccumMode         | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> .  |
| AccumWordLength   | Sets the word length used to store data in the accumulator/buffer.   |
| Arithmetic        | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.   |
| CastBeforeSum     | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.  |
| CoeffAutoScale    | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> to specify the precision used.  |
| CoeffWordLength   | Specifies the word length to apply to filter coefficients.   |
| FilterStructure   | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.  |
| InputFracLength   | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength   | Specifies the word length applied to interpret input data.   |
| Lattice           | Any lattice structure coefficients.  |
| LatticeFracLength | Sets the fraction length applied to the lattice coefficients.  |
| OutputFracLength  | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .   |
| OutputMode        | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |

| Property Name     | Brief Description   |
|-------------------|---|
| OutputWordLength  | Determines the word length used for the output data.  |
| OverflowMode      | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.  |
| ProductFracLength | For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |

| Property Name   | Brief Description  |
|-----------------|--|
| StateFracLength | When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.  |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to filtstates in Signal Processing Toolbox documentation or in the Help system. |
| StateWordLength | Sets the word length used to represent the filter states.  |

## Examples

Specify a third-order lattice autoregressive filter structure for a `dfilt` object, `hd`, with the following code that creates a fixed-point filter.

```
k = [.66 .7 .44];  
hd1=dfilt.latticear(k);  
hd1.arithmetic='fixed';  
specifyall(hd1);
```

## Version History

Introduced in R2011a

## dfilt.latticearma

Discrete-time, lattice, autoregressive, moving-average filter

### Syntax

```
hd = dfilt.latticearma(k)
hd dfilt.latticearma
```

### Description

`hd = dfilt.latticearma(k)` returns a discrete-time, lattice moving-average autoregressive filter object `hd`, with lattice coefficients, `k`.

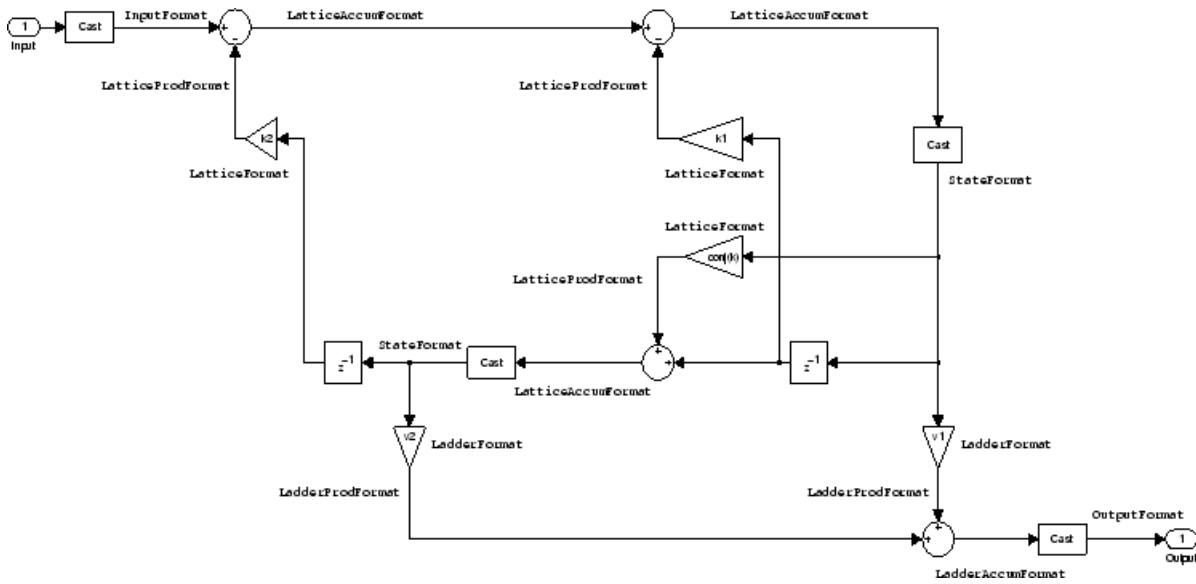

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  
`set(hd,'arithmetic','single');`
- To change to fixed-point filtering, enter  
`set(hd,'arithmetic','fixed');`

`hd dfilt.latticearma` returns a default, discrete-time, lattice moving-average, autoregressive filter object `hd`, with `k = [ ]`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the autoregressive lattice filter implemented by `dfilt.latticearma`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

**Notes About the Signal Flow Diagram**

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label  | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|--------------------|------------------------------------|--|--------------------|
| InputFormat        | InputWordLength                    | InputFracLength                        | None               |
| LadderAccumFormat  | AccumWordLength                    | LadderAccumFracLength                  | AccumMode          |
| LadderFormat       | CoeffWordLength                    | LadderFracLength                       | CoeffAutoScale     |
| LadderProdFormat   | ProductWordLength                  | LadderProdFracLength                   | ProductMode        |
| LatticeAccumFormat | AccumWordLength                    | LatticeAccumFracLength                 | AccumMode          |
| LatticeFormat      | CoeffWordLength                    | LatticeFracLength                      | CoeffAutoScale     |
| LatticeProdFormat  | ProductWordLength                  | LatticeProdFracLength                  | ProductMode        |
| OutputFormat       | OutputWordLength                   | OutputFracLength                       | OutputMode         |
| StateFormat        | StateWordLength                    | StateFracLength                        | States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label `LatticeProdFormat`, which always follows a coefficient multiplication element in the signal flow. The label indicates that lattice coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the `LatticeProdFormat` refers to the properties `ProductWordLength`, `LatticeProdFracLength`, and `ProductMode` that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the autoregressive moving-average lattice implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name                | Brief Description   |
|------------------------------|---|
| <code>AccumFracLength</code> | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.  |
| <code>AccumMode</code>       | Determines how the accumulator outputs stored values. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bits ( <code>KeepMSB</code> ) or least significant bits ( <code>KeepLSB</code> ) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set <code>AccumMode</code> to <code>SpecifyPrecision</code> . |
| <code>AccumWordLength</code> | Sets the word length used to store data in the accumulator/buffer.  |
| <code>Arithmetic</code>      | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter.  |
| <code>CastBeforeSum</code>   | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.   |
| <code>CoeffAutoScale</code>  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>LatticeFracLength</code> property to specify the precision used.  |

| Property Name         | Brief Description  |
|-----------------------|--|
| CoeffWordLength       | Specifies the word length to apply to filter coefficients.   |
| FilterStructure       | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering—gains, delays, sums, products, and input/output.  |
| InputFracLength       | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength       | Specifies the word length applied to interpret input data.   |
| Ladder                | Stores the ladder coefficients for lattice ARMA ( <code>dfilt.latticearma</code> ) filters.  |
| LadderAccumFracLength | Sets the fraction length used to interpret the output from sum operations that include the ladder coefficients. You can change this property value after you set <code>AccumMode</code> to <code>SpecifyPrecision</code> .   |
| LadderFracLength      | Determines the precision used to represent the ladder coefficients in ARMA lattice filters.  |
| Lattice               | Stores the lattice structure coefficients.   |
| LatticeFracLength     | Sets the fraction length applied to the lattice coefficients.  |
| OutputFracLength      | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .   |
| OutputMode            | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength      | Determines the word length used for the output data.   |
| OverflowMode          | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow—they maintain full precision.   |
| ProductFracLength     | For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |

| Property Name     | Brief Description   |
|-------------------|---|
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| StateFracLength   | When you set <code>StateAutoScale</code> to <code>false</code> , you enable the <code>StateFracLength</code> property that lets you set the fraction length applied to interpret the filter states.   |
| States            | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.  |
| StateWordLength   | Sets the word length used to represent the filter states.   |

# **Version History**

**Introduced in R2011a**

# dfilt.latticemamax

Discrete-time, lattice, moving-average filter with maximum phase

## Syntax

```
hd = dfilt.latticemamax(k)
hd = dfilt.latticemamax
```

## Description

`hd = dfilt.latticemamax(k)` returns a discrete-time, lattice, moving-average filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter
 

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hd,'arithmetic','fixed');
```

---

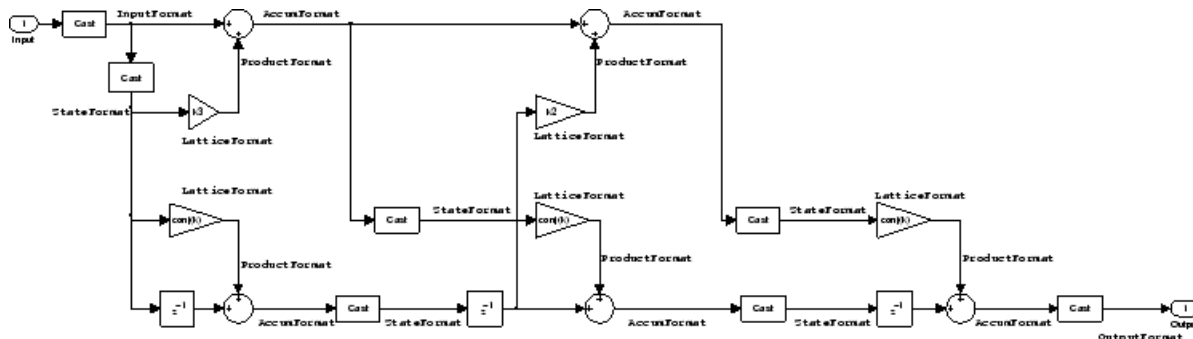

**Note** When the `k` coefficients define a maximum phase filter, the resulting filter in this structure is maximum phase. When your coefficients do not define a maximum phase filter, placing them in this structure does not produce a maximum phase filter.

---

`hd = dfilt.latticemamax` returns a default discrete-time, lattice, moving-average filter object `hd`, with `k = []`. This filter passes the input through to the output unchanged.

## Fixed-Point Filter Structure

The following figure shows the signal flow for the maximum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamax`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | AccumMode          |
| InputFormat       | InputWordLength                    | InputFracLength                        | None               |
| LatticeFormat     | CoeffWordLength                    | LatticeFracLength                      | CoeffAutoScale     |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | OutputMode         |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | ProductMode        |
| StateFormat       | StateWordLength                    | StateFracLength                        | States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the maximum phase, moving average lattice implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name     | Brief Description  |
|-------------------|--|
| AccumFracLength   | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.   |
| AccumMode         | Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.  |
| AccumWordLength   | Sets the word length used to store data in the accumulator/buffer.   |

## Examples

Specify a fourth-order lattice, moving-average, maximum phase filter structure for a dfilt object, hd, with the following code:

```
k = [.66 .7 .44 .33];
hd = dfilt.latticemamax(k);
```

## Version History

**Introduced in R2011a**

## dfilt.latticemamin

Discrete-time, lattice, moving-average filter with minimum phase

### Syntax

```
hd = dfilt.latticemamin(k)
hd = dfilt.latticemamin
```

### Description

`hd = dfilt.latticemamin(k)` returns a discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with lattice coefficients `k`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter  

```
set(hd,'arithmetic','single');
```
- To change to fixed-point filtering, enter  

```
set(hd,'arithmetic','fixed');
```

---

**Note** When the `k` coefficients define a minimum phase filter, the resulting filter in this structure is minimum phase. When your coefficients do not define a minimum phase filter, placing them in this structure does not produce a minimum phase filter.

---

`hd = dfilt.latticemamin` returns a default discrete-time, lattice, moving-average, minimum phase, filter object `hd`, with `k=[ ]`. This filter passes the input through to the output unchanged.

### Fixed-Point Filter Structure

The following figure shows the signal flow for the minimum phase implementation of a moving-average lattice filter implemented by `dfilt.latticemamin`. To help you see how the filter processes the coefficients, input, and states of the filter, as well as numerical operations, the figure includes the locations of the formatting objects within the signal flow.

## Notes About the Signal Flow Diagram

To help you understand where and how the filter performs fixed-point arithmetic during filtering, the figure shows various labels associated with data and functional elements in the filter. The following table describes each label in the signal flow and relates the label to the filter properties that are associated with it.

The labels use a common format — a prefix followed by the word “format.” In this use, “format” means the word length and fraction length associated with the filter part referred to by the prefix.

For example, the InputFormat label refers to the word length and fraction length used to interpret the data input to the filter. The format properties InputWordLength and InputFracLength (as shown in the table) store the word length and the fraction length in bits. Or consider NumFormat, which refers to the word and fraction lengths (CoeffWordLength, NumFracLength) associated with representing filter numerator coefficients.

| Signal Flow Label | Corresponding Word Length Property | Corresponding Fraction Length Property | Related Properties |
|-------------------|------------------------------------|--|--------------------|
| AccumFormat       | AccumWordLength                    | AccumFracLength                        | AccumMode          |
| InputFormat       | InputWordLength                    | InputFracLength                        | None               |
| LatticeFormat     | CoeffWordLength                    | LatticeFracLength                      | CoeffAutoScale     |
| OutputFormat      | OutputWordLength                   | OutputFracLength                       | OutputMode         |
| ProductFormat     | ProductWordLength                  | ProductFracLength                      | ProductMode        |
| StateFormat       | StateWordLength                    | StateFracLength                        | States             |

Most important is the label position in the diagram, which identifies where the format applies.

As one example, look at the label ProductFormat, which always follows a coefficient multiplication element in the signal flow. The label indicates that coefficients leave the multiplication element with the word length and fraction length associated with product operations that include coefficients. From reviewing the table, you see that the ProductFormat refers to the properties ProductFracLength, ProductWordLength, and ProductMode that fully define the coefficient format after multiply (or product) operations.

## Properties

In this table you see the properties associated with the minimum phase, moving average lattice implementation of `dfilt` objects.

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

| Property Name     | Brief Description  |
|-------------------|--|
| AccumFracLength   | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — DenAccumFracLength and NumAccumFracLength — that let you set the precision for numerator and denominator operations separately.   |
| AccumMode         | Determines how the accumulator outputs stored values. Choose from full precision (FullPrecision), or whether to keep the most significant bits (KeepMSB) or least significant bits (KeepLSB) when output results need shorter word length than the accumulator supports. To let you set the word length and the precision (the fraction length) used by the output from the accumulator, set AccumMode to SpecifyPrecision.  |
| AccumWordLength   | Sets the word length used to store data in the accumulator/buffer.   |
| Arithmetic        | Defines the arithmetic the filter uses. Gives you the options double, single, and fixed. In short, this property defines the operating mode for your filter.   |
| CastBeforeSum     | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.  |
| CoeffAutoScale    | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the LatticeFracLength property to specify the precision used.   |
| CoeffWordLength   | Specifies the word length to apply to filter coefficients.   |
| FilterStructure   | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| InputFracLength   | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength   | Specifies the word length applied to interpret input data.   |
| Lattice           | Any lattice structure coefficients.  |
| LatticeFracLength | Sets the fraction length applied to the lattice coefficients.  |
| OutputFracLength  | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set OutputMode to SpecifyPrecision.   |
| OutputMode        | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <b>AvoidOverflow</b> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <b>BestPrecision</b> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <b>SpecifyPrecision</b> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |

| Property Name     | Brief Description   |
|-------------------|---|
| OutputWordLength  | Determines the word length used for the output data.  |
| OverflowMode      | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.  |
| ProductFracLength | For the output from a product operation, this sets the fraction length used to interpret the data. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| ProductMode       | Determines how the filter handles the output of product operations. Choose from full precision ( <code>FullPrecision</code> ), or whether to keep the most significant bit ( <code>KeepMSB</code> ) or least significant bit ( <code>KeepLSB</code> ) in the result when you need to shorten the data words. For you to be able to set the precision (the fraction length) used by the output from the multiplies, you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .  |
| ProductWordLength | Specifies the word length to use for multiplication operation results. This property becomes writable (you can change the value) when you set <code>ProductMode</code> to <code>SpecifyPrecision</code> .   |
| PersistentMemory  | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.  |
| RoundMode         | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed            | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |

| Property Name   | Brief Description  |
|-----------------|--|
| StateFracLength | When you set StateAutoScale to false, you enable the StateFracLength property that lets you set the fraction length applied to interpret the filter states.  |
| States          | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system. |
| StateWordLength | Sets the word length used to represent the filter states.  |

## Examples

Specify a third-order lattice, moving-average, minimum phase, filter structure for a `dfilt` object, `hd`, with the following code:

```
k = [.66 .7 .44];  
hd = dfilt.latticemamin(k);
```

## Version History

**Introduced in R2011a**

## dfilt.parallel

Discrete-time, parallel structure filter

### Syntax

```
hd = dfilt.parallel(hd1,hd2,...)
```

### Description

`hd = dfilt.parallel(hd1,hd2,...)` returns a discrete-time filter object `hd`, which is a structure of two or more `dfilt` filter objects, `hd1`, `hd2`, and so on arranged in parallel.

You can also use the standard notation to combine filters into a parallel structure.

```
parallel(hd1,hd2,...)
```

In this syntax, `hd1`, `hd2`, and so on can be a mix of `dfilt` objects and other filtering objects.

`hd1`, `hd2`, and so on can be fixed-point filters. All filters in the parallel structure must be the same arithmetic format — double, single, or fixed. `hd`, the filter returned, inherits the format of the individual filters.

## Version History

Introduced in R2011a

## dfilt.scalar

Discrete-time, scalar filter

### Syntax

```
dfilt.scalar(g)
dfilt.scalar
```

### Description

`dfilt.scalar(g)` returns a discrete-time, scalar filter object with gain `g`, where `g` is a scalar.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hd` as follows:

- To change to single-precision filtering, enter

```
set(hd,'arithmetic','single');
```

- To change to fixed-point filtering, enter

```
set(hd,'arithmetic','fixed');
```

`dfilt.scalar` returns a default, discrete-time scalar gain filter object `hd`, with gain 1.

### Properties

In this table you see the properties associated with the scalar implementation of `dfilt` objects.

---

**Note** The table lists all the properties that a filter can have. Many of the properties are dynamic, meaning they exist only in response to the settings of other properties. You might not see all of the listed properties all the time. To view all the properties for a filter at any time, use

```
get(hd)
```

where `hd` is a filter.

---

| Property Name | Brief Description  |
|---------------|--|
| Arithmetic    | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operating mode for your filter. |
| CastBeforeSum | Specifies whether to cast numeric data to the appropriate accumulator format (as shown in the signal flow diagrams) before performing sum operations.  |

| Property Name    | Brief Description  |
|------------------|--|
| CoeffAutoScale   | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>CoeffFracLength</code> property to specify the precision used.   |
| CoeffFracLength  | Set the fraction length the filter uses to interpret coefficients. <code>CoeffFracLength</code> is always available, but it is read-only until you set <code>CoeffAutoScale</code> to <code>false</code> .   |
| CoeffWordLength  | Specifies the word length to apply to filter coefficients.   |
| FilterStructure  | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output.  |
| Gain             | Returns the gain for the scalar filter. Scalar filters do not alter the input data except by adding gain.  |
| InputFracLength  | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength  | Specifies the word length applied to interpret input data.   |
| OutputFracLength | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>OutputMode</code> to <code>SpecifyPrecision</code> .   |
| OutputMode       | Sets the mode the filter uses to scale the filtered data for output. You have the following choices: <ul style="list-style-type: none"> <li>• <code>AvoidOverflow</code> — directs the filter to set the output data word length and fraction length to avoid causing the data to overflow.</li> <li>• <code>BestPrecision</code> — directs the filter to set the output data word length and fraction length to maximize the precision in the output data.</li> <li>• <code>SpecifyPrecision</code> — lets you set the word and fraction lengths used by the output data from filtering.</li> </ul> |
| OutputWordLength | Determines the word length used for the output data.   |
| OverflowMode     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic). The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.   |
| PersistentMemory | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.   |

| Property Name | Brief Description   |
|---------------|---|
| RoundMode     | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. | States        | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system.  |

## Examples

Create a direct-form I filter object `hd_filt` and a scalar object with a gain of 3 `hd_gain` and cascade them together.

```
b = [0.3 0.6 0.3];
a = [1 0 0.2];
hd_filt = dfilt.df1(b,a);
hd_gain = dfilt.scalar(3);
hd_cascade=cascade(hd_gain,hd_filt);
fvtool_handle = fvtool(hd_filt,hd_gain,hd_cascade);
legend(fvtool_handle,'IIR Filter (direct form I)',...
'Gain','Cascaded Filter');
```

To view the stages of the cascaded filter, use

```
hd.Stage(1)
```

and

```
hd.Stage(2)
```

## Version History

Introduced in R2011a

## dfilt.wdfallpass

Wave digital allpass filter

### Syntax

```
hd = dfilt.wdfallpass(c)
```

### Description

`hd = dfilt.wdfallpass(c)` constructs an allpass wave digital filter structure given the allpass coefficients in vector `c`.

Vector `c` must have, one, two, or four elements (filter coefficients). Filters with three coefficients are not supported. When you use `c` with four coefficients, the first and third coefficients must be 0.

Given the coefficients in `c`, the transfer function for the wave digital allpass filter is defined by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}$$

Internally, the allpass coefficients are converted to wave digital filters for filtering. Note that `dfilt.wdfallpass` allows only stable filters. Also note that the leading coefficient in the denominator, a 1, does not need to be included in vector `c`.

Use the constructor `dfilt.cascadewdfallpass` to cascade `wdfallpass` filters.

To compare these filters to other similar filters, `dfilt.wdfallpass` and `dfilt.cascadewdfallpass` filters have the same number of multipliers as the non-wave digital filters `dfilt.allpass` and `dfilt.cascadeallpass`. However, the wave digital filters use fewer states and they may require more adders in the filter structure.

Wave digital filters are usually used to create other filters. This toolbox uses them to implement halfband filters, which the first example in Examples demonstrates. They are most often building blocks for filters.

### Properties

In the next table, the row entries are the filter properties and a brief description of each property.

| Property Name       | Brief Description   |
|---------------------|---|
| AllpassCoefficients | Contains the coefficients for the allpass wave digital filter object  |
| FilterStructure     | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. |

| Property Name    | Brief Description  |
|------------------|--|
| PersistentMemory | Specifies whether to reset the filter states and memory before each filtering operation. Lets you decide whether your filter retains states from previous filtering runs. <code>False</code> is the default setting.   |
| States           | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. They also provide linkage between the sections of a multisection filter, such as a cascade filter. For details, refer to <code>filtstates</code> in Signal Processing Toolbox documentation or in the Help system. |

## Filter Structure

When you change the order of the wave digital filters in the cascade, the filter structure changes as well.

As shown in this example, `realizemdl` lets you see the filter structure used for your filter, if you have Simulink installed.

```
section11=0.8;
section12=[1.5,0.7];
section13=[1.8,0.9];
hd1=dfilt.cascadewdfallpass(section11,section12,section13);
```

```
section21=[0.8,0.4];
section22=[0,1.5,0,0.7];
section23=[0,1.8,0,0.9];
hd2=dfilt.cascadewdfallpass(section21,section22,section23);
% If you have Simulink
realizemdl(hd2)
```

`hd1` has this filter structure with three sections.

The filter structure for `hd2` is somewhat different, with the different orders and interconnections between the three sections.

## Examples

Construct a second-order wave digital allpass filter with two coefficients. Note that to use `realizemdl`, you must have Simulink.

```
c = [1.5,0.7];
hd = dfilt.wdfallpass(c);
```

With Simulink installed, `realizemdl` returns this structure for `hd`.

`dsp.IIRHalfbandDecimator` | `dsp.CICInterpolator`

# disp

Display filter properties and values

## Syntax

```
disp(obj)
```

## Description

`disp(obj)` lists the property names and property values of the object `obj`. In all ways, it is the same as leaving the semicolon off an on the command line while creating the object, except that `disp` does not display the variable name.

## Examples

### Display Properties of Filter Object

Create a `dsp.FIRFilter` object.

```
filt = dsp.FIRFilter
filt =
    dsp.FIRFilter with properties:
        Structure: 'Direct form'
        NumeratorSource: 'Property'
        Numerator: [0.5000 0.5000]
        InitialConditions: 0
    Show all properties
```

Display its properties using the `disp` function.

```
disp(filt)
dsp.FIRFilter with properties:
    Structure: 'Direct form'
    NumeratorSource: 'Property'
    Numerator: [0.5000 0.5000]
    InitialConditions: 0
    Use get to show all properties
```

## Input Arguments

### **obj** — Input object

object

Input object, specified as one of the System objects or `fdesign` objects supported by DSP System Toolbox. For a list, see “Functions”.

## **Version History**

**Introduced in R2011a**

## **See Also**

`set`

## double

Cast fixed-point filter to use double-precision arithmetic

### Syntax

```
hd = double(h)
```

### Description

`hd = double(h)` returns a new filter `hd` that has the same structure and coefficients as `h`, but whose arithmetic property is set to `double` to use double-precision arithmetic for filtering. `double(h)` is not the same as the `refilter(h)` function:

- `hd`, the filter returned by `double` has the quantized coefficients of `h` represented in double-precision floating-point format
- The reference filter returned by `refilter` has double-precision, floating-point coefficients that have not been quantized.

You might find `double(h)` useful to isolate the effects of quantizing the coefficients of a filter by using `double` to create a filter `hd` that operates in double-precision but uses the quantized filter coefficients.

### Examples

#### Compare Fixed-point Output with Floating-Point Output

Construct a Lowpass Filter

```
h = dfilt.dffir(firgr(27,[0 .4 .6 1],...
[1 1 0 0]));
```

Set `h` to use fixed-point arithmetic to filter. Quantize the coefficients.

```
h.arithmetic = 'fixed';
```

Cast `h` to double-precision

```
hd = double(h);
```

Set up an input signal.

```
n = 0:99; x = sin(0.7*pi*n(:));
```

Fixed-point output.

```
y = filter(h,x);
```

Floating-point output.

```
yd = filter(hd,x);
```

Compare the Fixed-point output with Floating-point output

```
FixedFloatNormDiff=norm(yd-double(y),inf)
```

```
FixedFloatNormDiff = 2.1234e-05
```

## **Version History**

**Introduced in R2011a**

## dsp\_links

Identify whether blocks in model are current, deprecated, or obsolete

### Syntax

```
dsp_links
dsp_links('modelname')
```

### Description

`dsp_links` returns a structure with three elements that identify whether the DSP System Toolbox blocks in the current model are current, deprecated, or obsolete. Each element is one of the three block categories and contains a cell array of character vectors. Each character vector is the name of a library block in the current model.

`dsp_links('modelname')` returns the three-element structure for the specified model.

### Examples

#### Name of the First Current Block

Display block support information for the specified model, and then find the name of the first current block.

```
sys = 'cochlearimplantspeechprocessor';
```

Load the dspcochlear model

```
load_system(sys)
```

Run `dsp_links` on the model

```
links = dsp_links(sys)
```

```
links = struct with fields:
    obsolete: {}
    deprecated: {'cochlearimplantspeechprocessor/Info'}
    current: {1x23 cell}
```

Find the name of the first current block

```
links.current{1}
```

```
ans =
'cochlearimplantspeechprocessor/Filter bank signal processing/Subsystem3/IIR Filter Bank/Digital
```

## **More About**

### **Obsolete Blocks**

*Obsolete blocks* are blocks that the toolbox no longer supports. In some cases, these blocks no longer function properly.

### **Deprecated Blocks**

*Deprecated blocks* are blocks that the toolbox still supports but are likely to become obsolete in a future release. Refer to the block reference page for suggested replacements.

### **Current Blocks**

*Current blocks* are blocks that the toolbox supports and that represent the latest block functionality.

## **dspunfold**

Generates a multi-threaded MEX file from a MATLAB function

### **Syntax**

```
dspunfold file  
dspunfold options file
```

### **Description**

`dspunfold file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the unfolding technology. Unfolding is a technique to improve throughput through parallelization. The multi-threaded MEX file leverages the multicore CPU architecture of the host computer and can improve speed significantly. In addition to the multi-threaded MEX file, the function generates a single-threaded MEX file, a self-diagnostic analyzer function, and the corresponding help files.

`dspunfold options file` generates a multi-threaded MEX file from the entry-point MATLAB function specified by `file`, using the function arguments specified by `options`.

---

**Note** This function requires a MATLAB Coder license.

---

### **Input Arguments**

**options** — Function parameters

option value pairs

| Option          | Values     | Description  | Examples  |
|-----------------|------------|--|---|
| -args arguments | Cell array | <p>Argument types for the entry-point MATLAB function, specified as a cell array.</p> <p>The cell array accepts numeric elements, the <code>coder.typeof</code> function, and the <code>coder.Constant</code> function.</p> <p>The generated multi-threaded MEX file is specialized to the size, class, and complexity of arguments.</p> | <p>The number of elements in the cell array must be the same as the number of arguments that the entry-point MATLAB function expects.</p> <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {ones(10,1), 5}</code></li> </ul> <p><code>dspunfold</code> extracts the type (size, class, and complexity) information from the elements in the arguments cell array.</p> <p><code>fcn</code> is the entry-point MATLAB function.</p> <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {coder.typeof(ones(10,1)), coder.typeof(5)}</code></li> </ul> <p><code>coder.typeof</code> is used to specify the types of the <code>fcn</code> arguments.</p> <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {coder.Constant(ones(10,1)), coder.Constant(5)}</code></li> <li>• <code>dspunfold fcn -args {}</code></li> </ul> <p>By default, <code>arguments</code> is <code>{}</code>. An empty cell array <code>{}</code> indicates that <code>fcn</code> accepts no input arguments.</p> |

| Option    | Values           | Description  | Examples   |
|-----------|------------------|--|--|
| -o output | Character vector | Name of the output multi-threaded MEX file, specified as a character vector. If no output name is specified, the name of the generated multi-threaded MEX file is inherited from the input MATLAB function with an '_mt' suffix. <code>dspunfold</code> also adds a platform-specific extension to this name. In addition, <code>dspunfold</code> generates a single-threaded MEX file with an '_st' suffix, and a test bench file with an '_analyzer' suffix. | <ul style="list-style-type: none"><li>• No output name specified<br/><code>dspunfold fcn</code><br/>Files generated: <code>fcn_mt.mexw64</code>, <code>fcn_st.mexw64</code>, <code>fcn_analyzer.p</code></li><li>• output name specified<br/><code>dspunfold fcn -o foo</code><br/>Files generated: <code>foo.mexw64</code>, <code>foo_st.mexw64</code>, <code>foo_analyzer.p</code></li></ul> |

| Option         | Values   | Description  | Examples   |
|----------------|--|--|--|
| -s statelength | Scalar integer greater than or equal to zero<br><br>auto | <p>State length of the algorithm in the entry-point MATLAB function, specified as a scalar integer greater than or equal to zero, or auto. By default, the <code>statelength</code> is zero frames, indicating that the algorithm is stateless.</p> <p>If at least one entry of <code>frameinputs</code> is true, <code>statelength</code> is considered in samples.</p> <p>For information on frames and samples, see “Sample- and Frame-Based Concepts”</p> <p>-s auto triggers automatic state length detection. In this mode, you must provide numeric inputs to the <code>arguments</code> cell array. These inputs detect the state length of the algorithm. You can input <code>coder.Constant</code> but not <code>coder.typeof</code>. When automatic state length detection is invoked, it is recommended that you provide random inputs to the <code>arguments</code> array. See “Automatic State Length Detection” on page 5-365</p> | <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [false, false, false]</code><br/><br/>State length is three frames.</li> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]</code><br/><br/>State length is three samples. State length is considered in samples, because at least one entry of the -f option is true.</li> <li>• <code>dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s auto</code><br/><br/>Automatic state length detection is invoked.</li> <li>• <code>dspunfold fcn -args {coder.typeof (randn(10,1)), coder.typeof(randn(10,1)), coder.typeof(randn(10,1))} -s auto</code> generates this error message: The input argument 1 is of type <code>coder.PrimitiveType</code> which is not supported when using -s auto</li> </ul> |

| Option                | Values   | Description   | Examples  |
|-----------------------|--|---|---|
| <p>-f frameinputs</p> | <p>scalar logical<br/>vector of logical values</p> | <p>Frame status of input arguments for the entry-point MATLAB function, specified as one of true or false.</p> <ul style="list-style-type: none"> <li>• true — Input is in frames and can be subdivided into samples without changing the system behavior.</li> <li>• false — Input cannot be subdivided into samples without changing the system behavior. For example, you cannot subdivide the coefficients of a filter without changing the characteristics of the filter.</li> </ul> <p>By default, frameinputs is false.</p> <p>frameinputs set to a scalar logical value sets the frame status of all the inputs simultaneously.</p> <p>To specify stateLength in samples, set at least one entry of frameinputs to true.</p> <p>If frameinputs is not specified, the unit of stateLength is frames.</p> | <ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f true</li> </ul> <p>All the inputs are marked as frames. State length is three samples.</p> <ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3 -f [true, false, false]</li> </ul> <p>State length is three samples.</p> <ul style="list-style-type: none"> <li>• dspunfold fcn -args {randn(10,1), randn(10,1), randn(10,1)} -s 3</li> </ul> <p>The default value of frameinputs is false. State length is three frames.</p> |

| Option        | Values           | Description   | Examples  |
|---------------|------------------|---|---|
| -r repetition | Positive integer | Repetition factor used to generate the multi-threaded MEX file, specified as a positive integer. The default value of <code>repetition</code> is 1. See “Repetition Factor” on page 5-366.                                  | <code>dspunfold fcn -args {randn(10,2), randn(20,2), randn(30,3)} -r 2</code>   |
| -t threads    | Positive integer | Number of threads used by the multi-threaded MEX file, specified as a positive integer. The default value of <code>threads</code> is the number of physical CPU cores present on your machine. See “Threads” on page 5-366. | <code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -t 4</code>   |
| -v verbose    | Scalar logical   | Option to show verbose output during code generation, specified as <code>true</code> or <code>false</code> . The default is <code>true</code> .   | <ul style="list-style-type: none"> <li><code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v true</code></li> <li><code>dspunfold fcn -args {randn(10,1), randn(20,2), randn(30,3)} -v false</code></li> </ul> |

### file — entry-point MATLAB function

character vector

Entry-point MATLAB function from which `dspunfold` generates the multi-threaded MEX file. The function must support code generation.

Example: `dspunfold fcn -args {randn(10,1), randn(10,2), randn(20,1)}`

`fcn` is the entry-point MATLAB function and `{randn(10,1), randn(10,2), randn(20,1)}` are its input arguments.

## Output Files

When you invoke `dspunfold` on an entry-point MATLAB function, `dspunfold` generates the following files.

| File                                      | Value       | Description   | Examples  |
|---|-------------|---|---|
| Multi-threaded MEX file                   | MEX file    | Multi-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the output name. If no output name is specified, the name of this file is inherited from the MATLAB function with an '_mt' suffix. A platform-specific extension is also added to the name.   | <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -o foo</code> generates <code>foo.mexw64</code></li> <li>• <code>dspunfold fcn</code> generates <code>fcn_mt.mexw64</code></li> </ul>    |
| Help file for the multi-threaded MEX file | MATLAB file | <p>MATLAB help file for the multi-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type <code>help &lt;MEX filename&gt;</code> at the MATLAB command prompt.</p> <p>This help file displays information on how to invoke the MEX file, its syntax, latency, and types (size, class, and complexity) of the inputs to the MEX file. In addition, the help file documents the parameters used by <code>dspunfold</code> — <code>Threads</code>, <code>Repetition</code>, and <code>State length</code>. This information is useful when you are invoking the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.</p> | <ul style="list-style-type: none"> <li>• <code>help foo</code></li> <li>• <code>help fcn_mt</code></li> </ul>   |
| Single-threaded MEX file                  | MEX file    | Single-threaded MEX file generated from the entry-point MATLAB function. The MEX file inherits the output name with an '_st' suffix. If no output name is specified, the name of this file is inherited from the MATLAB function with an '_st' suffix. A platform-specific extension is also added to the name. Use this file as a benchmark to compare against the speed of the multi-threaded MEX file.   | <ul style="list-style-type: none"> <li>• <code>dspunfold fcn -o foo</code> generates <code>foo_st.mexw64</code></li> <li>• <code>dspunfold fcn</code> generates <code>fcn_st.mexw64</code></li> </ul> |

| File                                       | Value       | Description  | Examples  |
|--|-------------|--|---|
| Help file for the single-threaded MEX file | MATLAB file | <p>MATLAB help file for the single-threaded MEX file. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type <code>help &lt;MEX filename&gt;</code> at the MATLAB command prompt.</p> <p>The help file displays information on how to invoke the MEX file, its syntax, and types (size, class, and complexity) of the inputs to the MEX file. The syntax to invoke the MEX file should be the same as the syntax shown in the help file.</p> | <ul style="list-style-type: none"><li>• <code>help foo_st</code></li><li>• <code>help fcn_st</code></li></ul> |

| File                              | Value        | Description  | Examples  |
|-----------------------------------|--------------|--|---|
| Self-diagnostic analyzer function | P-coded file | <p><code>report = function_analyzer (input 1, input 2, ... input n)</code> measures the difference in speed between the multi-threaded MEX file and the single-threaded MEX file. This file verifies that the output values match.</p> <p><code>report = function_analyzer('latency')</code> reports the latency of the multi-threaded MEX file introduced by unfolding.</p> <p><code>report</code> contains the following fields:</p> <ul style="list-style-type: none"> <li>• Latency — The value of the latency (in frames)</li> <li>• Speedup — The speedup difference between the multi-threaded MEX file and single-threaded MEX file. If you specified <code>latency</code> option, the value of this field is empty <code>[]</code>.</li> <li>• Pass — Logical value that shows if the outputs match between the generated multi-threaded MEX file and the single-threaded MEX file. If you specified <code>latency</code> option, the value of this field is empty <code>[]</code>.</li> </ul> <p>The first dimension of the analyzer inputs must be a multiple of the first dimension of the corresponding inputs, given to the <code>-args</code> option. The other dimensions must match exactly.</p> <p>The analyzer inherits the <code>output</code> name with an <code>'_analyzer'</code> suffix. If no <code>output</code> name is specified, the name of this file is inherited from the MATLAB function with an <code>'_analyzer'</code> suffix.</p> | <ul style="list-style-type: none"> <li>• Multiple frames with different values are specified along the first dimension</li> </ul> <p>Example 1: <code>report = foo_analyzer(randn(10*2,1), randn(20*2,2), randn(30*3,3))</code></p> <p>Example 2: <code>report = foo_analyzer([randn(10,1); randn(10,1)], [randn(20,1); randn(20,1)], [randn(30,1); randn(30,1)]; randn(30,1))</code></p> <ul style="list-style-type: none"> <li>• <code>report = foo_analyzer('latency')</code></li> </ul> |

| File  | Value       | Description   | Examples                       |
|---|-------------|---|--------------------------------|
| Help file for the self-diagnostic analyzer function | MATLAB file | <p>Help file for the self-diagnostic analyzer function. The help file has the same name as the MEX file, but with an '.m' extension. To invoke the help file, type <code>help &lt;function_analyzer&gt;</code> in MATLAB.</p> <p>The help file for the self-diagnostic analyzer function displays information on how to invoke the analyzer function, its syntax, and types (size, class, and complexity) of the inputs to the analyzer function. The syntax to invoke the analyzer function should be the same as the syntax shown in the help file.</p> | <code>help foo_analyzer</code> |

## Limitations

### General Limitations:

- On Windows and Linux, you must use a compiler that supports the Open Multiprocessing (OpenMP) application interface. See [https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/).
- If you have a macOS with an Xcode version 12.0 or later, using the `dspunfold` function is not supported.
- If the input MATLAB function has runtime errors, the errors are not caught when you run the multi-threaded MEX file. Before you use the `dspunfold` function, call `codegen` on the MATLAB function and make sure that the MEX file is generated successfully.
- If the generated code uses a large amount of memory to store the local variables, around 4 MB on Windows platform, the generated multi-threaded MEX file can have unexpected behavior. This limit varies with each platform. As a workaround, reduce the size of the input signals or restructure the MATLAB function to use less local memory.
- `dspunfold` does not support:
  - `varargin` and `varargout` inside the MATLAB function
  - Variable-size inputs and outputs
  - Input signals with an arbitrary frame length to System objects that use the `DecimationFactor` property. The input signal is considered to have an arbitrary frame length when its frame length is not a multiple of the decimation factor. When this is the case, the output of the object in the generated code is a variable-size signal, and `dspunfold` does not support variable-size output signals.

In the case of the `dsp.FarrowRateConverter` object, you can determine the decimation factor using the `getRateChangeFactors` function.

- P-coded entry-point MATLAB functions

- Cell arrays as inputs and outputs

### Analyzer Limitations:

The following limitations apply to the analyzer function generated by the `dspunfold` function. For more information on the analyzer function, see 'Self-Diagnostic Analyzer' in the 'More About' section of `dspunfold`.

- If multiple frames of the analyzer input are identical, the analyzer might throw false positive pass results. It is recommended that you provide at least two different frames for each input of the analyzer.
- If the algorithm in the entry-point MATLAB function chooses its state length based on the input values, the analyzer might provide different *pass* results for different input values. For an example, see the `FIR_Mean` function in "Why Does the Analyzer Choose the Wrong State Length?".
- If the input to the entry-point MATLAB function does affect the output immediately, the analyzer might throw false positive *pass* results. For an example, see the `Input_Output` function in "Why Does the Analyzer Choose a Zero State Length?".
- If the output results of the multi-threaded MEX file and single-threaded MEX file match statistically but do not match numerically, the analyzer does not pass. Consider the `FilterNoise` function that follows, which filters a random noise signal with an FIR filter. The function calls `randn` from within itself to generate random noise. Hence, the output results of the `FilterNoise` function match statistically but not match numerically.

```
function Output = FilterNoise(x)

persistent FIRFilter
if isempty(FIRFilter)
    FIRFilter = dsp.FIRFilter('Numerator',fir1(12,0.4));
end
Output = FIRFilter(x+randn(1000,1));

end
```

When you run the automatic state length detection tool run on `FilterNoise`, the tool detects an infinite state length. Because the tool cannot find a numerical match for a finite state length, it chooses an infinite state length.

```
dspunfold FilterNoise -args {randn(1000,1)} -s auto
```

```
Analyzing input MATLAB function FilterNoise
Creating single-threaded MEX file FilterNoise_st.mexw64
Searching for minimal state length (this might take a while)
Checking stateless ... Insufficient
Checking 1 ... Insufficient
Checking Infinite ... Sufficient
Checking 2 ... Insufficient
Minimal state length is Inf
Creating multi-threaded MEX file FilterNoise_mt.mexw64
Warning: The multi-threading was disabled due to performance considerations.
This happens when the state length is greater than or
equal to (Threads-1)*Repetition frames (3 frames in this case).
> In coder.internal.warning (line 8)
   In unfoldingEngine/BuildParallelSolution (line 25)
   In unfoldingEngine/generate (line 207)
   In dspunfold (line 234)
Creating analyzer file FilterNoise_analyzer
```

The algorithm does not need an infinite state. The state length of the FIR filter, hence the algorithm is 12.

Call `dspunfold` with state length set to 12.

```
dspunfold FilterNoise -args {randn(1000,1)} -s 12 -f true
```

```
Analyzing input MATLAB function FilterNoise
Creating single-threaded MEX file FilterNoise_st.mexw64
Creating multi-threaded MEX file FilterNoise_mt.mexw64
Creating analyzer file FilterNoise_analyzer
```

Run the analyzer function.

```
FilterNoise_analyzer(randn(1000*4,1))
```

```
Analyzing multi-threaded MEX file FilterNoise_mt.mexw64 ...
Latency = 8 frames
Speedup = 0.5x
Warning: The output results of the multi-threaded MEX file FilterNoise_mt.mexw64 do not
match the output results of the single-threaded MEX file FilterNoise_st.mexw64. Check that
you provided the correct state length value to the dspunfold function when you generated the
multi-threaded MEX file FilterNoise_mt.mexw64. For best practices and possible solutions to
this problem, see the 'Tips' section in the dspunfold function reference page.
> In coder.internal.warning (line 8)
   In FilterNoise_analyzer
   ans =
       Latency: 8
       Speedup: 0.4970
       Pass: 0
```

The analyzer looks for a numerical match and fails the verification, even though the generated multi-threaded MEX file is valid.

### Speedup Limitations:

- If the entry-point MATLAB function contains code with low complexity, MATLAB overhead or multi-threaded MEX overhead overshadow any performance gains. In such cases, do not use `dspunfold`.
- If the number of operations in the input MATLAB function is small compared to the size of the input or output data, the multi-threaded MEX file does not provide any speedup gain. Sometimes, it can result in a speedup loss, even if the repetition value is increased. In such cases, do not use `dspunfold`.

## More About

### State Length

State length of the algorithm.

Most of the time, the state length used by `dspunfold` matches the state length of the algorithm in the entry-point MATLAB function. If the algorithm is simple, state length is easy to determine. For example, the state length of an FIR filter is the number of taps in the filter - 1. In some scenarios, to optimize speedup, `dspunfold` chooses a state length that is different from the algorithm state length or the state length specified using the `-s` option. For example, when the state length is greater than  $(threads - 1) \times repetition$  frames, `dspunfold` considers the state length to be infinite. Also, multi-threading gets disabled due to performance considerations.

### Automatic State Length Detection

You can automatically detect the minimum state length for which the outputs of the multi-threaded MEX and single-threaded MEX match.

In complex algorithms, it is not easy to determine the state length analytically. In such scenarios, use the analyzer to compute the state length. When you set `-s` to `auto`, `dspunfold` invokes the analyzer. The analyzer computes the outputs for different state lengths and detects the minimum state length for which the outputs of the multi-threaded MEX file and single-threaded MEX file match. The analyzer uses the numeric value of the inputs given to `-args`. To detect the most efficient state length, provide random inputs to `-args`. In this mode, you cannot input `coder.typeof` to arguments. Due to the extra analysis this tool requires, the time to generate the MEX file increases.

When you use automatic state length detection on an algorithm with code paths that depend on the input values, use inputs that choose the code path with the longest state length. Also, the inputs must have an immediate effect on the output. If inputs choose a code path that triggers runtime errors, automatic state length detection stops, and so does the analyzer. Make sure that the MATLAB function supports code generation and does not have run-time errors for the inputs under test. Before invoking `dspunfold`, call `codegen` on the entry-point MATLAB function. In addition, simulate the entry-point MATLAB function to make sure it has no run-time errors.

### Threads

The `-t` option specifies the number of threads used by the multi-threaded MEX file.

Increasing this value can improve the multi-threaded MEX speedup, at the cost of a larger latency. Decreasing this value reduces the latency and potentially decreases the multi-threaded MEX speedup.

### Repetition Factor

*Repetition factor* is the number of consecutive frames processed by each thread in one processing step.

Increasing this value reduces the overhead per frame of data, potentially improving the speedup at the cost of larger latency. Decreasing this value reduces the latency, and potentially decreases the multi-threaded MEX speedup.

### Self-Diagnostic Analyzer

The self-diagnostic analyzer function is a help tool that is generated with the MEX file. This function measures the speedup gain of the multi-threaded MEX file compared to the single-threaded MEX file. The analyzer function also verifies that the outputs of the multi-threaded MEX file and single-threaded MEX file match.

If you specify an incorrect state length value, the outputs usually do not match. To check for the numerical match between the multi-threaded MEX file and the single-threaded MEX file, provide at least two different frames for each input argument of the analyzer. The frames are appended along the first dimension. The analyzer alternates between these frames while verifying that the outputs match. Failure to provide multiple frames for each input can decrease the effectiveness of the analyzer and can lead to false positive verification results. In other words, the analyzer might produce `pass = 1` results even when an incorrect state length value is specified. The analyzer alternates through a maximum of  $3 \times (2 \times \text{threads} \times \text{repetition})$  frames. If your algorithm requires more than  $3 \times (2 \times \text{threads} \times \text{repetition})$  frames to verify the results, then the analyzer cannot verify accurately.

## Tips

### General

- Do not display plots, scopes, or execute other user interface operations from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior.
- Do not use `coder.extrinsic` inside the input MATLAB function. The generated MEX file can have unexpected behavior.

When the state length is less than or equal to  $(threads - 1) \times repetition$  frames:

- Do not use a random number inside the MATLAB function. The outputs of the single-threaded MEX file and the multi-threaded MEX file might not match. Also, the outputs of the consecutive executions of the multi-threaded MEX file might not match. The analyzer might not pass the numerical match verification.

It is recommended that you generate the random number outside the entry-point MATLAB function and pass it as an argument to the function.

- Do not use global or persistent variables anywhere other than in the entry-point MATLAB function. For example, avoid using persistent variables in subfunctions. The generated MEX file can produce inaccurate results. In general, global variables are not recommended.
- Do not access I/O resources from within the multi-threaded MEX file. The generated MEX file can have unexpected behavior. These resources include file writers and readers, UDP sockets, and audio players and recorders.
- Do not use functions with interactive inputs (for example, the keyboard) inside the multi-threaded MEX file. The generated MEX file can have unexpected behavior.

### Workflow

- To generate a valid multi-threaded MEX file with the required speedup and latency, follow the “Workflow for Generating a Multithreaded MEX File using dspunfold”.
- Before using `dspunfold`, call `codegen` on the entry-point MATLAB function and make sure that the function generates a MEX file successfully.
- After generating the multi-threaded MEX file using `dspunfold`, run the analyzer function. Make sure that the analyzer function passes. The exception to this rule is when the algorithm produces results that match statistically, but not numerically. In this exception, the analyzer function does not pass, even though the `dspunfold` function generates a valid multi-threaded MEX file. See 'Analyzer Limitations' for an example.
- For help on using the MEX file and analyzer, at the MATLAB command prompt, enter `help <mexfile name>` and `help <analyzer name>`.

### State Length

- If you choose a state length that is greater than or equal to the value of the exact state length, the analyzer passes. If the analyzer fails, increase the state length, regenerate the MEX file, and verify again.
- If the state length is greater than 0, the inputs marked as frames (through `-f` option) must all have the same dimensions.
- When generating the MEX file and running the analyzer, use inputs that invoke the same state length.

### Automatic State Length Detection

When you set `-s` to `auto`:

- If the algorithm in the entry-point MATLAB function chooses a code path based on the input values, use inputs that choose the code path with the longest state length.
- Provide random inputs to `-args`.
- Choose inputs that have an immediate effect on the output. See “Why Does the Analyzer Choose a Zero State Length?”.

### Analyzer

- Make sure the outputs of the multi-threaded MEX file and the single-threaded MEX file do not contain `NaN` or an `Inf`. The analyzer cannot do numeric checks and returns `pass` as `false`. The automatic state length detection tool detects infinite state length and displays a warning

---

**Warning** The output results of the multi-threaded MEX file do not match the output results of the single-threaded MEX file even for Infinite state length. A possible reason is that input MATLAB function generates different output results between consecutive runs even for the same input values.

---

- Provide multiple frames with different values for each input of the analyzer. To improve the analyzer effectiveness, append successive frames along the first dimension.
- Provide inputs to the analyzer that lead to efficient code coverage.

### Speedup

- To improve the speedup of the multi-threaded MEX file, specify the exact state length in samples. You can specify the state length in samples by setting at least one entry of `frameinputs` to `true`. The use of samples reduces the overhead and increases the speedup.
- To increase the speedup at the cost of larger latency, you can:
  - Increase the repetition factor. Use the `-r` option.
  - Increase the number of threads. Use the `-t` option.
- For each input that can be divided into samples without altering the algorithm behavior, set frame status to `true` using the `-f` option. The input is then considered in samples, which can increase the speedup of the generated multi-threaded MEX file.

## Algorithms

The multi-threaded MEX file buffers multiple-input signal frames into a buffer of  $2 \times \text{threads} \times \text{repetition}$  frames, where *threads* is the number of threads, and *repetition* is the repetition factor. The MEX file processes these frames simultaneously, using multiple cores. This process introduces some deterministic latency, where  $\text{latency} = 2 \times \text{threads} \times \text{repetition}$ . Latency is traded off with the speedup you might gain by increasing the number of threads or the repetition factor.

## ellip

Elliptic filter using specification object

### Syntax

```
ellipFilter = ellip(designSpecs, SystemObject=true)
ellipFilter = ellip(designSpecs, designoption=value, ... SystemObject=true)
ellipFilter = design(designSpecs, 'ellip', SystemObject=true)
```

### Description

`ellipFilter = ellip(designSpecs, SystemObject=true)` designs an elliptical IIR digital filter using the specifications in the object `designSpecs`.

Depending on the filter specification object `designSpecs`, the `ellip` design method might not be valid. Use `designmethods` with the filter specification object to determine if an elliptic IIR filter design is possible.

```
designmethods(designSpecs, SystemObject=true)
```

`ellipFilter = ellip(designSpecs, designoption=value, ... SystemObject=true)` returns an elliptic IIR digital filter with one or more specified designed options and the corresponding values.

To view a list of available design options, run the `designoptions` function on the specification object. The function also lists the default design options the filter uses.

```
designoptions(designSpecs, 'ellip')
```

`ellipFilter = design(designSpecs, 'ellip', SystemObject=true)` is an alternative syntax for designing the elliptic IIR digital filter.

For complete help about using the `ellip` design method for a specification object, `designSpecs`, enter the following at the MATLAB command prompt.

```
help(designSpecs, 'ellip')
```

## Examples

### Design a Bandpass Filter

Design an elliptic digital filter with bandpass frequency response. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

Construct the default bandpass filter specification object using `fdesign.bandpass`.

```
designSpecs = fdesign.bandpass

designSpecs =
    bandpass with properties:
        Response: 'Bandpass'
        Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'
        Description: {7x1 cell}
        NormalizedFrequency: 1
        Fstop1: 0.3500
        Fpass1: 0.4500
        Fpass2: 0.5500
        Fstop2: 0.6500
        Astop1: 60
        Apass: 1
        Astop2: 60
```

Determine the available design methods using the `designmethods` function. To design an elliptic digital filter, pick `ellip`.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.bandpass` (Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2):

```
butter
cheby1
cheby2
ellip
equiripple
kaiserwin
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'ellip',SystemObject=true)
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband' 'both'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'both'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

Use the `design` function to design the filter. Pass `'ellip'` and the specifications given by the variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'both'` to ensure the performance of the filter in both the passband and the stopband regions.

```
bandpassEllip = design(designSpecs,'ellip',matchexactly='both',...
    SystemObject=true)
```

```
bandpassEllip =
    dsp.SOSFilter with properties:
```

```

Structure: 'Direct form II'
CoefficientSource: 'Property'
Numerator: [4x3 double]
Denominator: [4x3 double]
HasScaleValues: true
ScaleValues: [0.4705 0.4705 0.0936 0.0936 1]

```

Show all properties

Use `fvtool` to view the frequency response of the designed filter.

```
fvtool(bandpassEllip)
```

### Design Lowpass Filter

Design an elliptic digital filter with lowpass frequency response.

Construct a lowpass filter specification object using `fdesign.lowpass`. Specify the filter order, passband edge frequency, stopband edge frequency, and the passband ripple of the filter.

```
designSpecs = fdesign.lowpass('n,fp,fst,ap',6,20,25,.8,80);
```

Determine the available design methods. To design an elliptic filter, pick `ellip`.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.lowpass (N,Fp,Fst,Ap)`:

```
ellip
equiripple
```

Use the `design` function to design the filter. Pass `'ellip'` and the specifications given by the variable `designSpecs`, as input arguments.

```
ellipLowpass = design(designSpecs,'ellip',SystemObject=true)
```

```
ellipLowpass =
  dsp.SOSFilter with properties:
    Structure: 'Direct form II'
    CoefficientSource: 'Property'
    Numerator: [3x3 double]
    Denominator: [3x3 double]
    HasScaleValues: true
    ScaleValues: [0.0968 0.4116 0.6792 1]
```

Show all properties

Use `fvtool` to visualize the lowpass frequency response.

```
fvtool(ellipLowpass)
```

## Input Arguments

### **designSpecs** — Filter specification object

object

Filter specification object, specified as one of the following:

- `fdesign.bandpass`
- `fdesign.bandstop`
- `fdesign.decimator`
- `fdesign.halfband`
- `fdesign.highpass`
- `fdesign.hilbert`
- `fdesign.interpolator`
- `fdesign.lowpass`
- `fdesign.nyquist`

## Output Arguments

### **ellipFilter** — Elliptical digital filter

System object

Elliptical digital filter, returned as a filter System object. The System object and the values of its properties depend on the input `designSpecs` object and the other design options specified to the function.

## Version History

**Introduced in R2011a**

### **R2022b: Designs `dsp.SOSFilter` object instead of `dsp.BiquadFilter` object**

*Behavior changed in R2022b*

The `ellip` design method now generates a `dsp.SOSFilter` object instead of the `dsp.BiquadFilter` object.

Initialize the default `fdesign.lowpass` filter specification object. Use the `design` function with the `SystemObject=true` flag to design a `dsp.SOSFilter` filter object.

```
designSpecs = fdesign.lowpass;  
filtObj = design(designSpecs, 'ellip', SystemObject=true)
```

```
filtObj =
```

```
    dsp.SOSFilter with properties:
```

```
        Structure: 'Direct form II'  
    CoefficientSource: 'Property'  
        Numerator: [3×3 double]  
        Denominator: [3×3 double]
```

```
HasScaleValues: true
ScaleValues: [0.8629 2.0523 0.0127 1]
```

Show all properties

To design a `dsp.BiquadFilter` object instead of the `dsp.SOSFilter` object, you can use the `UseLegacyBiquadFilter` flag and set it to `true`.

```
filtObj = design(designSpecs, 'ellip', SystemObject=true, ...
UseLegacyBiquadFilter=true)
```

```
filtObj =
```

`dsp.BiquadFilter` with properties:

```
Structure: 'Direct form II'
SOSMatrixSource: 'Property'
SOSMatrix: [3x6 double]
ScaleValues: [4x1 double]
InitialConditions: 0
OptimizeUnityScaleValues: true
```

Show all properties

## euclidfactors

Euclid factors for multirate filter

### Compatibility

`mfilt` will be removed in a future release. See `dsp.CICDecimator`, `dsp.CICInterpolator`, `dsp.FIRDecimator`, `dsp.FIRInterpolator`, `dsp.FilterCascade`, `dsp.FarrowRateConverter`, `dsp.FIRRateConverter`, `dsp.IIRHalfbandDecimator`, or `dsp.IIRHalfbandInterpolator` instead.

### Syntax

```
[lo,mo] = euclidfactors(hm)
```

### Description

`[lo,mo] = euclidfactors(hm)` returns integer factors `lo` and `mo` such that  $(lo*L)-(mo*M) = -1$ . `L` and `M` are relatively prime and represent the interpolation and decimation factors of the multirate filter `hm`.

`euclidfactors` works with the multirate filter `mfilt.firsc`. You cannot return `lo` and `mo` for decimators or interpolators.

### Examples

Use an FIR fractional decimator, with `L = 5` and `M = 7`, to show what `euclidfactors` does.

Indeed,  $(lo*L)-(mo*M) = (4*5)-(3*7) = -1$ .

# equiripple

Equiripple single-rate FIR filter from specification object

## Syntax

```
equiFilt = design(d,'equiripple','SystemObject',true)
equiFilt = design(d,'equiripple',designoption,value,...,'SystemObject',true)
```

## Description

`equiFilt = design(d,'equiripple','SystemObject',true)` designs an equiripple FIR digital filter using the specifications supplied in the object `d`. Equiripple filter designs minimize the maximum ripple in the passbands and stopbands.

When you use `equiripple` with Nyquist filter specification objects, you might encounter design cases where the filter design does not converge. Convergence errors occur mostly at large filter orders, or small transition widths, or large stopband attenuations. These specifications, alone or combined, can cause design failures. For more information, refer to `fdesign.nyquist` in the online Help system.

`equiFilt = design(d,'equiripple',designoption,value,...,'SystemObject',true)` returns an equiripple FIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `equiripple`, refer to the command line help system. For example, to get specific information about using `equiripple` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'equiripple')
```

## Examples

### Design a Single-Rate Equiripple Filter

Design a single-rate equiripple filter from a halfband filter specification object. Notice the help command used to learn about the options for the specification object and method.

```
d = fdesign.halfband('tw,ast',0.1,80);
designmethods(d,'Systemobject',true)
```

Design Methods that support System objects for class `fdesign.halfband` (TW,Ast):

```
butter
ellip
```

```
iirlinphase
equiripple
kaiserwin
```

```
help(d,'equiripple')
```

DESIGN Design a Equiripple FIR filter.

HD = DESIGN(D, 'equiripple') designs a Equiripple filter specified by the FDESIGN object D, and returns the DFILT/MFILT object HD.

HD = DESIGN(D, ..., 'SystemObject', true) implements the filter, HD, using a System object instead of a DFILT/MFILT object.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the structure STRUCTURE. STRUCTURE is 'dffir' by default and can be any of the following:

```
'dffir'
'dffirt'
'dfsymfir'
'fftfir'
```

Some of the listed structures may not be supported by System object filters. Type `validstructures(D, 'equiripple', 'SystemObject', true)` to get a list of structures supported by System objects.

HD = DESIGN(..., 'MinPhase', MPHASE) designs a minimum-phase filter when MPHASE is TRUE. MPHASE is FALSE by default.

HD = DESIGN(..., 'StopbandShape', SHAPE) designs a filter whose stopband has the shape defined by SHAPE. SHAPE can be 'flat', '1/f', or 'linear'. SHAPE is 'flat' by default.

HD = DESIGN(..., 'StopbandDecay', DECAY) specifies the decay to use when 'StopbandShape' is not set to 'flat'. When the shape is '1/f' this specifies the power that 1/f is raised. When shaped is 'linear' this specifies the slope of the stopband in dB/rad/s.

% Example #1 - Design a halfband lowpass equiripple filter with increased stopband attenuation

```
TW = 0.1; % Transition Width
Ast = 80; % Stopband Attenuation (dB)
h = fdesign.halfband('Type','Lowpass','TW,Ast',TW,Ast);
Hd = design(h, 'equiripple', 'StopbandShape','linear','StopbandDecay',50);
fvtool(Hd)
```

```
designopts(d,'equiripple')
```

```
ans = struct with fields:
  FilterStructure: 'dffir'
  MinPhase: 0
  StopbandShape: 'flat'
  StopbandDecay: 0
  SystemObject: 0
```

```
equiFilt = design(d,'equiripple','stopbandshape','flat','SystemObject',true);
fvtool(equiFilt);
```

The `fvtool` shows the equiripple nature of the filter.

### Design an Equiripple FIR Filter with a Direct-Form Transposed Structure

This example designs an equiripple filter with a direct-form transposed structure by specifying the 'FilterStructure' argument. To set the design options for the filter, use the `designopts` method and options object `opts`.

```
d = fdesign.lowpass('fp,fst,ap,ast');
opts = designopts(d,'equiripple');
opts.FilterStructure='dffirt';
opts.DensityFactor=20
```

```
opts = struct with fields:
  FilterStructure: 'dffirt'
  DensityFactor: 20
  MinPhase: 0
  MaxPhase: 0
  MinOrder: 'any'
  StopbandShape: 'flat'
  StopbandDecay: 0
  UniformGrid: 1
  SystemObject: 0
```

```
firFilt = design(d,'equiripple','SystemObject',true,opts)
```

```
firFilt =
```

```
  dsp.FIRFilter with properties:
```

```
    Structure: 'Direct form transposed'
```

```
    NumeratorSource: 'Property'
```

```
    Numerator: [-0.0024 -0.0021 0.0068 0.0167 0.0111 -0.0062 -0.0084 0.0093 0.0130 -0.0101]
```

```
    InitialConditions: 0
```

```
Show all properties
```

```
fvtool(firFilt);
```

The MaxPhase design option for equiripple FIR filters is currently only available for lowpass, highpass, bandpass, and bandstop filters.

### Functions

fdesign.nyquist | firls | kaiserwin

## fcfwrite

Write file containing filter coefficients

### Syntax

```
fcfwrite(h)
fcfwrite(h,filename)
fcfwrite(...,'fmt')
```

### Description

`fcfwrite(h)` writes a filter coefficient ASCII file in a folder you choose, or your current MATLAB working folder. `h` can be a single filter object or a vector of filter objects. On execution, `fcfwrite` opens the **Export Filter Coefficients to .FCF File** dialog box to let you assign a file name for the output file. You can choose the destination folder within this dialog as well.

The default file name is `untitled.fcf`. When you have DSP System Toolbox software, you can use `fcfwrite(h)` to write filter coefficient files for multirate filters, adaptive filters, and discrete-time filters.

`fcfwrite(h,filename)` writes the filter coefficients and general information to a text file called `filename` in your present MATLAB working folder and opens the file in the MATLAB editor for you to review or modify.

If you do not include a file extension in `filename`, `fcfwrite` adds the extension `fcf` to `filename`.

`fcfwrite(...,'fmt')` writes the filter coefficients in the format specified by the input argument `fmt`. Valid `fmt` values are `hex` for hexadecimal, `dec` for decimal, or `bin` for binary representation of the filter coefficients.

### Examples

To demonstrate `fcfwrite`, create a fixed-point IIR filter at the command line, and then write the filter coefficients to a file named `iirfilter.fcf`.

```
d=fdesign.lowpass;
hd=design(d,'butter');
set(hd,'arithmetic','fixed');
fcfwrite(hd,'iirfilter.fcf');
```

Here is the output from `fcfwrite` as it appears in the MATLAB editor. Not shown here is the filename — `iirfilter.fcf` as specified and some comments at the top of the file.

```
%

# filterDesigner

Open Filter Designer app

## Syntax

```
filterDesigner
```

## Description

`filterDesigner` opens the Filter Designer app. Use this tool to:

- Design filters
- Quantize filters (with DSP System Toolbox software installed)
- Analyze filters
- Modify existing filter designs
- Create multirate filters (with DSP System Toolbox software installed)
- Realize Simulink models of quantized, direct-form, FIR filters (with DSP System Toolbox software installed)
- Perform digital frequency transformations of filters (with DSP System Toolbox software installed)

Refer to “Use Filter Designer with DSP System Toolbox Software” for more information about using the analysis, design, and quantization features of filter designer. For general information about using filter designer, refer to “Using Filter Designer”.

When you open the filter designer app and you have DSP System Toolbox software installed, filter designer incorporates features that are added by DSP System Toolbox software. With DSP System Toolbox software installed, filter designer lets you design and analyze quantized filters, as well as convert quantized filters to various filter structures, transform filters, design multirate filters, and realize models of filters.

Use the buttons on the sidebar to configure the design area to use various tools in the filter designer app.

**Set Quantization Parameters** — provides access to the properties of the quantizers that compose a quantized filter. When you click **Set Quantization Parameters**, you see filter designer displaying the quantization options at the bottom of the dialog box (the design area), as shown in the figure.

**Transform Filter** — clicking this button opens the *Frequency Transformations* pane so you can use digital frequency transformations to change the magnitude response of your filter.

**Create a multirate filter** — clicking this button switches filter designer to multirate filter design mode so you can design interpolators, decimators, and fractional rate change filters.

**Realize Model** — starting from your quantized, direct-form, FIR filter, clicking this button creates a Simulink model of your filter structure in new model window.

Other options in the menu bar let you convert the filter structure to a new structure, change the order of second-order sections in a filter, or change the scaling applied to the filter, among many possibilities.

## Limitations

- The **Input/Output** section in the **Set quantization parameters** panel of the filterDesigner app supports only signed data types.
- The word length value specified by the **Input word length** and the **Output word length** settings in the **Input/Output** section of the **Set quantization parameters** panel must be 2 or more to support signed numeric types.

## Examples

- “Use Filter Designer with DSP System Toolbox Software”

# fdesign

Filter design specification object

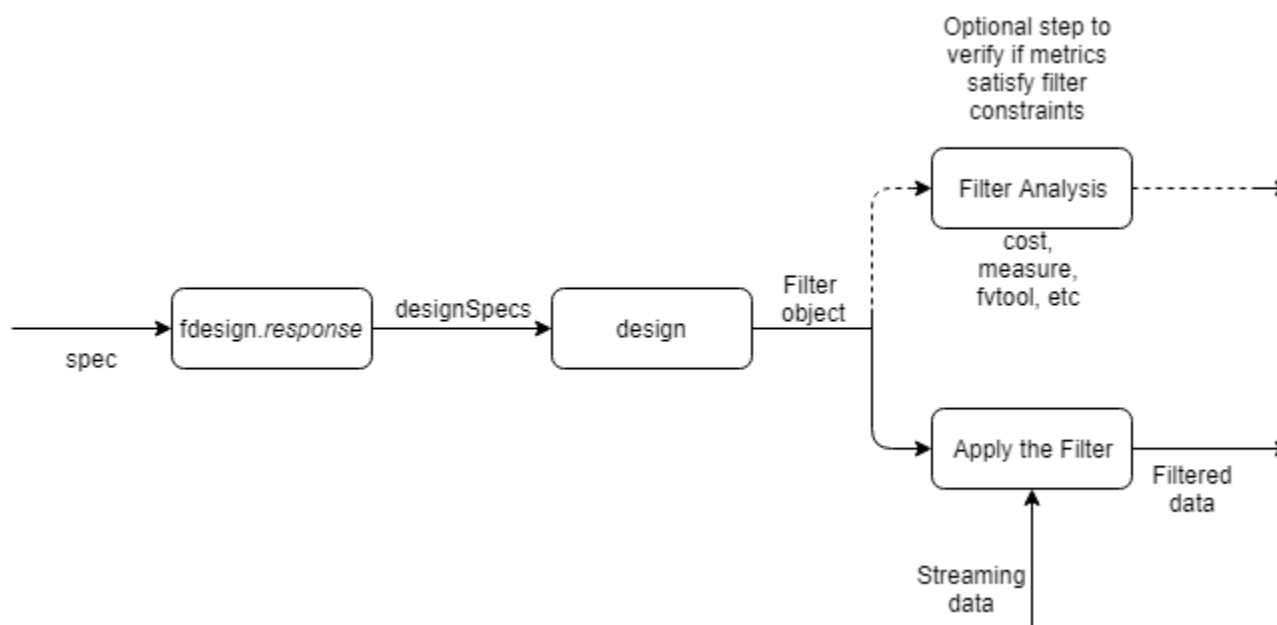

## Syntax

```
designSpecs = fdesign.response
designSpecs = fdesign.response(spec)
designSpecs = fdesign.response( __ ,Fs)
designSpecs = fdesign.response( __ ,magunits)
```

## Description

Use the `fdesign` function to create a filter design specification object that contains the specifications for a filter, such as passband ripple, stopband attenuation, and filter order. Then, use the `design` function to design the filter from the filter design specifications object. For an example, see “Design of Lowpass Decimator” on page 5-390.

Here is the workflow diagram that shows the simple procedure to design, analyze, and finally apply the filter on streaming data.

For more control options, see “Filter Design Procedure” on page 5-399. For a complete workflow, see “Design a Filter in Fdesign — Process Overview”.

`designSpecs = fdesign.response` returns a design specification object for the filter with a given *response*.

`designSpecs = fdesign.response(spec)` specifies the variables to use that define your filter design. The filter design parameters are applied to the filter design method you choose for your filter. The specification option you choose determines which design methods apply to the `fdesign` object.

`designSpecs = fdesign.response( ____, Fs)` specifies the sample rate in Hz to use in the filter specifications. The sample rate scalar must be the last input argument. If you specify a sample rate, all frequency specifications are in Hz.

`designSpecs = fdesign.response( ____, magunits)` specifies the units for any magnitude specification you provide in the input arguments.

## Examples

### Design of Lowpass Decimator

Design a 100-tap FIR lowpass decimator filter that reduces the sample rate of a signal from 60 kHz to 20 kHz. The passband of the filter extends up to 6 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 100 dB.

```

Fs = 60e3;
N = 99;
Fpass = 6e3;
Apass = 0.01;
Astop = 100;
M = Fs/20e3;

```

Setup the filter design specifications object using the `fdesign.decimator` function.

```

filtSpecs = fdesign.decimator(M, 'lowpass', 'N,Fp,Ap,Ast', N, Fpass, Apass, Astop, Fs);

```

Design the FIR lowpass decimator using the `design` function.

The resulting filter is a `dsp.FIRDecimator` System object™. For details on how to apply this filter to streaming data, refer to `dsp.FIRDecimator`.

```

decimFIR = design(filtSpecs, 'SystemObject', true)

```

```

decimFIR =
  dsp.FIRDecimator with properties:

```

```

  Main

```

```

  DecimationFactor: 3

```

```

  NumeratorSource: 'Property'

'
```

Visualize the magnitude response of the filter using `fvtool`.

```
fvtool(decimFIR, 'Fs',Fs)
```

### Design of Lowpass Filter

Design a lowpass filter to use on a signal sampled at 96 kHz. The passband of the filter extends up to 20 kHz. The stopband of the filter starts at 24 kHz. Specify a passband ripple of 0.01 dB and a stopband attenuation of 80 dB. Determine automatically the order required to meet the specifications.

Set up the filter design specifications object using the `fdesign.lowpass` function.

```
Fs = 96e3;
Fpass = 20e3;
Fstop = 24e3;
Apass = 0.01;
Astop = 80;
```

```
filtSpecs = fdesign.lowpass(Fpass,Fstop,Apass,Astop,Fs);
```

Determine the available design algorithms using the `designmethods` function.

```
designmethods(filtSpecs, 'SystemObject', true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Using the design function, design an equiripple FIR filter and an elliptic IIR filter that meet the specifications.

```
lpFIR = design(filtSpecs, 'equiripple', 'SystemObject', true)
```

```
lpFIR =
  dsp.FIRFilter with properties:
      Structure: 'Direct form'
      NumeratorSource: 'Property'
      Numerator: [1.0908e-04 2.1016e-05 -2.3369e-04 -2.8798e-04 9.0899e-05 3.6470e-04 -5.32e-05]
      InitialConditions: 0
```

```
Show all properties
```

```
lpIIR = design(filtSpecs, 'ellip', 'SystemObject', true)
```

```
lpIIR =
  dsp.SOSFilter with properties:
      Structure: 'Direct form II'
      CoefficientSource: 'Property'
      Numerator: [5x3 double]
      Denominator: [5x3 double]
      HasScaleValues: true
      ScaleValues: [0.8017 0.7532 0.7030 1.2976 0.0087 1]
```

```
Show all properties
```

You can also measure the designs to verify that the filters satisfy the constraints.

```
FIRmeas = measure(lpFIR)
```

```
FIRmeas =
  Sample Rate      : 96 kHz
  Passband Edge    : 20 kHz
  3-dB Point       : 21.4297 kHz
  6-dB Point       : 21.8447 kHz
```

```

Stopband Edge      : 24 kHz
Passband Ripple    : 0.0092309 dB
Stopband Atten.    : 80.6014 dB
Transition Width    : 4 kHz

```

```
IIRmeas = measure(lpIIR)
```

```

IIRmeas =
Sample Rate        : 96 kHz
Passband Edge      : 20 kHz
3-dB Point         : 20.5524 kHz
6-dB Point         : 20.7138 kHz
Stopband Edge      : 24 kHz
Passband Ripple    : 0.01 dB
Stopband Atten.    : 80 dB
Transition Width    : 4 kHz

```

Estimate and display the computational cost of each filter. The equiripple FIR filter requires many more coefficients than the elliptic IIR filter.

```
FIRcost = cost(lpFIR)
```

```

FIRcost = struct with fields:
    NumCoefficients: 101
    NumStates: 100
    MultiplicationsPerInputSample: 101
    AdditionsPerInputSample: 100

```

```
IIRcost = cost(lpIIR)
```

```

IIRcost = struct with fields:
    NumCoefficients: 20
    NumStates: 10
    MultiplicationsPerInputSample: 20
    AdditionsPerInputSample: 20

```

Use `fvtool` function to visualize the resulting designs and compare their properties.

```

hvft = fvtool(lpFIR,lpIIR,'Fs',Fs);
legend(hvft,'FIR Equiripple','Elliptic IIR')

```

### Lowpass Butterworth Filter Specification and Design

Design a lowpass Butterworth filter that has a passband edge frequency of  $0.4\pi$  rad/sample, a stopband frequency of  $0.5\pi$  rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 80 dB.

Create a `lowpass` filter design specification object using the `fdesign.lowpass` function. Specify the design parameters.

```
lowpassSpecs = fdesign.lowpass(0.4,0.5,1,80);
```

To view a list of design methods available for the specification object, use the `designmethods` function. If multiple methods are available, pick one that best meets the design criteria. For this example, pick `'butter'`.

```
designmethods(lowpassSpecs, SystemObject=true)
```

Design Methods that support System objects for class `fdesign.lowpass (Fp,Fst,Ap,Ast)`:

```
butter
cheby1
cheby2
ellip
```

```

equiripple
ifir
kaiserwin
multistage

```

Furthermore, you can specify the design options used in designing the filter. To see a list of available options, run the `designoptions` function on `lowpassSpecs`. The design options are dependent on the design method you pick. The design method, in this case, `'butter'`, must be specified as an argument to the `designoptions` function.

```
designoptions(lowpassSpecs,"butter",Systemobject=true)
```

```

ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascadeallpass'}
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]

```

The filter order necessary to meet a set of design constraints must also be rounded up to an integer value. This loosens some of the constraints, and as a consequence, some design specifications are met while others are exceeded. The `'MatchExactly'` option allows you to match the passband or stopband exactly while exceeding the specification for the other band. Design the filter so that it matches the passband exactly.

The resulting filter is a `dsp.SOSFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.SOSFilter`.

```
IIRbutter = design(lowpassSpecs,"butter",MatchExactly="passband", ...
    SystemObject=true)
```

```

IIRbutter =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II'
        CoefficientSource: 'Property'
        Numerator: [16x3 double]
        Denominator: [16x3 double]
        HasScaleValues: true
        ScaleValues: [0.3390 0.3104 0.2866 0.2667 0.2500 0.2359 0.2241 0.2142 0.2059 0.1990 0.1930 0.1870 0.1810 0.1750 0.1690 0.1630 0.1570 0.1510 0.1450 0.1390 0.1330 0.1270 0.1210 0.1150 0.1090 0.1030 0.0970 0.0910 0.0850 0.0790 0.0730 0.0670 0.0610 0.0550 0.0490 0.0430 0.0370 0.0310 0.0250 0.0190 0.0130 0.0070 0.0010]

```

```
Show all properties
```

Use `fvtool` to visualize the magnitude response of the filter.

```
fvtool(IIRbutter)
```

## Input Arguments

### response — Desired filter response

response entry

The table specifies the possible filter responses.

| <b>fdesign Response Method</b> | <b>Description</b>   |
|--------------------------------|--|
| arbgrpdelay                    | <code>fdesign.arbgrpdelay</code> creates an object to specify allpass arbitrary group delay filters.   |
| arbmag                         | <code>fdesign.arbmag</code> creates an object to specify IIR filters that have arbitrary magnitude responses defined by the input arguments.                 |
| arbmagnphase                   | <code>fdesign.arbmagnphase</code> creates an object to specify IIR filters that have arbitrary magnitude and phase responses defined by the input arguments. |
| bandpass                       | <code>fdesign.bandpass</code> creates an object to specify bandpass filters.   |
| bandstop                       | <code>fdesign.bandstop</code> creates an object to specify bandstop filters.   |
| ciccomp                        | <code>fdesign.ciccomp</code> creates an object to specify filters that compensate for the CIC decimator or interpolator response curves.                     |

| <b>fdesign Response Method</b> | <b>Description</b>  |
|--------------------------------|---|
| comb                           | <code>fdesign.comb</code> creates an object to specify a notching or peaking comb filter.           |
| decimator                      | <code>fdesign.decimator</code> creates an object to specify decimators.                             |
| differentiator                 | <code>fdesign.differentiator</code> creates an object to specify an FIR differentiator filter.      |
| fracdelay                      | <code>fdesign.fracdelay</code> creates an object to specify fractional delay filters.               |
| halfband                       | <code>fdesign.halfband</code> creates an object to specify halfband filters.                        |
| highpass                       | <code>fdesign.highpass</code> creates an object to specify highpass filters.                        |
| hilbert                        | <code>fdesign.hilbert</code> creates an object to specify an FIR Hilbert transformer.               |
| interpolator                   | <code>fdesign.interpolator</code> creates an object to specify interpolators.                       |
| isinchp                        | <code>fdesign.isinchp</code> creates an object to specify an inverse sinc highpass filter.          |
| isinclp                        | <code>fdesign.isinclp</code> creates an object to specify an inverse sinc lowpass filters.          |
| lowpass                        | <code>fdesign.lowpass</code> creates an object to specify lowpass filters.                          |
| notch                          | <code>fdesign.notch</code> creates an object to specify notch filters.                              |
| nyquist                        | <code>fdesign.nyquist</code> creates an object to specify Nyquist filters.                          |
| peak                           | <code>fdesign.peak</code> creates an object to specify peak filters.                                |
| polysrc                        | <code>fdesign.polysrc</code> creates an object to specify polynomial sample-rate converter filters. |
| rsrc                           | <code>fdesign.rsrc</code> creates an object to specify rational-factor sample-rate convertors.      |

Use the `doc fdesign.response` syntax at the MATLAB prompt to get help on a specific structure. For example, this command provides more information about the lowpass specification object:

```
doc fdesign.lowpass
```

Each response has a `Specification` property that defines the specifications to use to design your filter. You can use defaults or specify the `Specification` property when you construct the specifications object.

Using the `Specification` property, you can provide filter constraints such as the filter order or the passband attenuation to use when you construct your filter from the specification object.

### **spec — Filter design specifications**

character vector

Filter design specifications, specified as a character vector. The set of available specification options depends on the `fdesign.response` function. For more information, refer to the individual `fdesign.response` pages.

The filter design is based on the specifications provided by the `fdesign.response` object. For example, when you create a default lowpass filter design specification object, `fdesign.lowpass`, the

specification expression is set to 'Fp,Fst,Ap,Ast'. The filter design parameters — Fp (passband frequency), Fst (stopband frequency), Ap (passband ripple), and Ast (stopband attenuation) — are set to default values. The `design` function designs the filter based on these parameters.

Specifications that do not contain the filter order result in minimum-order designs when you invoke the `design` function:

```
d = fdesign.lowpass;           % Specification is 'Fp,Fst,Ap,Ast'
FIRReq = design(d,'equiripple','SystemObject',true);
length(FIRReq.Numerator)    % Returns 43. The filter order is 42
```

The specification option you choose determines which design methods are applicable. You can use the `setspecs` function to set all of the specifications simultaneously.

You can set filter specification values by passing them after the `Specification` argument, or by passing the values without the `Specification`.

Filter object constructors take the input arguments in the same order as `setspecs` and `Specification`.

When the first input to `fdesign.response` is not a valid `Specification` option, `fdesign` assumes that the input argument is a filter specification and applies it using the default `Specification` option. For example, 'Fp,Fst,Ap,Ast' is the default for a lowpass object.

### **Fs — Sample rate**

scalar

Sample rate to use in filter specifications, specified in Hz. The sample rate scalar must be the last input argument. If you specify a sample rate, all frequency specifications are in Hz.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **magunits — Units for magnitude specification**

'dB' (default) | 'linear' | 'squared'

Units for magnitude specification, specified as:

- 'dB' -- decibels
- 'linear' -- linear units
- 'squared' -- power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in dB. Note that `fdesign` stores all magnitude specifications in dB. If you set `magunits` to an option other than 'dB', the function converts the unit to 'dB'.

## **Output Arguments**

### **designSpecs — Filter design specification object**

`fdesign.response` object

`fdesign` returns a filter design specification object. Every filter design specification object has these properties:

| Property Name       | Default Value                         | Description  |
|---------------------|---------------------------------------|--|
| Response            | Depends on the chosen type            | Defines the type of filter to design, such as an interpolator or bandpass filter. This is a read-only value.   |
| Specification       | Depends on the chosen type            | Defines the filter characteristics used to define the desired filter performance, such as the cutoff frequency $F_c$ or the filter order $N$ .   |
| Description         | Depends on the filter type you choose | Contains descriptions of the filter specifications used to define the object, and the filter specifications you use when you create a filter from the object. This is a read-only value.   |
| NormalizedFrequency | Logical true                          | Determines whether the filter calculation uses a normalized frequency from 0 to 1, or the frequency band from 0 to $F_s/2$ , the sampling frequency. Accepts either <code>true</code> or <code>false</code> without single quotation marks. Audio weighting filters do not support normalized frequency. |

In addition to these properties, filter design specification objects can have other properties as well, depending on whether they design single-rate filters or multirate filters.

| Added Properties for Multirate Filters | Description   |
|--|---|
| DecimationFactor                       | Specifies the amount to decrease the sampling rate. Always a positive integer.  |
| InterpolationFactor                    | Specifies the amount to increase the sampling rate. Always a positive integer.  |
| PolyphaseLength                        | Polyphase length is the length of each polyphase subfilter that composes the decimator or interpolator or rate-change factor filters. Total filter length is the product of <code>pl</code> and the rate change factors. <code>pl</code> must be an even integer. |

## More About

### Filter Design Procedure

Here is the workflow diagram of the overall procedure for designing and analyzing the filter.

Here are the steps in detail:

- 1 Create an `fdesign.response` specification object to specify the design parameters.
- 2 Use `designmethods` to determine the filter design methods that work for your new filter specification object. If you choose to use the default design method, then this step is optional.
- 3 If you prefer to change the design options and would like to see a list of available options, run the `designoptions` function on the specification object. The output also shows the design options the filter uses by default.
- 4 Use `design` to design the filter from the filter specification object. Specify the design method (determined from step 2) as an input. If the design options must change from the default values, specify them as name-value pairs following the design method.

If you call the `design` function without any output arguments, FVTool is launched and shows the magnitude response of the designed filter.

Alternatively, use the `fvtool` function.

- 5 Further analysis, such as viewing the frequency response of the filter, computing the cost of implementing the filter, and measuring the filter response characteristics, can be done using one of the supported “Analysis Methods for Filter System Objects” on page 3-2.
- 6 Once you analyze the filter and determine that the filter satisfies the design constraints, you can apply the filter object to streaming input data. For details on how to pass data to the filter object, refer to the corresponding filter System object reference pages.

For a detailed example on the design and analysis, see “Lowpass Butterworth Filter Specification and Design” on page 5-394.

## fdesign.arbgrpdelay

Arbitrary group delay filter specification object

### Syntax

```
specObj = fdesign.arbgrpdelay
specObj = fdesign.arbgrpdelay(spec)
specObj = fdesign.arbgrpdelay(spec,value1,...,valueN)
specObj = fdesign.arbgrpdelay(N,F,Gd)
specObj = fdesign.arbgrpdelay( ____,Fs)
```

### Description

Arbitrary group delay filters are allpass filters that you can use to correct the phase distortion introduced by other filters. The `fdesign.arbgrpdelay` function uses an iterative least  $p$ -th norm optimization procedure to minimize the phase response error [1] on page 5-410.

The `fdesign.arbgrpdelay` function returns a filter design specification object containing filter specifications, such as filter order, number of bands, frequency vector, and group delay response. You then use the `design` function to design the filter from the filter design specifications object.

For more control options, see “Filter Design Procedure” on page 5-399. For a complete workflow, see “Design a Filter in Fdesign — Process Overview”.

`specObj = fdesign.arbgrpdelay` creates an allpass arbitrary group delay filter design specification object with the filter order of 10, frequency vector of [0 0.1 1], and group delay response vector of [2 3 1].

`specObj = fdesign.arbgrpdelay(spec)` creates a filter design specification object with the specification property `spec`. For more information on the specifications that the function supports, see `spec` on page 5-0 .

`specObj = fdesign.arbgrpdelay(spec,value1,...,valueN)` creates a filter design specification object with the specification values `value1,...,valueN`. Set the specification options in the expression `spec`. After the expression, specify a value for each option.

`specObj = fdesign.arbgrpdelay(N,F,Gd)` creates a filter design specification object with the filter order, frequency vector, and group delay response vector specified in `N`, `F`, and `Gd`, respectively. For more information on the filter order, frequency vector, and group delay vector inputs, see `spec` on page 5-0 .

`specObj = fdesign.arbgrpdelay( ____,Fs)` specifies the sample rate in Hz. If you specify a sample rate, the group delay response values in the filter design specification object are in seconds. If you do not specify a sample rate, the function normalizes all frequencies and the group delay response values are in samples.

### Examples

## Design Arbitrary Group Delay Filter

Create a signal consisting of two discrete-time windowed sinusoids (wave packets) with disjoint time support to illustrate frequency dispersion. One discrete-time sinusoid has a frequency of  $\pi/2$  radians/sample and the other has a frequency of  $\pi/4$  radians/sample. There are nine periods of the sinusoid with the higher frequency that precede five periods of the signal with the lower frequency.

Create the signal.

```
x = zeros(300,1);
x(1:36) = cos(pi/2*(0:35)).*hamming(36)';
x(40:40+39) = cos(pi/4*(0:39)).*hamming(40)';
```

Create an arbitrary group delay filter that delays the wave packet with the higher frequency by approximately 100 samples.

```
N = 18;
f = 0:.1:1;
gd = ones(size(f));
```

Delay  $\pi/2$  radians/sample by 100 samples.

```
gd(6) = 100;
d = fdesign.arbgrpdelay(N,f,gd);
Hd = design(d,'iirlpnorm',MaxPoleRadius=0.9,SystemObject=true);
```

Visualize the group delay.

```
fvtool(Hd,analysis='grpdelay');
```

Filter the input signal with the arbitrary group delay filter and plot the frequency dispersion. The high-frequency wave packet, which initially preceded the low-frequency wave packet, now occurs later because of the nonconstant group delay.

```
y = Hd(x);
subplot(211)
plot(x);
title('Input Signal');
grid on;
ylabel('Amplitude');
subplot(212);
plot(y);
title('Output Signal');
grid on;
xlabel('Samples');
ylabel('Amplitude');
```

### Design an Allpass Filter With an Arbitrary Group Delay

Design an allpass filter with an arbitrary group delay using the `fdesign.arbgrpdelay` and the `design` functions. Pass `iirlpnorm` as the design method.

```
N = 10;
f = [0 0.02 0.04 0.06 0.08 0.1 0.25 0.5 0.75 1];
g = [5 5 5 5 5 5 4 3 2 1];
```

```
w = [2 2 2 2 2 2 1 1 1 1];
hgd = fdesign.arbgrpdelay(N,f,g);
Hgd = design(hgd,'iirlpnorm',Weights=w,MaxPoleRadius=0.95,...
    SystemObject=true)
```

```
Hgd =
    dsp.SOSFilter with properties:

        Structure: 'Direct form II'
    CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [0.2274 1 1 1 1 1.3513]
```

Show all properties

```
fvtool(Hgd,Analysis='grpdelay') ;
```

### Multiband Delay Equalization

Perform group delay equalization of a bandstop Chebyshev filter operating with a sample rate of 1 kHz.

```

Fs = 1e3;
Hcheby2 = design(fdesign.bandstop('N,Fst1,Fst2,Ast',10,150,400,60,Fs),'cheby2',...
    SystemObject=true);
f1 = 0.0:0.5:150; % Hz
g1 = grpdelay(Hcheby2,f1,Fs).'/Fs; % seconds
f2 = 400:0.5:500; % Hz
g2 = grpdelay(Hcheby2,f2,Fs).'/Fs; % seconds
maxg = max([g1 g2]);

```

Design an arbitrary group delay allpass filter to equalize the group delay of the bandstop filter. Use an 18 order multiband design and specify two bands.

```

hgd = fdesign.arbgrpdelay('N,B,F,Gd',18,2,f1,maxg-g1,f2,maxg-g2,Fs);
Hgd = design(hgd,'iirlpnm',MaxPoleRadius=0.95,SystemObject=true);
Hcascade = cascade(Hcheby2,Hgd);
hft = fvtool(Hcheby2,Hgd,Hcascade,Analysis='grpdelay',Fs=Fs);
legend(hft,'Original Bandstop Filter','Allpass Arbitrary Group Delay Filter',...
    'Delay Equalization','Location','North');

```

## Input Arguments

### spec — Filter specification

'N, F, Gd' (default) | 'N, B, F, Gd'

Filter specification, specified as one of these character vectors:

- 'N,F,Gd'
- 'N,B,F,Gd'

This table describes the options available in each expression.

| Specification Option | Description                 |
|----------------------|-----------------------------|
| N                    | Filter order (must be even) |
| F                    | Frequency vector            |
| Gd                   | Group delay response vector |
| B                    | Number of frequency bands   |

The design methods that you can use to design the filter depend on the specification expression. You can obtain these methods using the `designmethods` function. This table lists the specification expressions supported by the `fdesign.arbgrpdelay` function and the corresponding design method.

| Specification Expression | Supported Design Method | Filter Description              |
|--------------------------|-------------------------|---------------------------------|
| 'N,F,Gd'                 | <code>iirlpnorm</code>  | Least P-norm optimal IIR filter |
| 'N,B,F,Gd'               | <code>iirlpnorm</code>  | Least P-norm optimal IIR filter |

To design the filter, call the `design` function with one of the design methods as an input. For more details on the procedure, see “Filter Design Procedure” on page 5-399. For an example, see “Design an Allpass Filter With an Arbitrary Group Delay” on page 5-404.

### value1, ..., valueN — Specification values

comma-separated list of values

Specification values, specified as a comma-separated list of values. Specify a value for each option in `spec` in the same order as the options in the specification expression.

Example: `specObj = fdesign.arbgrpdelay('N,F,Gd',N,F,Gd)`

The arguments below describe more details for each option in the expression.

#### N — Filter order

10 (default) | even positive integer

Filter order, specified as an even positive integer. The numerator and denominator orders are both equal to N. For more information on why the numerator and denominator filter orders are equal and even in the `fdesign.arbgrpdelay` function, see “Allpass Systems” on page 5-409.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### F — Frequency vector

[0 0.1 1] (default) | row vector

Frequency vector for the group delay specifications, specified as a row vector. The elements of the frequency vector must increase monotonically.

If you do not specify a sample rate  $F_s$ , the function normalizes the frequencies. For a single-band design, the first element of the normalized frequency vector must be 0 and the last element must be 1. These correspond to 0 and  $\pi$  radians/sample, respectively. For multiband designs, the union of the frequency vectors must range between [0, 1].

If you specify a sample rate  $F_s$ , the first element of the frequency vector in a single-band design must be 0. The last element must be the Nyquist frequency  $F_s/2$ . For multiband designs, the union of the frequency vectors must range between  $[0, F_s/2]$ .

Data Types: `double`

### **Gd — Group delay vector**

`[2 3 1]` (default) | row vector

Group delay vector, specified as a row vector with nonnegative elements and equal in length to the frequency vector  $F$ . The elements of  $Gd$  specify the nonnegative group delay at the corresponding element of the frequency vector  $F$ .

If you do not specify a sample rate  $F_s$  in Hz, the group delay values are in samples. If you specify a sample rate, the group delay values are in seconds.

Data Types: `double`

### **B — Number of frequency bands**

1 (default) | positive integer

Number of frequency bands, specified as a positive integer. To use this argument, you must specify a frequency vector  $F$  and a group delay vector  $Gd$  for each band. The union of the frequency vectors must range between  $[0, 1]$  in normalized frequency or  $[0, F_s/2]$  when you specify a sample rate. The elements in the union of the frequency bands must be monotonically increasing.

Example:

```
filtorder = 14;
freqband1 = [0 0.1 0.4]; grpdelay1 = [1 2 3];
freqband2 = [0.5 0.8 1]; grpdelay2 = [3 2 1];
D = fdesign.arbgrpdelay('N,B,F,Gd',filtorder,2,freqband1,grpdelay1,freqband2,grpdelay2);
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Fs — Sample rate**

positive scalar

Sample rate, specified as a positive scalar. Specify this argument after all the other input arguments. Specifying a sample rate forces the group delay units to be in seconds. If you specify a sample rate, the first element of the frequency vector must be 0 and the last element must be the Nyquist frequency  $F_s/2$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Output Arguments**

### **specObj — Allpass arbitrary group delay filter specification object**

`arbgrpdelay` object

Allpass arbitrary group delay filter design specification object, returned as a `arbgrpdelay` object. The object properties depend on the `spec` input argument.

The filter design specification object can contain one or more of these properties:

- `Specification`
- `NormalizedFrequency`

- FilterOrder
- Frequencies
- GroupDelay
- NBands -- Appears if the Specification property is set to 'N,B,F,Gd'.

Use the `normalizefreq` function to change the `NormalizedFrequency` property after constructing the specification object.

## More About

### Group Delay in Discrete-Time Filter Design

The frequency response of a rational discrete-time filter is:

$$H(e^{j\omega}) = \frac{B(e^{j\omega})}{A(e^{j\omega})}$$

The argument of the frequency response as a function of the angle,  $\omega$ , is referred to as the *phase response*.

The negative of the first derivative of the argument with respect to  $\omega$  is the group delay.

$$\tau(\omega) = -\frac{d}{d\omega} \text{Arg}(H(e^{j\omega}))$$

Systems with nonlinear phase responses have nonconstant group delay, which causes the frequency components of the signal to disperse. You may not want this phase distortion even if the magnitude distortion introduced by the filter produces the desired effect. See “Design Arbitrary Group Delay Filter” on page 5-402 for an illustration of frequency dispersion resulting from nonconstant group delay.

In these cases, you can cascade the frequency-selective filter with an allpass filter that compensates for the group delay. This process is often referred to as *delay equalization*.

### Allpass Systems

The general form of an allpass system function with a real-valued impulse response is:

$$H_{ap}(z) = \prod_{k=1}^M \frac{z^{-1} - d_k}{1 - d_k z^{-1}} \prod_{k=1}^N \frac{(z^{-1} - c_k)(z^{-1} - c_k^*)}{(1 - c_k z^{-1})(1 - c_k^* z^{-1})}$$

where the  $d_k$  denote the real-valued poles and the  $c_k$  denote the complex-valued poles, which occur in conjugate pairs.

This equation shows that allpass systems with real-valued impulse responses have  $2N+M$  zeros and poles. The poles and zeros occur in pairs with reciprocal magnitudes. The filter order is always the same for the numerator and denominator.

Because the `fdesign.arbgrpdelay` function uses robust second-order section (biquad) filter structures to implement the allpass arbitrary group delay filter, the filter order must be even.

## Tips

If your arbitrary group delay design produces the Poorly conditioned Hessian matrix error, perform one of the following or both.

- Set the `MaxPoleRadius` IIR lp norm design option to a number less than 1 when you design your filter.

```
design(d,'iirlpnorm','MaxPoleRadius',0.95)
```

For more information on the `MaxPoleRadius` design option, see the “Design Arbitrary Group Delay Filter” on page 5-402 and “Multiband Delay Equalization” on page 5-405 examples.

- Reduce the order of your filter design.

## Algorithms

The `fdesign.arbgrpdelay` function uses a least  $p$ -th norm iterative optimization described in [1] on page 5-410.

## Version History

## fdesign.arbmag

Arbitrary response magnitude filter specification object

### Syntax

```
D= fdesign.arbmag
D= fdesign.arbmag(SPEC)
D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)
D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)
D = fdesign.arbmag(...,Fs)
```

### Description

D= fdesign.arbmag constructs an arbitrary magnitude filter specification object D.

D= fdesign.arbmag(SPEC) initializes the Specification property to SPEC. The input argument SPEC must be one of the entries shown in the following table. Specification entries are not case sensitive.

---

**Note** Specification entries marked with an asterisk require the DSP System Toolbox software.

---

- 'N,F,A' — Single band design (default)
- 'F,A,R' — Single band minimum order design \*
- 'N,B,F,A' — Multiband design
- 'N,B,F,A,C' — Constrained multiband design \*
- 'B,F,A,R' — Multiband minimum order design \*
- 'Nb,Na,F,A' — Single band design \*
- 'Nb,Na,B,F,A' — Multiband design \*

The SPEC entries are defined as follows:

- A — Amplitude vector. Values in A define the filter amplitude at frequency points you specify in f, the frequency vector. If you use A, you must use F as well. Amplitude values must be real. For complex values designs, use fdesign.arbmagnphase.
- B — Number of bands in the multiband filter
- C — Constrained band flag. This enables you to constrain the passband ripple in your multiband design. You cannot constrain the passband ripple in all bands simultaneously.
- F — Frequency vector. Frequency values in specified in F indicate locations where you provide specific filter response amplitudes. When you provide F, you must also provide A.
- N — Filter order for FIR filters and the numerator and denominator orders for IIR filters.
- Nb — Numerator order for IIR filters
- Na — Denominator order for IIR filter designs
- R — Ripple

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

### Specifying Frequency and Amplitude Vectors

F and A are the input arguments you use to define the filter response desired. Each frequency value you specify in F must have a corresponding response value in A. The following table shows how F and A are related.

Define the frequency vector F as [0 0.25 0.3 0.4 0.5 0.6 0.7 0.75 1.0]

Define the response vector A as [1 1 0 0 0 0 0 1 1]

These specifications connect F and A as shown here:

| F (Normalized Frequency) | A (Response Desired at F) |
|--------------------------|---------------------------|
| 0                        | 1                         |
| 0.25                     | 1                         |
| 0.3                      | 0                         |
| 0.4                      | 0                         |
| 0.5                      | 0                         |
| 0.6                      | 0                         |
| 0.7                      | 0                         |
| 0.75                     | 1                         |
| 1.0                      | 1                         |

Different specifications can have different design methods available. Use `designmethods` to get a list of design methods available for a given specification and filter specification object.

Use `designopts` to get a list of design options available for a filter specification object and a given design method. Enter `help(D,METHOD)` to get detailed help on the available design options for a given design method.

`D = fdesign.arbmag(SPEC,specvalue1,specvalue2,...)` initializes the specifications with `specvalue1`, `specvalue2`. Use `get(D,'Description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ... `specvalueN`.

`D = fdesign.arbmag(specvalue1,specvalue2,specvalue3)` uses the default specification 'N,F,A', setting the filter order, filter frequency vector, and the amplitude vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`D = fdesign.arbmag(...,Fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `Fs`.

## Examples

### Design Multiband Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a three-band filter.

- Define the frequency vector  $F = [0 \ 0.25 \ 0.3 \ 0.4 \ 0.5 \ 0.6 \ 0.7 \ 0.75 \ 1.0]$ .
- Define the response vector  $A = [1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 1]$ .

```

N = 150;
B = 3;
F = [0 .25 .3 .4 .5 .6 .7 .75 1];
A = [1 1 0 0 0 0 0 1 1];
A1 = A(1:2);
A2 = A(3:7);
A3 = A(8:end);
F1 = F(1:2);
F2 = F(3:7);
F3 = F(8:end);
d = fdesign.arbmag('N,B,F,A',N,B,F1,A1,F2,A2,F3,A3);
Hd = design(d);
fvtool(Hd)

```

A response with two passbands -- one roughly between 0 and 0.25 and the second between 0.75 and 1 -- results from the mapping between  $F$  and  $A$ .

### Design Single-Band Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a single band equiripple filter.

Specify 100 frequency points.

```

n = 120;
f = linspace(0,1,100);

as = ones(1,100) - f*0.2;
absorb = [ones(1,30), 1-0.6*bohmanwin(10)', ones(1,5), ...
          1-0.5*bohmanwin(8)', ones(1,47)];
a = as.*absorb;

```

```

d = fdesign.arbmag('N,F,A',n,f,a);
hd1 = design(d,'equiripple');

```

Design a minimum-phase equiripple filter. Visualize the poles and zeros of the two filters.

```

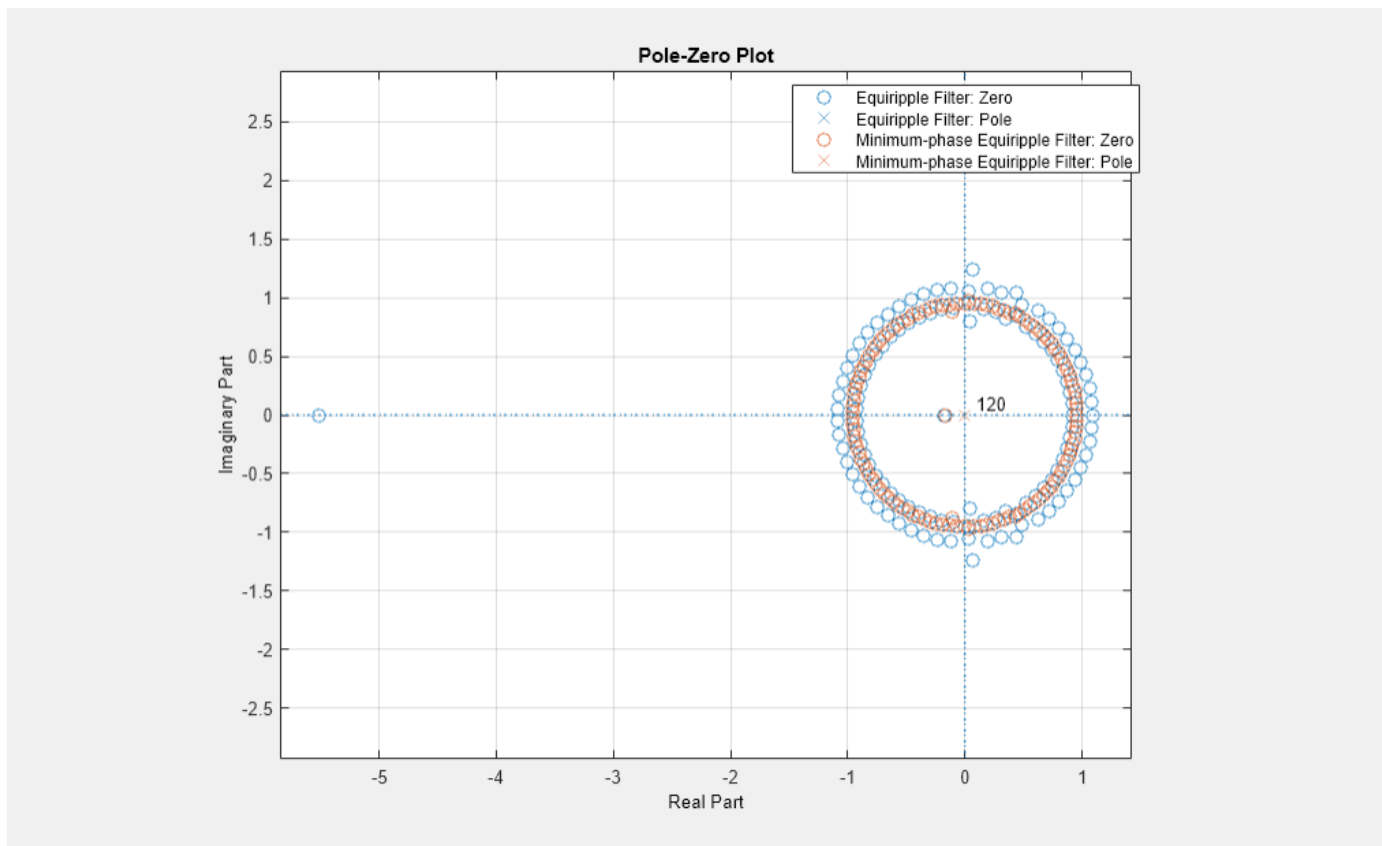

hd2 = design(d,'equiripple','MinPhase',true);

```

```

hfvt = fvtool(hd1,hd2,'Analysis','polezero');
legend(hfvt,'Equiripple Filter','Minimum-phase Equiripple Filter')

```

### Design Multiband Minimum-Order Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband minimum order filter.

Place the notches at  $0.25\pi$  and  $0.55\pi$  rad/sample.

```

d = fdesign.arbmag('B,F,A,R');
d.NBands = 5;

```

```

d.B1Frequencies = [0 0.2];
d.B1Amplitudes = [1 1];
d.B1Ripple = 0.25;
d.B2Frequencies = 0.25;
d.B2Amplitudes = 0;
d.B3Frequencies = [0.3 0.5];
d.B3Amplitudes = [1 1];
d.B3Ripple = 0.25;
d.B4Frequencies = 0.55;
d.B4Amplitudes = 0;
d.B5Frequencies = [0.6 1];
d.B5Amplitudes = [1 1];
d.B5Ripple = 0.25;
Hd = design(d,'equiripple');

```

Visualize the frequency response of the resulting filter.

```
fvtool(Hd)
```

### Design Multiband Constrained Arbitrary-Magnitude Filter

Use `fdesign.arbmag` to design a multiband constrained FIR filter.

Force the frequency response at  $0.15\pi$  rad/sample to 0 dB.

```
d = fdesign.arbmag('N,B,F,A,C',82,2);  
d.B1Frequencies = [0 0.06 0.1];  
d.B1Amplitudes = [0 0 0];  
d.B2Frequencies = [0.15 1];  
d.B2Amplitudes = [1 1];
```

Design a filter with no constraints.

```
Hd1 = design(d, 'equiripple', 'B2ForcedFrequencyPoints', 0.15);
```

Add a constraint to the first band to increase attenuation.

```
d.B1Constrained = true;  
d.B1Ripple = 0.001;  
Hd2 = design(d, 'equiripple', 'B2ForcedFrequencyPoints', 0.15);
```

Visualize the frequency response.

```
hfvt = fvtool(Hd1,Hd2);  
legend(hfvt, 'Original Design', 'Design with Constrained Stopband Ripple')
```

## Version History

## fdesign.arbmagnphase

Arbitrary response magnitude and phase filter specification object

### Syntax

```
d = fdesign.arbmagnphase
d = fdesign.arbmagnphase(specification)
d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)
d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)
d = fdesign.arbmagnphase(...,fs)
```

### Description

`d = fdesign.arbmagnphase` constructs an arbitrary magnitude filter specification object `d`.

`d = fdesign.arbmagnphase(specification)` initializes the `Specification` property for specifications object `d` to `specification`. The input argument `specification` must be one of the choices shown in the following table. Specification options are not case sensitive.

| Specification             | Description of Resulting Filter  |
|---------------------------|--|
| <code>n, f, h</code>      | Single band design (default). FIR and IIR ( <code>n</code> is the order for both numerator and denominator). |
| <code>n, b, f, h</code>   | FIR multiband design where <code>b</code> defines the number of bands.                                       |
| <code>nb, na, f, h</code> | IIR single band design.  |

The following table describes the specification arguments.

| Argument        | Description   |
|-----------------|---|
| <code>b</code>  | Number of bands in the multiband filter.  |
| <code>f</code>  | Frequency vector. Frequency values specified in <code>f</code> indicate locations where you provide specific filter response amplitudes. When you provide <code>f</code> you must also provide <code>h</code> which contains the response values. |
| <code>h</code>  | Complex frequency response values.  |
| <code>n</code>  | Filter order for FIR filters and the numerator and denominator orders for IIR filters (when not specified by <code>nb</code> and <code>na</code> ).   |
| <code>nb</code> | Numerator order for IIR filters.  |
| <code>na</code> | Denominator order for IIR filter designs.   |

By default, this method assumes that all frequency specifications are supplied in normalized frequency.

### Specifying `f` and `h`

`f` and `h` are the input arguments you use to define the filter response desired. Each frequency value you specify in `f` must have a corresponding response value in `h`. This example creates a filter with

two passbands ( $b = 4$ ) and shows how  $f$  and  $h$  are related. This example is for illustration only. It is not an actual filter.

Define the frequency vector  $f$  as `[0 0.1 0.2 0.4 0.5 0.6 0.9 1.0]`

Define the response vector  $h$  as `[0 0.5 0.5 0.1 0.1 0.8 0.8 0]`

These specifications connect  $f$  and  $h$  as shown in the following table.

| <b>f (Normalized Frequency)</b> | <b>h (Response Desired at f)</b> |
|---------------------------------|----------------------------------|
| 0                               | 0                                |
| 0.1                             | 0.5                              |
| 0.2                             | 0.5                              |
| 0.4                             | 0.1                              |
| 0.5                             | 0.1                              |
| 0.6                             | 0.8                              |
| 0.9                             | 0.8                              |
| 1.0                             | 0.0                              |

A response with two passbands—one roughly between 0.1 and 0.2 and the second between 0.6 and 0.9—results from the mapping between  $f$  and  $h$ . Plotting  $f$  and  $h$  yields the following figure that resembles a filter with two passbands.

The second example in Examples shows this plot in more detail with a complex filter response for  $h$ . In the example,  $h$  uses complex values for the response.

Different specification types often have different design methods available. Use `designmethods(d)` to get a list of design methods available for a given specification option and specifications object.

`d = fdesign.arbmagnphase(specification,specvalue1,specvalue2,...)` initializes the filter specification object with `specvalue1`, `specvalue2`, and so on. Use `get(d,'description')` for descriptions of the various specifications `specvalue1`, `specvalue2`, ...`specn`.

`d = fdesign.arbmagnphase(specvalue1,specvalue2,specvalue3)` uses the default specification option `n`, `f`, `h`, setting the filter order, filter frequency vector, and the complex frequency response vector to the values `specvalue1`, `specvalue2`, and `specvalue3`.

`d = fdesign.arbmagnphase(...,fs)` specifies the sampling frequency in Hz. All other frequency specifications are also assumed to be in Hz when you specify `fs`.

## Examples

### Construct a Complex Analog Filter

Use `fdesign.arbmagnphase` to model a complex analog filter.

```
d = fdesign.arbmagnphase('n,f,h',100); % N=100, f and h set to defaults.
design(d,'freqsamp','SystemObject',true);
```

For a more complex example, design a bandpass filter with low group delay by specifying the desired delay and using `f` and `h` to define the filter bands.

```
n = 50; % Group delay of a linear phase filter would be 25.
gd = 12; % Set the desired group delay for the filter.
```

```

f1=linspace(0,.25,30); % Define the first stopband frequencies.
f2=linspace(.3,.56,40); % Define the passband frequencies.
f3=linspace(.62,1,30); % Define the second stopband frequencies.
h1 = zeros(size(f1)); % Specify the filter response at the freqs in f1.
h2 = exp(-1j*pi*gd*f2); % Specify the filter response at the freqs in f2.
h3 = zeros(size(f3)); % Specify the response at the freqs in f3.
d=fdesign.arbmagnphase('n,b,f,h',50,3,f1,h1,f2,h2,f3,h3);
D = design(d,'equiripple','SystemObject',true);
fvtool(D,'Analysis','freq');

```

## fdesign.audioweighting

(To be removed) Audio weighting filter specification object

### Compatibility

---

**Note** The `fdesign.audioweighting` filter specification object will be removed from DSP System Toolbox in a future release. Existing instances of the object continue to run. For new code, use the `weightingFilter` System object instead. For more information on how to update your existing code, see “Compatibility Considerations” on page 5-426.

---

### Syntax

```
HAwf = fdesign.audioweighting
HAwf = fdesign.audioweighting(spec)
HAwf = fdesign.audioweighting(spec,specvalue1,specvalue2)
HAwf = fdesign.audioweighting(specvalue1,specvalue2)
HAwf = fdesign.audioweighting(...,Fs)
```

### Description

Supported audio weighting filter types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468-4 weighting.

`HAwf = fdesign.audioweighting` constructs an audio weighting filter specification object `HAwf` with a weighting type of A and a filter class of 1. Use the `design` method and set the 'SystemObject' flag to `true`, to instantiate a System object based on the specifications in `HAwf`. Use `designmethods` to find valid filter design methods. Because the standards for audio weighting filters are in Hz, normalized frequency specifications are not supported for `fdesign.audioweighting` objects. The default sampling frequency for A weighting, C weighting, C-message, and ITU-T 0.41 filters is 48 kHz. The default sampling frequency for the ITU-R 468-4 filter is 80 kHz. If you invoke the `normalizefreq` method, a warning is issued when you instantiate the System object and the default sampling frequencies in Hz are used.

`HAwf = fdesign.audioweighting(spec)` returns an audio weighting filter specification object using default values for the specification in `spec`. The following are valid entries for `spec`. The entries are not case sensitive.

- 'WT,Class' (default `spec`)

The 'WT,Class' specification is valid for A weighting and C weighting filters of class 1 or 2.

The weighting type is specified by the character vector: 'A' or 'C'. The class is the scalar 1 or 2.

The default values for 'WT,Class' are 'A',1.

- 'WT'

The 'WT' specification is valid for C-message (default), ITU-T 0.41, and ITU-R 468-4 weighting filters.

The weighting type is specified by the character vector: 'Cmessage', 'ITUT041', or 'ITUR4684'.

*HAWf* = fdesign.audioweighting(*spec*,*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAWf* and sets its specifications at construction time.

*HAWf* = fdesign.audioweighting(*specvalue1*,*specvalue2*) constructs an audio weighting filter specification object *HAWf* with the specification 'WT,Class' using the values you provide. The valid weighting types are 'A' or 'C'.

*HAWf* = fdesign.audioweighting(...,*Fs*) specifies the sampling frequency in Hz. The sampling frequency is a scalar trailing all other input arguments.

## Input Arguments

### Parameter Name/Value Pairs

#### WT

Weighting type

The weighting type defines the frequency response of the filter. The valid weighting types are: A weighting, C weighting, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. The weighting types are described in “More About” on page 5-425.

#### Class

Filter Class

Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards [1], [2]. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in **FVTool** for the analysis of the filter design.

**Default:** 1

## Examples

### Compare Class 1 A and ITU-R 468-4 Weighting Filters

Compare class 1 A weighting and ITU-R 468-4 filters between 0.1 and 12 kHz. Sampling frequency is 44.1 kHz

```
HawfA = fdesign.audioweighting('WT,Class','A',1,44.1e3);
HawfITUR = fdesign.audioweighting('WT','ITUR4684',44.1e3);
```

```
Afilter = design(HawfA,'SystemObject',true);
ITURfilter = design(HawfITUR,'SystemObject',true);
```

```
hfvt = fvtool(Afilter,ITURfilter);
```

```
axis([0.1 12 -80 20]);
legend(hfvt, 'A-weighting', 'ITU-R 468-4');
```

### Compare C-message and ITU-T 0.41 Weighting Filters

```
hCmessage = fdesign.audioweighting('WT','Cmessage',24e3);
hITUT = fdesign.audioweighting('WT','ITUT041',24e3);
dCmessage = design(hCmessage,'SystemObject',true);
dITUT = design(hITUT,'SystemObject',true);
hfvt = fvtool(dCmessage,dITUT);
legend(hfvt,'C-Message Weighting','ITU-T 0.41 Weighting');
axis([0.1 10 -50 5]);
```

### Construct an ITU-R 468-4 Weighting Filter

Construct an ITU-R 468-4 filter using all available design methods.

```
HAwf = fdesign.audioweighting('WT','ITUR4684');
ValidDesigns = designmethods(HAwf);
% returns iirlpnorm,equiripple,freqsamp in cell array
D = design(HAwf,'all','SystemObject',true); % returns all designs
hfvt = fvtool(D{1},D{2},D{3});
legend(hfvt,'Least P-norm IIR','FIR Equiripple',...,
'FIR Frequency Sampling')
```

### Design and Use Audio Weighting Filter

Design a class 2 A-weighted filter.

```
fs = 48e3;
audioWeightingFilterDesign = fdesign.audioweighting('A',2,fs);
```

Convert the design to a System object for use.

```
audioWeightingFilter = design(audioWeightingFilterDesign,...
'SystemObject',true);
```

Create a spectrumAnalyzer object to visualize original and filtered signals.

```
windowLength = 2048;
scope = spectrumAnalyzer( ...
    'SampleRate',fs, ...
    'PlotAsTwoSidedSpectrum',false, ...
    'SpectralAverages',50, ...
    'FrequencyScale','Log', ...
    'FrequencyResolutionMethod','WindowLength', ...
    'WindowLength',windowLength, ...
    'Title','A-Weighted Filtering', ...
    'ShowLegend',true, ...
    'ChannelNames',{'Original signal','Filtered signal'});
```

Apply the A-weighting filter to white noise.

```
tic
while toc < 10
    x = rand(windowLength,1) - 0.5;
    y = audioWeightingFilter(x);
    scope([x,y])
end
```

## More About

### A weighting

The specifications for the A weighting filter are found in ANSI standard S1.42-2001. The A weighting filter is based on the 40-phon Fletcher-Munson equal loudness contour [3]. One phon is equal to one dB sound pressure level (SPL) at one kHz. The Fletcher-Munson equal loudness contours are designed to account for frequency and level dependent differences in the perceived loudness of tonal stimuli. The 40-phon contour reflects the fact that the human auditory system is more sensitive to frequencies around 1-2 kHz than lower and higher frequencies. The filter roll off is more pronounced at lower frequencies and more modest at higher frequencies. While A weighting is based on the equal loudness contour for low-level (40-phon) tonal stimuli, it is commonly used in the United States for assessing potential health risks associated with noise exposure to narrowband and broadband stimuli at high levels.

### C weighting

The specifications for the C weighting filter are found in ANSI standard S1.42-2001. The C weighting filter approximates the 100-phon Fletcher-Munson equal loudness contour for tonal stimuli. The C weighting magnitude response is essentially flat with 3-dB frequencies at 31.5 Hz and 8000 Hz. While C weighting is not as common as A weighting, sound level meters frequently have a C weighting filter option.

### C-message

The specifications for the C-message weighting filter are found in Bell System Technical Reference, PUB 41009. C-message weighting filters are designed for measuring the impact of noise on telecommunications circuits used in speech transmission [6]. C-message weighting filters are commonly used in North America, while the ITU-T 0.41 filter is more commonly used outside of North America.

### ITU-R 468-4

The specifications for the ITU-R 468-4 weighting filter are found in the International Telecommunication Union Recommendation ITU-R BS.468-4. ITU-R 468-4 is an equal loudness contour weighting filter. Unlike the A weighting filter, the ITU-R 468-4 filter describes subjective loudness judgements for broadband stimuli [4]. A common criticism of the A weighting filter is that it underestimates the loudness judgement of real-world stimuli particularly in the frequency band from about 1-9 kHz. A comparison of A weighting and ITU-R 468-4 weighting curves shows that the ITU-R 468-4 curve applies more gain between 1 and 10 kHz with a peak difference of approximately 12 dB around 6-7 kHz.

### ITU-T 0.41

The specifications for the ITU-T 0.41 filter are found in the ITU-T Recommendation 0.41. ITU-T 0.41 weighting filters are designed for measuring the impact of noise on telecommunications circuits used

in speech transmission [5]. ITU-T 0.41 weighting filters are commonly used outside of North America, while the C-message weighting filter is more common in North America.

## Version History

Introduced in R2011a

### R2022a: `fdesign.audioweighting` will be removed

Warns starting in R2022a

The `fdesign.audioweighting` filter specification object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `weightingFilter` System object instead.

### Update Code

This table shows how the object is typically used and explains how to update the existing code to use the `weightingFilter` object. The `weightingFilter` object requires Audio Toolbox.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <p><b>A-weighting filter</b></p> <p>Design a class 2, A-weighting filter for a sample rate of 44.1 kHz.</p> <pre>Fs = 44100; d = fdesign.audioweighting('WT,Class','A',2,Fs); wf = design(d,'Systemobject',true);</pre> <p>Visualize the filter response and make sure it fits within the Class 2 mask.</p> <pre>fvtool(wf)</pre> | <p><b>A-weighting filter</b></p> <p>Design a class 2, A-weighting filter for a sample rate of 44.1 kHz.</p> <pre>Fs = 44100; wf = weightingFilter('A-weighting',Fs);</pre> <p>Visualize the filter response and make sure it fits within the Class 2 mask.</p> <pre>visualize(wf,'class 2');</pre> |
| <p><b>C-weighting filter</b></p> <p>Design a class 2, C-weighting filter for a sample rate of 44.1 kHz.</p> <pre>Fs = 44100; d = fdesign.audioweighting('WT,Class','C',2,Fs); wf = design(d,'Systemobject',true);</pre> <p>Visualize the filter response and make sure it fits within the Class 2 mask.</p> <pre>fvtool(wf)</pre> | <p><b>C-weighting filter</b></p> <p>Design a class 2, C-weighting filter for a sample rate of 44.1 kHz.</p> <pre>Fs = 44100; wf = weightingFilter('C-weighting',Fs);</pre> <p>Visualize the filter response and make sure it fits within the Class 2 mask.</p> <pre>visualize(wf,'class 2');</pre> |

## fdesign.bandpass

Bandpass filter design specification object

### Syntax

```
bandpassSpecs = fdesign.bandpass
bandpassSpecs = fdesign.bandpass(spec,value1,...,valueN)
bandpassSpecs = fdesign.bandpass( ___,Fs)
bandpassSpecs = fdesign.bandpass( ___,magunits)
```

### Description

The `fdesign.bandpass` function returns a bandpass filter design specification object that contains specifications for a filter such as passband frequency, stopband frequency, passband ripple, and filter order. Use the `design` function to design the filter from the filter design specifications object.

For more control options, see “Filter Design Procedure” on page 5-399. For a complete workflow, see “Design a Filter in Fdesign — Process Overview”.

`bandpassSpecs = fdesign.bandpass` constructs a bandpass filter design specifications object with the following default values:

- First stopband frequency set to 0.35.
- First passband frequency set to 0.45.
- Second passband frequency set to 0.55.
- Second stopband frequency set to 0.65.
- First stopband attenuation set to 60 dB.
- Passband ripple set to 1dB.
- Second stopband attenuation set to 60 dB.

`bandpassSpecs = fdesign.bandpass(spec,value1,...,valueN)` constructs a bandpass filter specification object with a particular filter order, stopband frequency, passband frequency, and other specification options. Indicate the options you want to specify in the expression `spec`. After the expression, specify a value for each option. If you do not specify values after the `spec` argument, the function assumes the default values.

`bandpassSpecs = fdesign.bandpass( ___,Fs)` provides the sample rate in Hz of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. In this case, all frequencies in the specifications are in Hz as well.

The design specification

```
fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',.4,.5,.6,.7,60,1,80)
```

designs the same filter as

```
fdesign.bandstop('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',1600,2000,2400,2800,60,1,80,8000)
```

`bandpassSpecs = fdesign.bandpass( ___,magunits)` provides the units for the specified magnitude. `magunits` can be one of the following: 'linear', 'dB', or 'squared'. If this argument

is omitted, the object assumes the units of magnitude specification to be 'dB'. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If Fs is provided, magunits must follow Fs in the input argument list.

## Examples

### Design Equiripple FIR Bandpass Filter

Design a constrained-band FIR equiripple filter of order 100 with a passband of [1, 1.4] kHz. Both stopband attenuation values are constrained to 60 dB. The sample rate is 10 kHz.

Create a `bandpass` filter design specification object using the `fdesign.bandpass` function and specify these design parameters.

```
bandpassSpecs = fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);
```

Constrain the two stopbands with a stopband attenuation of 60 dB.

```
bandpassSpecs.Stopband1Constrained = true;
bandpassSpecs.Astop1 = 60;
bandpassSpecs.Stopband2Constrained = true;
bandpassSpecs.Astop2 = 60;
```

Design the bandpass filter using the `design` function. The resulting filter is a `dsp.FIRFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.FIRFilter`.

```
bandpassFilt = design(bandpassSpecs,'Systemobject',true)
```

```
bandpassFilt =
  dsp.FIRFilter with properties:
      Structure: 'Direct form'
      NumeratorSource: 'Property'
      Numerator: [5.5055e-04 5.4751e-05 -2.2052e-05 6.5244e-05 3.6129e-04 5.7237e-04 1.982
      InitialConditions: 0
```

Show all properties

Visualize the frequency response of the designed filter using `fvtool`.

```
fvtool(bandpassFilt)
```

Measure the frequency response characteristics of the filter using `measure`. The passband ripple is slightly over 2 dB. Because the design constrains both stopbands, you cannot constrain the passband ripple.

```
measure(bandpassFilt)
```

```
ans =
Sample Rate           : 10 kHz
First Stopband Edge   : 800 Hz
First 6-dB Point      : 946.7621 Hz
First 3-dB Point      : 975.1807 Hz
First Passband Edge   : 1 kHz
Second Passband Edge  : 1.4 kHz
Second 3-dB Point     : 1.4248 kHz
Second 6-dB Point     : 1.4533 kHz
Second Stopband Edge  : 1.6 kHz
First Stopband Atten. : 60.0614 dB
Passband Ripple       : 2.1443 dB
Second Stopband Atten.: 60.0399 dB
First Transition Width : 200 Hz
Second Transition Width : 200 Hz
```

## Design Butterworth IIR Bandpass Filter

Design a Butterworth IIR bandpass filter. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

Construct a default bandpass filter design specification object using `fdesign.bandpass`.

```
bandpassSpecs = fdesign.bandpass

bandpassSpecs =
    bandpass with properties:
        Response: 'Bandpass'
        Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'
        Description: {7x1 cell}
        NormalizedFrequency: 1
            Fstop1: 0.3500
            Fpass1: 0.4500
            Fpass2: 0.5500
            Fstop2: 0.6500
            Astop1: 60
            Apass: 1
            Astop2: 60
```

Determine the available `designmethods` using the `designmethods` function. To design a Butterworth filter, pick `butter`.

```
designmethods(bandpassSpecs, 'Systemobject', true)
```

Design Methods that support System objects for class `fdesign.bandpass` (Fst1,Fp1,Fp2,Fst2,Ast1,Ap

```
butter
cheby1
cheby2
ellip
equiripple
kaiserwin
```

When designing the filter, you can specify additional design options. View a list of options using the `designoptions` function. The function also shows the default design options the filter uses.

```
designoptions(bandpassSpecs, 'butter')
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    SystemObject: 'bool'
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
```

```

DefaultSOSScaleNorm: ''
DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
DefaultSystemObject: 0

```

Use the `design` function to design the filter. Pass `'butter'` and the specifications given by variable `bandpassSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'`.

```
bpFilter = design(bandpassSpecs, 'butter', 'matchexactly', 'passband', 'SystemObject', true)
```

```

bpFilter =
  dsp.SOSFilter with properties:
    Structure: 'Direct form II'
    CoefficientSource: 'Property'
    Numerator: [7x3 double]
    Denominator: [7x3 double]
    HasScaleValues: true
    ScaleValues: [0.1657 0.1657 0.1561 0.1561 0.1504 0.1504 0.1485 1]

```

Show all properties

Visualize the frequency response of the designed filter.

```
fvtool(bpFilter)
```

## Bandpass Filtering of Sinusoids

Bandpass filter a discrete-time sine wave signal which consists of three sinusoids at frequencies, 1 kHz, 10 kHz, and 15 kHz.

Design an FIR Equiripple bandpass filter by first creating a bandpass filter design specifications object, and then designing a filter using these specifications.

### Design Bandpass Filter

Create a bandpass filter design specifications object using `fdesign.bandpass`.

```
bandpassSpecs = fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2', ...
    1/4,3/8,5/8,6/8,60,1,60);
```

List the available design methods for this object.

```
designmethods(bandpassSpecs)
```

```
Design Methods for class fdesign.bandpass (Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2):
```

```
butter
cheby1
cheby2
ellip
equiripple
kaiserwin
```

To design an Equiripple filter, pick 'equiripple'.

```
bpFilter = design(bandpassSpecs, 'equiripple', 'Systemobject', true)
```

```
bpFilter =
```

```
  dsp.FIRFilter with properties:
```

```
      Structure: 'Direct form'
      NumeratorSource: 'Property'
      Numerator: [-0.0043 -3.0812e-15 0.0136 3.7820e-15 -0.0180 -4.2321e-15 7.1634e-04 4.0
      InitialConditions: 0
```

```
  Show all properties
```

Visualize the frequency response of the designed filter.

```
fvtool(bpFilter, 'Fs', 44100)
```

### Create Sinusoidal Signal

Create a signal that is a sum of three sinusoids with frequencies at 1 kHz, 10 kHz, and 15 kHz. Initialize Spectrum Analyzer to view the original signal and the filtered signal.

```
Sine1 = dsp.SineWave('Frequency',1e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',44.1e3,'SamplesPerFrame',4000);
```

```
SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'ShowLegend',true, ...
    'YLimits',[-240,45]);
```

```
SpecAna.ChannelNames = {'Original noisy signal','Bandpass filtered signal'};
```

### Filter Sinusoidal Signal

Filter the sinusoidal signal using the bandpass filter that has been designed. View the original signal and the filtered signal in the Spectrum Analyzer. The tone at 1 kHz is filtered out and attenuated. The tone at 10 kHz is unaffected, and the tone at 15 kHz is mildly attenuated because it appears in the transition band of the filter.

```
for i = 1 : 1000
    x = Sine1()+Sine2()+Sine3();
    y = bpFilter(x);
    SpecAna(x,y);
```

```
end
release(SpecAna)
```

## Input Arguments

### spec — Specification

'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default) | 'N,F3dB1,F3dB2' | 'N,F3dB1,F3dB2,Ap' | ...

Specification expression, specified as one of these character vectors:

- 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default)
- 'N,F3dB1,F3dB2'
- 'N,F3dB1,F3dB2,Ap'
- 'N,F3dB1,F3dB2,Ast'
- 'N,F3dB1,F3dB2,Ast1,Ap,Ast2'
- 'N,F3dB1,F3dB2,BWp'
- 'N,F3dB1,F3dB2,BWst'
- 'N,Fc1,Fc2'
- 'N,Fc1,Fc2,Ast1,Ap,Ast2'
- 'N,Fp1,Fp2,Ap'

- 'N,Fp1,Fp2,Ast1,Ap,Ast2'
- 'N,Fst1,Fp1,Fp2,Fst2'
- 'N,Fst1,Fp1,Fp2,Fst2,C'
- 'N,Fst1,Fp1,Fp2,Fst2,Ap'
- 'N,Fst1,Fst2,Ast'
- 'Nb,Na,Fst1,Fp1,Fp2,Fst2'

This table describes each option that can appear in the expression.

| Specification option | Description  |
|----------------------|--|
| Ap                   | Amount of ripple allowed in passband, specified as <i>Apass</i> in dB.   |
| Ast                  | Stopband attenuation (dB), specified using <i>Astop</i> .  |
| Ast1                 | Attenuation in the first stopband (dB), specified using <i>Astop1</i> .  |
| Ast2                 | Attenuation in the second stopband (dB), specified using <i>Astop2</i> .   |
| BWp                  | Bandwidth of the filter passband, specified as <i>BWpass</i> in normalized frequency units.  |
| BWst                 | Frequency width between the two stopband frequencies, specified as <i>BWstop</i> in normalized frequency units.                              |
| F3dB1                | Frequency of the 3 dB point below the passband value for the first cutoff, specified in normalized frequency units. Applies to IIR filters.  |
| F3dB2                | Frequency of the 3 dB point below the passband value for the second cutoff, specified in normalized frequency units. Applies to IIR filters. |
| Fc1                  | First cutoff frequency (normalized frequency units), specified using <i>Fcutoff1</i> . Applies to FIR filters.                               |
| Fc2                  | Second cutoff frequency (normalized frequency units), specified using <i>Fcutoff1</i> . Applies to FIR filters.                              |
| Fp1                  | Frequency at the edge of the start of the passband, specified as <i>Fpass1</i> in normalized frequency units.                                |
| Fp2                  | Frequency at the edge of the end of the passband, specified as <i>Fpass2</i> in normalized frequency units.                                  |
| Fst1                 | Frequency at the edge of the end of the first stopband, specified as <i>Fstop1</i> in normalized frequency units.                            |

| Specification option | Description  |
|----------------------|--|
| Fst2                 | Frequency at the edge of the start of the second stop band, specified as Fstop2 in normalized frequency units.   |
| N                    | Filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when Na and Nb are not provided. Specified using FilterOrder.                             |
| Nb                   | Numerator order for IIR filters, specified using the NumOrder property.  |
| Na                   | Denominator order for IIR filters, specified using the DenOrder property.  |
| C                    | Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.<br><br>For more details, see c. |

Graphically, the filter specifications look similar to those shown in this figure.

Regions between specification values like Fst1 and Fp1 are transition regions where the filter response is not explicitly defined.

The design methods available for designing the filter depend on the specification expression. You can obtain these methods using the `designmethods` function. This table lists each specification expression supported by `fdesign.bandpass` and the available corresponding design methods.

| Specification expression               | Supported design methods                             |
|--|--|
| 'Fst1, Fp1, Fp2, Fst2, Ast1, Ap, Ast2' | butter, cheby1, cheby2, ellip, equiripple, kaiserwin |
| 'N, F3dB1, F3dB2'                      | butter   |
| 'N, F3dB1, F3dB2, Ap'                  | cheby1   |
| 'N, F3dB1, F3dB2, Ast'                 | cheby2, ellip  |
| 'N, F3dB1, F3dB2, Ast1, Ap, Ast2'      | ellip  |
| 'N, F3dB1, F3dB2, Bwp'                 | cheby1   |

| Specification expression  | Supported design methods      |
|---------------------------|-------------------------------|
| 'N,F3dB1,F3dB2,BWst'      | cheby2                        |
| 'N,Fc1,Fc2'               | window                        |
| 'N,Fc1,Fc2,Ast1,Ap,Ast2'  | fircls                        |
| 'N,Fp1,Fp2,Ap'            | cheby1                        |
| 'N,Fp1,Fp2,Ast1,Ap,Ast2'  | ellip                         |
| 'N,Fst1,Fp1,Fp2,Fst2'     | iirlpnorm, equiripple, fircls |
| 'N,Fst1,Fp1,Fp2,Fst2,C'   | equiripple                    |
| 'N,Fst1,Fp1,Fp2,Fst2,Ap'  | ellip                         |
| 'N,Fst1,Fst2,Ast'         | cheby2                        |
| 'Nb,Na,Fst1,Fp1,Fp2,Fst2' | iirlpnorm                     |

To design the filter, call the `design` function with one of these design methods as an input. You can choose the type of filter response by passing 'FIR' or 'IIR' to the `design` function. For more details, see `design`. Enter `help(bandpassSpecs, 'method')` at the MATLAB command line to obtain detailed help on the design options for a given design method.

#### **value1, ..., valueN — Specification values**

comma-separated list of values

Specification values, specified as a comma-separated list of values. Specify a value for each option in `spec` in the same order that the options appear in the expression.

Example: `bandpassSpecs = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',n,fc1,fc2,ast1,ap,ast2)`

The input arguments below provide more details for each option in the expression.

#### **n — Filter order**

positive integer

Filter order for FIR filters, specified as a positive integer. In the case of an IIR filter design, if `nb` and `na` are not provided, this value is interpreted as both the numerator order and the denominator order.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **nb — Numerator order for IIR filters**

nonnegative integer

Numerator order for IIR filters, specified as a nonnegative integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **na — Denominator order for IIR filters**

positive integer

Denominator order for IIR filters, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **c — Constrained band flag**

logical

This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification 'N,Fst1,Fp1,Fp2,Fst2,C', you cannot specify constraints for all three bands (two stopbands and one passband) simultaneously. You can specify constraints in any one or two bands.

Consider the following bandpass design specification where both the stopbands are constrained to the default value 60 dB.

```
Example: spec =
fdesign.bandpass('N,Fst1,Fp1,Fp2,Fst2,C',100,800,1e3,1.4e3,1.6e3,1e4);
spec.Stopband1Constrained=true; spec.Stopband2Constrained=true;
```

### ap — Passband ripple

positive scalar

Passband ripple, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the passband ripple is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### ast — Stopband attenuation

positive scalar

Stopband attenuation, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the stopband attenuation is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **ast1 — First stopband attenuation**

positive scalar

Attenuation in the first stopband, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the first stopband attenuation is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **ast2 — Second stopband attenuation**

positive scalar

Attenuation in the second stopband, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the second stopband attenuation is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **F3dB1 — First 3 dB frequency**

positive scalar

First 3 dB frequency, specified as positive scalar in normalized frequency units.

This is the frequency of the 3 dB point below the passband value for the first cutoff. This input argument applies to IIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **F3dB2 — Second 3 dB frequency**

positive scalar

Second 3 dB frequency, specified as positive scalar in normalized frequency units.

This is the frequency of the 3 dB point below the passband value for the second cutoff. This input argument applies to IIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**fc1 – First cutoff frequency**

positive scalar

First cutoff frequency, specified as positive scalar in normalized frequency units.

This input argument applies to FIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fc2 — Second cutoff frequency**

positive scalar

Second cutoff frequency, specified as positive scalar in normalized frequency units.

This input argument applies to FIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fst1 – First stopband frequency**

positive scalar

First stopband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the edge of the end of the first stopband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fst2 – Second stopband frequency**

positive scalar

Second stopband frequency, specified as a positive scalar in normalized frequency units.

This is the frequency at the edge of the start of the second stopband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fp1 – First passband frequency**

positive scalar

First passband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the edge of the start of the first passband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fp2 — Second passband frequency**

positive scalar

Second passband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the edge of the end of the passband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **bwp** — Passband frequency width

positive scalar

Bandwidth of the filter passband in normalized frequency units, specified as a positive scalar less than  $F_{3dB2} - F_{3dB1}$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**bwst — Frequency width between stopband frequencies**

positive scalar

Frequency width between the two stopband frequencies, specified as a positive scalar in normalized frequency units.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Fs — Sample rate**

scalar

Sample rate of the signal to be filtered, specified as a scalar in Hz. Specify the sample rate as a scalar trailing the other numerical values provided. When  $F_s$  is provided,  $F_s$  is assumed to be in Hz, as are all other frequency values. Note that you do not have to change the specification string.

The following design has the specification string set to ' $F_{st1}, F_{p1}, F_{p2}, F_{st2}, A_{st1}, A_p, A_{st2}$ ', and sample rate set to 8000 Hz.

```
bandpassSpecs =
fdesign.bandpass('Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2',1600,2000,2400,2800,60,1,80
,8000); filt = design(bandpassSpecs,'Systemobject',true);
```

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **magunits — Magnitude units**

'dB' (default) | 'linear' | 'squared'

Magnitude specification units, specified as 'dB', 'linear', or 'squared'. If this argument is omitted, the object assumes the units of magnitude to be 'dB'. Note that the magnitude specifications are always converted and stored in dB regardless of how they were specified. If  $F_s$  is one of the input arguments,  $magunits$  must be specified after  $F_s$  in the input argument list.

## Output Arguments

### **bandpassSpecs** — Bandpass filter design specification object

bandpass object

Bandpass filter design specification object, returned as a bandpass object. The fields of the object depend on the spec input character vector.

Consider an example where the spec argument is set to 'N, Fc1, Fc2', and the corresponding values are set to 10, 0.6, and 0.8, respectively. The bandpass filter design specification object is populated with the following fields:

```
>> bandpassSpecs = fdesign.bandpass('N, Fc1, Fc2', 10, 0.6, 0.8)
```

```
bandpassSpecs =
```

[bandpass](#) with properties:

```
        Response: 'Bandpass'  
    Specification: 'N, Fc1, Fc2'  
      Description: {3×1 cell}  
NormalizedFrequency: 1  
      FilterOrder: 10  
      Fcutoff1: 0.6000  
      Fcutoff2: 0.8000
```

## Version History

Introduced in R2009a

### Topics

“Design a Filter in Fdesign — Process Overview”

## fdesign.bandstop

Bandstop filter design specification object

### Syntax

```
bandstopSpecs = fdesign.bandstop
bandstopSpecs = fdesign.bandstop(spec,value1,...,valueN)
bandstopSpecs = fdesign.bandstop( ____,Fs)
bandstopSpecs = fdesign.bandstop( ____,magunits)
```

### Description

The `fdesign.bandstop` function returns a `bandstop` filter design specification object that contains the specifications for a filter, such as passband frequency, stopband frequency, passband ripple, and filter order. Then, use the `design` function to design the filter from the filter design specifications object.

For more control options, see “Filter Design Procedure” on page 5-399. For a complete workflow, see “Design a Filter in Fdesign — Process Overview”.

`bandstopSpecs = fdesign.bandstop` constructs a bandstop filter design specifications object with the following default values:

- First passband frequency set to 0.35.
- First stopband frequency set to 0.45.
- Second stopband frequency set to 0.55.
- Second passband frequency set to 0.65.
- First passband ripple 1 dB.
- Stopband attenuation set to 60 dB.
- Second passband ripple set to 1 dB.

`bandstopSpecs = fdesign.bandstop(spec,value1,...,valueN)` constructs a bandstop filter design specifications object with a particular filter order, passband frequencies, stopband frequencies, and other specification options. Indicate the options you want to specify in the expression `spec`. After the expression, specify a value for each option. If you do not specify values after the `spec` argument, the function assumes the default values.

`bandstopSpecs = fdesign.bandstop( ____,Fs)` provides the sample rate of the signal to be filtered, in Hz. `Fs` must be specified as a scalar trailing the other numerical values provided. In this case, all frequencies in the specifications are in Hz as well.

The design specification

```
fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',.4,.5,.6,.7,1,80,.5)
```

designs the same filter as

```
fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',1600,2000,2400,2800,1,80,0.5,8000)
```

`bandstopSpecs = fdesign.bandstop( ____,magunits)` provides the units for any magnitude specification given. `magunits` can be one of the following: 'linear', 'dB', or 'squared'. If this

argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in dB regardless of how they were specified. If Fs is provided, magunits must follow Fs in the input argument list.

## Examples

### Design Equiripple FIR Bandstop Filter

Design a constrained-band FIR equiripple filter of order 60 with a stopband of [12.8 22.4] kHz. Both passband ripple values are constrained to 1 dB. The sample rate is 64 kHz.

Create a `bandstop` filter design specification object using the `fdesign.bandstop` function and specify these design parameters.

```
bandstopSpecs = fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',60,9.6e3,12.8e3,22.4e3,25.6e3,64000);
```

Constrain the two passbands with a passband ripple of 1 dB.

```
bandstopSpecs.Passband1Constrained = true;
bandstopSpecs.Apass1 = 1;
bandstopSpecs.Passband2Constrained = true;
bandstopSpecs.Apass2 = 1;
```

Design the bandstop filter using the `design` function. The resulting filter is a `dsp.Filter System` object™. For details on how to apply this filter on streaming data, refer to `dsp.FIRFilter`.

```
bandstopFilt = design(bandstopSpecs,'Systemobject',true)
```

```
bandstopFilt =
  dsp.FIRFilter with properties:
    Structure: 'Direct form'
    NumeratorSource: 'Property'
    Numerator: [-3.6116e-04 -0.0027 -3.1395e-04 -0.0033 0.0030 0.0030 -8.4856e-04 0.0017
    InitialConditions: 0
```

Show all properties

Visualize the frequency response of the designed filter using `fvtool`.

```
fvtool(bandstopFilt)
```

Measure the frequency response characteristics of the filter using `measure`.

```
measure(bandstopFilt)
```

```
ans =
Sample Rate           : 64 kHz
First Passband Edge   : 9.6 kHz
First 3-dB Point      : 10.5255 kHz
First 6-dB Point      : 10.9058 kHz
First Stopband Edge   : 12.8 kHz
Second Stopband Edge  : 22.4 kHz
Second 6-dB Point     : 24.2866 kHz
Second 3-dB Point     : 24.6685 kHz
Second Passband Edge  : 25.6 kHz
First Passband Ripple : 0.11754 dB
Stopband Atten.       : 69.3934 dB
Second Passband Ripple : 0.11761 dB
First Transition Width : 3.2 kHz
Second Transition Width : 3.2 kHz
```

### Design Minimum Order Elliptic Bandstop Filter

Design a minimum order elliptic bandstop filter. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

Construct `fdesign.bandstop` in the default state and input the design specifications to the function.

```
bandstopSpecs = fdesign.bandstop(.3,.4,.6,.7,.5,60,1)
```

```
bandstopSpecs =
    bandstop with properties:
        Response: 'Bandstop'
        Specification: 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'
        Description: {7x1 cell}
        NormalizedFrequency: 1
            Fpass1: 0.3000
            Fstop1: 0.4000
            Fstop2: 0.6000
            Fpass2: 0.7000
            Apass1: 0.5000
            Astop: 60
            Apass2: 1
```

Determine the available `designmethods` using the `designmethods` function. To design an elliptic filter, pick `ellip`.

```
designmethods(bandstopSpecs,'Systemobject',true)
```

```
Design Methods that support System objects for class fdesign.bandstop (Fp1,Fst1,Fst2,Fp2,Ap1,Ast
```

```
butter
cheby1
cheby2
ellip
equiripple
kaiserwin
```

When designing the filter, you can specify additional design options. View a list of options using the `designoptions` function. The function also shows the default design options the filter uses.

```
designoptions(bandstopSpecs,'ellip')
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband' 'both'}
    SystemObject: 'bool'
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'both'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
    DefaultSystemObject: 0
```

Use the `design` function to design the filter. Pass `'ellip'` and the specifications given by the variable `'bandstopSpecs'`, as input arguments.

```
bsFilter = design(bandstopSpecs, 'ellip', 'Systemobject', true)
```

```
bsFilter =  
  dsp.SOSFilter with properties:  
    Structure: 'Direct form II'  
  CoefficientSource: 'Property'  
    Numerator: [5x3 double]  
  Denominator: [5x3 double]  
  HasScaleValues: true  
  ScaleValues: [0.5324 0.5324 0.6221 0.6221 0.8855 1]
```

Show all properties

Visualize the frequency response of the designed filter.

```
fvtool(bsFilter)
```

## Bandstop Filtering of Sinusoids

Construct a bandstop filter to reject the discrete frequency band between  $3\pi/8$  and  $5\pi/8$  rad/sample. With a sampling frequency of 48 kHz, these values translate to a frequency range of [9 15] kHz. Apply the filter to a discrete-time signal consisting of the superposition of three discrete-time sinusoids.

The filter is designed by first creating a bandstop filter design specifications object, and then passing the object as an input to the design function.

### Design Bandstop Filter

Create a bandstop filter design specifications object using `fdesign.bandstop`.

```
bandstopSpecs = fdesign.bandstop(1/4,3/8,5/8,6/8,1,60,1)
```

```
bandstopSpecs =
  bandstop with properties:

      Response: 'Bandstop'
  Specification: 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'
  Description: {7x1 cell}
  NormalizedFrequency: 1
      Fpass1: 0.2500
      Fstop1: 0.3750
      Fstop2: 0.6250
      Fpass2: 0.7500
      Apass1: 1
      Astop: 60
      Apass2: 1
```

List the available design methods for this object.

```
designmethods(bandstopSpecs)
```

```
Design Methods for class fdesign.bandstop (Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2):
```

```
butter
cheby1
cheby2
ellip
equiripple
kaiserwin
```

To design an equiripple filter, pick 'equiripple'.

```
bsFilter = design(bandstopSpecs,'equiripple','Systemobject',true)
```

```
bsFilter =
  dsp.FIRFilter with properties:

      Structure: 'Direct form'
  NumeratorSource: 'Property'
      Numerator: [0.0054 -1.9744e-15 0.0202 -3.1206e-15 0.0064 -4.0688e-15 -0.0306 -3.6307e-15]
  InitialConditions: 0

  Show all properties
```

Visualize the frequency response of the designed filter.

```
fvtool(bsFilter, 'Fs', 48000)
```

### Create Sinusoidal Signal

Create a signal that is a sum of three sinusoids with frequencies at 1 kHz, 12 kHz, and 16 kHz. Initialize Spectrum Analyzer to view the original signal and the filtered signal.

```
Sine1 = dsp.SineWave('Frequency', 1e3, 'SampleRate', 44.1e3, 'SamplesPerFrame', 4000);
Sine2 = dsp.SineWave('Frequency', 12e3, 'SampleRate', 44.1e3, 'SamplesPerFrame', 4000);
Sine3 = dsp.SineWave('Frequency', 16e3, 'SampleRate', 44.1e3, 'SamplesPerFrame', 4000);
```

```
SpecAna = spectrumAnalyzer('PlotAsTwoSidedSpectrum', false, ...
    'SampleRate', Sine1.SampleRate, ...
    'ShowLegend', true, ...
    'YLimits', [-240, 45]);
```

```
SpecAna.ChannelNames = {'Original noisy signal', 'Filtered signal'};
```

### Filter Sinusoidal Signal

Filter the sinusoidal signal using the bandstop filter that has been designed. View the original signal and the filtered signal in the Spectrum Analyzer. The tone at 1 kHz is unaffected. The tone at 12 kHz is filtered out and attenuated, and the tone at 16 kHz is mildly attenuated because it appears in the transition band of the filter.

```

for i = 1 : 10000
    x = Sine1()+Sine2()+Sine3();
    y = bsFilter(x);
    SpecAna(x,y);
end
release(SpecAna)

```

## Input Arguments

### spec — Specification

'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default) | 'N,F3dB1,F3dB2' | 'N,F3dB1,F3dB2,Ap' | ...

Specification expression, specified as one of these character vectors:

- 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default)
- 'N,F3dB1,F3dB2'
- 'N,F3dB1,F3dB2,Ap' \*
- 'N,F3dB1,F3dB2,Ap,Ast' \*
- 'N,F3dB1,F3dB2,Ast' \*
- 'N,F3dB1,F3dB2,BWp' \*
- 'N,F3dB1,F3dB2,BWst' \*
- 'N,Fc1,Fc2'

- 'N, Fc1, Fc2, Ap1, Ast, Ap2'
- 'N, Fp1, Fp2, Ap'
- 'N, Fp1, Fp2, Ap, Ast'
- 'N, Fp1, Fst1, Fst2, Fp2'
- 'N, Fp1, Fst1, Fst2, Fp2, C' \*
- 'N, Fp1, Fst1, Fst2, Fp2, Ap' \*
- 'N, Fst1, Fst2, Ast'
- 'Nb, Na, Fp1, Fst1, Fst2, Fp2' \*

This table describes each option that can appear in the expression.

| Specification option | Description  |
|----------------------|--|
| Ap                   | Amount of ripple allowed in passband, specified as <i>Apass</i> in dB.   |
| Ap1                  | Amount of ripple allowed in the first passband, specified as <i>Apass1</i> in dB.  |
| Ap2                  | Amount of ripple allowed in the second passband, specified as <i>Apass2</i> in dB.   |
| Ast                  | Stopband attenuation (dB), specified using <i>Astop</i> .  |
| BWp                  | Bandwidth of the filter passband, specified as <i>BWpass</i> in normalized frequency units.  |
| BWst                 | Bandwidth of the filter stopband, specified as <i>BWstop</i> in normalized frequency units.  |
| F3dB1                | Frequency of the 3 dB point below the passband value for the first cutoff, specified in normalized frequency units. Applies to IIR filters.  |
| F3dB2                | Frequency of the 3 dB point below the passband value for the second cutoff, specified in normalized frequency units. Applies to IIR filters. |
| Fc1                  | First cutoff frequency (normalized frequency units), specified using <i>Fcutoff1</i> . Applies to FIR filters.                               |
| Fc2                  | Second cutoff frequency (normalized frequency units), specified using <i>Fcutoff1</i> . Applies to FIR filters.                              |
| Fp1                  | Frequency at the start of the pass band, specified as <i>Fpass1</i> in normalized frequency units.   |
| Fp2                  | Frequency at the end of the pass band, specified as <i>Fpass2</i> in normalized frequency units.   |
| Fst1                 | Frequency at the end of the first stop band, specified as <i>Fstop1</i> in normalized frequency units.                                       |

| Specification option | Description   |
|----------------------|---|
| Fst2                 | Frequency at the start of the second stop band, specified as Fstop2 in normalized frequency units.  |
| N                    | Filter order for FIR filters. Or both the numerator and denominator orders for IIR filters when Na and Nb are not provided. Specified using FilterOrder.  |
| Nb                   | Numerator order for IIR filters, specified using the DenOrder property.   |
| Na                   | Denominator order for IIR filters, specified using the NumOrder property.   |
| C                    | <p>Constrained band flag. This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.</p> <p>In the specification 'N,Fp1,Fst1,Fst2,Fp2,C', you cannot specify constraints in both passbands and the stopband simultaneously. You can specify constraints in any one or two bands.</p> |

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like Fp1 and Fst1 are transition regions where the filter response is not explicitly defined.

The design methods available for designing the filter depend on the specification expression. You can obtain these methods using the `designmethods` function. The table lists each specification expression supported by `fdesign.bandstop` and the corresponding design methods available.

| Specification expression        | Supported design methods                             |
|---------------------------------|--|
| 'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' | butter, cheby1, cheby2, ellip, equiripple, kaiserwin |
| 'N,F3dB1,F3dB2'                 | butter   |
| 'N,F3dB1,F3dB2,Ap'              | cheby1   |

| Specification expression       | Supported design methods      |
|--------------------------------|-------------------------------|
| 'N, F3dB1, F3dB2, Ap, Ast'     | ellip                         |
| 'N, F3dB1, F3dB2, Ast'         | cheby2, ellip                 |
| 'N, F3dB1, F3dB2, BWp'         | cheby1                        |
| 'N, F3dB1, F3dB2, BWst'        | cheby2                        |
| 'N, Fc1, Fc2'                  | window                        |
| 'N, Fc1, Fc2, Ap1, Ast, Ap2'   | fircls                        |
| 'N, Fp1, Fp2, Ap'              | cheby1                        |
| 'N, Fp1, Fp2, Ap, Ast'         | ellip                         |
| 'N, Fp1, Fst1, Fst2, Fp2'      | iirlpnorm, equiripple, fircls |
| 'N, Fp1, Fst1, Fst2, Fp2, C'   | equiripple                    |
| 'N, Fp1, Fst1, Fst2, Fp2, Ap'  | ellip                         |
| 'N, Fst1, Fst2, Ast'           | cheby2                        |
| 'Nb, Na, Fp1, Fst1, Fst2, Fp2' | iirlpnorm                     |

To design the filter, call the `design` function with one of these design methods as an input. You can choose the type of filter response by passing 'FIR' or 'IIR' to the `design` function. For more details, see `design`. Enter `help(bandstopSpecs, 'method')` at the MATLAB command line to obtain detailed help on the design options for a given design method, 'method'.

For more details on the procedure, see “Filter Design Procedure” on page 5-399. For an example, see “Design Notch Filter” on page 5-543.

### **value1, ..., valueN — Specification values**

comma-separated list of values

Specification values, specified as a comma-separated list of values. Specify a value for each option in `spec` in the same order that the options appear in the expression.

Example: `bandstopSpecs = fdesign.bandstop('N, Fp1, Fst1, Fst2, Fp2, C', n, fp1, fst1, fst2, fp2, c)`

The arguments below describe more details for each option in the expression.

#### **n — Filter order**

positive integer

Filter order for FIR filters, specified as a positive integer. In the case of IIR filter design, if `nb` and `na` are not provided, this value is interpreted as both the numerator order and the denominator order.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **nb — Numerator order for IIR filters**

nonnegative integer

Numerator order for IIR filters, specified as a nonnegative integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **na — Denominator order for IIR filters**

positive integer

Denominator order for IIR filters, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **c** — Constrained band flag

logical

This enables you to specify passband ripple or stopband attenuation for fixed-order designs in one or two of the three bands.

In the specification `'N,Fp1,Fst1,Fst2,Fp2,C'`, you cannot specify constraints for all three bands (two passbands and one stopband) simultaneously. You can specify constraints in any one or two bands.

Consider the following bandstop design specification where both the passbands are constrained to the default value, 1 dB.

```
Example: spec =
fdesign.bandstop('N,Fp1,Fst1,Fst2,Fp2,C',10,0.35,0.45,0.55,0.65);
spec.Passband1Constrained=true; spec.Passband2Constrained=true;
```

### **ap** — Passband ripple

positive scalar

Passband ripple, specified as a positive scalar in dB. If `magunits` is `'linear'` or `'squared'`, the passband ripple is converted and stored in dB by the function regardless of how it has been specified.

The specified `ap` value applies to both the first passband and the second passband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### ap1 — First passband ripple in dB

positive scalar

Amount of ripple allowed in the first passband, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the first passband ripple is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### ap2 — Second passband ripple in dB

positive scalar

Amount of ripple allowed in the second passband, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the second passband ripple is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### ast — Stopband attenuation in dB

positive scalar

Stopband attenuation, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the stopband attenuation is converted and stored in dB by the function regardless of how it has been specified.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**bwp — Passband frequency width**

positive scalar

Bandwidth of the filter passband in normalized frequency units, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**bwst — Stopband frequency width**

positive scalar

Bandwidth of the filter stopband in normalized frequency units, specified as a positive scalar less than  $F_{3dB2} - F_{3dB1}$ .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**F3dB1 — First 3 dB frequency**

positive scalar

First 3 dB frequency, specified as positive scalar in normalized frequency units.

This is the frequency of the 3 dB point below the passband value for the first cutoff. Applies to IIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**F3dB2 — Second 3 dB frequency**

positive scalar

Second 3 dB frequency, specified as positive scalar in normalized frequency units.

This is the frequency of the 3 dB point below the passband value for the second cutoff. Applies to IIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**fc1 – First cutoff frequency**

positive scalar

First cutoff frequency, specified as positive scalar in normalized frequency units.

Applies to FIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**fc2 — Second cutoff frequency**

positive scalar

Second cutoff frequency, specified as positive scalar in normalized frequency units.

Applies to FIR filters only.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**fst1 — First stopband frequency**

positive scalar

First stopband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the start of the stopband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fst2 — Second stopband frequency**

positive scalar

Second stopband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the end of the stopband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**fp1 — First passband frequency**

positive scalar

First passband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the end of the first passband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **fp2 — Second passband frequency**

positive scalar

Second passband frequency, specified as positive scalar in normalized frequency units.

This is the frequency at the start of the second passband.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **Fs — Sample rate**

scalar

Sample rate of the signal to be filtered, specified as a scalar in Hz. Specify the sample rate as a scalar trailing the other numerical values provided. When `Fs` is provided, `Fs` is assumed to be in Hz, as are all other frequency values provided. Note that you do not have to change the specification string.

The following design has the specification string set to `'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2'`, and sample rate set to 8000 Hz.

```
bandstopSpecs =
fdesign.bandstop('Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2',1600,2000,2400,2800,1,80,.5,
8000); filt = design(bandstopSpecs,'Systemobject',true);
```

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **magunits — Magnitude units**

'dB' (default) | 'linear' | 'squared'

Magnitude specification units, specified as `'dB'`, `'linear'`, or `'squared'`. If this argument is omitted, `'dB'` is assumed. Note that the magnitude specifications are always converted and stored in dB regardless of how they were specified. If `Fs` is one of the input arguments, `magunits` must be specified after `Fs` in the input argument list.

## Output Arguments

### bandstopSpecs — Bandstop filter design specification object

bandstop object

Bandstop filter design specification object, returned as a bandstop object. The fields of the object depend on the spec input character vector.

Consider an example where the spec argument is set to 'N,Fc1,Fc2', and the corresponding values are set to 10, 0.6, and 0.8, respectively. The bandstop filter design specification object is populated with the following fields:

```
>> bandstopSpecs = fdesign.bandstop('N,Fc1,Fc2',10,0.6,0.8)
```

```
bandstopSpecs =
```

```
bandstop with properties:
```

```
    Response: 'Bandstop'  
 Specification: 'N,Fc1,Fc2'  
 Description: {3×1 cell}  
 NormalizedFrequency: 1  
    FilterOrder: 10  
    Fcutoff1: 0.6000  
    Fcutoff2: 0.8000
```

“Design a Filter in Fdesign — Process Overview”

## fdesign.ciccomp

CIC compensator filter specification object

### Syntax

```
d= fdesign.ciccomp
d= fdesign.ciccomp(d,nsections,rcic)
d= fdesign.ciccomp(...,spec)
h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)
```

### Description

`d= fdesign.ciccomp` constructs a CIC compensator specifications object `d`, applying default values for the properties `Fpass`, `Fstop`, `Apass`, and `Astop`. In this syntax, the filter has two sections and the differential delay is 1.

Using `fdesign.ciccomp` with `design` method creates a System object, if the 'SystemObject' flag is set to `true`.

`d= fdesign.ciccomp(d,nsections,rcic)` constructs a CIC compensator specifications object with the filter differential delay set to `d`, the number of sections in the filter set to `nsections`, and the CIC rate change factor set to `rcic`. The default values of these parameters are: the differential delay equal to 1, the number of sections equal to 2, and the CIC rate change factor equal to 1.

If the CIC rate change factor is equal to 1, the filter passband response is an inverse sinc that is an approximation to the true inverse passband response of the CIC filter.

If you specify a CIC rate change factor not equal to 1, the filter passband response is an inverse Dirichlet sinc that matches exactly the true inverse passband response of the CIC filter.

`d= fdesign.ciccomp(...,spec)` constructs a CIC Compensator specifications object and sets its `Specification` property to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown in the list below. The entries are not case sensitive.

- 'fp,fst,ap,ast' (default spec)
- 'n,fc,ap,ast'
- 'n,fp,ap,ast'
- 'n,fp,fst'
- 'n,fst,ap,ast'

The filter specifications are defined as follows:

- `ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.
- `ast` — attenuation in the stop band in decibels (the default units). Also called `Astop`.
- `fc` — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.

- $f_p$  — frequency at the end of the pass band. Specified in normalized frequency units. Also called  $F_{pass}$ .
- $f_{st}$  — frequency at the start of the stop band. Specified in normalized frequency units. Also called  $F_{stop}$ .
- $n$  — filter order.

In graphic form, the filter specifications look like this:

Regions between specification values like  $f_p$  and  $f_{st}$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a CIC compensator specifications object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

`h = fdesign.ciccomp(...,spec,specvalue1,specvalue2,...)` constructs an object and sets the specifications in the order they are specified in the `spec` input when you construct the object.

## Designing CIC Compensators

Typically, when they develop filters, designers want flat passbands and transition regions that are as narrow as possible. CIC filters present a  $(\sin x/x)$  profile in the passband and relatively wide transitions.

To compensate for this fall off in the passband, and to try to reduce the width of the transition region, you can use a CIC compensator filter that demonstrates an  $(x/\sin x)$  profile in the passband. `fdesign.ciccomp` is specifically tailored to designing CIC compensators.

You can design a compensator for CIC filter using differential delay,  $d$ , number of sections, `numberofsections`, and the usable passband frequency,  $F_{pass}$ .

By taking the number of sections, passband, and differential delay from your CIC filter and using them in the definition of the CIC compensator, the resulting compensator filter effectively corrects for the passband droop of the CIC filter, and narrows the transition region.

As a demonstration of this concept, this example creates a CIC decimator and its compensator.

```
fs = 96e3; % Input sampling frequency.
fpass = 4e3; % Frequency band of interest.
m = 6; % Decimation factor.
hcic = design(fdesign.decimator(m,'cic',1,fpass,60,fs),'SystemObject',true);
```

```

hd = design(fdesign.ciccomp(hcic.DifferentialDelay, ...
    hcic.NumSections, fpass, 4.5e3, .1, 60, fs/m), 'SystemObject', true);
hvft = fvtool(hcic, hd, ...
cascade(hcic, hd), 'ShowReference', 'off', 'Fs', [96e3 96e3/m 96e3]);
legend(hvft, 'CIC Decimator', 'CIC Compensator', 'Resulting Cascade Filter');

```

Here is a plot of a CIC filter and a compensator for that filter.

## Examples

### Design a CIC Compensator Using fdesign Object

Designed to compensate for the rolloff inherent in CIC filters, CIC compensators can improve the performance of your CIC design. This example designs a compensator  $d$  with five sections and a differential delay equal to one. The plot displayed after the code shows the increasing gain in the passband that is characteristic of CIC compensators, to overcome the droop in the CIC filter passband. Ideally, cascading the CIC compensator with the CIC filter results in a lowpass filter with flat passband response and narrow transition region.

```

h = fdesign.ciccomp;
set(h, 'NumberOfSections', 5, 'DifferentialDelay', 1);
cicComp = design(h, 'equiripple', 'SystemObject', true);
fvtool(cicComp)

```

This compensator would work for a decimator or interpolator that had differential delay of 1 and 5 sections.

## fdesign.comb

IIR comb filter specification object

### Syntax

```
d=fdesign.comb
d=fdesign.comb(combtype)
d=fdesign(combtype,specstring)
d=fdesign(combtype,specstring,specvalue1,specvalue2,...)
d=fdesign.comb(...,Fs)
```

### Description

`fdesign.comb` specifies a peaking or notching comb filter. Comb filters amplify or attenuate a set of harmonically related frequencies.

`d=fdesign.comb` creates a notching comb filter specification object and applies default values for the filter order ( $N=10$ ) and quality factor ( $Q=16$ ).

`d=fdesign.comb(combtype)` creates a comb filter specification object of the specified type and applies default values for the filter order and quality factor. The valid entries for `combtype` are shown in the following table. The entries are not case-sensitive.

| Argument | Description  |
|----------|--|
| notch    | creates a comb filter that attenuates a set of harmonically related frequencies. |
| peak     | creates a comb filter that amplifies a set of harmonically related frequencies.  |

`d=fdesign(combtype,specstring)` creates a comb filter specification object of type `combtype` and sets its `Specification` property to `specstring` with default values. The entries in `specstring` determine the number of peaks or notches in the comb filter as well as their bandwidth and slope. Valid entries for `specstring` are shown below. The entries are not case-sensitive.

- 'N,Q' (default)
- ''N,BW'
- 'L,BW,GWB,Nsh'

The following table describes the arguments in `specstring`.

| Argument | Description   |
|----------|---|
| BW       | Bandwidth of the notch or peak. By default the bandwidth is calculated at the point -3 dB down from the center frequency of the peak or notch. For example, setting <code>BW=0.01</code> specifies that the -3 dB point will be +/- 0.005 (in normalized frequency) from the center of the notch or peak. |

| Argument | Description  |
|----------|--|
| GWB      | Gain at which the bandwidth is measured. This allows the user to specify the bandwidth of the notch or peak at a gain different from the -3 dB default.  |
| L        | Upsampling factor for a shelving filter of order Nsh. L determines the number of peaks or notches, which are equally spaced over the normalized frequency interval [-1,1].   |
| N        | Filter order. Specifies a filter with N+1 numerator and denominator coefficients. The filter will have N peaks or notches equally spaced over the interval [-1,1].   |
| Nsh      | Shelving filter order. Nsh represents a positive integer that determines the sharpness of the peaks or notches. The greater the value of the shelving filter order, the steeper the slope of the peak or notch. This results in a filter of order L*Nsh. |
| Q        | Peak or notch quality factor. Q represents the ratio of the lowest center frequency peak or notch (not including DC) to the bandwidth calculated at the -3 dB point.   |

`d=fdesign(combtype,specstring,specvalue1,specvalue2,...)` creates an IIR comb filter specification object of type `combtype` and sets its `Specification` property to the values in `specvalue1,specvalue2,...`

`d=fdesign.comb(...,Fs)` creates an IIR comb filter specification object using the sampling frequency, `Fs`, of the signal to be filtered. The function assumes that `Fs` is in Hertz and must be specified as a scalar trailing all other provided values.

## Examples

### Construct a Peaking and Notching Combining Filter

These examples demonstrate how to create IIR comb filter specification objects.

First, create a default specification object.

```
d = fdesign.comb; %#ok
```

In the next example, create a notching filter of order 8 with a bandwidth of 0.02 (normalized frequency) referenced to the -3 dB point.

```
d = fdesign.comb('notch','N,BW',8,0.02);
Hd = design(d,'SystemObject',true);
fvtool(Hd);
```

Next, create a peaking comb filter with 5 peaks and a quality factor of 25.

```
d = fdesign.comb('peak', 'N,Q', 5, 25);  
Hd = design(d, 'SystemObject', true);  
fvtool(Hd);
```

In the next example, create a notching filter to remove interference at 60 Hz and its harmonics. The following code creates a filter with 10 notches and a notch bandwidth of 5 Hz referenced to the -4dB level. The filter has a shelving filter order of 4 and a sampling frequency of 600 Hz. Because the notches are equidistantly spaced in the interval [-300, 300] Hz, they occur at multiples of 60 Hz.

```
d = fdesign.comb('notch','L,BW,GBW,Nsh',10,5,-4,4,600);
Hd=design(d,'SystemObject',true);
fvtool(Hd);
```

## Version History

# fdesign.decimator

Decimator filter specification object

---

## Note

---

**Note** The 'Raised Cosine' and 'Square Root Raised Cosine' response methods in the `fdesign.decimator` object will be removed in a future release. Use `rcosdesign` and `comm.RaisedCosineReceiveFilter` instead.

---

---

**Note** Support for designing an `mfilt.firdecim` object using the `fdesign.decimator` and the design functions will be removed in a future release. Use the `design` function with the `SystemObject=true` flag to design an FIR decimator System object™.

---

---

**Note** Support for multistage filter design using the `fdesign.decimator` object will be removed in a future release. Use the `designMultistageDecimator` function instead.

---

For more information, see “Compatibility Considerations”.

---

## Syntax

```
decimSpecs = fdesign.decimator(M)
decimSpecs = fdesign.decimator(M, RESPONSE)
decimSpecs = fdesign.decimator(M, CICRESPONSE, D)
decimSpecs = fdesign.decimator(M, RESPONSE, SPEC)
decimSpecs = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)
decimSpecs = fdesign.decimator(...,Fs)
decimSpecs = fdesign.decimator(...,MAGUNITS)
```

## Description

`decimSpecs = fdesign.decimator(M)` constructs a decimator filter specification object `decimSpecs` with the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to 'Nyquist'. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `M` is unspecified, `M` defaults to 2.

`decimSpecs = fdesign.decimator(M, RESPONSE)` constructs a decimator specification object with the decimation factor `M` and the 'Response' property.

`decimSpecs = fdesign.decimator(M, CICRESPONSE, D)` constructs a CIC or CIC compensator decimator specification object with the decimation factor, `M`, 'Response' property equal to 'CIC' or 'CICCOMP', and `D` equal to the differential delay on page 4-252. The differential delay `D` must precede any specification option.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters. The decimation factor  $M$  is not included in the specification options. Different filter responses support different specifications. The following table lists the supported response types and specification options. The options are not case sensitive.

| Design Method                   | Valid Specification Options   |
|---------------------------------|---|
| 'Arbitrary Magnitude'           | See <code>fdesign.arbmag</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,A' (default option)</li> <li>'N,B,F,A'</li> </ul>   |
| 'Arbitrary Magnitude and Phase' | See <code>fdesign.arbmagnphase</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,H' (default option)</li> <li>'N,B,F,H'</li> </ul>   |
| 'Bandpass'                      | See <code>fdesign.bandpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default option)</li> <li>'N,Fc1,Fc2'</li> <li>'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>   |
| 'Bandstop'                      | See <code>fdesign.bandstop</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,Fc1,Fc2'</li> <li>'N,Fp1,Fst1,Fst2,Fp2'</li> <li>'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default option)</li> </ul>  |
| 'CIC'                           | 'Fp,Ast' — Only valid specification. Fp is the passband frequency and Ast is the stopband attenuation in decibels.<br><br>To specify a CIC decimator, include the differential delay after 'CIC' and before the filter specification option: 'Fp,Ast'. For example:<br><code>d = fdesign.decimator(2,'cic',4,'Fp,Ast',0.4,40);</code>   |
| 'CIC Compensator'               | See <code>fdesign.ciccomp</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fst,Ap,Ast'</li> </ul><br>To specify a CIC compensator decimator, include the differential delay after 'CICCOMP' and before the filter specification. For example:<br><code>d = fdesign.decimator(2,'ciccomp',4);</code> |

| 'Hilbert'               | <p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N, TW' (default option)</li> <li>• 'TW, Ap'</li> </ul>  |
| 'Inverse-sinc Lowpass'  | <p>See <code>fdesign.isinclp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp, Fst, Ap, Ast' (default option)</li> <li>• 'N, Fc, Ap, Ast'</li> <li>• 'N, Fp, Fst'</li> <li>• 'N, Fst, Ap, Ast'</li> </ul>  |
| 'Inverse-sinc Highpass' | <p>See <code>fdesign.isinchp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst, Fp, Ast, Ap' (default option)</li> <li>• 'N, Fc, Ast, Ap'</li> <li>• 'N, Fst, Fp'</li> <li>• 'N, Fst, Ast, Ap'</li> </ul>  |

| Design Method | Valid Specification Options  |
|---------------|--|
| 'Lowpass'     | See <code>fdesign.lowpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,F3dB'</li> <li>'N,Fc'</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fp,Fst,Ap'</li> <li>'N,Fp,Fst,Ast'</li> <li>'N,Fst,Ap,Ast'</li> </ul>       |
| 'Nyquist'     | See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the <i>L</i> th band. This typically corresponds to the <code>DecimationFactor</code> . <ul style="list-style-type: none"> <li>'TW,Ast' (default option)</li> <li>'N'</li> <li>'N,Ast'</li> <li>'N,Ast'</li> </ul> |

`decimSpecs = fdesign.decimator(M, RESPONSE, SPEC)` constructs object `decimSpecs` and sets the `Specification` property to `SPEC` for the response type, `RESPONSE`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` depend on the `RESPONSE` type.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with such response types as `fdesign.lowpass`. The options are not case sensitive.

The decimation factor `M` is not in the specification options.

`decimSpecs = fdesign.decimator(...,SPEC,specvalue1,specvalue2,...)` constructs an object `decimSpecs` and sets its specifications at construction time.

`decimSpecs = fdesign.decimator(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`decimSpecs = fdesign.decimator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Construct a Decimator Using fdesign Object

These examples show how to construct decimating filter specification objects.

First, create a default specifications object without using input arguments except for the decimation factor  $m$ .

```
d = fdesign.decimator(2, 'Nyquist', 2, 0.1, 80) %#ok % Set tw=0.1, and ast=80.
```

```
d =
  decimator with properties:
      MultirateType: 'Decimator'
      Response: 'Nyquist'
  DecimationFactor: 2
      Specification: 'TW,Ast'
      Description: {2x1 cell}
      Band: 2
  NormalizedFrequency: 1
      TransitionWidth: 0.1000
      Astop: 80
```

Now create an object by passing a specification type option 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design - the resulting object uses default values for the filter specifications. You must provide the design input argument, bandpass in this example, when you include a specification.

```
d = fdesign.decimator(8, 'bandpass', ...
  'fst1,fp1,fp2,fst2,ast1,ap,ast2'); %#ok
```

Create another decimating filter specification object, passing the specification values to the object rather than accepting the default values for fp,fst,ap,ast.

```
d = fdesign.decimator(3, 'lowpass', .45, 0.55, .1, 60); %#ok
```

Now pass the filter specifications that correspond to the specifications - n,fc,ap,ast.

```
d = fdesign.decimator(3, 'ciccomp', 1, 2, 'n,fc,ap,ast', ...
  20, 0.45, .05, 50);
```

Now design a decimator using the equiripple design method.

```
equiDecimator = design(d, 'equiripple', SystemObject=true);
```

Pass a new specification type for the filter, specifying the filter order. Note that the inputs must include the differential delay  $dd$  with the CIC input argument to design a CIC specification object.

```
m = 5;
dd = 2;
d = fdesign.decimator(m, 'cic', dd, 'fp,ast', 0.55, 55); %#ok
```

In this example, you specify a sampling frequency as the last input argument. Here is it 1000 Hz. Design an equiripple filter and plot the magnitude response:

```
d = fdesign.decimator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2',...
100,150,250,300,50,.05,50,1000);
fvtool(design(d, 'equiripple', SystemObject=true))
```

## Version History

Introduced in R2011a

**R2022a: 'Raised Cosine' and 'Square Root Raised Cosine' response methods will be removed**

*Warns starting in R2022a*

The 'Raised Cosine' and 'Square Root Raised Cosine' response methods in the `fdesign.decimator` object will be removed in a future release. Use `rcosdesign` and `comm.RaisedCosineReceiveFilter` instead.

**R2022b: Support for multistage design in `fdesign.decimator` will be removed**

*Warns starting in R2022b*

Support for multistage filter design using the `fdesign.decimator` object will be removed in a future release. Use the `designMultistageDecimator` function instead.

### Update Code

This table shows how to update your code.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| Using the design function and passing the 'multistage' flag as an input.<br><br><pre>D = 9; % Decimation factor TW = 2205; % Transition width Astop = 80; % Stopband attenuation Fs = 44100; % Input sample rate filtSpec = fdesign.decimator(D,'nyquist',D,TW,Astop,Fs) filtObj = design(filtSpec,'multistage',SystemObject=true)</pre> | When you set the cost method to 'design', the function designs an optimal number of stages so that the overall cost of implementation is low.<br><br><pre>filtObj = designMultistageDecimator(D,Fs,TW,Astop,... CostMethod='design')</pre> |
| Using the multistage function directly.<br><br><pre>filtObj = multistage(filtSpec,SystemObject=true)</pre>   |  |

### R2022b: Support for designing `mfilt.firdecim` will be removed

Warns starting in R2022b

Support for designing an `mfilt.firdecim` object using the `fdesign.decimator` and the `design` functions will be removed in a future release.

To design an FIR decimator using the `fdesign.decimator` filter specification object, use the `design` function with the `SystemObject=true` flag. Setting this flag to true ensures that the output object is a filter `System` object instead of an `mfilt.firdecim` object.

```
fdesignObj = fdesign.decimator;
FIRDecimObj = design(fdesignObj,SystemObject=true)
```

```
FIRDecimObj =
```

```
    dsp.FIRDecimator with properties:
```

```
    DecimationFactor: 2
    NumeratorSource: 'Property'
        Numerator: [-1.5162e-05 0 4.1707e-05 0 ... ]
        Structure: 'Direct form'
```

```
    Show all properties
```

## fdesign.differentiator

Differentiator filter specification object

### Syntax

```
D = fdesign.differentiator
D = fdesign.differentiator(SPEC)
D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)
D = fdesign.differentiator(specvalue1)
D = fdesign.differentiator(...,Fs)
D = fdesign.differentiator(...,MAGUNITS)
```

### Description

`D = fdesign.differentiator` constructs a default differentiator filter designer `D` with the filter order set to 31.

`D = fdesign.differentiator(SPEC)` initializes the filter designer `Specification` property to `SPEC`. You provide one of the following filter entries as input to replace `SPEC`. These entries are not case sensitive.

---

**Note** Specifications marked with an asterisk require the DSP System Toolbox software.

---

- 'N' — Full band differentiator (default)
- 'N,Fp,Fst' — Partial band differentiator
- 'N,Fp,Fst,Ap' — Partial band differentiator \*
- 'N,Fp,Fst,Ast' — Partial band differentiator \*
- 'Ap' — Minimum order full band differentiator \*
- 'Fp,Fst,Ap,Ast' — Minimum order partial band differentiator \*

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.
- `Ast` — attenuation in the stop band in decibels (the default units). Also called `Astop`.
- `Fp` — frequency at the start of the pass band. Specified in normalized frequency units. Also called `Fpass`.
- `Fst` — frequency at the end of the stop band. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

By default, `fdesign.differentiator` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Use `designopts` to determine the design options for a given design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed help on the design options for a given design method, `METHOD`.

`D = fdesign.differentiator(SPEC,specvalue1,specvalue2, ...)` initializes the filter designer specifications in `SPEC` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1`, `specvalue2`, and more, enter

```
get(d,'description')
```

at the Command prompt.

`D = fdesign.differentiator(specvalue1)` assumes the default specification `N`, setting the filter order to the value you provide.

`D = fdesign.differentiator(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.differentiator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### FIR Differentiator Filters

Design a 33rd-order FIR differentiator using least squares. Plot the zero-phase response of the filter.

```
d = fdesign.differentiator(33);
hd = design(d,'firls','SystemObject',true);

zerophase(hd)
```

Design a 54th-order narrowband equiripple differentiator. Differentiate the lowest 25% of the frequencies in the Nyquist range and filter the higher frequencies. Specify a sample rate of 20 kHz, a passband frequency of 2.5 kHz, and a stopband frequency of 3 kHz.

```
Fs = 20000;
```

```
d = fdesign.differentiator('N,Fp,Fst',54,2500,3000,Fs);
Hd = design(d,'equiripple','SystemObject',true);
```

Redesign the filter, but this time weight the stopband to increase the attenuation.

```
Hd1 = design(d,'equiripple','Wstop',4,'SystemObject',true);
hfv1 = fvtool(Hd,Hd1,'MagnitudeDisplay','zero-phase',...
    'FrequencyRange',[0, Fs/2]);
legend(hfv1,'No stopband weighting','Stopband weighting');
```

## Version History

Introduced in R2009a

## fdesign.fracdelay

Fractional delay filter specification object

### Syntax

```
d = fdesign.fracdelay(delta)
d = fdesign.fracdelay(delta, 'N')
d = fdesign.fracdelay(delta, 'N', n)
d = fdesign.fracdelay(delta, n)
d = fdesign.fracdelay(..., fs)
```

### Description

`d = fdesign.fracdelay(delta)` constructs a default fractional delay filter designer `d` with the filter order set to 3 and the delay value set to `delta`. The fractional delay `delta` must be between 0 and 1 samples.

`d = fdesign.fracdelay(delta, 'N')` initializes the filter designer specification to `N`, where `N` specifies the fractional delay filter order and defaults to filter order of 3.

Use `designmethods(d)` to get a list of the design methods available for a specification.

`d = fdesign.fracdelay(delta, 'N', n)` initializes the filter designer to `N` and sets the filter order to `n`.

`d = fdesign.fracdelay(delta, n)` assumes the default specification `N`, filter order, and sets the filter order to the value you provide in input `n`.

`d = fdesign.fracdelay(..., fs)` adds the argument `fs`, specified in units of Hertz (Hz) to define the sampling frequency. In this case, specify the fractional delay `delta` to be between 0 and  $1/fs$ .

### Examples

#### Create a Fractional Delay Filter Using fdesign Object

Design a second-order fractional delay filter of 0.2 samples using the Lagrange method. Implement the filter using a Farrow fractional delay (`fd`) structure.

```
d = fdesign.fracdelay(0.2, 'N', 2);
secondOrderFrac = design(d, 'lagrange', 'filterstructure', 'farrowfd');
fvtool(secondOrderFrac, 'analysis', 'grpdelay')
```

Design a cubic fractional delay filter with a sampling frequency of 8 kHz and fractional delay of 50 microseconds using the Lagrange method.

```
d = fdesign.fracdelay(50e-6, 'N', 3, 8000);  
cubicFrac = design(d, 'lagrange', 'FilterStructure', 'farrowfd');
```

## Version History

Introduced in R2011a

## fdesign.halfband

Halfband filter specification object

### Syntax

```
d = fdesign.halfband
d = fdesign.halfband('type',type)
d = fdesign.halfband(spec)
d = fdesign.halfband(spec,specvalue1,specvalue2,...)
d = fdesign.halfband(specvalue1,specvalue2)
d = fdesign.halfband(...,fs)
d = fdesign.halfband(...,magunits)
```

### Description

`d = fdesign.halfband` constructs a halfband filter specification object `d`, applying default values for the properties `tw` and `ast`.

Using `fdesign.halfband` along with `design` method generates a `System` object, if the `'SystemObject'` flag in the `design` method is set to `true`.

`d = fdesign.halfband('type',type)` initializes the filter designer `'Type'` property with `type`. `'type'` must be either `lowpass` or `highpass` and is not case sensitive.

`d = fdesign.halfband(spec)` constructs object `d` and sets its `'Specification'` to `spec`. Entries in `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. These options are not case sensitive.

- `tw,ast` (default `spec`)
- `n,tw`
- `n`
- `n,ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

By default, all frequency specifications are assumed to be in normalized frequency units. Moreover, all magnitude specifications are assumed to be in dB. Different specification types may have different design methods available.

The filter design methods that apply to a halfband filter specification object change depending on the `Specification` choice. Use `designmethods` to determine which design method applies to an object and its specification choice. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.halfband('N,TW');
designmethods(f)
```

`d = fdesign.halfband(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.halfband(specvalue1,specvalue2)` constructs an object `d` assuming the default Specification property `tw,ast`, using the values you provide for the input arguments `specvalue1` and `specvalue2` for `tw` and `ast`.

`d = fdesign.halfband(...,fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.halfband(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Create Halfband Filters Using fdesign Object

Create a default halfband filter specifications object.

```
d=fdesign.halfband;
```

Create another halfband filter object, passing the specification values to the object rather than accepting the default values for `n` and `ast`.

```
d2 = fdesign.halfband('n,ast', 42, 80);
```

For another example, pass the filter values that correspond to the default Specification - `n,ast`.

```
d3 = fdesign.halfband(.01, 80);
```

This example designs an equiripple FIR filter, starting by passing a new specification type and specification values to `fdesign.halfband`.

```
hs = fdesign.halfband('n,ast',80,70);
hd =design(hs,'equiripple','SystemObject',true);
```

In this example, pass the specifications for the filter, and then design a least-squares FIR filter from the object, using `firls` as the design method.

```
hs = fdesign.halfband('n,tw', 42, .04);
hd2 = design(hs,'firls','SystemObject',true);
```

Create two equiripple halfband filters with and without a nonnegative zero phase response:

```
f=fdesign.halfband('N,TW',12,0.2);
```

Equiripple halfband filter with nonnegative zero phase response

```
Hd1 = design(f,'equiripple','ZeroPhase',true,'SystemObject',true);
```

Equiripple halfband filter with zero phase false 'zerophase',false is the default

```
Hd2=design(f,'equiripple','ZeroPhase',false,'SystemObject',true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase,~]=zerophase(Hd1);
```

```
[Hr,W]=zerophase(Hd2);
```

Plot and compare response

```
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'' true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies. The 'ZeroPhase' option is valid only for equiripple halfband designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

## fdesign.highpass

Highpass filter specification object

### Syntax

```
D = fdesign.highpass
D = fdesign.highpass(SPEC)
D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.highpass(specvalue1,specvalue2,specvalue3,
specvalue4)
D = fdesign.highpass(...,Fs)
D = fdesign.highpass(...,MAGUNITS)
```

### Description

`D = fdesign.highpass` constructs a highpass filter specification object `D`, applying default values for the specification, 'Fst,Fp,Ast,Ap'.

`D = fdesign.highpass(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. These entries are not case sensitive.

---

**Note** Specification entries marked with an asterisk require the DSP System Toolbox software.

---

- 'Fst,Fp,Ast,Ap' (default spec)
- 'N,F3db'
- 'N,F3db,Ap' \*
- 'N,F3db,Ast' \*
- 'N,F3db,Ast,Ap' \*
- 'N,F3db,Fp' \*
- 'N,Fc'
- 'N,Fc,Ast,Ap'
- 'N,Fp,Ap'
- 'N,Fp,Ast,Ap'
- 'N,Fst,Ast'
- 'N,Fst,Ast,Ap'
- 'N,Fst,F3db' \*
- 'N,Fst,Fp'
- 'N,Fst,Fp,Ap' \*
- 'N,Fst,Fp,Ast' \*
- 'Nb,Na,Fst,Fp' \*

The filter specifications are defined as follows:

- $A_p$  — amount of ripple allowed in the pass band in decibels (the default units). Also called  $A_{pass}$ .
- $A_{st}$  — attenuation in the stop band in decibels (the default units). Also called  $A_{stop}$ .
- $F_{3db}$  — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- $F_c$  — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- $F_p$  — frequency at the start of the pass band. Specified in normalized frequency units. Also called  $F_{pass}$ .
- $F_{st}$  — frequency at the end of the stop band. Specified in normalized frequency units. Also called  $F_{stop}$ .
- $N$  — filter order.
- $N_a$  and  $N_b$  are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_{st}$  and  $F_p$  are transition regions where the filter response is not explicitly defined.

The filter design methods that apply to a highpass filter specification object change depending on the `Specification`. Use `designmethods` to determine which design method applies to an object and its specification.

Use `designopts` to determine which design options are valid for a given design method. For detailed information on design options for a given design method, `METHOD`, enter `help(D,METHOD)` at the MATLAB command line.

`D = fdesign.highpass(SPEC,specvalue1,specvalue2,...)` constructs an object `d` and sets its specification values at construction time.

`D = fdesign.highpass(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` with the default `Specification` property and the values you enter for `specvalue1,specvalue2,...`

`D = fdesign.highpass(...,Fs)` provides the sampling frequency for the filter specification object. `Fs` is in Hz and must be specified as a scalar trailing the other numerical values provided. If you specify a sampling frequency, all other frequency specifications are in Hz.

`D = fdesign.highpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Design Butterworth Filter

Design a butterworth filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

### Lowpass Filter

Construct a default lowpass filter design specification object using `fdesign.lowpass`.

```
designSpecs = fdesign.lowpass

designSpecs =
    lowpass with properties:
        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
            Fpass: 0.4500
            Fstop: 0.5500
            Apass: 1
            Astop: 60
```

Determine the available design methods using the `designmethods` function. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
```

```
kaiserwin
multistage
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs, 'butter', SystemObject=true)
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascade...
    SOSScaleNorm: 'ustring'
    SOSScale0pts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScale0pts: [1x1 fdopts.sosscaling]
```

Use the `design` function to design the filter. Pass `'butter'` and the specifications given by variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'`.

```
lpFilter = design(designSpecs, 'butter', matchexactly='passband', SystemObject=true);
```

Visualize the frequency response of the designed filter.

```
fvtool(lpFilter)
```

## Highpass Filter

Construct a highpass filter design specification object using `fdesign.highpass`. Specify the order to be 7 and the 3 dB frequency to be  $0.6\pi$  radians/sample.

```
designSpecs = fdesign.highpass('N,F3dB',7,.6);
```

Determine the available design methods. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass (N,F3dB)`:

```
butter
maxflat
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'butter',SystemObject=true)
```

```
ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    DefaultFilterStructure: 'df2sos'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]
```

To design the butterworth filter, use the design function and specify `'butter'` as an input. Set `'FilterStructure'` to `'cascadeallpass'`.

```
hpFilter = design(designSpecs,'butter',FilterStructure='cascadeallpass',SystemObject=true);
```

Visualize the highpass frequency response.

```
fvtool(hpFilter)
```

## Highpass Filtering of Sinusoids

Highpass filter a discrete-time signal consisting of two sine waves.

Create a highpass filter specification object. Specify the passband frequency to be  $0.25\pi$  rad/sample and the stopband frequency to be  $0.15\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.highpass('Fst,Fp,Ast,Ap',0.15,0.25,60,1);
```

Query the valid design methods for your filter specification object.

```
designmethods(d)
```

```
Design Methods for class fdesign.highpass (Fst,Fp,Ast,Ap):
```

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
```

Create an FIR equiripple filter and view the filter magnitude response with FVTool.

```
Hd = design(d, 'equiripple');
fvtool(Hd)
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  rad/sample and amplitudes of 1 and 0.25 respectively. Filter the discrete-time signal with the FIR equiripple filter object.

```
n = 0:159;
x = cos(pi/8*n)+0.25*sin(pi/4*n);
y = filter(Hd,x);
```

Plot the original and filtered signals in the frequency domain.

```
freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);

plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
plot(freq/pi,abs(ydft(1:length(y)/2+1)),'r','linewidth',2)
hold off
legend('Original Signal','Lowpass Signal','Location','NorthEast')
ylabel('Magnitude')
xlabel('Normalized Frequency (\times\pi rad/sample)')
```

### Window Method Highpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sample rate of 48 kHz. Look at the available design methods.

```
d=fdesign.highpass('N,Fc',10,9600,48000);
designmethods(d)
```

```
Design Methods for class fdesign.highpass (N,Fc):
```

```
window
```

The only available method is the FIR window method. Design the filter and display its magnitude response.

```
Hd = design(d);
```

```
fvtool(Hd)
```

### Stopband Constraints

You can specify the shape of the stopband and the rate at which the stopband decays.

Create two FIR equiripple filters with different linear stopband slopes. Specify the passband frequency to be  $0.3\pi$  rad/sample and the stopband frequency to be  $0.35\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB. Design one filter with a 20 dB/(rad/sample) stopband slope and another filter with a slope of 40 dB/(rad/sample).

```
D = fdesign.highpass('Fst,Fp,Ast,Ap',0.3,0.35,60,1);
Hd1 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',20);
Hd2 = design(D,'equiripple','StopBandShape','linear','StopBandDecay',40);
```

Visualize the magnitude responses of the filters.

```
hfvt = fvtool([Hd1 Hd2]);
legend(hfvt,'20 dB/rad/sample','40 dB/rad/sample')
```

## Version History

## fdesign.hilbert

Hilbert filter specification object

### Syntax

```
d = fdesign.hilbert
d = fdesign.hilbert(specvalue1,specvalue2)
d = fdesign.hilbert(spec)
d = fdesign.hilbert(spec,specvalue1,specvalue2)
d = fdesign.hilbert(...,Fs)
d = fdesign.hilbert(...,MAGUNITS)
```

### Description

`d = fdesign.hilbert` constructs a default Hilbert filter designer `d` with `N`, the filter order, set to 30 and `TW`, the transition width set to  $0.1\pi$  radians/sample.

`d = fdesign.hilbert(specvalue1,specvalue2)` constructs a Hilbert filter designer `d` assuming the default specification `'N,TW'`. You input `specvalue1` and `specvalue2` for `N` and `TW`.

`d = fdesign.hilbert(spec)` initializes the filter designer `Specification` property to `spec`. You provide one of the following as input to replace `spec`. The specification options are not case sensitive.

---

**Note** Specifications marked with an asterisk require the DSP System Toolbox software.

---

- `'N,TW'` default specification option.
- `'TW,Ap'` \*

The filter specifications are defined as follows:

- `Ap` — amount of ripple allowed in the pass band in decibels (the default units). Also called `Apass`.
- `N` — filter order.
- `TW` — width of the transition region between the passband and the stopband.

By default, `fdesign.hilbert` assumes that all frequency specifications are provided in normalized frequency units. Also, decibels is the default for all magnitude specifications.

Different specifications may have different design methods available. Use `designmethods(d)` to get a list of the design methods available for a given specification.

`d = fdesign.hilbert(spec,specvalue1,specvalue2)` initializes the filter designer specifications in `spec` with `specvalue1`, `specvalue2`, and so on. To get a description of the specifications `specvalue1` and `specvalue2`, enter

```
get(d, 'description')
```

at the Command prompt.

`d = fdesign.hilbert(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.hilbert(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Hilbert Transformers

Design a Hilbert transformer of order 30 with a transition width of  $0.2\pi$  rad/sample. Use least-squares minimization to obtain an equiripple linear-phase FIR filter. Plot the zero-phase response in the interval  $[-\pi,\pi)$ .

```
d = fdesign.hilbert('N,TW',30,0.2);
Hd = design(d,'equiripple','SystemObject',true);
zerophase(Hd,'whole')
```

The impulse response of this even-order type-3 filter is antisymmetric.

```
impz(Hd)
```

```
ftype = firtype(Hd)
```

```
ftype = 3
```

Design a minimum-order Hilbert transformer that has a sample rate of 1 kHz. Specify the width of the transition region as 10 Hz and the passband ripple as 1 dB. Display the zero-phase response of the filter.

```
fs = 1e3;
d = fdesign.hilbert('TW,Ap',10,1,fs);
hd = design(d,'equiripple','SystemObject',true);
zerophase(hd,-fs/2:0.1:fs/2,fs)
```

## fdesign.interpolator

Interpolator filter specification

---

### Note

**Note** The 'Raised Cosine' and 'Square Root Raised Cosine' response methods in the `fdesign.interpolator` object will be removed in a future release. Use `rcosdesign` and `comm.RaisedCosineTransmitFilter` instead.

---

**Note** You can no longer design an `mfilt.firinterp` object using the `fdesign.interpolator` and the `design` functions. Use the `design` function with the `SystemObject=true` flag to design an FIR interpolator System object™.

---

**Note** Support for multistage filter design using the `fdesign.interpolator` object will be removed in a future release. Use the `designMultistageInterpolator` function instead.

For more information, see “Compatibility Considerations”.

---

### Syntax

```
D = fdesign.interpolator(L)
D = fdesign.interpolator(L,RESPONSE)
D = fdesign.interpolator(L,CICRESPONSE,D)
D = fdesign.interpolator(L,RESPONSE,spec)
D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)
D = fdesign.interpolator(...,Fs)
d = fdesign.interpolator(...,MAGUNITS)
```

### Description

`D = fdesign.interpolator(L)` constructs an interpolator filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L` and the `Response` property set to 'Nyquist'. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 2.

`D = fdesign.interpolator(L,RESPONSE)` constructs a interpolator specification object with the interpolation factor `L` and the 'Response' property set to one of the supported types.

`D = fdesign.interpolator(L,CICRESPONSE,D)` constructs a CIC or CIC compensator interpolator specification object with the interpolation factor, `L`, and 'Response' property equal to 'CIC' or 'CICCOMP'. `D` is the differential delay. The differential delay, `D`, must precede any specification option.

`D = fdesign.interpolator(L,RESPONSE,spec)` constructs object `D` and sets its `Specification` property to `spec`. Entries in the `spec` represent various filter response features,

such as the filter order, that govern the filter design. Valid entries for `spec` depend on the design type of the specifications object.

When you add the `spec` input argument, you must also add the `RESPONSE` input argument.

Because you are designing multirate filters, the specification options available are not the same as the specifications for designing single-rate filters with design methods such as `fdesign.lowpass`. The options are not case sensitive.

The interpolation factor `L` is not in the specification options. The different filter responses support different specifications. The following table lists the supported response types and specification options.

| Design Method                   | Valid Specification Options  |
|---------------------------------|--|
| 'Arbitrary Magnitude'           | See <code>fdesign.arbmag</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,A' (default option)</li> <li>'N,B,F,A'</li> </ul>  |

| 'Hilbert'         | <p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,TW' (default option)</li> <li>• 'TW,Ap'</li> </ul>   |

| Design Method           | Valid Specification Options  |
|-------------------------|--|
| 'Inverse-sinc Lowpass'  | See <code>fdesign.isinclp</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fst,Ap,Ast'</li> </ul>   |
| 'Inverse-sinc Highpass' | See <code>fdesign.isinchp</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fst,Fp,Ast,Ap' (default option)</li> <li>'N,Fc,Ast,Ap'</li> <li>'N,Fst,Fp'</li> <li>'N,Fst,Ast,Ap'</li> </ul>   |
| 'Lowpass'               | See <code>fdesign.lowpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,F3dB'</li> <li>'N,Fc'</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fp,Fst,Ap'</li> <li>'N,Fp,Fst,Ast'</li> <li>'N,Fst,Ap,Ast'</li> </ul>   |
| 'Nyquist'               | See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the <i>L</i> th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. <ul style="list-style-type: none"> <li>'TW,Ast' (default option)</li> <li>'N'</li> <li>'N,Ast'</li> <li>'N,Ast'</li> </ul> |

`D = fdesign.interpolator(...,spec,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.interpolator(...,Fs)` adds the argument `Fs`, specified in Hz, to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.interpolator(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).

- 'squared' — specify the magnitude in power units.

When you omit the MAGUNITS argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Create an Interpolator Using `fdesign` Object

These examples show how to construct interpolating filter specification objects.

First, create a default specifications object without using input arguments except for the interpolation factor `l`.

```
l = 2;
d = fdesign.interpolator(l); %#ok
```

Now create an object by passing a specification option 'fst1,fp1,fp2,fst2,ast1,ap,ast2' and a design - the resulting object uses default values for all of the filter specifications. You must provide the design input argument when you include a specification.

```
d = fdesign.interpolator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2'); %#ok
```

Create another interpolating filter object, passing the specification values to the object rather than accepting the default values for, in this case, `fp`, `fst`, `ap`, `ast`.

```
d = fdesign.interpolator(3, 'lowpass', .45,0.55,.1,60); %#ok
```

Now pass the filter specifications that correspond to the specifications - `n`, `fc`, `ap`, `ast`.

```
d = fdesign.interpolator(3, 'ciccomp', 1,2, 'n,fc,ap,ast', ...
    20,0.45,.05,50);
```

With the specifications object in your workspace, design an interpolator using the equiripple design method.

```
hm = design(d, 'equiripple', SystemObject=true); %#ok
```

Pass a new specification type for the filter, specifying the filter order.

```
d = fdesign.interpolator(5, 'CIC', 1, 'fp,ast', 0.05,55);
```

With the specifications object in your workspace, design an interpolator using the multisection design method.

```
hm = design(d, 'multisection', SystemObject=true); %#ok
```

In this example, you specify a sampling frequency as the right most input argument. Here, it is set to 1000 Hz.

```
d = fdesign.interpolator(8, 'bandpass', 'fst1,fp1,fp2,fst2,ast1,ap,ast2', ...
    0.25,0.35,.55,.65,50,.05,1e3); %#ok
```

In this, the last example, use the linear option for the filter specification object and specify the stopband ripple attenuation in linear form.

```
d = fdesign.interpolator(4,'lowpass','n,fst,ap,ast',15,0.55,.05,0.001,...
    'linear'); %#ok
```

Now design a CIC interpolator for a signal sampled at 19200 Hz. Specify the differential delay of 2 and set the attenuation of information beyond 50 Hz to be at least 80 dB.

*% The filter object sampling frequency is (l x fs) where fs is the sampling frequency of the input signal.*

```
dd = 2;      % Differential delay.
fp = 50;     % Passband of interest.
ast = 80;    % Minimum attenuation of alias components in passband.
fs = 600;    % Sampling frequency for input signal.
l = 32;      % Interpolation factor.
d = fdesign.interpolator(l,'cic',dd,'fp,ast',fp,ast,l*fs);
hm = design(d,SystemObject=true); %Use the default design method.
```

This next example results in a minimum-order CIC compensator that interpolates by 4 and compensates for the droop in the passband for the CIC filter hm from the previous example.

```
nsecs = hm.NumSections;
d = fdesign.interpolator(4,'ciccomp',dd,nsecs,...
    50,100,0.1,80,fs);
hmc = design(d,'equiripple',SystemObject=true);
```

hmc is designed to compensate for hm. To see the effect of the compensating CIC filter, use fvtool to analyze both filters individually and include the compound filter response by cascading hm and hmc.

```
hfvt = fvtool(hmc,hm,cascade(hmc,hm),'fs',[fs,l*fs,l*fs],ShowReference='off');
legend(hfvt,'CIC Compensator','CIC Interpolator',...
    'Overall Response');
```

fvtool returns with this plot.

For the third example, use `fdesign.interpolator` to design a minimum-order Nyquist interpolator that uses a Kaiser window. For comparison, design a multistage interpolator as well and compare the responses.

```

l = 15; % Set the interpolation factor and the Nyquist band.
tw = 0.05; % Specify the normalized transition width.
ast = 40; % Set the minimum stopband attenuation in dB.
Fs = 2; % For normalized frequency units
d = fdesign.interpolator(l,'nyquist',l,tw,ast);
hm = design(d,'kaiserwin',SystemObject=true);
hm2 = designMultistageInterpolator(l,Fs,tw,ast); % Design the multistage interpolator.
hfvt = fvtool(hm,hm2);
legend(hfvt,'Kaiser Window','Multistage')

```

fvtool shows both responses.

Design a lowpass interpolator for an interpolation factor of 8. Compare the single-stage equiripple design to a multistage design with the same interpolation factor.

```
l = 8; % Interpolation factor.
d = fdesign.interpolator(l,'lowpass');
hm1 = design(d,'equiripple',SystemObject=true);
% Use halfband filters whenever possible.
hm2 = designMultistageInterpolator(l)

hm2 =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRInterpolator]
        Stage2: [1x1 dsp.FIRInterpolator]
        Stage3: [1x1 dsp.FIRInterpolator]
        CloneStages: false

hfvtlp = fvtool(hm1,hm2);
legend(hfvtlp,'Single-Stage Equiripple','Multistage')
```

## Version History

### Introduced in R2011a

#### **R2022a: 'Raised Cosine' and 'Square Root Raised Cosine' response methods will be removed**

*Warns starting in R2022a*

The 'Raised Cosine' and 'Square Root Raised Cosine' response methods in the `fdesign.interpolator` object will be removed in a future release. Use `rcosdesign` and `comm.RaisedCosineTransmitFilter` instead.

#### **R2022b: Support for designing `mfilt.firinterp` has been removed**

*Errors starting in R2022b*

You can no longer design an `mfilt.firinterp` object using the `fdesign.interpolator` and the design functions.

To design an FIR interpolator using the `fdesign.interpolator` filter specification object, use the design function with the `SystemObject=true` flag. Setting this flag to true ensures that the output object is a filter System object instead of an `mfilt.firinterp` object.

```
fdesignObj = fdesign.interpolator;
FIRInterpObj = design(fdesignObj, SystemObject=true)
```

```
FIRInterpObj =
    dsp.FIRInterpolator with properties:
        InterpolationFactor: 2
        NumeratorSource: 'Property'
        Numerator: [-3.0325e-05 0 8.3413e-05 0 ... ]

    Show all properties
```

## R2022b: Support for multistage design in fdesign.interpolator will be removed

Warns starting in R2022b

Support for multistage filter design using the `fdesign.interpolator` object will be removed in a future release. Use the `designMultistageInterpolator` function instead.

### Update Code

This table shows how to update your code.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| Using the <code>design</code> function and passing the 'multistage' flag as an input.<br><br><pre>L = 12; % Interpolation factor TW = 2205; % Transition width Astop = 80; % Stopband attenuation Fs = 44100; % Output sample rate filtSpec = fdesign.interpolator(L, 'nyquist', L, TW, Astop, Fs); filtObj = design(filtSpec, 'multistage', SystemObject=true)</pre> | When you set the cost method to 'design', the function designs an optimal number of stages so that the overall cost of implementation is low.<br><br><pre>filtObj = designMultistageInterpolator(L, Fs, TW, Astop, CostMethod='design')</pre> |
| Using the <code>multistage</code> function directly.<br><br><pre>filtObj = multistage(filtSpec, SystemObject=true)</pre>  |   |

## fdesign.isinchnp

Inverse sinc highpass filter specification

### Syntax

```
D = fdesign.isinchnp
D = fdesign.isinchnp(SPEC)
D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)
D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.isinchnp(...,Fs)
D = fdesign.isinchnp(...,MAGUNITS)
```

### Description

`D = fdesign.isinchnp` constructs an inverse sinc highpass filter specification object `D`, applying default values for the default specification `'Fst,Fp,Ast,Ap'`.

`D = fdesign.isinchnp(SPEC)` constructs object `D` and sets the `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The entries are not case sensitive.

- `'Fst,Fp,Ast,Ap'` (default spec)
- `'N,Fc,Ast,Ap'`
- `'N,Fst,Fp'`
- `'N,Fp,Ast,Ap'`
- `'N,Fst,Ast,Ap'`

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called `Fpass`.
- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

The filter design methods that apply to an inverse sinc highpass filter specification object change depending on the value of the `Specification` property. Use `designmethods` to determine which design method applies to a specific `Specification`.

Use `designopts` to see the available design options for a specific design method. Enter `help(D,METHOD)` at the MATLAB command line to obtain detailed information on the design options for a given design method, `METHOD`.

`D = fdesign.isinchnp(SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets the specifications at construction time.

`D = fdesign.isinchnp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `D` assuming the default `Specification` property `'Fst,Fp,Ast,Ap'`, using the values you provide in `specvalue1,specvalue2, specvalue3, and specvalue4`.

`D = fdesign.isinchnp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.isinchnp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- `'linear'` — specify the magnitude in linear units
- `'dB'` — specify the magnitude in dB (decibels)
- `'squared'` — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinchnp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C(1 - \omega))^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the `'SincFrequencyFactor'` and `'SincPower'` options in the design method. `'SincFrequencyFactor'` and `'SincPower'` default to 0.5 and 1 respectively.

## Examples

### Construct an Inverse Sinc Highpass Filter Using `fdesign` Object

Design a minimum order inverse sinc highpass filter and shape the stopband to have a slope of 20 dB/radian/sample.

```
d = fdesign.isinchnp('Fst,Fp,Ast,Ap',.4,.5,40,0.01);
Hd = design(d,'SystemObject',true);
```

Shape the stopband to have a linear slope of 20 dB/rad/sample

```
Hd1 = design(d,'StopbandShape','linear','StopbandDecay',20,'SystemObject',...
    true);
fvtool(Hd,Hd1);
```

Design a 50th order inverse sinc highpass filter. Set the sinc frequency factor to 0.25, and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(\omega) = \text{sinc}(0.25*(1-\omega))^{-16}$ .

```
d = fdesign.isinchp('N,Fst,Fp',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,...
'SystemObject',true);
fvtool(Hd);
```

## fdesign.isinclp

Inverse sinc lowpass filter specification

### Syntax

```
d = fdesign.isinclp
d = fdesign.isinclp(spec)
d = fdesign.isinclp(spec,specvalue1,specvalue2,...)
d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)
d = fdesign.isinclp(...,Fs)
d = fdesign.isinclp(...,MAGUNITS)
```

### Description

`d = fdesign.isinclp` constructs an inverse sinc lowpass filter specification object `d`, applying default values for the default specification, 'Fp,Fst,Ap,Ast'.

`d = fdesign.isinclp(spec)` constructs object `d` and sets its 'Specification' to `spec`. Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The options are not case sensitive.

- 'Fp,Fst,Ap,Ast' (default option)
- 'N,Fc,Ap,Ast'
- 'N,Fp,Ap,Ast'
- 'N,Fp,Fst'
- 'N,Fst,Ap,Ast'

The filter specifications are defined as follows:

- `Ast` — attenuation in the stopband in decibels (the default units). Also called `Astop`.
- `Ap` — amount of ripple allowed in the passband in decibels (the default units). Also called `Apass`.
- `Fp` — frequency at the start of the passband. Specified in normalized frequency units. Also called `Fpass`.
- `Fst` — frequency at the end of the stopband. Specified in normalized frequency units. Also called `Fstop`.
- `N` — filter order.

The filter design methods that apply to an inverse sinc lowpass filter specification object change depending on the Specification. Use `designmethods` to determine which design method applies to an object and its specification.

`d = fdesign.isinclp(spec,specvalue1,specvalue2,...)` constructs an object `d` and sets its specifications at construction time.

`d = fdesign.isinclp(specvalue1,specvalue2,specvalue3,specvalue4)` constructs an object `d` assuming the default Specification property 'Fp,Fst,Ap,Ast', using the values you provide in `specvalue1`, `specvalue2`, `specvalue3`, and `specvalue4`.

`d = fdesign.isinclp(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.isinclp(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

The design method of `fdesign.isinclp` implements a filter with a passband magnitude response equal to:

$$H(\omega) = \text{sinc}(C\omega)^{-P}$$

You can control the values of the sinc frequency factor,  $C$ , and the sinc power,  $P$ , using the 'SincFrequencyFactor' and 'SincPower' options in the design method. 'SincFrequencyFactor' and 'SincPower' default to 0.5 and 1 respectively.

## Examples
