### Construct an Inverse Sinc Lowpass Filter Using fdesign Object

Pass the specifications for the default specification - 'Fp,Fst,Ap,Ast', as input arguments to the specifications object.

```
d = fdesign.isinclp(.4,.5,.01,40);
hd = design(d,'equiripple','SystemObject',true);
fvtool(hd);
```

Design a 50th order inverse sinc lowpass filter. Set the sinc frequency factor to 0.25 and the sinc power to 16 to achieve a magnitude response in the passband of the form  $H(w) = \text{sinc}(0.25*w)^{-16}$ .

```
d = fdesign.isinclp('N,Fp,Fst',50,.4,.5);
Hd = design(d,'SincFrequencyFactor',0.25,'SincPower',16,'SystemObject',...
    true);
fvtool(Hd,'MagnitudeDisplay','Magnitude');
```

## fdesign.lowpass

Lowpass filter specification

---

### Note

**Note** Multistage filter design using the `fdesign.lowpass` and `design` functions now requires you to set the `SystemObject` flag to `true` unless the resulting design is a single-stage filter and not a cascade. This setting generates a `dsp.FilterCascade` object instead of the `mfilt.cascade` object.

For more information, see “Compatibility Considerations”.

---

### Syntax

```
D = fdesign.lowpass
D = fdesign.lowpass(SPEC)
D = fdesign.lowpass(SPEC,specvalue1,specvalue2,...)
D = fdesign.lowpass(specvalue1,specvalue2,specvalue3,specvalue4)
D = fdesign.lowpass(...,Fs)
D = fdesign.lowpass(...,MAGUNITS)
```

### Description

`D = fdesign.lowpass` constructs a lowpass filter specification object `D`, applying default values for the default specification option `'Fp,Fst,Ap,Ast'`.

`D = fdesign.lowpass(SPEC)` constructs object `D` and sets the `Specification` property to the entry in `SPEC`. Entries in `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` are shown below. The options are not case sensitive.

---

**Note** Specifications options marked with an asterisk require the DSP System Toolbox software.

---

- `'Fp,Fst,Ap,Ast'` (default option)
- `'N,F3db'`
- `'N,F3db,Ap' *`
- `'N,F3db,Ap,Ast' *`
- `'N,F3db,Ast' *`
- `'N,F3db,Fst' *`
- `'N,Fc'`
- `'N,Fc,Ap,Ast'`
- `'N,Fp,Ap'`

- 'N,Fp,Ap,Ast'
- 'N,Fp,Fst,Ap' \*
- 'N,Fp,F3db' \*
- 'N,Fp,Fst'
- 'N,Fp,Fst,Ast' \*
- 'N,Fst,Ap,Ast' \*
- 'N,Fst,Ast'
- 'Nb,Na,Fp,Fst' \*

The filter specifications are defined as follows:

- $A_p$  — amount of ripple allowed in the pass band in decibels (the default units). Also called  $A_{pass}$ .
- $A_s$  — attenuation in the stop band in decibels (the default units). Also called  $A_{stop}$ .
- $F_{3db}$  — cutoff frequency for the point 3 dB point below the passband value. Specified in normalized frequency units.
- $F_c$  — cutoff frequency for the point 6 dB point below the passband value. Specified in normalized frequency units.
- $F_p$  — frequency at the start of the pass band. Specified in normalized frequency units. Also called  $F_{pass}$ .
- $F_{st}$  — frequency at the end of the stop band. Specified in normalized frequency units. Also called  $F_{stop}$ .
- $N$  — filter order.
- $N_a$  and  $N_b$  are the order of the denominator and numerator.

Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values like  $F_p$  and  $F_{st}$  are transition regions where the filter response is not explicitly defined.

$D = \text{fdesign.lowpass}(\text{SPEC}, \text{specvalue1}, \text{specvalue2}, \dots)$  constructs an object  $D$  and sets the specification values at construction time using  $\text{specvalue1}$ ,  $\text{specvalue2}$ , and so on for all of the specification variables in  $\text{SPEC}$ .

$D = \text{fdesign.lowpass}(\text{specvalue1}, \text{specvalue2}, \text{specvalue3}, \text{specvalue4})$  constructs an object  $D$  with values for the default Specification property 'Fp,Fst,Ap,Ast' using the specifications you provide as input arguments  $\text{specvalue1}$ ,  $\text{specvalue2}$ ,  $\text{specvalue3}$ ,  $\text{specvalue4}$ .

`D = fdesign.lowpass(...,Fs)` adds the argument `Fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`D = fdesign.lowpass(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units
- 'dB' — specify the magnitude in dB (decibels)
- 'squared' — specify the magnitude in power units

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Design Butterworth Filter

Design a butterworth filter with lowpass and highpass frequency responses. The filter design procedure is:

- 1 Specify the filter design specifications using a `fdesign` function.
- 2 Pick a design method provided by the `designmethods` function.
- 3 To determine the available design options to choose from, use the `designoptions` function.
- 4 Design the filter using the `design` function.

### Lowpass Filter

Construct a default lowpass filter design specification object using `fdesign.lowpass`.

```
designSpecs = fdesign.lowpass

designSpecs =
    lowpass with properties:

        Response: 'Lowpass'
        Specification: 'Fp,Fst,Ap,Ast'
        Description: {4x1 cell}
        NormalizedFrequency: 1
            Fpass: 0.4500
            Fstop: 0.5500
            Apass: 1
            Astop: 60
```

Determine the available design methods using the `designmethods` function. To design a butterworth filter, pick `butter`.

```
designmethods(designSpecs,SystemObject=true)
```

```
Design Methods that support System objects for class fdesign.lowpass (Fp,Fst,Ap,Ast):
```

```

butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage

```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs, 'butter', SystemObject=true)
```

```

ans = struct with fields:
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascad
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    MatchExactly: {'passband' 'stopband'}
    DefaultFilterStructure: 'df2sos'
    DefaultMatchExactly: 'stopband'
    DefaultSOSScaleNorm: ''
    DefaultSOSScaleOpts: [1x1 fdopts.sosscaling]

```

Use the `design` function to design the filter. Pass `'butter'` and the specifications given by variable `designSpecs`, as input arguments. Specify the `'matchexactly'` design option to `'passband'`.

```
lpFilter = design(designSpecs, 'butter', matchexactly='passband', SystemObject=true);
```

Visualize the frequency response of the designed filter.

```
fvtool(lpFilter)
```

## Highpass Filter

Construct a highpass filter design specification object using `fdesign.highpass`. Specify the order to be 7 and the 3 dB frequency to be  $0.6\pi$  radians/sample.

```
designSpecs = fdesign.highpass('N,F3dB',7,.6);
```

Determine the available design methods. To design a butterworth filter, pick `butter`.

```
designMethods(designSpecs,SystemObject=true)
```

Design Methods that support System objects for class `fdesign.highpass(N,F3dB)`:

```
butter
maxflat
```

While designing the filter, you can specify additional design options. View a list of the options using the `designoptions` function. This function also shows the default design options the filter uses.

```
designoptions(designSpecs,'butter',SystemObject=true)
```

```
ans = struct with fields:
```

```
    FilterStructure: {'df1sos' 'df2sos' 'df1tsos' 'df2tsos' 'cascadeallpass' 'cascadeallpass'}
    SOSScaleNorm: 'ustring'
    SOSScaleOpts: 'fdopts.sosscaling'
    DefaultFilterStructure: 'df2sos'
    DefaultSOSScaleNorm: ''
```

```
DefaultSOSScale0pts: [1x1 fdopts.sosscaling]
```

To design the butterworth filter, use the design function and specify 'butter' as an input. Set 'FilterStructure' to 'cascadeallpass'.

```
hpFilter = design(designSpecs, 'butter', FilterStructure='cascadeallpass', SystemObject=true);
```

Visualize the highpass frequency response.

```
fvtool(hpFilter)
```

### Lowpass Filtering of Sinusoids

Lowpass filter a discrete-time signal consisting of two sine waves.

Create a lowpass filter specification object. Specify the passband frequency to be  $0.15\pi$  rad/sample and the stopband frequency to be  $0.25\pi$  rad/sample. Specify 1 dB of allowable passband ripple and a stopband attenuation of 60 dB.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',0.15,0.25,1,60);
```

Query the valid design methods for your filter specification object, d.

```
designmethods(d)
```

Design Methods for class `fdesign.lowpass (Fp,Fst,Ap,Ast)`:

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Create an FIR equiripple filter and view the filter magnitude response with `fvtool`.

```
Hd = design(d,'equiripple');
fvtool(Hd)
```

Create a signal consisting of the sum of two discrete-time sinusoids with frequencies of  $\pi/8$  and  $\pi/4$  rad/sample and amplitudes of 1 and 0.25, respectively. Filter the discrete-time signal with the FIR equiripple filter object, `Hd`.

```
n = 0:159;
x = (0.25*cos((pi/8)*n)+sin((pi/4)*n));
y = filter(Hd,x);
```

Compute the Fourier transform of the original signal and the filtered signal. Verify that the high-frequency component has been filtered out.

```

freq = 0:(2*pi)/160:pi;
xdft = fft(x);
ydft = fft(y);

figure
plot(freq/pi,abs(xdft(1:length(x)/2+1)))
hold on
plot(freq/pi,abs(ydft(1:length(y)/2+1)))
hold off

legend('Original Signal','Filtered Signal')
ylabel('Magnitude')
xlabel('Normalized Frequency (\times\pi rad/sample)')

```

### Window Method Lowpass Design

Create a filter of order 10 with a 6-dB frequency of 9.6 kHz and a sampling frequency of 48 kHz. Look at the available design methods.

```

d = fdesign.lowpass('N,Fc',10,9600,48000);
designmethods(d)

```

Design Methods for class fdesign.lowpass (N,Fc):

```
window
```

The only valid design method is the FIR window method. Design the filter.

```
Hd = design(d);
```

Display the filter magnitude response. The -6 dB point is at 9.6 kHz, as expected.

```
fvtool(Hd)
```

### Stopband Shape and Decay

Create an FIR equiripple filter with a passband frequency of  $0.2\pi$  rad/sample, a stopband frequency of  $0.25\pi$  rad/sample, a passband ripple of 1 dB, and a stopband attenuation of 60 dB. Design the filter with a 20 dB/rad/sample linear stopband.

```
D = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.25,1,60);
Hd = design(D,'equiripple','StopbandShape','linear','StopbandDecay',20);
```

Visualize the frequency response of the filter.

```
fvtool(Hd)
```

## Version History

Introduced in R2009a

**R2022b: Support for designing `mfilt.cascade` object using the `fdesign.lowpass` object has been removed**

*Errors starting in R2022b*

Multistage filter design using the `fdesign.lowpass` object and the design function now requires you to set the `SystemObject` flag to `true` unless the resulting design is a single-stage filter and not a cascade. This setting generates a `dsp.FilterCascade` object instead of the `mfilt.cascade` object.

```
fdesignObj = fdesign.lowpass('Fp,Fst,Ap,Ast',...
0.1,0.12,0.1,1e-4,'linear');
FIRInterpObj = design(fdesignObj,'multistage',...
SystemObject=true)
```

FIRInterpObj =

dsp.FilterCascade with properties:

```
Stage1: [1x1 dsp.FIRDecimator]
Stage2: [1x1 dsp.FIRDecimator]
Stage3: [1x1 dsp.FIRDecimator]
```

```
Stage4: [1x1 dsp.FIRInterpolator]  
Stage5: [1x1 dsp.FIRInterpolator]  
Stage6: [1x1 dsp.FIRInterpolator]  
CloneStages: true
```

# fdesign.notch

Notch filter specification

## Syntax

```
notchSpecs = fdesign.notch
notchSpecs = fdesign.notch(n, f0, q)
notchSpecs = fdesign.notch(spec, value1, ..., valueN)
notchSpecs = fdesign.notch( ____, Fs)
notchSpecs = fdesign.notch( ____, magunits)
```

## Description

The `fdesign.notch` function returns a notch filter design specification object that contains the specifications for a filter, such as passband ripple, stopband attenuation, and filter order. Then, use the `design` function to design the filter from the filter design specifications object.

For more control options, see “Filter Design Procedure” on page 5-399. For a complete workflow, see “Design a Filter in Fdesign — Process Overview”.

`notchSpecs = fdesign.notch` constructs a notch filter specification object with the filter order set to 10, center frequency set to 0.5, and quality factor set to 2.5.

`notchSpecs = fdesign.notch(n, f0, q)` constructs a notch filter specification object with the filter order, center frequency, and quality factor specified by `n`, `f0`, and `q`, respectively.

`notchSpecs = fdesign.notch(spec, value1, ..., valueN)` constructs a notch filter specification object with a particular filter order, center frequency, and other specification options. Indicate the options you want to specify in the expression `spec`. After the expression, specify a value for each option.

`notchSpecs = fdesign.notch( ____, Fs)` provides the sample rate of the signal to be filtered.

`notchSpecs = fdesign.notch( ____, magunits)` provides the units for any magnitude specification given.

`magunits` can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `magunits` must follow `Fs` in the input argument list.

## Examples

### Design Notch Filter

Design a direct-form I notching filter that has a filter order of 6, center frequency of 0.5, quality factor of 10, and a passband ripple of 1 dB.

Create a notch filter design specification object using the `fdesign.notch` function and specify these design parameters.

```
notchSpecs = fdesign.notch('N,F0,Q,Ap',6,0.5,10,1);
```

Design the notch filter using the `design` function. The resulting filter is a `dsp.SOSFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.SOSFilter`.

```
notchFilt = design(notchSpecs,SystemObject=true)
```

```
notchFilt =  
  dsp.SOSFilter with properties:  
    Structure: 'Direct form II'  
  CoefficientSource: 'Property'  
    Numerator: [3x3 double]  
   Denominator: [3x3 double]  
  HasScaleValues: true  
   ScaleValues: [0.7722 0.7722 1.3597 1]
```

Show all properties

Visualize the frequency response of the designed filter using `fvtool`.

```
fvtool(notchFilt)
```

## Input Arguments

### spec — Specification

'N,F0,Q' (default) | 'N,F0,Q,Ap' | 'N,F0,Q,Ast' | ...

Specification expression, specified as one of these character vectors:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

This table describes each option that can appear in the expression.

| Specification option | Description                 |
|----------------------|-----------------------------|
| N                    | Filter order (must be even) |
| F0                   | Center frequency            |
| Q                    | Quality factor              |
| BW                   | 3 dB bandwidth              |
| Ap                   | Passband ripple (dB)        |
| Ast                  | Stopband attenuation (dB)   |

The design methods available for designing the filter depend on the specification expression. You can obtain these methods using the `designmethods` function. The table lists each specification expression supported by `fdesign.notch` and the corresponding design methods available.

| Specification expression | Supported design method | Filter description               |
|--------------------------|-------------------------|----------------------------------|
| 'N,F0,Q'                 | butter                  | Butterworth digital filter       |
| 'N,F0,Q,Ap'              | cheby1                  | Chebyshev Type I digital filter  |
| 'N,F0,Q,Ast'             | cheby2                  | Chebyshev Type II digital filter |
| 'N,F0,Q,Ap,Ast'          | ellip                   | Elliptical digital filter        |
| 'N,F0,BW'                | butter                  | Butterworth digital filter       |
| 'N,F0,BW,Ap'             | cheby1                  | Chebyshev Type I digital filter  |
| 'N,F0,BW,Ast'            | cheby2                  | Chebyshev Type II digital filter |
| 'N,F0,BW,Ap,Ast'         | ellip                   | Elliptical digital filter        |

To design the filter, call the `design` function with one of these design methods as an input. You can choose the type of filter response by passing 'FIR' or 'IIR' to the `design` function. For more details, see `design`.

For more details on the procedure, see “Filter Design Procedure” on page 5-399. For an example, see “Design Notch Filter” on page 5-543.

**value1, ..., valueN — Specification values**

comma-separated list of values

Specification values, specified as a comma-separated list of values. Specify a value for each option in `spec` in the same order that the options appear in the expression.

Example: `d = fdesign.notch('N,F0,BW,Ast',n,f0,bw,ast)`

The arguments below describe more details for each option in the expression.

**n — Filter order**

even positive integer

Filter order, specified as an even positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**f0 — Center frequency**

scalar

Center frequency of the filter, specified as a scalar. When the input sampling frequency  $F_s$  is specified, the center frequency is in Hz. When the input sample rate is not specified, the center frequency is in normalized units between 0 and 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**q — Quality factor**

positive scalar

Quality factor of the filter, specified as a real positive scalar.

Quality factor of the filter is defined as the ratio of the center frequency to the 3 dB bandwidth.

$$q = f_0/bw$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**bw — 3 dB Bandwidth**

scalar

3 dB bandwidth of the filter, specified as a real scalar.

Specify the 3 dB bandwidth value in normalized frequency units between 0 and 1. If you specify the sample rate  $F_s$ , then specify the bandwidth value in Hz instead.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**ap — Passband ripple**

positive scalar

Passband ripple, specified as a positive scalar in dB. If `magunits` is `'linear'` or `'squared'`, the passband ripple is converted and stored in dB by the function regardless of how it has been specified.

Data Types: `double`

**ast — Stopband attenuation**

positive scalar

Stopband attenuation of the filter, specified as a positive scalar in dB. If `magunits` is 'linear' or 'squared', the stopband attenuation is converted and stored in dB by the function regardless of how it has been specified.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Fs — Sample rate**

scalar

Sample rate of the signal to be filtered, specified as a scalar in Hz. Specify the sample rate as a scalar trailing the other numerical values provided. When `Fs` is provided, `Fs` is assumed to be in Hz, as are all other frequency values provided. Note that you do not have to change the specification string.

Consider a design specification where `N` is set to 4, `F0` is set to 1200 Hz, and `Q` is set to 6.5. Specify the sample rate of the input signal as 8000 Hz. Here is how the design looks:

```
d = fdesign.notch('N,F0,Q',4,1200,6.5,8e3); filt =
design(d,'Systemobject',true);
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **magunits — Magnitude units**

'dB' (default) | 'linear' | 'squared'

Magnitude specification units, specified as 'dB', 'linear', or 'squared'. If this argument is omitted, 'dB' is assumed. Note that the magnitude specifications are always converted and stored in dB regardless of how they were specified. If `Fs` is one of the input arguments, `magunits` must be specified after `Fs` in the input argument list.

## **Output Arguments**

### **notchSpecs — Notch filter design specification object**

`notch` object

Notch filter design specification object, returned as a `notch` object. The fields of the object depend on the `spec` input character vector.

Consider an example where the `spec` argument is set to 'N,F0,Q,Ap,Ast', and the corresponding values are set to 6, 0.5, 10, 1, 80, respectively. The `notch` filter design specification object is populated with the following fields:

```
>> notchSpecs = fdesign.notch('N,F0,Q,Ap,Ast',6,0.5,10,1,80)
```

```
notchSpecs =
```

```
notch with properties:
```

```
    Response: 'Notching Filter'  
Specification: 'N,F0,Q,Ap,Ast'  
Description: {5×1 cell}  
NormalizedFrequency: 1  
FilterOrder: 6  
           F0: 0.5000  
           Q: 10  
           Apass: 1  
           Astop: 80
```

# fdesign.nyquist

Nyquist filter specification

## Syntax

```
d = fdesign.nyquist
d = fdesign.nyquist(l, spec)
d = fdesign.nyquist(l, spec, specvalue1, specvalue2, ...)
d = fdesign.nyquist(l, specvalue1, specvalue2)
d = fdesign.nyquist(..., fs)
d = fdesign.nyquist(..., magunits)
```

## Description

`d = fdesign.nyquist` constructs a Nyquist or L-band filter specification object `d`, applying default values for the properties `tw` and `ast`. By default, the filter object designs a minimum-order half-band ( $L=2$ ) Nyquist filter.

Using `fdesign.nyquist` along with `design` method generates a System object, if the 'SystemObject' flag in the `design` method is set to `true`.

`d = fdesign.nyquist(l, spec)` constructs object `d` and sets its `Specification` property to `spec`. Use `l` to specify the desired value for  $L$ .  $L = 2$  designs a half-band FIR filter,  $L = 3$  a third-band FIR filter, and so on. When you use a Nyquist filter as an interpolator,  $l$  or  $L$  is the interpolation factor. The first input argument must be `l` when you are not using the default syntax `d = fdesign.nyquist`.

Entries in the `spec` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `spec` are shown below. The entries are not case sensitive.

- `tw,ast` (default option)
- `n,tw`
- `n`
- `n,ast`

where,

- `ast` — attenuation in the stop band in decibels (the default units).
- `n` — filter order.
- `tw` — width of the transition region between the pass and stop bands. Specified in normalized frequency units.

The filter design methods that apply to a Nyquist filter specification object change depending on the `Specification` option. Use `designmethods` to determine which design method applies to an object and its specification option. Different filter design methods also have options that you can specify. Use `designopts` with the design method to see the available options. For example:

```
f=fdesign.nyquist(4, 'N,TW');
designmethods(f)
```

`d = fdesign.nyquist(l, spec, specvalue1, specvalue2, ...)` constructs an object `d` and sets its specification to `spec`, and the specification values to `specvalue1`, `specvalue2`, and so on at construction time.

`d = fdesign.nyquist(l, specvalue1, specvalue2)` constructs an object `d` with the values you provide in `l`, `specvalue1`, `specvalue2` as the values for `l`, `tw` and `ast`.

`d = fdesign.nyquist(..., fs)` adds the argument `fs`, specified in Hz to define the sampling frequency to use. In this case, all frequencies in the specifications are in Hz as well.

`d = fdesign.nyquist(..., magunits)` specifies the units for any magnitude specification you provide in the input arguments. `magunits` can be one of

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

### Limitations of the Nyquist `fdesign` Object

Using Nyquist filter specification objects with the `equiripple` design method imposes a few limitations on the resulting filter, caused by the `equiripple` design algorithm.

- When you request a minimum-order design from `equiripple` with your Nyquist object, the design algorithm might not converge and can fail with a filter convergence error.
- When you specify the order of your desired filter, and use the `equiripple` design method, the design might not converge.
- Generally, the following specifications, alone or in combination with one another, can cause filter convergence problems with Nyquist objects and the `equiripple` design method.
  - very high order
  - small transition width
  - very large stopband attenuation

Note that halfband filters (filters where `band = 2`) do not exhibit convergence problems.

When convergence issues arise, either in the cases mentioned or in others, you might be able to design your filter with the `kaiserwin` method.

In addition, if you use Nyquist objects to design decimators or interpolators (where the interpolation or decimation factor is not a prime number), using multistage filter designs might be your best approach.

## Examples

### Construct a Nyquist Filter Using `fdesign` Object

These examples show how to construct a Nyquist filter specification object.

First, create a default specifications object without using input arguments.

```
d = fdesign.nyquist; %#ok
```

Now create an object by passing a specification type 'n,ast' - the resulting object uses default values for n and ast.

```
d = fdesign.nyquist(2, 'n,ast'); %#ok
```

Create another Nyquist filter object, passing the specification values to the object rather than accepting the default values for n and ast.

```
d = fdesign.nyquist(3, 'n,ast', 42, 80) %#ok
```

```
d =
  nyquist with properties:
      Response: 'Nyquist'
  Specification: 'N,Ast'
  Description: {2x1 cell}
NormalizedFrequency: 1
  FilterOrder: 42
      Astop: 80
      Band: 3
```

Finally, pass the filter specifications that correspond to the default Specification - tw,ast. When you pass only the values, fdesign.nyquist assumes the default Specification option.

```
d = fdesign.nyquist(4, .01, 80)
```

```
d =
  nyquist with properties:
      Response: 'Nyquist'
  Specification: 'TW,Ast'
  Description: {2x1 cell}
NormalizedFrequency: 1
  TransitionWidth: 0.0100
      Astop: 80
      Band: 4
```

Now design a Nyquist filter using the kaiserwin design method.

```
hd = design(d, 'kaiserwin', 'SystemObject', true);
```

Create two equiripple Nyquist 4th-band filters with and without a nonnegative zero phase response:

```
f = fdesign.nyquist(4, 'N,TW', 12, 0.2);
```

Equiripple Nyquist 4th-band filter with nonnegative zero phase response

```
Hd1 = design(f, 'equiripple', 'zerophase', true, 'SystemObject', true);
```

Equiripple Nyquist 4th-band filter with 'ZeroPhase' set to false 'zerophase', false is the default

```
Hd2 = design(f, 'equiripple', 'zerophase', false, 'SystemObject', true);
```

Obtain real-valued amplitudes (not magnitudes)

```
[Hr_zerophase,~] = zerophase(Hd1);
[Hr,W] = zerophase(Hd2);
```

Plot and compare response

```
plot(W,Hr_zerophase,'k','linewidth',2);
xlabel('Radians/sample'); ylabel('Amplitude');
hold on;
plot(W,Hr,'r');
axis tight; grid on;
legend('with ''ZeroPhase'', true','with ''ZeroPhase'' false');
```

Note that the amplitude of the zero phase response (black line) is nonnegative for all frequencies.

The 'ZeroPhase' option is valid only for equiripple Nyquist designs with the 'N,TW' specification. You cannot specify 'MinPhase' and 'ZeroPhase' to be simultaneously 'true'.

## fdesign.octave

(To be removed) Octave filter specification

### Compatibility

---

**Note** The `fdesign.octave` filter specification object will be removed from DSP System Toolbox in a future release. Existing instances of the object continue to run. For new code, use the `octaveFilter` System object instead. For more information on how to update your existing code, see “Compatibility Considerations” on page 5-556.

---

### Syntax

```
d = fdesign.octave(l)
d = fdesign.octave(l, MASK)
d = fdesign.octave(l, MASK, spec)
d = fdesign.octave(..., Fs)
```

### Description

`d = fdesign.octave(l)` constructs an octave filter specification object `d`, with `l` bands per octave. The default value for `l` is one.

---

**Note** The filters created by `fdesign.octave` comply with the ANSI<sup>®</sup> S1.11-2004 and IEC 61260:1995 standards.

---

`d = fdesign.octave(l, MASK)` constructs an octave filter specification object `d` with `l` bands per octave and `MASK` specification for the FVTool. The available values for mask are:

- 'class 0'
- 'class 1'
- 'class 2'

`d = fdesign.octave(l, MASK, spec)` constructs an octave filter specification object `d` with `l` bands per octave, `MASK` specification for the FVTool, and the `spec` specification character vector. The specifications available are:

- 'N, F0'

(not case sensitive), where:

- `N` is the filter order
- `F0` is the center frequency. The center frequency is specified in normalized frequency units assuming a sampling frequency of 48 kHz, unless a sampling frequency in Hz is included in the specification: `d = fdesign.octave(..., Fs)`. If you specify an invalid center frequency, a warning is issued and the center frequency is rounded to the nearest valid value. You can

determine the valid center frequencies for your design by using `validfrequencies` with your octave filter specification object. For example:

```
d = fdesign.octave(1, 'Class 1', 'N,F0', 6, 1000, 44.1e3);
validcenterfreq = validfrequencies(d);
```

Valid center frequencies:

- Must be greater than 20 Hz and less than 20 kHz if you specify a sampling frequency. The range 20 Hz to 20 kHz is the standard range of human hearing.
- Are calculated according to the following algorithm if the number of bands per octave,  $L$ , is even:

```
G = 10^(3/10);
x = -1000:1350;
validcenterfreq = 1000*(G.^((2*x-59)/(2*L)));
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

- Are calculated according to the following algorithm if the number of bands per octave,  $L$ , is odd:

```
G = 10^(3/10);
x = -1000:1350;
validcenterfreq = 1000*(G.^((x-30)/L));
validcenterfreq = validcenterfreq(validcenterfreq>20 & validcenterfreq<2e4);
```

Only center frequencies greater than 20 and less than 20,000 are retained. The center frequencies and the corresponding upper band frequencies must be less than the Nyquist frequency, which is half the sampling rate (`samplingfreq`). The vector of upper band frequencies (`upperbandfreq`) corresponding to the center frequencies (`validcenterfreq`) is computed using the following algorithm:

```
upperbandfreq = validcenterfreq.*(G^(1/(2*L)));
```

The algorithm removes the center frequencies whose corresponding upper band frequencies do not obey the Nyquist rule.

```
validcenterfreq = validcenterfreq(upperbandfreq < samplingfreq/2);
```

If you do not specify a sampling frequency, `fdesign.octave` assumes a `samplingfreq` of 48 kHz. To obtain valid normalized center frequencies, the remaining center frequencies are divided by 24,000.

```
validcenterfreq = validcenterfreq/24000;
```

## Examples

### Design an Octave Band Filter

Design a sixth order, octave-band class 0 filter with a center frequency of 1000 Hz and, a sampling frequency of 44.1 kHz.

```
d = fdesign.octave(1, 'Class 0', 'N,F0', 6, 1000, 44100)
d = octave with properties:
    Response: 'Octave and Fractional Octave'
    BandsPerOctave: 1
    Mask: 'Class 0'
    Specification: 'N,F0'
```

```

        Description: {2x1 cell}
NormalizedFrequency: 0
                Fs: 44100
        FilterOrder: 6
                F0: 1000

```

```

biquad = design(d,'SystemObject',true)

biquad = BiquadFilter with properties:
    Structure: 'Direct form II'
    SOSMatrixSource: 'Property'
    SOSMatrix: [3x6 double]
    ScaleValues: [4x1 double]
    InitialConditions: 0
    OptimizeUnityScaleValues: true

Show all properties

```

Plot the magnitude response of the filter using `fvtool`. The logarithmic scale for frequency is automatically set by `fvtool` for the octave filters.

```
fvtool(biquad)
```

Filter a sinusoidal signal using the above designed filter. The input is a sum of two tones - one at 0.3 kHz and the other at 3 kHz. Initialize a spectrum analyzer to view the filtered output power spectrum.

```

Fs = 2500;
Sineobject1 = dsp.SineWave('SamplesPerFrame',1024,...
    'SampleRate',Fs,'Frequency',100);
Sineobject2 = dsp.SineWave('SamplesPerFrame',1024,...
    'SampleRate',Fs,'Frequency',1000);

sa = spectrumAnalyzer('SampleRate',Fs,'NumInputPorts',2,...
    'PlotAsTwoSidedSpectrum',false,'YLimits',[-250,50],...
    'ChannelNames',{'Input','FilteredOutput'},'ShowLegend',true);

```

Stream the sinusoidal signal and pass it as an input to the biquadratic filter. View the input and the filtered output power spectra using the spectrum analyzer.

```

for Iter = 1:3000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    filteredOutput = biquad(Input);
    sa(Input,filteredOutput);
end

```

## Version History

**Introduced in R2011a**

**R2022a: `fdesign.octave` will be removed**

*Warns starting in R2022a*

The `fdesign.octave` filter specification object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `octaveFilter` System object instead.

### Update Code

This table shows how the object is typically used and explains how to update the existing code to use the `octaveFilter` object. The `octaveFilter` object requires Audio Toolbox.

## fdesign.parmeq

(To be removed) Parametric equalizer filter specification

### Compatibility

---

**Note** The `fdesign.parmeq` filter specification object will be removed from DSP System Toolbox in a future release. Existing instances of the object continue to run. For new code, use the `designParamEQ` function instead. For more information on how to update your existing code, see “Compatibility Considerations” on page 5-561.

---

### Syntax

```
d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)
d = fdesign.parmeq(... fs)
```

### Description

`d = fdesign.parmeq(spec, specvalue1, specvalue2, ...)` constructs a parametric equalizer filter design object, where `spec` is a non-case sensitive specification character vector. The choices for `spec` are as follows:

- 'F0, BW, BWp, Gref, G0, GBW, Gp' (minimum order default)
- 'F0, BW, BWst, Gref, G0, GBW, Gst'
- 'F0, BW, BWp, Gref, G0, GBW, Gp, Gst'
- 'N, F0, BW, Gref, G0, GBW'
- 'N, F0, BW, Gref, G0, GBW, Gp'
- 'N, F0, Fc, Qa, G0'
- 'N, F0, Fc, S, G0'
- 'N, F0, BW, Gref, G0, GBW, Gst'
- 'N, F0, BW, Gref, G0, GBW, Gp, Gst'
- 'N, Flow, Fhigh, Gref, G0, GBW'
- 'N, Flow, Fhigh, Gref, G0, GBW, Gp'
- 'N, Flow, Fhigh, Gref, G0, GBW, Gst'
- 'N, Flow, Fhigh, Gref, G0, GBW, Gp, Gst'

where the parameters are defined as follows:

- BW — Bandwidth
- BWp — Passband Bandwidth
- BWst — Stopband Bandwidth
- Gref — Reference Gain (decibels)
- G0 — Center Frequency Gain (decibels)

- GBW — Gain at which Bandwidth (BW) is measured (decibels)
- Gp — Passband Gain (decibels)
- Gst — Stopband Gain (decibels)
- N — Filter Order
- F0 — Center Frequency
- Fc— Cutoff frequency
- Fhigh - Higher Frequency at Gain GBW
- Flow - Lower Frequency at Gain GBW
- Qa-Quality Factor
- S-Slope Parameter for Shelving Filters

Regardless of the specification chosen, there are some conditions that apply to the specification parameters. These are as follows:

- Specifications for parametric equalizers must be given in decibels
- To boost the input signal, set  $G_0 > G_{ref}$ ; to cut, set  $G_{ref} > G_0$
- For boost:  $G_0 > G_p > GBW > G_{st} > G_{ref}$ ; For cut:  $G_0 < G_p < GBW < G_{st} < G_{ref}$
- Bandwidth must satisfy:  $BW_{st} > BW > BW_p$

`d = fdesign.parmeq(... fs)` adds the input sampling frequency. Fs must be specified as a scalar trailing the other numerical values provided, and is assumed to be in Hz.

## Examples

Design a Chebyshev Type II parametric equalizer filter that cuts by 12 dB:

```
d = fdesign.parmeq('N,Flow,Fhigh,Gref,G0,GBW,Gst',...
    4, .3, .5, 0, -12, -10, -1);
Hd = design(d, 'cheby2');
fvtool(Hd)
```

Design a 4th order audio lowpass ( $F_0 = 0$ ) shelving filter with cutoff frequency of  $F_c = 0.25$ , quality factor  $Q_a = 10$ , and boost gain of  $G_0 = 8$  dB:

```
d = fdesign.parmeq('N,F0,Fc,Qa,G0',4,0,0.25,10,8);
Hd = design(d);
fvtool(Hd)
```

Design 4th-order highpass shelving filters with  $S=1.5$  and  $S=3$ :

```
N=4;
F0 = 1;
Fc = .4; % Cutoff Frequency
G0 = 10;
S = 1.5;
S2=3;
f = fdesign.parmeq('N,F0,Fc,S,G0',N,F0,Fc,S,G0);
h1 = design(f);
f.S=3;
h2=design(f);
hfvt=fvtool([h1 h2]);
set(hfvt,'Filters',[h1 h2]);
legend(hfvt,'S=1.5','S=3');
```

designParamEQ

## fdesign.peak

Peak filter specification

### Syntax

```
d = fdesign.peak(specstring, value1, value2, ...)  
d = fdesign.peak(n,f0,q)  
d = fdesign.peak(...,Fs)  
d = fdesign.peak(...,MAGUNITS)
```

### Description

`d = fdesign.peak(specstring, value1, value2, ...)` constructs a peaking filter specification object `d`, with specification set to `specstring` and values provided for all members of the `specstring`. The possible specification options, which are not case sensitive, are listed as follows:

- 'N,F0,Q' (default)
- 'N,F0,Q,Ap'
- 'N,F0,Q,Ast'
- 'N,F0,Q,Ap,Ast'
- 'N,F0,BW'
- 'N,F0,BW,Ap'
- 'N,F0,BW,Ast'
- 'N,F0,BW,Ap,Ast'

where the variables are defined as follows:

- N - Filter Order (must be even)
- F0 - Center Frequency
- Q - Quality Factor
- BW - 3-dB Bandwidth
- Ap - Passband Ripple (decibels)
- Ast - Stopband Attenuation (decibels)

Different specification options, resulting in different specification objects, may have different design methods available. Use the function `designmethods` to get a list of design methods available for a given specification. For example:

```
>> d = fdesign.peak('N,F0,Q,Ap',6,0.5,10,1);  
>> designmethods(d)
```

Design Methods for class `fdesign.peak (N,F0,Q,Ap)`:

`cheby1`

`d = fdesign.peak(n,f0,q)` constructs a peaking filter specification object using the default specstring ('N,F0,Q') and setting the corresponding values to `n`, `f0`, and `q`.

By default, all frequency specifications are assumed to be in normalized frequency units. All magnitude specifications are assumed to be in decibels.

`d = fdesign.peak(...,Fs)` constructs a peak filter specification object while providing the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other values provided. If you specify an `Fs`, it is assumed to be in Hz, as all the other frequency values provided.

`d = fdesign.peak(...,MAGUNITS)` constructs a notch filter specification while providing the units for any magnitude specification given. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. If this argument is omitted, 'dB' is assumed. The magnitude specifications are always converted and stored in decibels regardless of how they were specified. If `Fs` is provided, `MAGUNITS` must follow `Fs` in the input argument list.

## Examples

### Design a Chebyshev Type II Peaking Filter

Design a Chebyshev Type II peaking filter with a stopband attenuation of 80 dB.

```
d = fdesign.peak('N,F0,BW,Ast',8,.65,.02,80);  
Hd = design(d,'cheby2','SystemObject',true);  
fvtool(Hd)
```

## Version History

Introduced in R2011a

## fdesign.polysrc

Construct polynomial sample-rate converter (POLYSRC) filter designer

### Syntax

```
d = fdesign.polysrc(l,m)
d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)
d = fdesign.polysrc(...,Fs)
```

### Description

`d = fdesign.polysrc(l,m)` constructs a polynomial sample-rate converter filter designer `D` with an interpolation factor `L` and a decimation factor `M`. `L` defaults to 3. `M` defaults to 2. `L` and `M` can be arbitrary positive numbers.

`d = fdesign.polysrc(l,m,'Fractional Delay','Np',Np)` initializes the filter designer specification with `Np` and sets the polynomial order to the value `Np`. If omitted `Np` defaults to 3.

`d = fdesign.polysrc(...,Fs)` specifies the sampling frequency (in Hz).

### Examples

#### Design a Sample-Rate Converter

This example shows how to design sample-rate converter that uses a third order Lagrange interpolation filter to convert from 44.1kHz to 48kHz.

```
FsIn = 44.1e3;
FsOut = 48e3;
[L,M] = rat(FsOut/FsIn);
f = fdesign.polysrc(L,M,'Fractional Delay',Np=3);
FRCObj = design(f,'lagrange',SystemObject=true);
```

9408 samples of data is 0.2133 seconds long.

```
n = (0:9407)';
```

Input signal is a sinusoid at 1 kHz.

```
F0 = 1e3;
x = sin(2*pi*F0/FsIn*n);
```

The output has 10241 samples (still 0.2133 seconds long).

```
y = FRCObj(x);
```

Plot one cycle of the input signal, sampled at 44.1kHz.

```
stem(n/FsIn, x);
hold on;
xlim([0, 1/F0])
```

```
xlabel('Time (sec)');
ylabel('Signal value')
```

Plot fractionally interpolated signal (48kHz) in red.

```
D = outputDelay(FRCObj, Fc=0, FsIn=FsIn);

## fdesign.pulseshaping

(To be removed) Pulse-shaping filter specification object

---

**Note** The `fdesign.pulseshaping` filter specification object will be removed in a future release. Use `rcosdesign` or `gaussdesign` instead. For more information on how to update your existing code, see “Compatibility Considerations”.

---

### Syntax

```
D = fdesign.pulseshaping
D = fdesign.pulseshaping(sps)
D = fdesign.pulseshaping(sps,shape)
d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)
d = fdesign.pulseshaping(...,fs)
d = fdesign.pulseshaping(...,magunits)
```

### Description

`D = fdesign.pulseshaping` constructs a specification object `D`, which can be used to design a minimum-order raised cosine filter object with a default stop band attenuation of 60 dB and a rolloff factor of 0.25.

`D = fdesign.pulseshaping(sps)` constructs a minimum-order raised cosine filter specification object `d` with a positive integer-valued oversampling factor, `SamplesPerSymbol`.

`D = fdesign.pulseshaping(sps,shape)` constructs `d` where `shape` specifies the `PulseShape` property. Valid entries for `shape` are:

- 'Raised Cosine'
- 'Square Root Raised Cosine'
- 'Gaussian'

`d = fdesign.pulseshaping(sps,shape,spec,value1,value2,...)` constructs `d` where `spec` defines the `Specification` properties. The entries for `spec` specify various properties of the filter, including the order and frequency response. Valid entries for `spec` depend upon the `shape` property. For 'Raised Cosine' and 'Square Root Raised Cosine' filters, the valid entries for `spec` are:

- 'Ast,Beta' (minimum order; default)
- 'Nsym,Beta'
- 'N,Beta'

The filter specifications are defined as follows:

- `Ast` —stopband attenuation (in dB). The default stopband attenuation for a raised cosine filter is 60 dB. The default stopband attenuation for a square root raised cosine filter is 30 dB. If `Ast` is specified, the minimum-order filter is returned.

- **Beta** —rolloff factor expressed as a real-valued scalar ranging from 0 to 1. Smaller rolloff factors result in steeper transitions between the passband and stopband of the filter.
- **Nsym** —filter order in symbols. The length of the impulse response is given by  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **N** —filter order (must be even). The length of the impulse response is  $N + 1$ .

If the `shape` property is specified as `'Gaussian'`, the valid entries for `spec` are:

- `'Nsym,BT'` (default)

The filter specifications are defined as follows:

- **Nsym**—filter order in symbols. `Nsym` defaults to 6. The length of the filter impulse response is  $Nsym * SamplesPerSymbol + 1$ . The product  $Nsym * SamplesPerSymbol$  must be even.
- **BT** —the 3 dB bandwidth-symbol time product. `BT` is a positive real-valued scalar, which defaults to 0.3. Larger values of `BT` produce a narrower pulse width in time with poorer concentration of energy in the frequency domain.

`d = fdesign.pulseshaping(...,fs)` specifies the sampling frequency of the signal to be filtered. `fs` must be specified as a scalar trailing the other numerical values provided. For this case, `fs` is assumed to be in Hz and is used for analysis and visualization.

`d = fdesign.pulseshaping(...,magunits)` specifies the units for any magnitude specification you provide in the input arguments. Valid entries for `magunits` are:

- `linear` — specify the magnitude in linear units
- `dB` — specify the magnitude in dB (decibels)
- `squared` — specify the magnitude in power units

When you omit the `magunits` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

After creating the specification object `d`, you can use the `design` function to create a filter object such as `h` in the following example:

```
d = fdesign.pulseshaping(8,'Raised Cosine','Nsym,Beta',6,0.25);
h = design(d);
```

Normally, the `Specification` property of the specification object also determines which design methods you can use when you create the filter object. Currently, regardless of the `Specification` property, the `design` function uses the `window` design method with all `fdesign.pulseshaping` specification objects. The `window` method creates an FIR filter with a windowed impulse response.

## Examples

Pulse-shaping can be used to change the waveform of transmitted pulses so the signal bandwidth matches that of the communication channel. This helps to reduce distortion and intersymbol interference (ISI).

This example shows how to design a minimum-order raised cosine filter that provides a stop band attenuation of 60 dB, rolloff factor of 0.50, and 8 samples per symbol.

```
h = fdesign.pulseshaping(8,'Raised Cosine','Ast,Beta',60,0.50);
Hd = design(h);
fvtool(Hd)
```

This code generates the following figure.

This example shows how to design a raised cosine filter that spans 8 symbol durations (i.e., of order 8 symbols), has a rolloff factor of 0.50, and oversampling factor of 10.

```
h = fdesign.pulseshaping(10,'Raised Cosine','Nsym,Beta',8,0.50);
Hd = design(h);
fvtool(Hd, 'impulse')
```

This example shows how to design a square root raised cosine filter of order 42, rolloff factor of 0.25, and 10 samples per symbol.

```
h = fdesign.pulseshaping(10,'Square Root Raised Cosine','N,Beta',42);
Hd = design(h);
fvtool(Hd, 'impulse')
```

The following example demonstrates how to create a Gaussian pulse-shaping filter with an oversampling factor (sps) of 10, a bandwidth-time symbol product of 0.2, and 8 symbol periods. The sampling frequency is specified as 10 kHz.

## Version History

Introduced in R2011a

**R2022a: fdesign.pulseshaping will be removed**

*Warns starting in R2022a*

The `fdesign.pulseshaping` filter specification object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `rcosdesign` or `gaussdesign` functions instead.

**Update Code**

This table shows how the object is typically used and explains how to update the existing code to use the `rcosdesign` and `gaussdesign` functions.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <p><b>Square Root Raised Cosine Filter</b></p> <p>Design a square root raised cosine FIR filter than spans 4 symbol durations and has a roll-off factor of 0.25 and an oversampling factor of 6.</p> <pre>d = fdesign.pulseshaping(4, 'Square Root Raised Cosine',     'Nsym,Beta',6,0.25); filt = design(d, 'Systemobject', true); fvtool(filt, 'impulse')</pre> | <p><b>Square Root Raised Cosine Filter</b></p> <p>Design a square root raised cosine FIR filter than spans 4 symbol durations and has a roll-off factor of 0.25 and an oversampling factor of 6.</p> <pre>filtCoeffs = rcosdesign(0.25,6,4, 'sqrt'); fvtool(filtCoeffs, 'Analysis', 'impulse')</pre> |
| <p><b>Gaussian windowed FIR filter</b></p> <p>Design a Gaussian-window FIR filter of order 3 symbols, with the bandwidth-symbol time product of 0.4, and with 10 samples per symbol.</p> <pre>d = fdesign.pulseshaping(10, 'Gaussian', ...     'Nsym,BT',3,0.4); filt = design(d, 'Systemobject', true); fvtool(filt)</pre>                                       | <p><b>Gaussian windowed FIR filter</b></p> <p>Design a Gaussian-window FIR filter of order 3 symbols, with the bandwidth-symbol time product of 0.4, and with 10 samples per symbol.</p> <pre>filtCoeffs = gaussdesign(0.4,3,10) fvtool(filtCoeffs)</pre>  |

# fdesign.rsrc

Rational-factor sample-rate converter specification

---

## Note

**Note** Support for designing an `mfilt.firsrc` object using the `fdesign.rsrc` and the `design` functions will be removed in a future release. Use the `design` function with the `SystemObject=true` flag to design an FIR rate converter System object™. For more information, see “Compatibility Considerations”.

---

## Syntax

```
D = fdesign.rsrc(L,M)
D = fdesign.rsrc(L,M,RESPONSE)
D = fdesign.rsrc(L,M,CICRESPONSE,D)
D = fdesign.rsrc(L,M,RESPONSE,SPEC)
D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)
D = fdesign.rsrc(...,Fs)
D = fdesign.rsrc(...,MAGUNITS)
```

## Description

`D = fdesign.rsrc(L,M)` constructs a rational-factor sample-rate filter specification object `D` with the `InterpolationFactor` property equal to the positive integer `L`, the `DecimationFactor` property equal to the positive integer `M` and the `Response` property set to `'Nyquist'`. The default values for the transition width and stopband attenuation in the Nyquist design are  $0.1\pi$  radians/sample and 80 dB. If `L` is unspecified, `L` defaults to 3. If `M` is unspecified, `M` defaults to 2.

`D = fdesign.rsrc(L,M,RESPONSE)` constructs an rational-factor sample-rate converter with the interpolation factor `L`, decimation factor `M`, and the response you specify in `RESPONSE`.

`D = fdesign.rsrc(L,M,CICRESPONSE,D)` constructs a CIC or CIC compensator rational-factor sample-rate convertor filter specification object with the `'RESPONSE'` property equal to `'CIC'` or `'CICCOMP'`. `D` is the differential delay. The differential delay, `D`, must precede the filter specification.

Because you are designing multirate filters, the specification options available are not the same as the specification options for designing single-rate filters. The interpolation and decimation factors are not included in the specification. Different filter responses support different specifications. The following table lists the supported response types and specification options. These options are not case sensitive.

| Design Method                   | Valid Specification Options  |
|---------------------------------|--|
| 'Arbitrary Magnitude'           | See <code>fdesign.arbmag</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,A' (default option)</li> <li>'N,B,F,A'</li> </ul>  |
| 'Arbitrary Magnitude and Phase' | See <code>fdesign.arbmagnphase</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,F,H' (default option)</li> <li>'N,B,F,H'</li> </ul>  |
| 'Bandpass'                      | See <code>fdesign.bandpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2' (default option)</li> <li>'N,Fc1,Fc2'</li> <li>'N,Fst1,Fp1,Fp2,Fst2'</li> </ul>  |
| 'Bandstop'                      | See <code>fdesign.bandstop</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'N,Fc1,Fc2'</li> <li>'N,Fp1,Fst1,Fst2,Fp2'</li> <li>'Fp1,Fst1,Fst2,Fp2,Ap1,Ast,Ap2' (default option)</li> </ul>   |
| 'CIC'                           | 'Fp,Fst,Ap,Ast' — Only valid specification. Fp is the passband frequency, Fst is the stopband frequency, Ap is the passband ripple, and Ast is the stopband attenuation in decibels.<br><br>To specify a CIC rational-factor sample-rate convertor, include the differential delay after 'CIC' and before the filter specification: 'Fp,Ast'. For example:<br><code>d = fdesign.rsrc(2,2,'cic',4);</code>  |
| 'CIC Compensator'               | See <code>fdesign.ciccomp</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fst,Ap,Ast'</li> </ul><br>To specify a CIC compensator rational-factor sample-rate convertor, include the differential delay after 'CICCOMP' and before the filter specification. For example:<br><code>d = fdesign.rsrc(2,2,'ciccomp',4);</code> |
| 'Differentiator'                | 'N' — filter order   |
| 'Gaussian'                      | 'Nsym,BT — Nsym is the filter order in symbols and BT is the bandwidth-symbol time product.<br><br>The filter specification must be preceded by an integer-valued <code>SamplesPerSymbol</code> .  |

| Design Method           | Valid Specification Options   |
|-------------------------|---|
| 'Halfband'              | <p>See <code>fdesign.halfband</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'TW,Ast' (default option)</li> <li>• 'N,TW'</li> <li>• 'N'</li> <li>• 'N,Ast'</li> </ul> <p>If you use the quasi-linear IIR design method, <code>iirlinphase</code>, with a halfband specification, the interpolation factor must be 2.</p> |
| 'Highpass'              | <p>See <code>fdesign.highpass</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,F3db'</li> <li>• 'N,Fc'</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fp,Ast,Ap'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> <li>• 'N,Fst,Fp,Ast'</li> </ul>     |
| 'Hilbert'               | <p>See <code>fdesign.hilbert</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'N,TW' (default option)</li> <li>• 'TW,Ap'</li> </ul>  |
| 'Inverse-sinc Lowpass'  | <p>See <code>fdesign.isinclp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fp,Fst,Ap,Ast' (default option)</li> <li>• 'N,Fc,Ap,Ast'</li> <li>• 'N,Fp,Fst'</li> <li>• 'N,Fst,Ap,Ast'</li> </ul>   |
| 'Inverse-sinc Highpass' | <p>See <code>fdesign.isinchp</code> for a description of the specification entries.</p> <ul style="list-style-type: none"> <li>• 'Fst,Fp,Ast,Ap' (default option)</li> <li>• 'N,Fc,Ast,Ap'</li> <li>• 'N,Fst,Fp'</li> <li>• 'N,Fst,Ast,Ap'</li> </ul>   |

| Design Method | Valid Specification Options  |
|---------------|--|
| 'Lowpass'     | See <code>fdesign.lowpass</code> for a description of the specification entries. <ul style="list-style-type: none"> <li>'Fp,Fst,Ap,Ast' (default option)</li> <li>'N,F3dB'</li> <li>'N,Fc'</li> <li>'N,Fc,Ap,Ast'</li> <li>'N,Fp,Ap,Ast'</li> <li>'N,Fp,Fst'</li> <li>'N,Fp,Fst,Ap'</li> <li>'N,Fp,Fst,Ast'</li> <li>'N,Fst,Ap,Ast'</li> </ul>   |
| 'Nyquist'     | See <code>fdesign.nyquist</code> for a description of the specification entries. For all Nyquist specifications, you must specify the <i>L</i> th band. This typically corresponds to the interpolation factor so that the nonzero samples of the upsampler output are preserved. <ul style="list-style-type: none"> <li>'TW,Ast' (default option)</li> <li>'N'</li> <li>'N,Ast'</li> <li>'N,Ast'</li> </ul> |

`D = fdesign.rsrc(L,M,RESPONSE,SPEC)` constructs object `D` and sets its `Specification` property to `SPEC`. Entries in the `SPEC` represent various filter response features, such as the filter order, that govern the filter design. Valid entries for `SPEC` depend on the design type of the specifications object.

When you add the `SPEC` input argument, you must also add the `RESPONSE` input argument.

`D = fdesign.rsrc(L,M,SPEC,specvalue1,specvalue2,...)` constructs an object `D` and sets its specifications at construction time.

`D = fdesign.rsrc(...,Fs)` provides the sampling frequency of the signal to be filtered. `Fs` must be specified as a scalar trailing the other numerical values provided. `Fs` is assumed to be in Hz as are all other frequency values provided.

`D = fdesign.rsrc(...,MAGUNITS)` specifies the units for any magnitude specification you provide in the input arguments. `MAGUNITS` can be one of

- 'linear' — specify the magnitude in linear units.
- 'dB' — specify the magnitude in dB (decibels).
- 'squared' — specify the magnitude in power units.

When you omit the `MAGUNITS` argument, `fdesign` assumes that all magnitudes are in decibels. Note that `fdesign` stores all magnitude specifications in decibels (converting to decibels when necessary) regardless of how you specify the magnitudes.

## Examples

### Construct a Sample-Rate Converter Using fdesign Object

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use the default Nyquist design with a transition width of  $0.05\pi$  radians/sample and stopband attenuation of 40 dB. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,.05,40);
%design with Kaiser window
hm = design(d,'kaiserwin','SystemObject',true);
```

Design a rational-factor sample-rate converter. Set the rational sample-rate change to 5/3. Use a Nyquist design with the filter specification set to 'N,TW'. Set the order equal to 12 and the transition width to  $0.1\pi$  radians/sample. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(5,3,'nyquist',5,'N,TW',12,0.1); %#ok
```

Design a rational-factor sample-rate converter. Assume the data are sampled at 10 kHz. Set the rational sample-rate change to 3/2. Use a Nyquist design with the filter specification set to 'N,TW'. Set the order equal to 12 and the transition width to 100 Hz. The Lth band factor in the Nyquist design is equal to the interpolation factor.

```
d = fdesign.rsrc(3,2,'nyquist',3,'N,TW',12,100,1e4);
hd = design(d,'equiripple','SystemObject',true);
```

## Version History

### Introduced in R2011a

### R2022b: Support for designing mfilt.firsrc will be removed

*Warns starting in R2022b*

Support for designing an `mfilt.firsrc` object using the `fdesign.rsrc` and the `design` functions will be removed in a future release.

To design an FIR rate converter using the `fdesign.rsrc` filter specification object, use the `design` function with the `SystemObject=true` flag. Setting this flag to `true` ensures that the output object is a filter System object instead of an `mfilt.firsrc` object.

```
fdesignObj = fdesign.rsrc;
FIRRCobj = design(fdesignObj,SystemObject=true)
```

```
FIRRCobj =
```

```
    dsp.FIRRateConverter with properties:
```

```
    InterpolationFactor: 3
    DecimationFactor: 2
    NumeratorSource: 'Property'
    Numerator: [-3.2490e-05 0 9.1277e-05 1.3523e-04 ... ]
```

```
Show all properties
```

## fftcoeffs

Frequency-domain coefficients

### Syntax

```
c = fftcoeffs(hd)
```

### Description

`c = fftcoeffs(hd)` return the frequency-domain coefficients used when filtering with the `dfilt.fftfilter` object. `c` contains the coefficients

### Examples

#### Frequency Domain Coefficients of FIR Filter

This example demonstrates returning the FFT coefficients from the discrete-time filter `hd`.

```
b = [0.05 0.9 0.05];  
len = 50;  
hd = dfilt.fftfilter(b, len);  
c = fftcoeffs(hd);
```

Plot the impulse response of the coefficients.

```
impz(c);
```

## Version History

# filterBuilder

Interactive filter design

## Syntax

```
filterBuilder(h)
filterBuilder('response')
```

## Description

`filterBuilder` starts an interactive tool for building filters. It relies on the `fdesign` object-oriented filter design paradigm, and is intended to reduce development time during the filter design process. `filterBuilder` uses a specification-centered approach to find the best algorithm for the desired response.

---

**Note** You must have the Signal Processing Toolbox installed to use `fdesign` and `filterBuilder`. Some of the features described below may be unavailable if your installation does not additionally include the DSP System Toolbox. You can verify the presence of both toolboxes by typing `ver` at the command prompt.

---

For more information on how to use `filterBuilder`, see “Filter Builder Design Process”.

To use `filterBuilder`, enter `filterBuilder` at the MATLAB command line using one of three approaches:

- Simply enter `filterBuilder`. MATLAB opens a dialog for you to select a filter response type. After you select a filter response type, `filterBuilder` launches the appropriate filter design dialog box.
- Enter `filterBuilder(h)`, where `h` is an existing filter object. For example, if `h` is a bandpass filter, `filterBuilder(h)` opens the bandpass filter design dialog box. The `h` object must have been created using `filterBuilder` or using `fdesign`.

---

**Note** You must have the DSP System Toolbox software to create and import filter System objects.

- Enter `filterBuilder('response')` to replace `response` with a response method from the following table. MATLAB opens a filter design dialog that corresponds to the specified response.

---

**Note** You must have the DSP System Toolbox software to implement a number of the filter designs listed in the following table. If you only have the Signal Processing Toolbox software, you can design a limited set of the following filter-response types.

**Note** Because they do not change the filter structure, the magnitude specifications and design method are tunable when using `filterBuilder`.

## Filter Builder Design Panes

### Main Design Pane

The main pane of Filter Builder varies depending on the filter response type, but the basic structure is the same. The following figure shows the basic layout of the dialog box.

As you choose the response for the filter, the available options and design parameters displayed in the dialog box change. This display allows you to focus only on parameters that make sense in the context of your filter design.

Every filter design dialog box includes the options displayed at the top of the dialog box, shown in the following figure.

- **Save variable as** — When you click **Apply** to apply your changes or **OK** to close this dialog box, filterBuilder saves the current filter to your MATLAB workspace as a filter object with the name you enter.
- **View Filter Response** — Displays the magnitude response for the current filter specifications and design method by opening the Filter Visualization Tool (**FVTool**). If you specify the input sample rate, then **FVTool** plots the magnitude response as a function of frequency in Hz. If you do not specify the input sample rate, then **FVTool** plots the magnitude response as a function of normalized frequency in rad/sample.

---

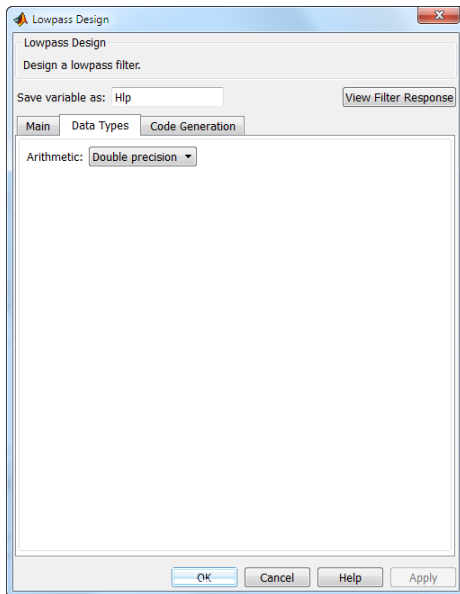

**Note** The filterBuilder dialog box includes an **Apply** option. Each time you click **Apply**, filterBuilder writes the modified filter to your MATLAB workspace. This modified filter has the variable name you assign in **Save variable as**. To apply changes without overwriting the variable in your workspace, change the variable name in **Save variable as** before you click **Apply**.

---

There are three tabs in the Filter Builder dialog box, containing three panes: **Main**, **Data Types**, and **Code Generation**. The first pane changes according to the filter being designed. The last two panes are the same for all filters. These panes are discussed in the following sections.

### Data Types Pane

The second tab in the Filter Builder dialog box is shown in the following figure.

The **Arithmetic** drop down box allows the choice of **Double precision**, **Single precision**, or **Fixed point**. Some of these options may be unavailable depending on the filter parameters. The following table describes these options.

| Arithmetic List Entry | Effect on the Filter  |
|-----------------------|---|
| Double precision      | All filtering operations and coefficients use double-precision, floating-point representations and math. When you use <code>filterBuilder</code> to create a filter, <code>double precision</code> is the default value for the <code>Arithmetic</code> property.   |
| Single precision      | All filtering operations and coefficients use single-precision floating-point representations and math.   |
| Fixed point           | This entry applies selected default values, typically used on many digital processors, for the properties in the fixed-point filter. These properties include coefficient word lengths, fraction lengths, and various operating modes. This setting allows signed fixed data types only. Fixed-point filter design with <code>filterBuilder</code> is available only when you install Fixed-Point Designer software along with DSP System Toolbox software. |

The following figure shows the **Data Types** pane after you select **Fixed point** for **Arithmetic** and set **Filter internals** to **Specify precision**. This figure shows the **Data Types** pane for the case where the **Use a System object to implement filter** check box is not selected in the **Main** pane.

Lowpass Design

Design a lowpass filter.

Filter output variable name:

Main Data Types Code Generation

Arithmetic:

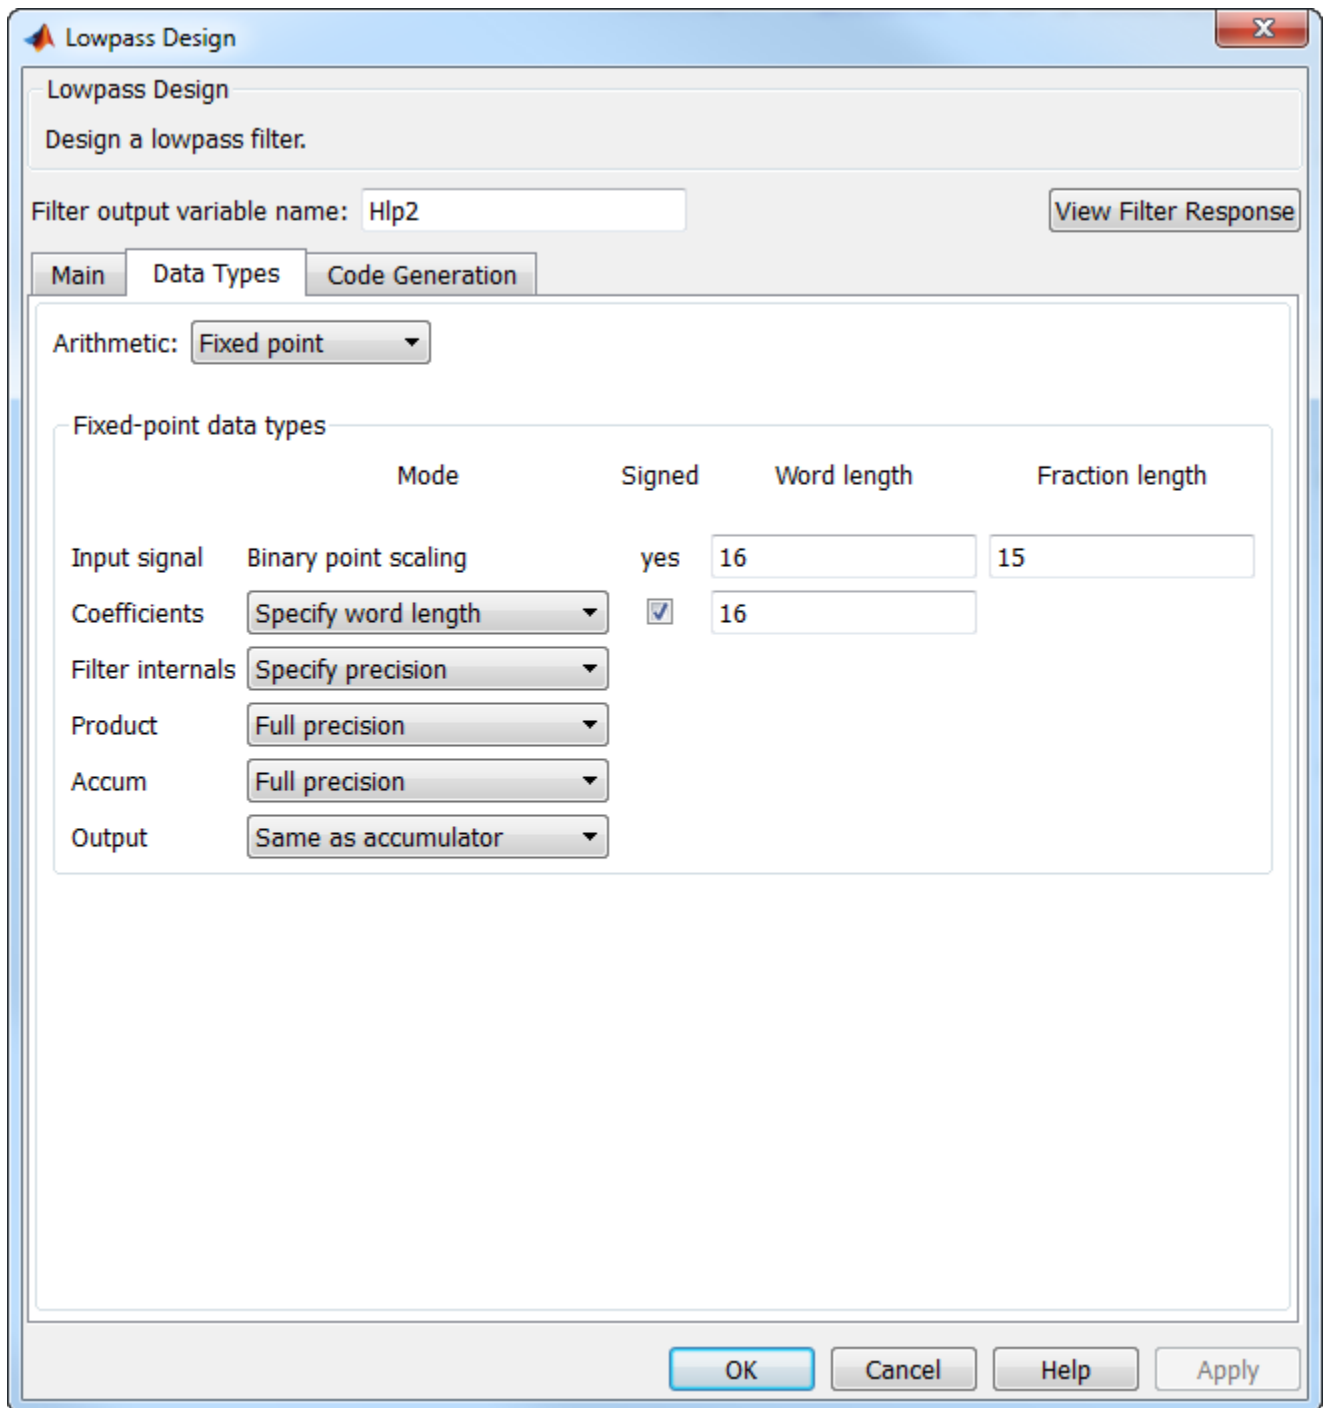

Fixed-point data types

|                  | Mode   | Signed                              | Word length                     | Fraction length                 |
|------------------|--|-------------------------------------|---------------------------------|---------------------------------|
| Input signal     | Binary point scaling                             | yes                                 | <input type="text" value="16"/> | <input type="text" value="15"/> |
| Coefficients     | <input type="text" value="Specify word length"/> | <input checked="" type="checkbox"/> | <input type="text" value="16"/> |                                 |
| Filter internals | <input type="text" value="Specify precision"/>   |                                     |                                 |                                 |
| Product          | Binary point scaling                             | yes                                 | <input type="text" value="32"/> | <input type="text" value="29"/> |
| Accum            | Binary point scaling                             | yes                                 | <input type="text" value="40"/> | <input type="text" value="29"/> |
| Output           | Binary point scaling                             | yes                                 | <input type="text" value="16"/> | <input type="text" value="15"/> |

Fixed-point operational parameters

Rounding mode:  Overflow mode:

When you select **Use a System object to implement filter** check box in the **Main** pane, the **Data Types** pane appears as below:

Not all parameters described in the following section apply to all filters. For example, FIR filters do not have the **Section input** and **Section output** parameters.

### Input signal

Specify the format the filter applies to data to be filtered. For all cases, `filterBuilder` implements filters that use binary point scaling and signed input. You set the word length and fraction length as needed.

## Coefficients

Choose how you specify the word length and the fraction length of the filter numerator and denominator coefficients:

- **Specify word length** enables you to enter the word length of the coefficients in bits. In this mode, `filterBuilder` automatically sets the fraction length of the coefficients to the binary-point only scaling that provides the best possible precision for the value and word length of the coefficients.
- **Binary point scaling** enables you to enter the word length and the fraction length of the coefficients in bits. If applicable, enter separate fraction lengths for the numerator and denominator coefficients.
- The filter coefficients do not obey the **Rounding mode** and **Overflow mode** parameters that are available when you select **Specify precision** from the Filter internals list. Coefficients are always saturated and rounded to Nearest.

## Section Input

Choose how you specify the word length and the fraction length of the fixed-point data type going into each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- **Binary point scaling** enables you to enter the word and fraction lengths of the section input in bits.
- **Specify word length** enables you to enter the word lengths in bits.

## Section Output

Choose how you specify the word length and the fraction length of the fixed-point data type coming out of each section of an SOS filter. This parameter is visible only when the selected filter structure is IIR and SOS.

- **Binary point scaling** enables you to enter the word and fraction lengths of the section output in bits.
- **Specify word length** enables you to enter the output word lengths in bits.

## State

Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Use this parameter to specify how to designate the state word and fraction lengths. This parameter is not visible for direct form and direct form I filter structures because `filterBuilder` deduces the state directly from the input format. States always use signed representation:

- **Binary point scaling** enables you to enter the word length and the fraction length of the accumulator in bits.
- **Specify precision** enables you to enter the word length and fraction length in bits (if available).

## Product

Determines how the filter handles the output of product operations. Choose from the following options:

- **Full precision** — Maintain full precision in the result.

- **Keep LSB** — Keep the least significant bit in the result when you need to shorten the data words.
- **Specify Precision** — Enables you to set the precision (the fraction length) used by the output from the multiplies.

**Filter internals**

Specify how the fixed-point filter performs arithmetic operations within the filter. The affected filter portions are filter products, sums, states, and output. Select one of these options:

- **Full precision** — Specifies that the filter maintains full precision in all calculations for products, output, and in the accumulator.
- **Specify precision** — Set the word and fraction lengths applied to the results of product operations, the filter output, and the accumulator. Selecting this option enables the word and fraction length controls.

**Signed**

Selecting this option directs the filter to use signed representations for the filter coefficients.

**Word length**

Sets the word length for the associated filter parameter in bits.

**Fraction length**

Sets the fraction length for the associate filter parameter in bits.

**Accum**

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

Determines how the accumulator outputs stored values. Choose from the following options:

- **Full precision** — Maintain full precision in the accumulator.
- **Keep MSB** — Keep the most significant bit in the accumulator.
- **Keep LSB** — Keep the least significant bit in the accumulator when you need to shorten the data words.
- **Specify Precision** — Enables you to set the precision (the fraction length) used by the accumulator.

**Output**

Sets the mode the filter uses to scale the output data after filtering. You have the following choices:

- **Avoid Overflow** — Set the output data fraction length to avoid causing the data to overflow. **Avoid overflow** is considered the conservative setting because it is independent of the input data values and range.
- **Best Precision** — Set the output data fraction length to maximize the precision in the output data.
- **Specify Precision** — Set the fraction length used by the filtered data.

**Fixed-point operational parameters**

Parameters in this group control how the filter rounds fixed-point values and how it treats values that overflow.

## Rounding mode

Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).

- `ceil` — Round toward positive infinity.
- `convergent` — Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.
- `zero/fix` — Round toward zero.
- `floor` — Round toward negative infinity.
- `nearest` — Round toward nearest. Ties round toward positive infinity.
- `round` — Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

## Overflow mode

Sets the mode the filter uses to respond to overflow conditions in fixed-point arithmetic. Choose from the following options:

- `Saturate` — Limit the output to the largest positive or negative representable value.
- `Wrap` — Set overflowing values to the nearest representable value using modular arithmetic.

The choice you make affects everything except coefficient values and input data which always round. In most cases, products do not overflow—they maintain full precision.

## Cast before sum

Specifies whether to cast numeric data to the appropriate accumulator format before performing sum operations. Selecting **Cast before sum** ensures that the results of the affected sum operations match most closely the results found on most digital signal processors. Performing the cast operation before the summation adds one or two additional quantization operations that can add error sources to your filter results.

If you clear **Cast before sum**, the filter prevents the addends from being cast to the sum format before the addition operation. Choose this setting to get the most accurate results from summations without considering the hardware your filter might use. The input format referenced by **Cast before sum** depends on the filter structure you are using.

The effect of clearing or selecting **Cast before sum** is as follows:

- `Cleared` — Configures filter summation operations to retain the addends in the format carried from the previous operation.
- `Selected` — Configures filter summation operations to convert the input format of the addends to match the summation output format before performing the summation operation. Usually, selecting **Cast before sum** generates results from the summation that more closely match those found from digital signal processors.

## Code Generation Pane

The code generation pane contains options for various implementations of the completed filter design. Depending on your installation, you can generate MATLAB, VHDL, and Verilog code from the

designed filter. You can also choose to create or update a Simulink model from the designed filter. The following section explains these options.

## HDL

For more information on this option, see “Opening the Filter Design HDL Coder UI from the Filter Builder” (Filter Design HDL Coder).

## MATLAB

### Generate MATLAB code based on filter specifications

- **Generate function that returns your filter as an output**

Selecting this option generates a function that designs a filter object using `fdesign`.

- **Generate function that filters your data**

Selecting this option generates a function that takes data as input, and outputs data filtered with the designed filter. The data type of the filter output is set according to the data type settings in the **Data Types** pane.

Clicking on the **Generate MATLAB code** button, brings up a Save File dialog. Specify the file name and location, and save. The filter is now contained in an editable file.

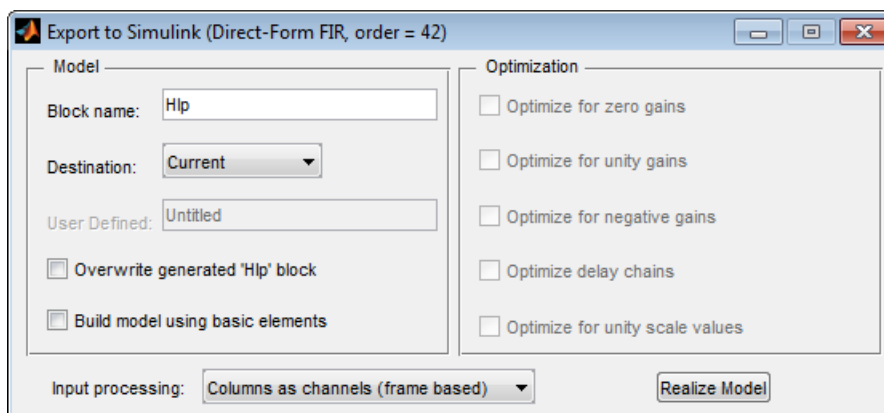

## Simulink Model

### Generate Simulink blocks and subsystems from your designed filters

When you click **Generate Model**, the filter builder generates Simulink blocks and subsystems from your designed filters.

Clicking on the **Generate Model** button opens the Export to Simulink dialog box.

- **Block Name** — The name for the new subsystem block, set to **Filter** by default.
- **Destination** — **Current** saves the generated model to the current Simulink model. **New** creates a new model to contain the generated block. **User Defined** creates a new model or subsystem at the location specified in **User Defined**.
- **Overwrite generated 'Filter' block** — Overwrites an existing block with the name specified in **Block Name**. Clear this check box to create a new block with the same name.
- **Build model using basic elements** — Builds the model using only basic blocks.
- **Optimize for zero gains** — Removes all zero-gain blocks from the model.
- **Optimize for unity gains** — Replaces all unity gains with direct connections.
- **Optimize for negative gains** — Removes all negative unity gain blocks, and changes sign at the nearest summation block.
- **Optimize delay chains** — Replaces delay chains made up of  $n$  unit delays with a single delay by  $n$ .
- **Optimize for unity scale values** — Removes all scale value multiplications by 1 from the filter structure.
- **Input processing** — Specify how the generated filter block or subsystem block processes the input. Depending on the type of filter you are designing, one or both of the following options may be available:
  - **Columns as channels (frame based)** — The block treats each column of the input as a separate channel.
  - **Elements as channels (sample based)** — The block treats each element of the input as a separate channel.

For more information about sample-based and frame-based processing, see “Sample- and Frame-Based Concepts”.

- **Realize Model** — Builds the model with the set parameters.

When the **Use a System object to implement filter** check box is selected in the **Main** pane, the **Generate Model** button in the **Simulink model** panel is disabled under the following conditions:

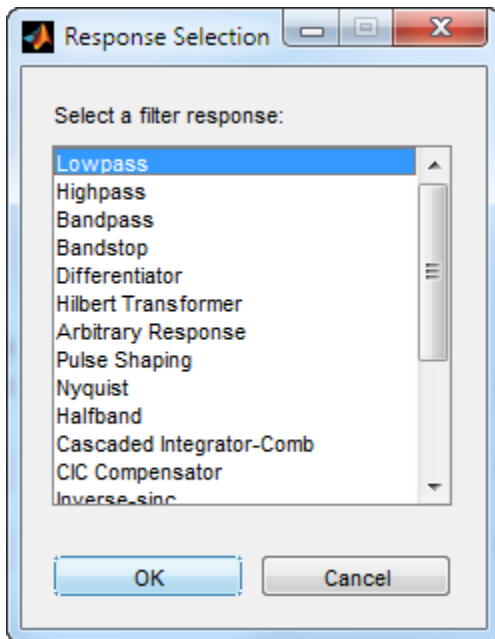

- Select **Filter response** as **Comb** and **Arithmetic** on the **Data Types** pane as **Fixed point**.
- Select **Filter response** as **Arbitrary Response**, **Impulse response** as **IIR**, set **Specify response as** to either **Magnitudes and phases** or **Frequency response**, and **Arithmetic** on the **Data Types** pane as **Fixed point**.

These settings design a `dsp.IIRFilter` System object with fixed point arithmetic. Generating a Simulink model for fixed point `dsp.IIRFilter` object is not supported.

## Filter Responses

Select your filter response from the `filterBuilder` **Response Selection** main menu.

If you have the DSP System Toolbox software, the following **Response Selection** menu appears.

Select your desired filter response from the menu and design your filter.

The following sections describe the options available for each response type.

### Arbitrary Response Filter Design – Main Pane

#### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

This dialog only applies if you have the DSP System Toolbox software. Select either FIR or IIR from the drop down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly. Arbitrary group delay designs are only available if **Impulse response** is IIR.

Without the DSP System Toolbox, the only available arbitrary response filter design is FIR.

#### Order mode

This dialog only applies if you have the DSP System Toolbox software. Choose `Minimum` or `Specify`. Choosing `Specify` enables the **Order** dialog.

#### Order

This dialog only applies when **Order mode** is `Specify`. For an FIR design, specify the filter order. For an IIR design, you can specify an equal order for the numerator and denominator, or

you can specify different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box. Because the Signal Processing Toolbox only supports FIR arbitrary-magnitude filters, you do not have the option to specify a denominator order.

### Denominator order

Select the check box and enter the denominator order. This option is enabled only if IIR is selected for **Impulse response**.

### Filter type

This dialog only applies if you have the DSP System Toolbox software and is only available for FIR filters. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2 for **Decimator** and 3 for **Sample-rate converter**.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

## Response Specification

### Number of Bands

Select the number of bands in the filter. Multiband design is available for both FIR and IIR filters.

### Specify response as:

Specify the response as **Amplitudes**, **Magnitudes and phase**, **Frequency response**, or **Group delay**. **Amplitudes** is the only option if you do not have the DSP System Toolbox software. **Group delay** is only available for IIR designs.

### Frequency units

Specify frequency units as either **Normalized**, **Hz**, **kHz**, **MHz**, or **GHz**.

### Input sample rate

Enter the input sampling frequency in the units specified in the **Frequency units** drop-down box. This option is enabled when **Frequency units** is set to an option in hertz.

## Band Properties

These properties are modified automatically depending on the response chosen in the **Specify response as** drop-down box. Two or three columns are presented for input. The first column is always **Frequencies**. The other columns are either **Amplitudes**, **Magnitudes**, **Phases**, or **Frequency Response**. Enter the corresponding vectors of values for each column.

- **Frequencies** and **Amplitudes** — These columns are presented for input if you select **Amplitudes** in the **Specify response as** drop-down box.
- **Frequencies**, **Magnitudes**, and **Phases** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is **Magnitudes and phases**.
- **Frequencies** and **Frequency response** — These columns are presented for input if the response chosen in the **Specify response as** drop-down box is **Frequency response**.

### Algorithm

The options for each design are specific for each design method. In the arbitrary response design, the available options also depend on the **Response specifications**. This section does not present all of the available options for all designs and design methods.

### Design Method

Select the design method for the filter. Different methods are enabled depending on the defining parameters entered in the previous sections.

### Design Options

- **Window** — Valid when the **Design method** is **Frequency Sampling**. Replace the square brackets with the name of a window function or function handle. For example, `'hamming'` or `@hamming`. If the window function takes parameters other than the length, use a cell array. For example, `{'kaiser', 3.5}` or `{@chebwin, 60}`.
- **Density factor** — Valid when the **Design method** is **equiripple**. Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

The default changes to 20 for an IIR arbitrary group delay design.

- **Phase constraint** — Valid when the **Design method** is **equiripple**, you have the DSP System Toolbox installed, and **Specify response as** is set to **Amplitudes**. Choose one of **Linear**, **Minimum**, or **Maximum**.
- **Weights** — Uses the weights in **Weights** to weight the error for a single-band design. If you have multiple frequency bands, the **Weights** design option changes to **B1 Weights**, **B2 Weights** to designate the separate bands. Use **Bi Weights** to specify weights for the *i*-th band. The **Bi Weights** design option is only available when you specify the *i*-th band as an unconstrained.
- **Bi forced frequency point** — This option is only available in a multi-band constrained equiripple design when **Specify response as** is **Amplitudes**. **Bi forced frequency point** is the frequency point in the *i*-th band at which the response is forced to be zero. The index *i* corresponds to the frequency bands in **Band properties**. For example, if you specify two bands in **Band properties**, you have **B1 forced frequency point** and **B2 forced frequency point**.
- **Norm** — Valid only for IIR arbitrary group delay designs. **Norm** is the norm used in the optimization. The default value is 128, which essentially equals the L-infinity norm. The norm must be even.

- **Max pole radius** — Valid only for IIR arbitrary group delay designs. Constrains the maximum pole radius. The default is 0.999999. Reducing the **Max pole radius** can produce a transfer function more resistant to quantization.
- **Init norm** — Valid only for IIR arbitrary group delay designs. The initial norm used in the optimization. The default initial norm is 2.
- **Init numerator** — Specifies an initial estimate of the filter numerator coefficients.
- **Init denominator** — Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems. In allpass filters, you only have to specify either the denominator or numerator coefficients. If you specify the denominator coefficients, you can obtain the numerator coefficients.

## Filter implementation

### Structure

Select the structure for the filter. The available filter structures depend on the parameters you select for your filter.

### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## Audio Weighting Filter Design — Main Pane

### Filter specifications

- **Weighting type** — The weighting type defines the frequency response of the filter. The valid weighting types are: A, C, C-message, ITU-T 0.41, and ITU-R 468-4 weighting. See `fdesign.audioweighting` for definitions of the weighting types.
- **Class** — Filter class is only applicable for A weighting and C weighting filters. The filter class describes the frequency-dependent tolerances specified in the relevant standards. There are two possible class values: 1 and 2. Class 1 weighting filters have stricter tolerances than class 2 filters. The filter class value does not affect the design. The class value is only used to provide a specification mask in **FVTool** for the analysis of the filter design.
- **Impulse response** — Impulse response type as one of IIR or FIR. For A, C, C-message, and ITU-R 468-4 filter, IIR is the only option. For a ITU-T 0.41 weighting filter, FIR is the only option.
- **Frequency units** — Choose Hz, kHz, MHz, or GHz. Normalized frequency designs are not supported for audio weighting filters.
- **Input sample rate** — The sampling frequency in **Frequency units**. For example, if **Frequency units** is set to kHz, setting **Input sample rate** to 40 is equivalent to a 40 kHz sampling frequency.

### Algorithm

- **Design method** — Valid design methods depend on the weighting type. For type A and C weighting filters, the only valid design type is **ANSI S1.42**. This is an IIR design method that follows ANSI standard S1.42-2001. For a C message filter, the only valid design method is **Bell 41009**, which is an IIR design method following the Bell System Technical Reference PUB 41009. For a ITU-R 468-4 weighting filter, you can design an IIR or FIR filter. If you choose an IIR design,

the design method is IIR least  $p$ -norm. If you choose an FIR design, the design method choices are: Equiripple or Frequency Sampling. For an ITU-T 0.41 weighting filter, the available FIR design methods are Equiripple or Frequency Sampling

- **Scale SOS filter coefficients to reduce chance of overflow** — Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Filter implementation

- **Structure** — For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. For audio weighting IIR filter designs, you can choose direct form I or II biquad (SOS). You can also choose to implement these structures in transposed form.

For FIR designs, you can choose direct form, direct-form transposed, direct-form symmetric, direct-form asymmetric structures, or an overlap and add structure.

- **Use a System object to implement filter** — Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

### Bandpass Filter Design — Main Pane

#### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select Minimum (the default) or Specify from the drop-down box. Selecting Specify enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

**Filter type** — This dialog only applies if you have the DSP System Toolbox software.

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.

- Selecting **Sample-rate converter** activates both factors.

### Order

Enter the filter order. This option is enabled only if you select **Specify** for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as Stopband frequency 1 ( $F_{stop1}$ ) and Passband frequency 1 ( $F_{pass1}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequency** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3-dB point is the frequency for the point 3 dB below the passband value.
- **Half power (3dB) frequencies and passband width** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the passband. (IIR filters)

- **Half power (3dB) frequencies and stopband width** — Define the filter by specifying frequencies for the 3-dB points in the filter response and the width of the stopband. (IIR filters)
- **Cutoff (6dB) frequency** — Define the filter response by specifying the locations of the 6-dB points. The 6-dB point is the frequency for the point 6 dB below the passband value. (FIR filters)

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in hertz, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Stopband frequency 1

Enter the frequency at the edge of the end of the first stopband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Passband frequency 1

Enter the frequency at the edge of the start of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Passband frequency 2

Enter the frequency at the edge of the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency 2

Enter the frequency at the edge of the start of the second stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude constraints

Specify as **Unconstrained** or **Constrained bands**. You must have the DSP System Toolbox software to select **Constrained bands**. Selecting **Constrained bands** enables dialogs for both stopbands and the passband: **Stopband attenuation 1**, **Stopband attenuation 2**, and **Passband ripple**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to **Constrained bands** enables the **Wstop** and **Wpass** options under **Design options**.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.

- dB — Specify the magnitude in dB (decibels). This is the default setting.
- Squared — Specify the magnitude in squared units.

**Stopband attenuation 1**

Enter the filter attenuation in the first stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Stopband attenuation 2**

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

**Minimum order**

This option only applies when you have the DSP System Toolbox software and **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wstop1**

Weight for the first stopband.

**Wpass**

Passband weight.

**Wstop2**

Weight for the second stopband.

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

**Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

**Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

**Bandstop Filter Design — Main Pane****Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

**Impulse response**

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option so you can enter the filter order.

If you have the DSP System Toolbox software installed, you can specify IIR filters with different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. This dialog applies only when **Order mode** is **Specify**.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Half power (3dB) frequency** — Define the filter response by specifying the locations of the 3 dB points (IIR filters). The 3 dB point is the frequency for the point 3 dB point below the passband value.
- **Half power (3dB) frequencies and passband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the passband (IIR filters).
- **Half power (3dB) frequencies and stopband width** — Define the filter by specifying frequencies for the 3 dB points in the filter response and the width of the stopband (IIR filters).
- **Cutoff (6dB) frequency** — Define the filter response by specifying the locations of the 6-dB points (FIR filters). The 6-dB point is the frequency for the point 6 dB point below the passband value.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized** (0 to 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Output sample rate

When you design an interpolator,  $F_s$  represents the sampling frequency at the filter output rather than the filter input. This option is available only when you set **Filter type** is **interpolator**.

### Passband frequency 1

Enter the frequency at the edge of the end of the first passband. Specify the value in either normalized frequency units or the absolute units you select in **Frequency units**.

### Stopband frequency 1

Enter the frequency at the edge of the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency 2

Enter the frequency at the edge of the end of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Passband frequency 2

Enter the frequency at the edge of the start of the second passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

#### Magnitude constraints

Specify as **Unconstrained** or **Constrained** bands. You must have the DSP System Toolbox software to select **Constrained** bands. Selecting **Constrained** bands enables dialogs for both passbands and the stopband: **Passband ripple 1**, **Passband ripple 2**, and **Stopband attenuation**. You cannot specify constraints for all three bands simultaneously.

Setting **Magnitude constraints** to **Constrained** bands enables the **Wstop** and **Wpass** options under **Design options**.

#### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

#### Passband ripple 1

Enter the filter ripple allowed in the first passband in the units you choose for **Magnitude units**, either linear or decibels.

#### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels

#### Passband ripple 2

Enter the filter ripple allowed in the second passband in the units you choose for **Magnitude units**, either linear or decibels

### Algorithm

The parameters in this group allow you to specify the design method and structure that **filterBuilder** uses to implement your filter.

#### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

#### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Phase constraint**

Valid when the **Design method** is equiripple and you have the DSP System Toolbox installed. Choose one of Linear, Minimum, or Maximum.

**Minimum order**

This option only applies when you have the DSP System Toolbox software and **Order mode** is Minimum.

Select Any (default), Even, or Odd. Selecting Even or Odd forces the minimum-order design to be an even or odd order.

**Wpass1**

Weight for the first passband.

**Wstop**

Stopband weight.

**Wpass2**

Weight for the second passband.

**Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband .

**Max pole radius**

Valid only for IIR designs. Constrains the maximum pole radius. The default is 1. Reducing the max pole radius can produce a transfer function more resistant to quantization.

**Init norm**

Valid only for IIR designs. The initial norm used in the optimization. The default initial norm is 2.

**Init numerator**

Specifies an initial estimate of the filter numerator coefficients. This may be useful in difficult optimization problems.

**Init denominator**

Specifies an initial estimate of the filter denominator coefficients. This may be useful in difficult optimization problems.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## CIC Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your CIC filter format, such as the filter type and the differential delay.

#### Filter type

Select whether your filter will be a `decimator` or an `interpolator`. Your choice determines the type of filter and the design methods and structures that are available to implement your filter. Selecting `decimator` or `interpolator` activates the **Factor** option. When you design an interpolator, you enable the **Output sample rate** parameter.

When you design either a decimator or interpolator, the resulting filter is a CIC filter that decimates or interpolates your input signal.

#### Differential Delay

Specify the differential delay of your CIC filter as an integer value greater than or equal to 1. The default value is 1. The differential delay changes the shape, number, and location of nulls in the filter response. Increasing the differential delay increases the sharpness of the nulls and the response between the nulls. In practice, differential delay values of 1 or 2 are the most common.

#### Factor

Specify the decimation or interpolation factor for your filter as an integer value greater than or equal to 1. The default value is 2.

### Frequency specifications

#### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select `Normalized (0 to 1)` to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—`Hz`, `KHz`, `MHz`, or `GHz`. Selecting one of the unit options enables the **Input sample rate** parameter.

#### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Output sample rate**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

**Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude specifications****Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**CIC Compensator Design — Main Pane****Filter specifications**

Parameters in this group enable you to specify your filter format, such as the filter order mode and the filter type.

**Order mode**

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

**Filter type**

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting Decimator or Interpolator activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting Sample-rate converter activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

**Order**

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

**Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Number of CIC sections

Specify the number of sections in the CIC filter for which you are designing this compensator. Select the number of sections from the drop-down list or enter the number.

### Differential Delay

Specify the differential delay of your target CIC filter. The default value is 1. Most CIC filters use 1 or 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve.

#### Frequency specifications

##### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

##### Input sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

##### Output sample rate

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter output. When you provide an output sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available only when you design interpolators.

##### Passband frequency

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

##### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

#### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels

**Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is `equiripple`.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

**Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal `equiripple` filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

**Minimum phase**

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

**Minimum order**

When you select this parameter, the design method determines and design the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select `Any`, `Even`, or `Odd` from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

**Match exactly**

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select `passband` or `stopband` or both from the drop-down list.

## Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

## Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, this check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## Comb Filter Design —Main Pane

### Filter specifications

Parameters in this group enable you to specify the type of comb filter and the number of peaks or notches.

### Comb Type

Select **Notch** or **Peak** from the drop-down list. **Notch** creates a comb filter that attenuates a set of harmonically related frequencies. **Peak** creates a comb filter that amplifies a set of harmonically related frequencies.

### Order mode

Select **Order** or **Number of Peaks/Notches** from the drop-down menu.

Select **Order** to enter the desired filter order in the dialog box. The comb filter has notches or peaks at increments of  $2/\text{Order}$  in normalized frequency units.

Select **Number of Peaks** or **Number of Notches** to specify the number of peaks or notches and the **Shelving filter order**

### Shelving filter order

The **Shelving filter order** is a positive integer that determines the sharpness of the peaks or notches. Larger values result in sharper peaks or notches.

### Frequency specifications

Parameters in this group enable you to specify the frequency constraints and frequency units.

#### Frequency specifications

Select **Quality factor** or **Bandwidth**.

**Quality factor** is the ratio of the center frequency of the peak or notch to the bandwidth calculated at the -3 dB point.

**Bandwidth** specifies the bandwidth of the peak or notch. By default the bandwidth is measured at the -3 dB point. For example, setting the bandwidth equal to 0.1 results in 3 dB frequencies at normalized frequencies 0.05 above and below the center frequency of the peak or notch.

#### Frequency Units

Specify the frequency units. The default is normalized frequency. Choosing an option in Hz enables the **Input sample rate** dialog box.

#### Magnitude specifications

Specify the units for the magnitude specification and the gain at which the bandwidth is measured. This menu is disabled if you specify a filter order. Select one of the following magnitude units from the drop down list:

- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

**Bandwidth gain** — Specify the gain at which the bandwidth is measured. The default is -3 dB.

## Algorithm

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### Design Method

The IIR Butterworth design is the only option for peaking or notching comb filters.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

#### Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

## Differentiator Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, regions between specification values such as **Passband frequency** ( $f_1$ ) and **Stopband frequency** ( $f_3$ ) represent transition regions where the filter response is not explicitly defined.

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, Interpolator, or Sample-rate converter. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### **Order**

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### **Decimation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### **Interpolation Factor**

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### **Frequency specifications**

The parameters in this group allow you to specify your filter response curve.

#### **Frequency constraints**

This option is only available when you specify the order of the filter design. Supported options are **Unconstrained** and **Passband edge and stopband edge**.

#### **Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—**Hz**, **KHz**, **MHz**, or **GHz**. Selecting one of the unit options enables the **Input sample rate** parameter.

#### **Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

#### **Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

#### **Stopband frequency**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

#### **Magnitude constraints**

This option is only available when you specify the order of your filter design. The options for **Magnitude constraints** depend on the value of the **Frequency constraints**. If the value of **Frequency constraints** is **Unconstrained**, **Magnitude constraints** must be **Unconstrained**.

If the value of **Frequency constraints** is Passband edge and stopband edge, **Magnitude constraints** can be Unconstrained, Passband ripple, or Stopband attenuation.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).
- Squared — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### Stopband attenuation 2

Enter the filter attenuation in the second stopband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Wpass

Passband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

**Wstop**

Stopband weight. This option is only available for a specified-order design when **Frequency constraints** is equal to Passband edge and stopband edge and the **Design method** is Equiripple.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

**Fractional Delay Design — Main Pane****Frequency specifications**

Parameters in this group enable you to specify your filter format, such as the fractional delay and the filter order.

**Order**

If you choose **Specify** for **Order mode**, enter your filter order in this field, or select the order from the drop-down list. `filterBuilder` designs a filter with the order you specify.

**Fractional delay**

Specify a value between 0 and 1 samples for the filter fractional delay. The default value is 0.5 samples.

**Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

**Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Halfband Filter Design — Main Pane****Filter specifications**

Parameters in this group enable you to specify your filter type and order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select Single-rate, Decimator, or Interpolator. By default, filterBuilder specifies single-rate filters.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that decimates or interpolates your input by a factor of two.

### Order

Enter the filter order. This option is enabled only if Specify was selected for **Order mode**.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications for a halfband lowpass filter look similar to those shown in the following figure.

In the figure, the transition region lies between the end of the passband and the start of the stopband. The width is defined explicitly by the value of **Transition width**.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select Normalized (0 to 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

**Input sample rate**

$F_s$ , specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Transition width**

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default).

**Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. For FIR halfband filters, the available design options are `Equiripple` and `Kaiser window`. For IIR halfband filters, the available design options are `Butterworth`, `Elliptic`, and `IIR quasi-linear phase`.

**Design Options**

The following design options are available for FIR halfband filters when the user specifies an equiripple design:

**Minimum phase**

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

**Stopband Shape**

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- Flat — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- Linear — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- $1/f$  — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterBuilder applies that slope to the stopband.
- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterBuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to either Interpolator or Decimator. The filter builder always implements the filter as a System object.

### Highpass Filter Design — Main Pane

#### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

#### Order mode

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

This option is only available if you have the DSP System Toolbox software. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a highpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the interpolation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the region between specification values Stopband frequency ( $F_{stop}$ ) and Passband frequency ( $F_{pass}$ ) represents the transition region where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Stopband edge and passband edge** — Define the filter by specifying the frequencies for the edges for the stopband and passband.
- **Passband frequency** — Define the filter by specifying the frequency for the edge of the passband.
- **Stopband frequency** — Define the filter by specifying the frequency for the edges of the stopband.

- **Stopband and half power (3dB) frequencies** — Define the filter by specifying the stopband edge frequency and the 3-dB down point (IIR designs).
- **Half power (3dB) and passband frequencies** — Define the filter by specifying the 3-dB down point and passband edge frequency (IIR designs).
- **Half power (3dB) frequency** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **Cutoff (6dB) frequency** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Passband frequency

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Stopband frequency

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default).
- **Squared** — Specify the magnitude in squared units.

### Stopband attenuation

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

## Algorithm

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is equiripple. Select one of **Linear**, **Minimum**, or **Maximum**.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is **Minimum**.

Select **Any** (default), **Even**, or **Odd**. Selecting **Even** or **Odd** forces the minimum-order design to be an even or odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select **Passband** or **Stopband**.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.

- $1/f$  — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterBuilder applies that slope to the stopband.
- When you set **Stopband shape** to  $1/f$ , enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterBuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Wpass

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

### Wstop

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

## Hilbert Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

This option is only available if you have the DSP System Toolbox software. Select either **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

This option is only available if you have the DSP System Toolbox software. Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

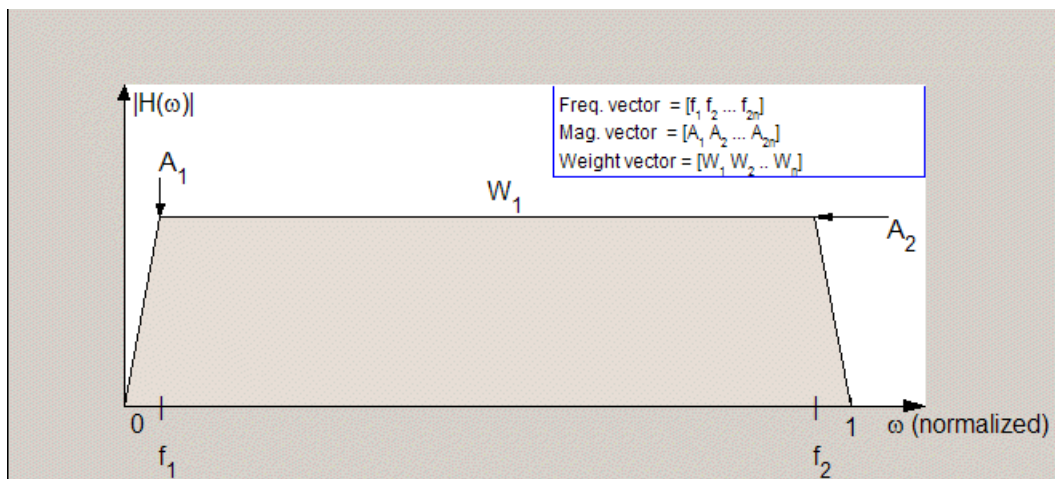

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure, the regions between 0 and  $f_1$  and between  $f_2$  and 1 represent the transition regions where the filter response is explicitly defined by the transition width.

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### Input sample rate

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### Transition width

Specify the width of the transitions at the ends of the passband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

### Magnitude specifications

The parameters in this group let you specify the filter response in the passbands and stopbands.

### Magnitude units

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default)
- **Squared** — Specify the magnitude in squared units.

### Passband ripple

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

### Algorithm

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### Design Method

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

### Scale SOS filter coefficients to reduce chance of overflow

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### Design Options

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as

you select different design methods and filter specifications. The following options represent some of the most common ones available.

### **Density factor**

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### **FIR Type**

This option is only available in a minimum-order design. Specify whether to design a type 3 or a type 4 FIR filter. The filter type is defined as follows:

- Type 3 — FIR filter with even order antisymmetric coefficients
- Type 4 — FIR filter with odd order antisymmetric coefficients

Select 3 or 4 from the drop-down list.

### **Filter implementation**

#### **Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

#### **Use a System object to implement filter**

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

### **Inverse Sinc Filter Design — Main Pane**

#### **Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

#### **Order mode**

Select **Minimum** (the default) or **Specify** from the drop-down list. Selecting **Specify** enables the **Order** option (see the following sections) so you can enter the filter order.

#### **Response type**

Select **Lowpass** or **Highpass** to design an inverse sinc lowpass or highpass filter.

#### **Filter type**

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

Regions between specification values such as Passband frequency ( $F_{pass}$ ) and Stopband frequency ( $F_{stop}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

This option is only available when you specify the filter order. The following options are available:

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edges for the stop- and passbands.
- **Passband frequency** — Define the filter by specifying frequencies for the edges of the passband.
- **Stopband frequency** — Define the filter by specifying frequencies for the edges of the stopbands.
- **Cutoff (6dB) frequency** — The 6-dB point is the frequency for the point 6 dB below the passband value.

**Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

**Input sample rate**

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Passband frequency**

Enter the frequency at the end of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Stopband frequency**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default)
- **Squared** — Specify the magnitude in squared units.

**Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

**Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

Available options are Linear, Minimum, and Maximum.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options;

- Flat — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- Linear — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- 1/f — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to Flat, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to Linear, enter the slope of the stopband in units of dB/rad/s. filterBuilder applies that slope to the stopband.
- When you set **Stopband shape** to 1/f, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. filterBuilder applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

### Sinc frequency factor

A frequency dilation factor. The sinc frequency factor,  $C$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

### Sinc power

Negative power of passband magnitude response. The sinc power,  $P$ , parameterizes the passband magnitude response for a lowpass design through  $H(\omega) = \text{sinc}(C\omega)^{-P}$  and for a highpass design through  $H(\omega) = \text{sinc}(C(1-\omega))^{-P}$ .

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

### Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## Lowpass Filter Design — Main Pane

### Filter specifications

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

### Impulse response

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

### Order mode

Select `Minimum` (the default) or `Specify` from the drop-down list. Selecting `Specify` enables the **Order** option (see the following sections) so you can enter the filter order.

If your **Impulse response** is IIR, you can specify an equal order for the numerator and denominator, or different numerator and denominator orders. The default is equal orders. To specify a different denominator order, check the **Denominator order** box.

### Filter type

This option is only available if you have the DSP System Toolbox. Select `Single-rate`, `Decimator`, `Interpolator`, or `Sample-rate converter`. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, `filterBuilder` specifies single-rate filters.

- Selecting `Decimator` or `Interpolator` activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting `Sample-rate converter` activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if `Specify` was selected for **Order mode**.

### Decimation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Decimator or Sample-rate converter. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to Interpolator or Sample-rate converter. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to the one shown in the following figure.

In the figure, regions between specification values such as Passband frequency ( $F_{\text{pass}}$ ) and Stopband frequency ( $F_{\text{stop}}$ ) represent transition regions where the filter response is not explicitly defined.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Passband and stopband frequencies** — Define the filter by specifying the frequencies for the edge of the stopband and passband.
- **Passband frequency** — Define the filter by specifying the frequency for the edge of the passband.
- **Stopband frequency** — Define the filter by specifying the frequency for the edges of the stopband.
- **Passband edge and 3dB point** — Define the filter by specifying the passband edge frequency and the 3-dB down point (IIR designs).
- **Half power (3dB) and stopband frequencies** — Define the filter by specifying the 3-dB down point and stopband edge frequency (IIR designs).
- **Half power (3dB) frequency** — Define the filter by specifying the frequency for the 3-dB point (IIR designs or maxflat FIR).
- **Cutoff (6dB) frequency** — Define the filter by specifying the frequency for the 6-dB point in the filter response (FIR designs).

### Frequency units

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized (0 to 1)** to enter frequencies in normalized form. This behavior

is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

### **Input sample rate**

Fs, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

### **Passband frequency**

Enter the frequency at the of the passband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### **Stopband frequency**

Enter the frequency at the start of the stopband. Specify the value in either normalized frequency units or the absolute units you select **Frequency units**.

### **Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

#### **Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- Linear — Specify the magnitude in linear units.
- dB — Specify the magnitude in decibels (default)
- Squared — Specify the magnitude in squared units.

#### **Passband ripple**

Enter the filter ripple allowed in the passband in the units you choose for **Magnitude units**, either linear or decibels.

#### **Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

#### **Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

#### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Phase constraint

This option only applies when you have the DSP System Toolbox software and when the **Design method** is equiripple. Select one of **Linear**, **Minimum**, or **Maximum**.

**Minimum order** — This option only applies when you have the DSP System Toolbox software and the **Order mode** is **Minimum**.

Select **Any** (default), **Even**, or **Odd**. Selecting **Even** or **Odd** forces the minimum-order design to be an even or odd order.

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband when you select **Passband** or **Stopband**.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. The following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no effect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

**Wpass**

Passband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Wstop**

Stopband weight. This option only applies when **Impulse response** is FIR and **Order mode** is Specify.

**Filter implementation****Structure**

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

**Use a System object to implement filter**

This check box appears when you set **Filter type** to Single-rate. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to Interpolator, Decimator, or Sample-rate converter. The filter builder always implements the filter as a System object.

**Notch**

See “Peak/Notch Filter Design — Main Pane” on page 5-642.

**Nyquist Filter Design — Main Pane****Filter specifications**

Parameters in this group enable you to specify your filter format, such as the impulse response and the filter order.

**Band**

Specifies the location of the center of the transition region between the passband and the stopband. The center of the transition region, *bw*, is calculated using the value for Band:

$$bw = Fs/(2 \times \text{Band}).$$

**Impulse response**

Select FIR or IIR from the drop-down list, where FIR is the default impulse response. When you choose an impulse response, the design methods and structures you can use to implement your filter change accordingly.

---

**Note** The design methods and structures for FIR filters are not the same as the methods and structures for IIR filters.

---

**Order mode**

Select Minimum (the default) or Specify from the drop-down list. Selecting Specify enables the **Order** option (see the following sections) so you can enter the filter order.

### Filter type

Select **Single-rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. Your choice determines the type of filter as well as the design methods and structures that are available to implement your filter. By default, filterBuilder specifies single-rate filters.

- Selecting **Decimator** or **Interpolator** activates the **Decimation Factor** or the **Interpolation Factor** options respectively.
- Selecting **Sample-rate converter** activates both factors.

When you design either a decimator or an interpolator, the resulting filter is a bandpass filter that either decimates or interpolates your input signal.

### Order

Enter the filter order. This option is enabled only if **Specify** was selected for **Order mode**.

### Decimation Factor

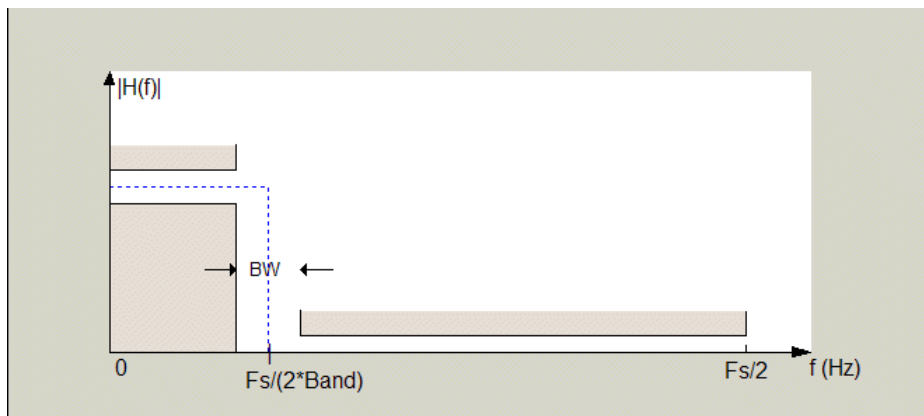

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Decimator** or **Sample-rate converter**. The default factor value is 2.

### Interpolation Factor

Enter the decimation factor. This option is enabled only if the **Filter type** is set to **Interpolator** or **Sample-rate converter**. The default factor value is 2.

### Frequency specifications

The parameters in this group allow you to specify your filter response curve. Graphically, the filter specifications look similar to those shown in the following figure.

In the figure,  $BW$  is the width of the transition region and **Band** determines the location of the center of the region.

### Frequency constraints

Select the filter features to use to define the frequency response characteristics. The list contains the following options, when available for the filter specifications.

- **Transition width** — Define the filter using transition width and stopband attenuation or transition width and order.
- **Unconstrained** — Define the filter by specifying the filter order and having no constraints on the transition width and stopband attenuation. You can add constraints on the magnitude by specifying the stopband attenuation.

**Frequency units**

Use this parameter to specify whether your frequency settings are normalized or in absolute frequency. Select **Normalized** (0 to 1) to enter frequencies in normalized form. This behavior is the default. To enter frequencies in absolute values, select one of the frequency units from the drop-down list—Hz, kHz, MHz, or GHz. Selecting one of the unit options enables the **Input sample rate** parameter.

**Input sample rate**

F<sub>s</sub>, specified in the units you selected for **Frequency units**, defines the sampling frequency at the filter input. When you provide an input sampling frequency, all frequencies in the specifications are in the selected units as well. This parameter is available when you select one of the frequency options from the **Frequency units** list.

**Transition width**

Specify the width of the transition between the end of the passband and the edge of the stopband. Specify the value in normalized frequency units or the absolute units you select in **Frequency units**.

**Magnitude specifications**

The parameters in this group let you specify the filter response in the passbands and stopbands.

**Magnitude units**

Specify the units for any parameter you provide in magnitude specifications. Select one of the following options from the drop-down list.

- **Linear** — Specify the magnitude in linear units.
- **dB** — Specify the magnitude in decibels (default)
- **Squared** — Specify the magnitude in squared units.

**Stopband attenuation**

Enter the filter attenuation in the stopband in the units you choose for **Magnitude units**, either linear or decibels.

**Algorithm**

The parameters in this group allow you to specify the design method and structure that `filterBuilder` uses to implement your filter.

**Design Method**

Lists the design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter, such as changing the impulse response, the methods available to design filters changes as well. The default IIR design method is usually Butterworth, and the default FIR method is equiripple.

**Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

**Design Options**

The options for each design are specific for each design method. This section does not present all of the available options for all designs and design methods. There are many more that you encounter as

you select different design methods and filter specifications. The following options represent some of the most common ones available.

### Density factor

Density factor controls the density of the frequency grid over which the design method optimization evaluates your filter response function. The number of equally spaced points in the grid is the value you enter for **Density factor** times (filter order + 1).

Increasing the value creates a filter that more closely approximates an ideal equiripple filter but increases the time required to design the filter. The default value of 16 represents a reasonable trade between the accurate approximation to the ideal filter and the time to design the filter.

### Minimum phase

To design a filter that is minimum phase, select **Minimum phase**. Clearing the **Minimum phase** option removes the phase constraint—the resulting design is not minimum phase.

### Minimum order

When you select this parameter, the design method determines and designs the minimum order filter to meet your specifications. Some filters do not provide this parameter. Select Any, Even, or Odd from the drop-down list to direct the design to be any minimum order, or minimum even order, or minimum odd order.

---

**Note** Generally, **Minimum order** designs are not available for IIR filters.

---

### Match Exactly

Specifies that the resulting filter design matches either the passband or stopband or both bands when you select passband or stopband or both from the drop-down list.

### Stopband Shape

Stopband shape lets you specify how the stopband changes with increasing frequency. Choose one of the following options:

- **Flat** — Specifies that the stopband is flat. The attenuation does not change as the frequency increases.
- **Linear** — Specifies that the stopband attenuation changes linearly as the frequency increases. Change the slope of the stopband by setting **Stopband decay**.
- **1/f** — Specifies that the stopband attenuation changes exponentially as the frequency increases, where  $f$  is the frequency. Set the power (exponent) for the decay in **Stopband decay**.

### Stopband Decay

When you set Stopband shape, Stopband decay specifies the amount of decay applied to the stopband. the following conditions apply to Stopband decay based on the value of Stopband Shape:

- When you set **Stopband shape** to **Flat**, **Stopband decay** has no affect on the stopband.
- When you set **Stopband shape** to **Linear**, enter the slope of the stopband in units of dB/rad/s. `filterBuilder` applies that slope to the stopband.
- When you set **Stopband shape** to **1/f**, enter a value for the exponent  $n$  in the relation  $(1/f)^n$  to define the stopband decay. `filterBuilder` applies the  $(1/f)^n$  relation to the stopband to result in an exponentially decreasing stopband attenuation.

## Filter implementation

### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure, and IIR filters use direct-form II filters with SOS.

### Use a System object to implement filter

This check box appears when you set **Filter type** to **Single-rate**. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to **Interpolator**, **Decimator**, or **Sample-rate converter**. The filter builder always implements the filter as a System object.

## Octave Filter Design — Main Pane

### Filter specifications

#### Order

Specify filter order. Possible values are: 4, 6, 8, 10.

#### Bands per octave

Specify the number of bands per octave. Possible values are: 1, 3, 6, 12, 24.

#### Frequency units

Specify frequency units as Hz or kHz.

#### Input sample rate

Specify the input sampling frequency in the frequency units specified previously.

#### Center Frequency

Select from the drop-down list of available center frequency values.

### Algorithm

#### Design Method

Butterworth is the design method used for this type of filter.

#### Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

## Filter implementation

### Structure

Specify filter structure. Choose from:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

### Use a System object to implement filter

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a system object filter, then this check box is disabled.

## Parametric Equalizer Filter Design — Main Pane

### Filter specifications

#### Order mode

Select **Minimum** to design a minimum order filter that meets the design specifications, or **Specify** to enter a specific filter order. The order mode also affects the possible frequency constraints, which in turn limit the gain specifications. For example, if you specify a **Minimum** order filter, the available frequency constraints are:

- Center frequency, bandwidth, passband width
- Center frequency, bandwidth, stopband width

If you select **Specify**, the available frequency constraints are:

- Center frequency, bandwidth
- Center frequency, quality factor
- Shelf type, cutoff frequency, quality factor
- Shelf type, cutoff frequency, shelf slope parameter
- Low frequency, high frequency

#### Order

This parameter is enabled only if the **Order mode** is set to **Specify**. Enter the filter order in this text box.

### Frequency specifications

Depending on the filter order, the possible frequency constraints change. Once you choose the frequency constraints, the input boxes in this area change to reflect the selection.

#### Frequency constraints

Select the specification to represent the frequency constraints. The following options are available:

- Center frequency, bandwidth, passband width (available for minimum order only)
- Center frequency, bandwidth, stopband width (available for minimum order only)
- Center frequency, bandwidth (available for a specified order only)
- Center frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, quality factor (available for a specified order only)
- Shelf type, cutoff frequency, shelf slope parameter (available for a specified order only)
- Low frequency, high frequency (available for a specified order only)

**Frequency units**

Select the frequency units from the available drop down list (Normalized, Hz, kHz, MHz, GHz). If Normalized is selected, then the **Input sample rate** box is disabled for input.

**Input sample rate**

Enter the input sampling frequency. This input box is disabled for input if Normalized is selected in the **Frequency units** input box.

**Center frequency**

Enter the center frequency in the units specified by the value in **Frequency units**.

**Bandwidth**

The bandwidth determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Bandwidth gain** in the **Gain specifications** section. By default, the **Bandwidth gain** defaults to  $\text{db}(\text{sqrt}(.5))$ , or -3 dB relative to the center frequency. The **Bandwidth** property only applies when the **Frequency constraints** are: Center frequency, bandwidth, passband width, Center frequency, bandwidth, stopband width, or Center frequency, bandwidth.

**Passband width**

The passband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Passband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, passband width.

**Stopband width**

The stopband width determines the frequency points at which the filter magnitude is attenuated by the value specified as the **Stopband gain** in the **Gain specifications** section. This option is enabled only if the filter is of minimum order, and the frequency constraint selected is Center frequency, bandwidth, stopband width.

**Low frequency**

Enter the low frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

**High frequency**

Enter the high frequency cutoff. This option is enabled only if the filter order is user specified and the frequency constraint selected is Low frequency, high frequency. The filter magnitude is attenuated by the amount specified in **Bandwidth gain**.

**Gain specifications**

Depending on the filter order and frequency constraints, the possible gain constraints change. Also, once you choose the gain constraints the input boxes in this area change to reflect the selection.

**Gain constraints**

Select the specification array to represent gain constraints, and remember that not all of these options are available for all configurations. The following is a list of all available options:

- Reference, center frequency, bandwidth, passband
- Reference, center frequency, bandwidth, stopband
- Reference, center frequency, bandwidth, passband, stopband

- Reference, center frequency, bandwidth

### Gain units

Specify the gain units either dB or squared. These units are used for all gain specifications in the dialog box.

### Reference gain

The reference gain determines the level to which the filter magnitude attenuates in **Gain units**. The reference gain is a *floor* gain for the filter magnitude response. For example, you may use the reference gain together with the **Center frequency gain** to leave certain frequencies unattenuated (reference gain of 0 dB) while boosting other frequencies.

### Bandwidth gain

Specifies the gain in **Gain units** at which the bandwidth is defined. This property applies only when the **Frequency constraints** specification contains a bandwidth parameter, or is Low frequency, high frequency.

### Center frequency gain

Specify the center frequency in **Gain units**

### Passband gain

The passband gain determines the level in **Gain units** at which the passband is defined. The passband is determined either by the **Passband width** value, or the **Low frequency** and **High frequency** values in the **Frequency specifications** section.

### Stopband gain

The stopband gain is the level in **Gain units** at which the stopband is defined. This property applies only when the **Order mode** is minimum and the **Frequency constraints** are Center frequency, bandwidth, stopband width.

### Boost/cut gain

The boost/cut gain applies only when the designing a shelving filter. Shelving filters include the Shelf type parameter in the **Frequency constraints** specification. The gain in the passband of the shelving filter is increased by **Boost/cut gain** dB from a *floor* gain of 0 dB.

## Algorithm

### Design method

Select the design method from the drop-down list. Different IIR design methods are available depending on the filter constraints you specify.

### Scale SOS filter coefficients to reduce chance of overflow

Select the check box to scale the filter coefficients.

## Filter implementation

### Structure

Select filter structure. The possible choices are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

**Use a System object to implement filter**

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

**Peak/Notch Filter Design – Main Pane****Filter specifications**

In this area you can specify whether you want to design a peaking filter or a notching filter, as well as the order of the filter.

**Response**

Select Peak or Notch from the drop-down box.

**Order**

Enter the filter order. The order must be even.

**Frequency specifications**

This group of parameters allows you to specify frequency constraints and units.

**Frequency Constraints**

Select the frequency constraints for filter specification. There are two choices as follows:

- Center frequency and quality factor
- Center frequency and bandwidth

**Frequency units**

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz.

**Input sample rate**

This input box is enabled if **Frequency units** other than Normalized (0 to 1) are specified. Enter the input sampling frequency.

**Center frequency**

Enter the center frequency in the units you specified in **Frequency units**.

**Quality Factor**

This input box is enabled only when Center frequency and quality factor is chosen for the **Frequency Constraints**. Enter the quality factor.

**Bandwidth**

This input box is enabled only when Center frequency and bandwidth is chosen for the **Frequency Constraints**. Enter the bandwidth.

**Magnitude specifications**

This group of parameters allows you to specify the magnitude constraints, as well as their values and units.

### **Magnitude Constraints**

Depending on the choice of constraints, the other input boxes are enabled or disabled. Select from four magnitude constraints available:

- Unconstrained
- Passband ripple
- Stopband attenuation
- Passband ripple and stopband attenuation

### **Magnitude units**

Select the magnitude units: either dB or squared.

### **Passband ripple**

This input box is enabled if the magnitude constraints selected are Passband ripple or Passband ripple and stopband attenuation. Enter the passband ripple.

### **Stopband attenuation**

This input box is enabled if the magnitude constraints selected are Stopband attenuation or Passband ripple and stopband attenuation. Enter the stopband attenuation.

### **Algorithm**

The parameters in this group allow you to specify the design method and structure that filterBuilder uses to implement your filter.

### **Design Method**

Lists all design methods available for the frequency and magnitude specifications you entered. When you change the specifications for a filter the methods available to design filters changes as well.

### **Scale SOS filter coefficients to reduce chance of overflow**

Selecting this parameter directs the design to scale the filter coefficients to reduce the chances that the inputs or calculations in the filter overflow and exceed the representable range of the filter. Clearing this option removes the scaling. This parameter applies only to IIR filters.

### **Filter implementation**

#### **Structure**

Lists all available filter structures for the filter specifications and design method you select. The typical options are:

- Direct-form I SOS
- Direct-form II SOS
- Direct-form I transposed SOS
- Direct-form II transposed SOS

#### **Use a System object to implement filter**

Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared. When the current design method or structure is not supported by a System object filter, then this check box is disabled.

## Pulse-shaping Filter Design —Main Pane

### Filter specifications

Parameters in this group enable you to specify the shape and length of the filter.

#### Pulse shape

Select the shape of the impulse response from the following options:

- Raised Cosine
- Square Root Raised Cosine
- Gaussian

#### Order mode

This specification is only available for raised cosine and square root raised cosine filters. For these filters, select one of the following options:

- **Minimum**— This option will result in the minimum-length filter satisfying the user-specified **Frequency specifications**.
- **Specify order**—This option allows the user to construct a raised cosine or square root cosine filter of a specified order by entering an even number in the **Order** input box. The length of the impulse response will be  $\text{Order}+1$ .
- **Specify symbols**—This option enables the user to specify the length of the impulse response in an alternative manner. If **Specify symbols** is chosen, the **Order** input box changes to the **Number of symbols** input box.

#### Samples per symbol

Specify the oversampling factor. Increasing the oversampling factor guards against aliasing and improves the FIR filter approximation to the ideal frequency response. If **Order** is specified in **Number of symbols**, the filter length will be  $\text{Number of symbols} * \text{Samples per symbol} + 1$ . The product  $\text{Number of symbols} * \text{Samples per symbol}$  must be an even number.

If a Gaussian filter is specified, the filter length must be specified in **Number of symbols** and **Samples per symbol**. The product  $\text{Number of symbols} * \text{Samples per symbol}$  must be an even number. The filter length will be  $\text{Number of symbols} * \text{Samples per symbol} + 1$ .

#### Filter Type

This option is only available if you have the DSP System Toolbox software. Choose **Single rate**, **Decimator**, **Interpolator**, or **Sample-rate converter**. If you select **Decimator** or **Interpolator**, the decimation and interpolation factors default to the value of the **Samples per symbol**. If you select **Sample-rate converter**, the interpolation factor defaults to **Samples per symbol** and the decimation factor defaults to 3.

### Frequency specifications

Parameters in this group enable you to specify the frequency response of the filter. For raised cosine and square root raised cosine filters, the frequency specifications include:

#### Rolloff factor

The rolloff factor takes values in the range [0,1]. The smaller the rolloff factor, the steeper the transition in the stopband.

### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

For a Gaussian pulse shape, the available frequency specifications are:

### Bandwidth-time product

This option allows the user to specify the width of the Gaussian filter. Note that this is independent of the length of the filter. The bandwidth-time product (BT) must be a positive real number. Smaller values of the bandwidth-time product result in larger pulse widths in time and steeper stopband transitions in the frequency response.

### Frequency units

The frequency units are normalized by default. If you specify units other than normalized, `filterBuilder` assumes that you wish to specify an input sampling frequency, and enables this input box. The choice of frequency units are: Normalized (0 to 1), Hz, kHz, MHz, GHz

### Magnitude specifications

If the **Order mode** is specified as Minimum, the **Magnitude units** may be selected from:

- dB— Specify the magnitude in decibels (default).
- Linear— Specify the magnitude in linear units.

### Algorithm

The only **Design method** available for FIR pulse-shaping filters is the Window method.

### Filter implementation

#### Structure

For the filter specifications and design method you select, this parameter lists the filter structures available to implement your filter. By default, FIR filters use direct-form structure.

#### Use a System object to implement filter

This check box appears when you set **Filter type** to `Single-rate`. Selecting this check box gives you the choice of using a System object to implement the filter. By default, the check box is cleared.

This check box no longer appears when you set **Filter type** to `Interpolator`, `Decimator`, or `Sample-rate converter`. The filter builder always implements the filter as a System object.

## Version History

Introduced in R2009a

## filtstates.cic

Store CIC filter states

### Description

`filtstates.cic` objects hold the states information for CIC filters. Once you create a CIC filter, the states for the filter are stored in `filtstates.cic` objects, and you can access them and change them as you would any property of the filter. This arrangement parallels that of the `filtstates` object that IIR direct-form I filters use (refer to `filtstates` for more information).

Each `States` property in the CIC filter comprises two properties — `Numerator` and `Comb` — that hold `filtstates.cic` objects. Within the `filtstates.cic` objects are the numerator-related and comb-related filter states. The states are column vectors, where each column represents the states for one section of the filter. For example, a CIC filter with four decimator sections and four interpolator sections has `filtstates.cic` objects that contain four columns of states each.

### Examples

#### Integrator and Comb States of a CIC Filter

Construct an object with integrator and comb states as vectors of zeros.

```
h = filtstates.cic(zeros(4,1),zeros(4,1));
```

`h` has zero states now. You can use `int` to see the states as 32-bit integers.

```
intStates = int(h.Integrator)
```

```
intStates = 4x1 int32 column vector
```

```
0  
0  
0  
0
```

```
combStates = int(h.Comb)
```

```
combStates = 4x1 int32 column vector
```

```
0  
0  
0  
0
```

### Version History

Introduced in R2011a

`dsp.CICDecimator` | `dsp.CICInterpolator` | `filtstates`

## firband

Constrained-band equiripple FIR filter

### Syntax

```
b = firband(n,f,a,w,c)
b = firband(n,f,a,s)
b = firband( __ , '1')
b = firband( __ , 'minphase')
b = firband( __ , 'check')
b = firband( __ , {lgrid})
[b,err] = firband( __ )
[b,err,res] = firband( __ )
```

### Description

`b = firband(n,f,a,w,c)` designs filters having constrained error magnitudes (ripples) using the minimax filter design algorithm.

`b = firband(n,f,a,s)` is used to design filters with special properties at certain frequency points specified by `s`.

`b = firband( __ , '1')` designs a type 1 filter (even-order symmetric). You can also specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), or type 4 (odd-order antisymmetric) filters. Note there are restrictions on `a` at `f = 0` or `f = 1` for types 2, 3, and 4.

`b = firband( __ , 'minphase')` designs a minimum-phase FIR filter. You can also specify `'maxphase'`.

`b = firband( __ , 'check')` produces a warning when there are potential transition-region anomalies in the filter response.

`b = firband( __ , {lgrid})`, where `{lgrid}` is a scalar cell array containing an integer, controls the density of the frequency grid.

`[b,err] = firband( __ )` returns the unweighted approximation error magnitudes. `err` has one element for each independent approximation error.

`[b,err,res] = firband( __ )` returns a structure `res` of optional results computed by `firband`.

### Examples

#### Design a Constrained Lowpass Filter

Design a 12th-order lowpass filter with a constraint on the filter response.

```
b = firband(12,[0 0.4 0.5 1], [1 1 0 0], ...
[1 0.2], {'w' 'c'});
```

Using fvtool to display the result b shows you the response of the filter you designed.

```
fvtool(b)
```

Design two filters of different order with the stopband constrained to 60 dB. Use excess order (80) in the second filter to improve the passband ripple.

```
b1 = firband(60,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
b2 = firband(80,[0 .2 .25 1],[1 1 0 0],...
[1 .001],{'w','c'});
hfvt = fvtool(b1,1,b2,1);
legend(hfvt,'Filter Order 60','Filter Order 80');
```

## Input Arguments

### **n** — Filter order

integer greater than or equal to 3

Filter order, specified as an integer greater than or equal to 3.

### **f** — Normalized frequency points

real-valued vector

Normalized frequency points, specified as a real-valued vector. The argument must be in the range  $[0, 1]$ , where 1 corresponds to the Nyquist frequency. The number of elements in the vector is always a multiple of 2. The frequencies must be in increasing order.

### **a** — Desired amplitude

vector

Desired amplitudes at the points specified in **f**, specified as a vector. **f** and **a** must be of the same length. The length must be an even number.

### **w** — Weights

real-valued vector

Weights used to adjust the fit in each frequency band, specified as a real-valued vector. The length of **w** is half the length of **f** and **a**, so there is exactly one weight per band.

**c — Constrained error magnitudes (ripples)**

cell array of character vectors | array of strings

Constrained error magnitudes (ripples), specified as a cell array of character vectors or an array of strings. *c* must have the same length as *w*.

The entries of *c* must be either:

- 'c' or "c" -- To indicate that the corresponding element in *w* is a constraint (the ripple for that band cannot exceed that value).
- 'w' or "w" -- To indicate that the corresponding entry in *w* is a weight.

There must be at least one unconstrained band — *c* must contain at least one *w* entry. For instance, the “Design a Constrained Lowpass Filter” on page 5-648 example uses a weight of 1 in the passband, and constrains the stopband ripple not to exceed 0.2 (about 14 dB).

---

**Note** If your constrained filter does not touch the constraints, increase the error weighting you apply to the unconstrained bands.

---

---

**Note** When you work with constrained stopbands, enter the stopband constraint according to the standard conversion formula for power — the resulting filter attenuation or constraint equals  $20 \cdot \log(\text{constraint})$  where *constraint* is the value you enter in the function. For example, to set 20 dB of attenuation, use a value for the constraint equal to 0.1. This applies to constrained stopbands only.

---

Data Types: char | string

**s — Special properties at certain frequency points**

cell array of character vectors | array of strings

Special properties at certain frequency points, specified as a cell array of character vectors or an array of strings. *s* must have the same length as *f* and *a*. Entries of *s* must be one of:

- 'n' or "n" — Normal frequency point.
- 's' or "s" — Single-point band. The frequency “band” is given by a single point. Specify the corresponding gain at this frequency point in *a*.
- 'f' or "f" — Forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- 'i' or "i" — Indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

Data Types: char | string

**lgrid — Density of frequency grid**

16 (default) | 1-by-1 cell array with integer value

Control the density of the frequency grid, which has roughly  $(\text{lgrid} \cdot n) / (2 \cdot \text{bw})$  frequency points, where *bw* is the fraction of the total frequency band interval [0,1] covered by *f*. Increasing *lgrid* often results in filters that more exactly match an equiripple filter, but that take longer to compute. The default value of 16 is the minimum value that should be specified for *lgrid*.

## Output Arguments

### **b** — Filter coefficients

row vector

Filter coefficients, returned as a row vector of length  $n + 1$ .

The `firband` uses the minimax filter design algorithm to design the following types of real FIR filters:

- Types 1-4 linear phase
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd)
- Extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain
- Arbitrary shape frequency response curve filters

### **err** — Unweighted approximation error magnitude

scalar | vector

Unweighted approximation error magnitudes, returned as a scalar or a vector. `err` contains one element for each independent approximation error returned by the function.

### **res** — Frequency response characteristics

structure

Frequency response characteristics, returned as a structure. The structure `res` has the following fields:

| Structure Field        | Contents   |
|------------------------|--|
| <code>res.fgrid</code> | Vector containing the frequency grid used in the filter design optimization    |
| <code>res.des</code>   | Desired response on <code>fgrid</code>   |
| <code>res.wt</code>    | Weights on <code>fgrid</code>  |
| <code>res.h</code>     | Actual frequency response on the frequency grid                                |
| <code>res.error</code> | Error at each point (desired response - actual response) on the frequency grid |
| <code>res.iextr</code> | Vector of indices into <code>fgrid</code> of external frequencies              |

| Structure Field | Contents  |
|-----------------|---|
| res.fextr       | Vector of extremely frequencies   |
| res.order       | Filter order  |
| res.edgecheck   | Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax. |
| res.iterations  | Number of Remez iterations for the optimization   |
| res.evals       | Number of function evaluations for the optimization   |

## Version History

Introduced in R2011a

### R2022b: Constrained error magnitudes and special properties support array of strings

Starting in R2022b, you can specify the constrained error magnitudes (c) and the special properties (s) as an array of strings.

```
b1 = fircband(60,[0 .2 .25 1],[1 1 0 0],...
[1 .001],["w","c"]);
```

### See Also

firceqrip | firgr | firfs | firpm

## fireqint

Equiripple FIR interpolators

### Syntax

```
b = fireqint(n,l,alpha)
b = fireqint(n,l,alpha,w)
b = fireqint('minorder', l,alpha,r)
b = fireqint({'minorder',initord},l,alpha,r)
```

### Description

`b = fireqint(n,l,alpha)` designs an FIR equiripple filter useful for interpolating input signals.

`b = fireqint(n,l,alpha,w)` allows you to specify a vector of weights in `w`.

`b = fireqint('minorder', l,alpha,r)` allows you to design a minimum-order filter that meets the design specifications. When you use the input argument `'minorder'`, you must provide the maximum ripple vector `r`.

`b = fireqint({'minorder',initord},l,alpha,r)` allows you to provide an initial estimate of the filter order in the input argument `initord`. Again, you must provide `r`, the vector of maximum deviation or ripples from the ideal filter magnitude response.

### Examples

#### Design an FIR Equiripple Filter

Design a minimum order interpolation filter with interpolation factor set to 6, and inverse measure of transition bandwidth set to 0.8. A vector of ripples must be supplied with the input argument, `minorder`.

```
b = fireqint('minorder',6,.8,[0.01 .1 .05 .02]);
```

Create a polyphase interpolation filter.

```
hm = dsp.FIRInterpolator(6,'Numerator',b);
```

Plot the zero-phase response of the interpolator.

```
zerophase(hm)
```

## Input Arguments

### **n** — Order of equiripple filter

positive integer

Order of the equiripple filter, specified as a positive integer. Filter order must be three or more.

Data Types: `double`

### **l** — Interpolation factor

positive integer

Interpolation factor, specified as a positive integer.

Data Types: `double`

### **alpha** — Inverse measure of transition bandwidth

positive scalar in the range  $(0, 1)$

Inverse measure of the transition bandwidth, specified as a positive scalar in the range  $(0, 1)$ .

The `alpha` argument is inversely proportional to the transition bandwidth of the filter. It also affects the bandwidth of the don't-care regions in the stopband. Specifying `alpha` allows you to control how much of the Nyquist interval your input signal occupies. This can be beneficial for signals to be interpolated because it allows you to increase the transition bandwidth without affecting the

interpolation, resulting in better stopband attenuation for a given  $l$ . If you set `alpha` argument to 1, then `fireqint` function assumes that your signal occupies the entire Nyquist interval. Setting the `alpha` argument to a value less than one allows for don't-care regions in the stopband. For example, if your input occupies half the Nyquist interval, you could set the `alpha` to 0.5.

The signal to be interpolated is assumed to have zero (or negligible) power in the frequency band between  $(\alpha*\pi)$  and  $\pi$ . The input argument, `alpha` must therefore be a positive scalar between 0 and 1. The `fireqint` function treats such bands as don't-care regions for assessing filter design.

Data Types: `double`

### **w — Weights**

row vector of positive scalars

Weights applied to passband ripple and stopband attenuation, specified as a row vector of positive scalars. The number of weights required in `w` is given by  $1 + \text{floor}(l/2)$ . Using weights enables you to specify different attenuations in different parts of the stopband, as well as providing the ability to adjust the compromise between passband ripple and stopband attenuation.

Data Types: `double`

### **r — Maximum deviation from ideal filter magnitude response**

vector

Maximum deviations or ripples from the ideal filter magnitude response, specified as a vector. The number of elements required in `r` is given by  $1 + \text{floor}(l/2)$ .

Data Types: `double`

### **initord — Initial filter order**

positive integer

Initial filter order when designing a minimum order filter that meets design specifications, specified as a positive integer.

Data Types: `double`

## **Output Arguments**

### **b — Filter coefficients**

real-valued row vector

Filter coefficients of the equiripple filter, returned as a real-valued row vector.

Data Types: `double`

## firceqrip

Constrained equiripple FIR filter

### Syntax

```
B = firceqrip(n,Fo,DEV)
B = firceqrip(...,'slope',r)
B = firceqrip('minorder',[Fp Fst],DEV)
B = firceqrip(...,'passedge')
B = firceqrip(...,'stopedge')
B = firceqrip(...,'high')
B = firceqrip(...,'min')
B = firceqrip(...,'invsinc',C)
B = firceqrip(...,'invdiric',C)
```

### Description

`B = firceqrip(n,Fo,DEV)` designs an order  $n$  filter (filter length equal  $n + 1$ ) lowpass FIR filter with linear phase.

`firceqrip` produces the same equiripple lowpass filters that `firpm` produces using the Parks-McClellan algorithm. The difference is how you specify the filter characteristics for the function.

The input argument `Fo` specifies the frequency at the upper edge of the passband in normalized frequency ( $0 < Fo < 1$ ). The two-element vector `dev` specifies the peak or maximum error allowed in the passband and stopbands. Enter `[d1 d2]` for `dev` where `d1` sets the passband error and `d2` sets the stopband error.

`B = firceqrip(...,'slope',r)` uses the input keyword 'slope' and input argument `r` to design a filter with a nonequiripple stopband. `r` is specified as a positive constant and determines the slope of the stopband attenuation in dB/normalized frequency. Greater values of `r` result in increased stopband attenuation in dB/normalized frequency.

`B = firceqrip('minorder',[Fp Fst],DEV)` designs filter with the minimum number of coefficients required to meet the deviations in  $DEV = [d1 d2]$  while having a transition width no greater than  $Fst - Fp$ , the difference between the stopband and passband edge frequencies. You can specify 'mineven' or 'minodd' instead of 'minorder' to design minimum even order (odd length) or minimum odd order (even length) filters, respectively. The 'minorder' option does not apply when you specify the 'min' (minimum-phase), 'invsinc', or the 'invdiric' options.

`B = firceqrip(...,'passedge')` designs a filter where `Fo` specifies the frequency at which the passband starts to rolloff.

`B = firceqrip(...,'stopedge')` designs a filter where `Fo` specifies the frequency at which the stopband begins.

`B = firceqrip(...,'high')` designs a high pass FIR filter instead of a lowpass filter.

`B = firceqrip(...,'min')` designs a minimum-phase filter.

$B = \text{firceqrip}(\dots, 'invsinc', C)$  designs a lowpass filter whose magnitude response has the shape of an inverse sinc function. This may be used to compensate for sinc-like responses in the frequency domain such as the effect of the zero-order hold in a D/A converter. The amount of compensation in the passband is controlled by  $C$ , which is specified as a scalar or two-element vector. The elements of  $C$  are specified as follows:

- If  $C$  is supplied as a real-valued scalar or the first element of a two-element vector, `firceqrip` constructs a filter with a magnitude response of  $1/\text{sinc}(C*\pi*F)$  where  $F$  is the normalized frequency.
- If  $C$  is supplied as a two-element vector, the inverse-sinc shaped magnitude response is raised to the positive power  $C(2)$ . If we set  $P=C(2)$ , `firceqrip` constructs a filter with a magnitude response  $1/\text{sinc}(C*\pi*F)^P$ .

If this FIR filter is used with a cascaded integrator-comb (CIC) filter, setting  $C(2)$  equal to the number of stages compensates for the multiplicative effect of the successive sinc-like responses of the CIC filters.

---

**Note** Since the value of the inverse sinc function becomes unbounded at  $C=1/F$ , the value of  $C$  should be greater than the reciprocal of the passband edge frequency. This can be expressed as  $F_0 < 1/C$ . For users familiar with CIC decimators,  $C$  is equal to  $1/2$  the product of the differential delay and decimation factor.

---

$B = \text{firceqrip}(\dots, 'invdiric', C)$  designs a lowpass filter with a passband that has the shape of an inverse Dirichlet sinc function. The frequency response of the inverse Dirichlet sinc function is given by  $\left\{ rC \left( \frac{\sin(f/2r)}{\sin(Cf/2)} \right)^p \right\}$  where  $C$ ,  $r$ , and  $p$  are scalars. The input  $C$  can be a scalar or vector containing 2 or 3 elements. If  $C$  is a scalar,  $p$  and  $r$  equal 1. If  $C$  is a two-element vector, the first element is  $C$  and the second element is  $p$ ,  $[C \ p]$ . If  $C$  is a three-element vector, the third element is  $r$ ,  $[C \ p \ r]$ .

## Examples

To introduce a few of the variations on FIR filters that you design with `firceqrip`, these five examples cover both the default syntax  $b = \text{firceqrip}(n, wo, del)$  and some of the optional input arguments. For each example, the input arguments  $n$ ,  $wo$ , and  $del$  remain the same.

### Filter design using `firceqrip`

Design a 30th order FIR filter using `firceqrip`.

```
b = firceqrip(30,0.4,[0.05 0.03]); fvtool(b)
```

Design a minimum order FIR filter using `firceqrip`. The passband edge and stopband edge frequencies are  $0.35\pi$  and  $0.45\pi$  rad/sample. The allowed deviations are 0.02 and  $1e-4$ .

```
b = firceqrip('minorder',[0.35 0.45],[0.02 1e-4]); fvtool(b)
```

Design a 30th order FIR filter with the stopedge keyword to define the response at the edge of the filter stopband.

```
b = firceqrip(30,0.4,[0.05 0.03], 'stopedge'); fvtool(b)
```

Design a 30th order FIR filter with the `slope` keyword and `r = 20`.

```
b = firceqrip(30,0.4,[0.05 0.03], 'slope',20, 'stopedge'); fvtool(b)
```

Design a 30th order FIR filter defining the stopband and specifying that the resulting filter is minimum phase with the `min` keyword.

```
b = firceqrip(30,0.4,[0.05 0.03], 'stopedge', 'min'); fvtool(b)
```

Comparing this filter to the filter in Figure 1. The cutoff frequency  $\omega_0 = 0.4$  now applies to the edge of the stopband rather than the point at which the frequency response magnitude is 0.5.

Viewing the zero-pole plot shown here reveals this is a minimum phase FIR filter - the zeros lie on or inside the unit circle,  $z = 1$

```
fvtool(b, 'polezero')
```

Design a 30th order FIR filter with the `invsinc` keyword to shape the filter passband with an inverse sinc function.

```
b = firceqip(30,0.4,[0.05 0.03], 'invsinc', [2 1.5]); fvtool(b)
```

The inverse sinc function being applied is defined as  $1/\text{sinc}(2*w)^{1.5}$ .

### Inverse-Dirichlet-Sinc-Shaped Passband

Design two order 30 constrained equiripple FIR filters with inverse-Dirichlet-sinc-shaped passbands. The cutoff frequency in both designs is  $\pi/4$  radians/sample. Set  $C=1$  in one design  $C=2$  in the second design. The maximum passband and stopband ripple is 0.05. Set  $p=1$  in one design and  $p=2$  in the second design.

Design the filters.

```
b1 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[1 1]);
b2 = firceqrip(30,0.25,[0.05 0.05],'invdiric',[2 2]);
```

Obtain the filter frequency responses using `freqz`. Plot the magnitude responses.

```
[h1,~] = freqz(b1,1);
[h2,w] = freqz(b2,1);
plot(w,abs(h1)); hold on;
plot(w,abs(h2),'r');
axis([0 pi 0 1.5]);
xlabel('Radians/sample');
ylabel('Magnitude');
legend('C=1 p=1','C=2 p=2');
```

Inspect the stopband ripple in the design with  $C=1$  and  $p=1$ . The constrained design sets the maximum ripple to be 0.05. Zoom in on the stopband from the cutoff frequency of  $\pi/4$  radians/sample to  $3\pi/4$  radians/sample.

```
figure;  
plot(w,abs(h1));  
set(gca,'xlim',[pi/4 3*pi/4]);  
grid on;
```

# fircls

FIR Constrained Least Squares filter

## Syntax

```
clsFilter = design(d,'fircls','SystemObject',true)
clsFilter = design(d,'fircls','FilterStructure',value,'SystemObject',true)
clsFilter = design(d,'fircls','PassbandOffset',value,'SystemObject',true)
clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)
```

## Description

`clsFilter = design(d,'fircls','SystemObject',true)` designs a FIR Constrained Least Squares (CLS) filter, `clsFilter`, from a filter specifications object, `d`.

`clsFilter = design(d,'fircls','FilterStructure',value,'SystemObject',true)` where `value` is one of the following filter structures:

- 'dffir', a discrete-time, direct-form FIR filter (the default value)
- 'dffirt', a discrete-time, direct-form FIR transposed filter
- 'dfsymfir', a discrete-time, direct-form symmetric FIR filter

`clsFilter = design(d,'fircls','PassbandOffset',value,'SystemObject',true)` where `value` sets the passband band gain in dB. The `PassbandOffset` and `Ap` values affect the upper and lower approximation bound in the passband as follows:

- Lower bound =  $(\text{PassbandOffset} - A_p/2)$
- Upper bound =  $(\text{PassbandOffset} + A_p/2)$

For bandstop filters, the `PassbandOffset` is a vector of length two that specifies the first and second passband gains. The `PassbandOffset` value defaults to 0 for lowpass, highpass and bandpass filters. The `PassbandOffset` value defaults to [0 0] for bandstop filters.

`clsFilter = design(d,'fircls','zerophase',value,'SystemObject',true)` where `value` is either 'true' ('1') or 'false' ('0'). If `zerophase` is true, the lower approximation bound in the stopband is forced to zero (i.e., the filter has a zero phase response). `Zerophase` is false (0) by default.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'fircls')
```

For complete help about using `fircls`, refer to the command line help system. For example, to get specific information about using `fircls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'fircls')
```

## Examples

### Create an FIR Constrained Least Squares (CLS) Filter

The following example designs a constrained least-squares FIR lowpass filter.

```
h = fdesign.lowpass('n,fc,ap,ast', 50, 0.3, 2, 30);
firLPFilter = design(h, 'fircls','SystemObject',true);
fvtool(firLPFilter)
```

The following example constructs a constrained least-squares FIR bandpass filter.

```
d = fdesign.bandpass('N,Fc1,Fc2,Ast1,Ap,Ast2',...
30,0.4,0.6,60,1,60);
firBPFfilter = design(d,'fircls','SystemObject',true);
fvtool(firBPFfilter)
```

## firgr

Parks-McClellan FIR filter

### Syntax

```

b = firgr(n,f,a,w)
b = firgr(n,f,a,ftype)
b = firgr(m,f,a,r),
b = firgr({m,ni},f,a,r)
b = firgr(n,f,a,w,e)
b = firgr(n,f,a,s)
b = firgr(n,f,a,s,w,e)
b = firgr(____,'l')
b = firgr(____,'minphase')
b = firgr(____,'check')
b = firgr(____,{lgrid}),
[b,err] = firgr(____)
[b,err,res] = firgr(____)
b = firgr(n,f,fresp,w)
b = firgr(n,f,{fresp,p1,p2,...},w)
b = firgr(n,f,a,w)
b = firgr(____,'h')
```

### Description

`b = firgr(n,f,a,w)` uses a minimax filter design algorithm to design a real linear phase FIR filter `b` of length `n+1`. The filter has the best approximation to the desired frequency response described by `f` and `a` in the minimax sense. `w` is a vector of weights, one per band. When you omit `w`, all bands are weighted equally. For more information on the input arguments, see `firpm`.

`b = firgr(n,f,a,ftype)` design a filter of type specified by `ftype`

`b = firgr(m,f,a,r)`, designs filters repeatedly until the minimum order filter as specified in `m` and that meets the specifications `f,a` is found. `m` can be one of 'minorder', 'mineven' or 'minodd'. `r` is a vector containing the peak ripple per frequency band. You must specify `r`. When you specify 'mineven' or 'minodd', the minimum even or odd order filter is found.

`b = firgr({m,ni},f,a,r)` where `m` is one of 'minorder', 'mineven' or 'minodd', uses `ni` as the initial estimate of the filter order. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

`b = firgr(n,f,a,w,e)` specifies independent approximation errors for different bands. Use this syntax to design extra ripple or maximal ripple filters. These filters have interesting properties such as having the minimum transition width. `e` is a cell array of character vectors specifying the approximation errors to use. Its length must equal the number of bands.

`b = firgr(n,f,a,s)` is used to design filters with special properties `s` at certain frequency points.

`b = firgr(n,f,a,s,w,e)` specifies weights and independent approximation errors for filters with special properties. The weights and properties are included in vectors `w` and `e`. Sometimes, you may

need to use independent approximation errors to get designs with forced values to converge. For example,

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1] ,{'e1' 'e2' 'e3'});
```

`b = firgr( ____, '1' )` designs a type 1 filter (even-order symmetric). You can specify type 2 (odd-order symmetric), type 3 (even-order antisymmetric), and type 4 (odd-order antisymmetric) filters as well. Note that restrictions apply to `a` at `f = 0` or `f = 1` for FIR filter types 2, 3, and 4.

`b = firgr( ____, 'minphase' )` designs a minimum-phase FIR filter. You can use the argument `'maxphase'` to design a maximum phase FIR filter.

`b = firgr( ____, 'check' )` returns a warning when there are potential transition-region anomalies.

`b = firgr( ____, {lgrid} )`, where `{lgrid}` is a scalar cell array. The value of the scalar controls the density of the frequency grid by setting the number of samples used along the frequency axis.

`[b,err] = firgr( ____ )` returns the unweighted approximation error magnitudes. `err` contains one element for each independent approximation error returned by the function.

`[b,err,res] = firgr( ____ )` returns the structure `res` comprising optional results computed by `firgr`.

`b = firgr(n,f,fresp,w)` returns a length `n + 1` FIR filter which has the best approximation to the desired frequency response as returned by the user-defined function `fresp`.

`firgr` includes a predefined frequency response function named `'firpmfrf2'`. You can write your own based on the simpler `'firpmfrf'`. See the help for `private/firpmfrf` for more information.

`b = firgr(n,f,{fresp,p1,p2,...},w)` specifies optional arguments `p1`, `p2`,..., `pn` to be passed to the response function `fresp`.

`b = firgr(n,f,a,w)` is a synonym for `b = firgr(n,f,{'firpmfrf2',a},w)`, where `a` is a vector containing your specified response amplitudes at each band edge in `f`. By default, `firgr` designs symmetric (even) FIR filters. `'firpmfrf2'` is the predefined frequency response function. If you do not specify your own frequency response function (the `fresp` variable), `firgr` uses `'firpmfrf2'`.

`b = firgr( ____, 'h' )` and `b = firgr( ____, 'd' )` design antisymmetric (odd) filters. When you omit the `'h'` or `'d'` arguments from the `firgr` command syntax, each frequency response function `fresp` can tell `firgr` to design either an even or odd filter. Use the command syntax `sym = fresp('defaults',{n,f,[],w,p1,p2,...})`.

`firgr` expects `fresp` to return `sym = 'even'` or `sym = 'odd'`. If `fresp` does not support this call, `firgr` assumes even symmetry.

For more information about the input arguments to `firgr`, refer to `firpm`.

## Examples

### Design a Filter Using firgr

Design an FIR filter with two single-band notches at 0.25 and 0.55.

```
b1 = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],[1 1 0 1 1 0 1 1],...
{'n' 'n' 's' 'n' 'n' 's' 'n' 'n'});
```

Design a highpass filter whose gain at 0.06 is forced to be zero. The gain at 0.055 is indeterminate since it should be about the band.

```
b2 = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],...
{'n' 'i' 'f' 'n' 'n' 'n'});
```

Design a second highpass filter with forced values and independent approximation errors.

```
b3 = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1], ...
{'n' 'i' 'f' 'n' 'n' 'n'}, [10 1 1], {'e1' 'e2' 'e3'});
```

Use the filter visualization tool to view the results of the filters.

```
hvft = fvtool(b1,1,b2,1,b3,1);
legend(hvft,'Filter b1','Filter b2','Filter b3')
```

### Input Arguments

#### **n** — Filter order

integer greater than or equal to 3

Filter order, specified as an integer greater than or equal to 3.

### **f — Normalized frequency points**

real-valued vector

Normalized frequency points, specified as a real-valued vector. The argument must be in the range  $[0, 1]$ , where 1 corresponds to the Nyquist frequency. The length of **f** must be even. The frequencies must be in increasing order.

### **a — Desired amplitude**

vector

Desired amplitudes at the points specified in **f**, specified as a vector. **f** and **a** must be of the same length. The length of **a** must be even.

### **w — Weights**

real-valued vector

Weights used to adjust the fit in each frequency band, specified as a real-valued vector. The length of **w** is half the length of **f** and **a**, so there is exactly one weight per band.

### **f type — Filter type**

'hilbert' | 'differentiator'

Filter type for linear-phase filters with odd symmetry (type III and type IV), specified as either 'hilbert' or 'differentiator':

- 'hilbert' — The output coefficients in **b** obey the relation  $b(k) = -b(n + 2 - k)$ ,  $k = 1, \dots, n + 1$ . This class of filters includes the Hilbert transformer, which has a desired amplitude of 1 across the entire band.

For example,

```
b = firgr(30,[0.1 0.9],[1 1],'hilbert');
```

designs an approximate FIR Hilbert transformer of length 31.

- 'differentiator' — For nonzero amplitude bands, the filter weighs the error by a factor of  $1/f$  so that the error at low frequencies is much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, these filters minimize the maximum relative error (the maximum of the ratio of the error to the desired amplitude).

### **m — Type of minimum order filter**

'minorder' | 'mineven' | 'minodd'

Type of minimum order filter, specified as 'minorder', 'mineven', or 'minodd'. When you specify 'mineven' or 'minodd', the function designs a minimum even order or minimum odd order filter.

### **r — Peak ripple per frequency band**

real-valued vector

Peak ripple per frequency band, specified as a real-valued vector. The length of **r** is half the length of **f** and **a**, so there is exactly one weight per band.

**ni — Initial estimate of filter order**

integer greater than or equal to 3

Initial estimate of the filter order, specified as an integer greater than or equal to 3. The function accepts this value in the `b = firgr({m,ni},f,a,r)` syntax. `ni` is optional for common filter designs, but it must be specified for designs in which `firpmord` cannot be used, such as while designing differentiators or Hilbert transformers.

**e — Approximation errors**

cell array of character vectors | array of strings

Independent approximation errors to use for different bands, specified as a cell array of character vectors or an array of strings. The length of `e` must equal the number of bands. Entries of `e` must be in the form `'e#'` or `"e#"` where `#` indicates which approximation error to use for the corresponding band. For example, when `e = ["e1", "e2", "e1"]`, the first and third bands use the same approximation error `"e1"` and the second band uses a different one `"e2"`. When all bands use the same approximation error, such as `["e1", "e1", "e1", ...]`, it is equivalent to omitting `e`, as in `b = firgr(n,f,a,w)`.

Data Types: char | string

**s — Special properties at certain frequency points**

cell array of character vectors | array of strings

Special properties at certain frequency points, specified as a cell array of character vectors or an array of strings. `s` must have the same length as `f` and `a`. Entries of `s` must be one of:

- `'n'` or `"n"` — Normal frequency point.
- `'s'` or `"s"` — Single-point band. The frequency “band” is given by a single point. Specify the corresponding gain at this frequency point in `a`.
- `'f'` or `"f"` — Forced frequency point. Forces the gain at the specified frequency band to be the value specified.
- `'i'` or `"i"` — Indeterminate frequency point. Use this argument when adjacent bands abut one another (no transition region).

For example, the following command designs a bandstop filter with zero-valued single-point stopbands (notches) at 0.25 and 0.55.

```
b = firgr(42,[0 0.2 0.25 0.3 0.5 0.55 0.6 1],...
[1 1 0 1 1 0 1 1],[ "n" "n" "s" "n" "n" "s" "n" "n"])
```

`b = firgr(82,[0 0.055 0.06 0.1 0.15 1],[0 0 0 0 1 1],[ "n" "i" "f" "n" "n" "n"])` designs a highpass filter with the gain at 0.06 forced to be zero. The band edge at 0.055 is indeterminate since the first two bands actually touch. The other band edges are normal.

Data Types: char | string

**lgrid — Density of frequency grid**

16 (default) | 1-by-1 cell array with integer value

Control the density of the frequency grid, which has roughly  $(lgrid*n)/(2*bw)$  frequency points, where `bw` is the fraction of the total frequency band interval `[0,1]` covered by `f`. Increasing `lgrid` often results in filters that more exactly match an equiripple filter, but that take longer to compute. The default value of 16 is the minimum value that should be specified for `lgrid`.

**fresp — Frequency response**

function handle

Frequency response, specified as a function handle. The function is called from within `firgr` with this syntax:

```
[dh,dw] = fresp(n,f,gf,w)
```

where:

- `fresp` identifies the function that you use to define your desired filter frequency response.
- `n` is the filter order.
- `f` is the vector of frequency band edges which must appear monotonically between 0 and 1, where 1 is one-half of the sampling frequency. The frequency bands span  $f(k)$  to  $f(k+1)$  for  $k$  odd. The intervals  $f(k+1)$  to  $f(k+2)$  for  $k$  odd are “transition bands” or “don't care” regions during optimization.
- `gf` is a vector of grid points that have been chosen over each specified frequency band by `firgr`, and determines the frequencies at which `firgr` evaluates the response function.
- `w` is a vector of real, positive weights, one per band, for use during optimization. `w` is optional in the call to `firgr`. If you do not specify `w`, it is set to unity weighting before being passed to `fresp`.
- `dh` and `dw` are the desired frequency response and optimization weight vectors, evaluated at each frequency in grid `gf`.

**Output Arguments****b — Filter coefficients**

row vector

Filter coefficients, returned as a row vector of length  $n + 1$ .

The `firgr` uses the minimax filter design algorithm to design the following types of real FIR filters:

- Types 1-4 linear phase:
  - Type 1 is even order, symmetric
  - Type 2 is odd order, symmetric
  - Type 3 is even order, antisymmetric
  - Type 4 is odd order, antisymmetric
- Minimum phase
- Maximum phase
- Minimum order (even or odd)
- Extra ripple
- Maximal ripple
- Constrained ripple
- Single-point band (notching and peaking)
- Forced gain

- Arbitrary shape frequency response curve filters

### **err** — Unweighted approximation error magnitude

scalar | vector

Unweighted approximation error magnitudes, returned as a scalar or a vector. `err` contains one element for each independent approximation error returned by the function.

### **res** — Frequency response characteristics

structure

Frequency response characteristics, returned as a structure. The structure `res` has the following fields:

| Structure Field             | Contents  |
|-----------------------------|---|
| <code>res.fgrid</code>      | Vector containing the frequency grid used in the filter design optimization   |
| <code>res.des</code>        | Desired response on <code>fgrid</code>  |
| <code>res.wt</code>         | Weights on <code>fgrid</code>   |
| <code>res.h</code>          | Actual frequency response on the frequency grid   |
| <code>res.error</code>      | Error at each point (desired response - actual response) on the frequency grid  |
| <code>res.iextr</code>      | Vector of indices into <code>fgrid</code> of external frequencies   |
| <code>res.fextr</code>      | Vector of external frequencies  |
| <code>res.order</code>      | Filter order  |
| <code>res.edgecheck</code>  | Transition-region anomaly check. One element per band edge. Element values have the following meanings: 1 = OK, 0 = probable transition-region anomaly, -1 = edge not checked. Computed when you specify the 'check' input option in the function syntax. |
| <code>res.iterations</code> | Number of <code>s</code> iterations for the optimization  |
| <code>res.evals</code>      | Number of function evaluations for the optimization   |

## Version History

Introduced in R2011a

### **R2022b: Approximation errors and special properties support array of strings**

Starting in R2022b, you can specify the approximation errors (`e`) and the special properties (`s`) as an array of strings.

```
b = firgr(82,[0 0.055 0.06 0.1 0.15 1], [0 0 0 0 1 1],...
["n" "i" "f" "n" "n" "n"],[10 1 1],["e1" "e2" "e3"]);
```

## Extended Capabilities

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- All inputs must be constant. Expressions or variables are allowed if their values do not change.
- Does not support syntaxes that have cell array input.

## firhalfband

Halfband FIR filter design

### Syntax

```
b = firhalfband(n,fp)
b = firhalfband(n,win)
b = firhalfband(n,dev,'dev')
b = firhalfband('minorder',fp,dev)
b = firhalfband('minorder',fp,dev,'kaiser')
b = firhalfband( ____, 'high')
b = firhalfband( ____, 'minphase')
```

### Description

`b = firhalfband(n,fp)` designs a lowpass FIR halfband filter of order  $n$  with an equiripple characteristic.  $n$  must be an even integer. `fp` determines the passband edge frequency such that  $0 < fp < 1/2$ , where  $1/2$  corresponds to  $\pi/2$  rad/sample.

`b = firhalfband(n,win)` designs a lowpass  $n^{\text{th}}$ -order filter using the truncated windowed-impulse response method instead of the equiripple method. `win` should be an  $n+1$  length vector. The function truncates the ideal response to length  $n+1$ , then multiplies it point-by-point with the window specified in `win`.

`b = firhalfband(n,dev,'dev')` designs an  $n^{\text{th}}$ -order lowpass halfband filter with an equiripple characteristic. `dev` sets the value for the maximum passband and stopband ripple.

`b = firhalfband('minorder',fp,dev)` designs a lowpass minimum-order filter with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the equiripple method.

`b = firhalfband('minorder',fp,dev,'kaiser')` designs a lowpass minimum-order filter with passband edge `fp`. The peak ripple is constrained by the scalar `dev`. This design uses the Kaiser window method.

`b = firhalfband( ____, 'high')` returns a highpass halfband FIR filter.

`b = firhalfband( ____, 'minphase')` designs a minimum-phase FIR filter such that the filter is a spectral factor of a halfband filter. Recall that `h = conv(b,flip1r(b))` is a halfband filter. This can be useful for designing perfect reconstruction two-channel FIR filter banks. The **'minphase'** option is not available for window-based halfband filter designs such as `b = firhalfband(n,win)` and `b = firhalfband('minorder',fp,dev,'kaiser')`.

In the minimum phase case, the filter order  $n$  must be odd.

### Examples

#### Design Halfband Filter using firhalfband

Design a minimum order halfband filter with maximum ripple set to 0.0001.

```
b = firhalfband('minorder',.45,0.0001);
impz(b)
```

The impulse response is zero for every alternate sample.

## Input Arguments

### **n** – FIR halfband filter order

positive integer

FIR halfband filter order, specified as an integer

If you specify the `firhalfband` function to design a minimum phase filter using the `'minphase'` argument, the filter order must be odd. In all other cases, the filter order must be even.

Data Types: `single` | `double`

### **fp** – Passband edge frequency

scalar in the range  $(0, \frac{1}{2})$

Passband edge frequency, specified as a scalar in the range  $(0, \frac{1}{2})$ , where  $\frac{1}{2}$  corresponds to  $\pi/2$  rad/sample.

Data Types: `single` | `double`

**win — Window to apply to filter***n*+1 length vector

Window to apply to the filter, specified as an *n*+1 length vector. The function truncates the ideal response to length *n*+1, then multiplies it point-by-point with the window specified in *win*.

Data Types: `single` | `double`

Complex Number Support: Yes

**dev — Maximum passband and stopband ripple**

scalar

Maximum passband and stopband ripple in the halfband filter, specified as a scalar.

Data Types: `single` | `double`**Output Arguments****b — FIR halfband filter coefficients**

vector

FIR halfband filter coefficients, returned as a vector.

Data Types: `single` | `double`

Complex Number Support: Yes

**More About****Halfband Filters**

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- Equal to 0 for all even-indexed samples.
- Equal to 1/2 at *n*=0. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at  $n=0$

The `firhalfband` function uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the  $\ell^\infty$  norm of the error (minimax).

### Kaiser Window

The coefficients of a Kaiser window are computed using this equation:

$$w(n) = \frac{I_0\left(\beta\sqrt{1 - \left(\frac{n - N/2}{N/2}\right)^2}\right)}{I_0(\beta)}, \quad 0 \leq n \leq N,$$

where  $I_0$  is the zeroth-order modified Bessel function of the first kind.

To obtain a Kaiser window that represents an FIR filter with stopband attenuation of  $\alpha$  dB, use this  $\beta$ .

$$\beta = \begin{cases} 0.1102(\alpha - 8.7), & \alpha > 50 \\ 0.5842(\alpha - 21)^{0.4} + 0.07886(\alpha - 21), & 50 \geq \alpha \geq 21 \\ 0, & \alpha < 21 \end{cases}$$

The filter order  $n$  is given by:

$$n = \frac{\alpha - 7.95}{2.285(\Delta\omega)}$$

where  $\Delta\omega$  is the transition width.

For more details, see "Algorithms" on page 5-683.

## Algorithms

The `firhalfband` function uses the equiripple or the Kaiser window method to design the FIR halfband filter. You can also specify a custom window using the `win` argument.

### Halfband Equiripple Design

In the equiripple method, the algorithm uses a minimax (minimize the maximum error) FIR design to design a fullband linear phase filter with the desired specifications. The algorithm upsamples a fullband filter to replace the even-indexed samples of the filter with zeros and creates a halfband filter. It then sets the filter tap corresponding to the group delay of the filter in samples to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 5-682. See [2] for a description of this filter design method using the Remez exchange algorithm. As you can design a filter using this approximation method with a constant ripple both in the passband and stopband, the filter is also known as the equiripple filter.

### Window-based Design

In the window-based design method, the algorithm first truncates the ideal halfband filter defined in "Halfband Filters" on page 5-682, then it applies the user-specified window. This yields a causal

linear-phase FIR filter approximation to the ideal halfband filter. If you provide the 'kaiser' argument, the function calculates the window as mentioned in "Kaiser Window" on page 5-683.

For more information on designing FIR halfband filters, see "FIR Halfband Filter Design".

## Version History

### Introduced in R2011a

#### **R2022b: Iterative filter design**

*Behavior change in future release*

Starting R2022b, when you provide the 'kaiser' argument, if the designed filter does not meet the required specifications, the `firhalfband` function designs the filter by iterating on the filter order obtained using the empirical formula in "Kaiser Window" on page 5-683.

## **fir2lp**

Transform FIR Type I lowpass to FIR Type 1 lowpass with inverse bandwidth

### **Syntax**

```
g = fir2lp(b)
```

### **Description**

`g = fir2lp(b)` transforms the Type I lowpass FIR filter `b` with zero-phase response  $H_r(w)$  to a Type I lowpass FIR filter `g` with zero-phase response  $[1 - H_r(\pi-w)]$ .

When `b` is a narrowband filter, `g` will be a wideband filter and vice versa. The passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`, respectively.

### **Examples**

#### **Convert Narrowband Lowpass Filter to Wideband Lowpass Filter**

Create a narrowband lowpass filter to use as a prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 5]);  
zerophase(b)
```

Convert the prototype filter to a wideband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
h = fir1p2lp(b);
```

```
hold on  
zerophase(h)
```

Convert the previous filter back to a narrowband lowpass filter. Add to the plot the zero-phase response of the new filter.

```
g = fir2lp(h);
```

```
[gr,w] = zerophas(g);  
plot(w/pi,gr,'--')  
hold off
```

## Input Arguments

### **b** — Lowpass FIR filter coefficients

row vector

Type 1 lowpass FIR filter coefficients with zero-phase response  $H_r(w)$ , specified as a row vector.

Data Types: single | double

## Output Arguments

### **g** — Transformed lowpass FIR filter coefficients

row vector

Transformed Type 1 lowpass FIR filter coefficients with zero-phase response  $1-H_r(\pi-w)$ , specified as a row vector.

Data Types: single | double

## firlp2hp

Transform FIR lowpass filter to Type I FIR highpass filter

### Syntax

```
g = firlp2hp(b)
g = firlp2hp(b,'narrow')
g = firlp2hp(b,'wide')
```

### Description

`g = firlp2hp(b)` transforms the lowpass FIR filter `b` with zero-phase response  $H_r(w)$  into a Type I highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . Filter `b` can be any FIR filter, including a nonlinear-phase filter.

The passband and stopband ripples of `g` will be equal to the passband and stopband ripples of `b`, respectively.

`g = firlp2hp(b,'narrow')` transforms the lowpass FIR filter `b` into a Type I narrowband highpass FIR filter `g` with zero-phase response  $H_r(\pi-w)$ . `b` can be any FIR filter, including a nonlinear-phase filter.

`g = firlp2hp(b,'wide')` transforms the Type I lowpass FIR filter `b` with zero-phase response  $H_r(w)$  into a Type I wideband highpass FIR filter `g` with zero-phase response  $1 - H_r(w)$ .

---

**Note** The `b` must be a Type I linear-phase filter.

---

For this case, the passband and stopband ripples of `g` will be equal to the stopband and passband ripples of `b`.

### Examples

#### Convert Narrowband Lowpass Filter to Highpass Filter

Create a narrowband lowpass filter to use as a prototype. Display its zero-phase response.

```
b = firgr(36,[0 0.2 0.25 1],[1 1 0 0],[1 3]);
zerophase(b)
```

Convert the prototype filter to a narrowband highpass filter. Add to the plot the zero-phase response of the new filter.

```
h = fir1p2hp(b);
```

```
hold on  
zerophase(h)
```

Convert the prototype filter to a wideband highpass filter. Add to the plot the zero-phase response of the new filter.

```
g = fir1p2hp(b, 'wide');
```

```
zerophase(g)  
hold off
```

## Input Arguments

### **b** — Lowpass FIR filter coefficients

row vector

Lowpass FIR filter coefficients, specified as a row vector.

Data Types: `single` | `double`

## Output Arguments

### **g** — Type I highpass FIR filter coefficients

row vector

Type I highpass FIR filter coefficients, returned as a row vector.

Data Types: `single` | `double`

firlp2lp | zerophase

# firlpnorm

Least P-norm optimal FIR filter

## Syntax

```
b = firlpnorm(n,f,edges,a)
b = firlpnorm(n,f,edges,a,w)
b = firlpnorm(n,f,edges,a,w,p)
b = firlpnorm(n,f,edges,a,w,p,dens)
b = firlpnorm(n,f,edges,a,w,p,dens,initnum)
b = firlpnorm(...,'minphase')
[b,err] = firlpnorm(...)
```

## Description

`b = firlpnorm(n,f,edges,a)` returns a filter of numerator order `n` which represents the best approximation to the frequency response described by `f` and `a` in the least-Pth norm sense. `P` is set to 128 by default, which is essentially equivalent to the infinity norm. Vector `edges` specifies the band-edge frequencies for multiband designs. `firlpnorm` uses an unconstrained quasi-Newton algorithm to design the specified filter.

`f` and `a` must have the same number of elements, which can exceed the number of elements in `edges`. This lets you specify filters with any gain contour within each band. However, the frequencies in `edges` must also be in vector `f`. Always use `freqz` to check the resulting filter.

---

**Note** `firlpnorm` uses a nonlinear optimization routine that may not converge in some filter design cases. Furthermore the algorithm is not well-suited for certain large-order (order > 100) filter designs.

---

`b = firlpnorm(n,f,edges,a,w)` uses the weights in `w` to weight the error. `w` has one entry per frequency point (the same length as `f` and `a`) which tells `firlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points. For example,

```
b = firlpnorm(20,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband, and with emphasis placed on minimizing the error in the stopband.

`b = firlpnorm(n,f,edges,a,w,p)` where `p` is a two-element vector [`pmin pmax`] lets you specify the minimum and maximum values of `p` used in the least-pth algorithm. Default is [2 128] which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even numbers. The design algorithm starts optimizing the filter with `pmin` and moves toward an optimal filter in the `pmax` sense. When `p` is set to **'inspect'**, `firlpnorm` does not optimize the resulting filter. You might use this feature to inspect the initial zero placement.

`b = firlpnorm(n,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is [`dens*(n+1)`]. The default is 20. You can specify `dens` as a single-element cell array. The grid is equally spaced.

`b = firlnorm(n,f,edges,a,w,p,dens,initnum)` lets you determine the initial estimate of the filter numerator coefficients in vector `initnum`. This can prove helpful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum`.

`b = firlnorm(...,'minphase')` where `'minphase'` is the last argument in the argument list generates a minimum-phase FIR filter. By default, `firlnorm` design mixed-phase filters. Specifying input option `'minphase'` causes `firlnorm` to use a different optimization method to design the minimum-phase filter. As a result of the different optimization used, the minimum-phase filter can yield slightly different results.

`[b,err] = firlnorm(...)` returns the least-pth approximation error `err`.

## Examples

### Design a Lowpass and Highpass Filter Using `firlnorm`

Lowpass filter with a peak of 1.4 in the passband.

```
b = firlnorm(22,[0 .15 .4 .5 1],[0 .4 .5 1],[1 1.4 1 0 0],...
[1 1 1 2 2]);
fvtool(b)
```

The resulting filter is lowpass, with the desired 1.4 peak in the passband (notice the 1.4 specified in vector `a`).

Highpass minimum-phase filter optimized for the 4-norm.

```
b = firlpnorm(44,[0 .4 .45 1],[0 .4 .45 1],[0 0 1 1],[5 1 1 1],...  
[2 4], 'minphase');  
fvtool(b)
```

This is a minimum-phase, highpass filter.

The zero-pole plot shows the minimum phase nature more clearly.

```
fvtool(b, 'polezero')
```

## firls

Least-square linear-phase FIR filter design

### Syntax

```
b = firls(n,f,a)
b = firls(n,f,a,w)
b = firls(n,f,a,ftype)
b = firls(n,f,a,w,ftype)
```

### Description

`b = firls(n,f,a)` returns row vector `b` containing the  $n+1$  coefficients of the order  $n$  FIR filter. This filter has frequency-amplitude characteristics approximately matching those given by vectors, `f` and `a`.

`b = firls(n,f,a,w)` uses the weights in vector `w`, to weigh the error.

`b = firls(n,f,a,ftype)` specifies a filter type where `ftype` is:

- 'hilbert'
- 'differentiator'

`b = firls(n,f,a,w,ftype)` uses the weights in vector `w` to weigh the error. It also specifies a filter type where `ftype` is:

- 'hilbert'
- 'differentiator'

### Examples

#### Design a Lowpass Filter with Transition Band

The following illustrates how to design a lowpass filter of order 225 with transition band.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.25 0.3 1]
```

```
f = 1×4
```

```
0    0.2500    0.3000    1.0000
```

```
a = [1 1 0 0]
```

```
a = 1×4
```

```
1    1    0    0
```

Use `firls` to obtain the  $n+1$  coefficients of the order  $n$  lowpass FIR filter.

```
b = firls(255,f,a);
```

Show the impulse response of the filter

```
fvtool(b,'impulse')
```

### Design an Antisymmetric Filter with Piecewise Linear Passbands

The following shows how to design a 24th-order anti-symmetric filter with piecewise linear passbands, and plot the desired and actual amplitude responses.

Create the frequency and amplitude vectors, `f` and `a`.

```
f = [0 0.3 0.4 0.6 0.7 0.9];
a = [0 1 0 0 0.5 0.5];
```

Use `firls` to obtain the 25 coefficients of the filter.

```
b = firls(24,f,a,'hilbert');
```

Plot the ideal amplitude response along with the transition regions.

```
plot(f.*pi,a,'o','markerfacecolor',[1 0 0]);  
hold on;  
plot(f.*pi,a,'r--','linewidth',2);
```

Use `freqz` to obtain the frequency response of the designed filter and plot the magnitude response of the filter.

```
[H,F] = freqz(b,1);  
plot(F,abs(H));  
set(gca,'xlim',[0 pi])  
legend('Filter Specification','Transition Regions','Magnitude Response')
```

## Input Arguments

### **n** – Filter order

integer scalar

Order of the filter, specified as an integer scalar. For odd orders, the frequency response at the Nyquist frequency is necessarily 0. For this reason, `firls` always uses an even filter order for configurations with a passband at the Nyquist frequency. If you specify an odd-valued `n`, `firls` increments it by 1.

Example: 8

Data Types: `int8` | `int16` | `int32` | `int64`

### **f** – Pairs of frequency points

vector of numeric values

Pairs of frequency points, specified as a vector of values ranging between 0 and 1, where 1 corresponds to the Nyquist frequency. The frequencies must be in increasing order, and duplicate frequency points are allowed. You can use duplicate frequency points to design filters exactly like those returned by the `fir1` and `fir2` functions with a rectangular (`rectwin`) window.

`f` and `a` are the same length. This length must be an even number.

Example: `[0 0.3 0.4 1]`

Data Types: double | single

### **a — Amplitude values**

vector of numeric values

Amplitude values of the function at each frequency point, specified as a vector of the same length as *f*. This length must be an even number.

The desired amplitude at frequencies between pairs of points ( $f(k)$ ,  $f(k+1)$ ) for  $k$  odd, is the line segment connecting the points ( $f(k)$ ,  $a(k)$ ) and ( $f(k+1)$ ,  $a(k+1)$ ).

The desired amplitude at frequencies between pairs of points ( $f(k)$ ,  $f(k+1)$ ) for  $k$  even is unspecified. These are transition or “don't care” regions.

Example: [1 1 0 0]

Data Types: double | single

### **w — Weights**

vector of numeric values

Weights to weigh the fit for each frequency band, specified as a vector of length half the length of *f* and *a*, so there is exactly one weight per band. *w* indicates how much emphasis to put on minimizing the integral squared error in each band, relative to the other bands.

Example: [0.5 1]

Data Types: double | single

### **ftype — Filter type**

'hilbert' and 'differentiator'

Filter type, specified as either 'hilbert' or 'differentiator'.

Example: 'hilbert'

Data Types: char

## **Output Arguments**

### **b — Filter coefficients**

vector of numeric values

Filter coefficients, returned as a numeric vector of  $n+1$  values, where  $n$  is the filter order.

$b = \text{firls}(n, f, a)$  designs a linear-phase filter of type I ( $n$  odd) and type II ( $n$ ). The output coefficients, or “taps,” in *b* obey the relation:

$$b(k) = b(n+2-k), k = 1, \dots, n + 1$$

$b = \text{firls}(n, f, a, \text{'hilbert'})$  designs a linear-phase filter with odd symmetry (type III and type IV). The output coefficients, or “taps,” in *b* obey the relation:

$$b(k) = -b(n+2-k), k = 1, \dots, n + 1$$

$b = \text{firls}(n, f, a, \text{'differentiator'})$  designs type III and type IV filters, using a special weighting technique. For nonzero amplitude bands, the integrated squared error has a weight of  $(1/$

$f)^2$ . This weighting causes the error at low frequencies to be much smaller than at high frequencies. For FIR differentiators, which have an amplitude characteristic proportional to frequency, the filters minimize the relative integrated squared error. This value is the integral of the square of the ratio of the error to the desired amplitude.

## More About

### Diagnostics

Error and warning messages

One of the following diagnostic messages is displayed when an incorrect argument is used:

```
F must be even length.
F and A must be equal lengths.
Requires symmetry to be 'hilbert' or 'differentiator'.
Requires one weight per band.
Frequencies in F must be nondecreasing.
Frequencies in F must be in range [0,1].
```

A more serious warning message is

```
Warning: Matrix is close to singular or badly scaled.
```

This tends to happen when the product of the filter length and transition width grows large. In this case, the filter coefficients  $b$  might not represent the desired filter. You can check the filter by looking at its frequency response.

## Algorithms

`firls` designs a linear-phase FIR filter. This filter minimizes the weighted, integrated squared error between an ideal piecewise linear function and the magnitude response of the filter over a set of desired frequency bands.

Reference [1] describes the theoretical approach behind `firls`. The function solves a system of linear equations involving an inner product matrix of size roughly  $n/2$  using the MATLAB `\` operator.

This function designs type I, II, III, and IV linear-phase filters. Type I and II are the defaults for  $n$  even and odd respectively. The 'hilbert' and 'differentiator' flags produce type III ( $n$  even) and IV ( $n$  odd) filters. The various filter types have different symmetries and constraints on their frequency responses (see [2] for details).

| Linear Phase Filter Type | Filter Order | Symmetry of Coefficients               | Response $H(f)$ , $f = 0$ | Response $H(f)$ , $f = 1$ (Nyquist) |
|--------------------------|--------------|--|---------------------------|-------------------------------------|
| Type I                   | Even         | $b(k) = b(n+2-k)$ , $k=1, \dots, n+1$  | No restriction            | No restriction                      |
| Type II                  | Odd          | $b(k) = b(n+2-k)$ , $k=1, \dots, n+1$  | No restriction            | $H(1) = 0$                          |
| Type III                 | Even         | $b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$ | $H(0) = 0$                | $H(1) = 0$                          |
| Type IV                  | Odd          | $b(k) = -b(n+2-k)$ , $k=1, \dots, n+1$ | $H(0) = 0$                | No restriction                      |

# firminphase

Minimum-phase FIR spectral factor

## Syntax

```
h = firminphase(b)
h = firminphase(b,nz)
```

## Description

`h = firminphase(b)` computes the minimum-phase FIR spectral factor `h` of a linear-phase FIR filter `b`.

You can find the maximum-phase spectral factor, `g`, by reversing `h` such that `g = flip1r(h)`, and `b = conv(h, g)`.

`h = firminphase(b, nz)` specifies the number of zeros, `nz`, of `b` that lie on the unit circle.

## Examples

### Design Constrained Least Squares Filter

Design a constrained least squares filter with a nonnegative zero-phase response, and then use the `firminphase` function to compute the minimum-phase spectral factor.

```
f = [0 0.4 0.8 1];
a = [0 1 0];
up = [0.02 1.02 0.01];
lo = [0 0.98 0]; % The zeros ensure nonnegative zero-phase resp.
n = 32;
b = fircls(n, f, a, up, lo);
h = firminphase(b)
```

```
h = 1×17
```

```
0.2397 -0.1556 -0.2834 0.3866 0.0415 -0.2529 0.0584 -0.0028 0.0868 0.0
```

## Input Arguments

### **b** — Lowpass FIR filter coefficients

row vector

Lowpass FIR filter coefficients, specified as a row vector. Elements of `b` must be real, of even order, and have nonnegative zero-phase response.

Data Types: `single` | `double`

### **nz** — Number of zeros

positive integer

Number of zeros of **b** that lie on the unit circle, specified as a positive integer. You must specify **nz** as an even number to compute the minimum-phase spectral factor because every root on the unit circle must have even multiplicity. Including **nz** can help the `firminphase` function calculate the required FIR spectral factor. Zeros with multiplicity greater than two on the unit circle cause problems in the spectral factor determination.

Data Types: `single` | `double` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64`

## Output Arguments

### **h** — Minimum-phase FIR spectral factor coefficients

row vector

Minimum-phase FIR spectral factor coefficients of a linear-phase FIR filter **b**, returned as a row vector.

Data Types: `single` | `double`

# firnyquist

Lowpass Nyquist (Lth-band) FIR filter

## Syntax

```
b = firnyquist(n,l,r)
b = firnyquist('minorder',l,r,dev)
b = firnyquist(n,l,r,decay)
b = firnyquist(n,l,r,'nonnegative')
b = firnyquist(n,l,r,'minphase')
```

## Description

`b = firnyquist(n,l,r)` designs an Nth order, Lth band, Nyquist FIR filter with a rolloff factor  $r$  and an equiripple characteristic.

The rolloff factor  $r$  is related to the normalized transition width  $tw$  by  $tw = 2\pi(r/l)$  (rad/sample). The order,  $n$ , must be even.  $l$  must be an integer greater than one. If  $l$  is not specified, it defaults to 4.  $r$  must satisfy  $0 < r < 1$ . If  $r$  is not specified, it defaults to 0.5.

`b = firnyquist('minorder',l,r,dev)` designs a minimum-order, Lth band Nyquist FIR filter with a rolloff factor  $r$  using the Kaiser window. The peak ripple is constrained by the scalar `dev`.

`b = firnyquist(n,l,r,decay)` designs an Nth order ( $n$ ), Lth band ( $l$ ), Nyquist FIR filter where the scalar `decay`, specifies the rate of decay in the stopband. `decay` must be nonnegative. If you omit or leave it empty, `decay` defaults to 0 which yields an equiripple stopband. A nonequiripple stopband (`decay`  $\neq$  0) may be desirable for decimation purposes.

`b = firnyquist(n,l,r,'nonnegative')` returns an FIR filter with nonnegative zero-phase response. This filter can be spectrally factored into minimum-phase and maximum-phase “square-root” filters. This allows you to use the spectral factors in applications such as matched-filtering.

`b = firnyquist(n,l,r,'minphase')` returns the minimum-phase spectral factor `bmin` of order  $n$ . `bmin` meets the condition `b=conv(bmin,bmax)` so that `b` is an Lth band FIR Nyquist filter of order  $2n$  with filter rolloff factor  $r$ . Obtain `bmax`, the maximum phase spectral factor by reversing the coefficients of `bmin`. For example, `bmax = bmin(end:-1:1)`.

## Examples

### Design a Nyquist Filter Using firnyquist

This example designs a minimum phase factor of a Nyquist filter.

```
bmin = firnyquist(47,10,.45,'minphase');
b = firnyquist(2*47,10,.45,'nonnegative');
[h,w,s] = freqz(b); hmin = freqz(bmin);
fvtool(b,1,bmin,1);
```

This example compares filters with different decay rates.

```
b1 = firnyquist(72,8,.3,0); % Equiripple  
b2 = firnyquist(72,8,.3,15);  
b3 = firnyquist(72,8,.3,25);  
fvtool(b1,1,b2,1,b3,1);
```

## firpr2chfb

Two-channel FIR filter bank for perfect reconstruction

### Syntax

```
[h0,h1,g0,g1] = firpr2chfb(n,fp)
[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')
[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)
```

### Description

`[h0,h1,g0,g1] = firpr2chfb(n,fp)` designs four FIR filters for the analysis sections (`h0` and `h1`) and synthesis section is (`g0` and `g1`) of a two-channel perfect reconstruction filter bank. The design corresponds to the orthogonal filter banks also known as power-symmetric filter banks.

`n` is the order of all four filters. It must be an odd integer. `fp` is the passband-edge for the lowpass filters `h0` and `g0`. The passband-edge argument `fp` must be less than 0.5. `h1` and `g1` are highpass filters with the passband-edge given by  $(1-fp)$ .

`[h0,h1,g0,g1] = firpr2chfb(n,dev,'dev')` designs the four filters such that the maximum stopband ripple of `h0` is given by the scalar `dev`. Specify `dev` in linear units, not decibels. The stopband-ripple of `h1` is also be given by `dev`, while the maximum stopband-ripple for both `g0` and `g1` is  $(2*dev)$ .

`[h0,h1,g0,g1] = firpr2chfb('minorder',fp,dev)` designs the four filters such that `h0` meets the passband-edge specification `fp` and the stopband-ripple `dev` using minimum order filters to meet the specification.

### Examples

#### Design a Filter Bank Using `firpr2chfb`

Design a filter bank with filters of order `n` equal to 99 and passband edges of 0.45 and 0.55.

```
n = 99;
[h0,h1,g0,g1] = firpr2chfb(n,.45);
fvtool(h0,1,h1,1,g0,1,g1,1);
```

Here are the filters, showing clearly the passband edges.

Use the following stem plots to verify perfect reconstruction using the filter bank created by `firpr2chfb`.

```
stem(1/2*conv(g0,h0)+1/2*conv(g1,h1))
n=0:n;
stem(1/2*conv((-1).^n.*h0,g0)+1/2*conv((-1).^n.*h1,g1))
stem(1/2*conv((-1).^n.*g0,h0)+1/2*conv((-1).^n.*g1,h1))
stem(1/2*conv((-1).^n.*g0,(-1).^n.*h0)+...
1/2*conv((-1).^n.*g1,(-1).^n.*h1))
stem(conv((-1).^n.*h1,h0)-conv((-1).^n.*h0,h1))
```

# firtype

**Package:** dsp

Determine type (1-4) of linear phase FIR filter System object

## Syntax

```
type = firtype(sysobj)
```

## Description

`type = firtype(sysobj)` determines the type (1 through 4) of the FIR filter System object

For more input options, see `firtype` in Signal Processing Toolbox.

## Examples

### Hilbert Transformers

Design a Hilbert transformer of order 30 with a transition width of  $0.2\pi$  rad/sample. Use least-squares minimization to obtain an equiripple linear-phase FIR filter. Plot the zero-phase response in the interval  $[-\pi, \pi)$ .

```
d = fdesign.hilbert('N,TW',30,0.2);  
Hd = design(d,'equiripple','SystemObject',true);  
zerophase(Hd,'whole')
```

The impulse response of this even-order type-3 filter is antisymmetric.

`impz(Hd)`

```
ftype = firtype(Hd)
```

```
ftype = 3
```

Design a minimum-order Hilbert transformer that has a sample rate of 1 kHz. Specify the width of the transition region as 10 Hz and the passband ripple as 1 dB. Display the zero-phase response of the filter.

```
fs = 1e3;
d = fdesign.hilbert('TW,Ap',10,1,fs);
hd = design(d,'equiripple','SystemObject',true);
zerophase(hd,-fs/2:0.1:fs/2,fs)
```

## Input Arguments

### **sysobj** — Input FIR filter

FIR filter System object

Input FIR filter with real and linear phase, specified as one of the following filter System objects:

- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.Differentiator`
- `dsp.HighpassFilter`
- `dsp.FilterCascade`
- `dsp.FIRFilter`
- `dsp.FIRDecimator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FIRHalfbandDecimator`

- `dsp.FIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.VariableBandwidthFIRFilter`

To check if a filter has linear phase, use the `islinphase` function. To check if a filter has real coefficients, use the `isreal` function.

## Output Arguments

**type** — FIR filter type

1 | 2 | 3 | 4

FIR filter type, defined as one of the following:

- 1 -- Type 1 filter with even order symmetric coefficients.
- 2 -- Type 2 filter with odd order symmetric coefficients.
- 3 -- Type 3 filter with even order antisymmetric coefficients.
- 4 -- Type 4 filter with odd order antisymmetric coefficients.

## Version History

Introduced in R2013a

# freqrespest

**Package:** dsp

Frequency response estimate via filtering

## Syntax

```
[h,w] = freqrespest(sysobj)
[h,w] = freqrespest(sysobj,L)
[h,w] = freqrespest(sysobj,L,Name,Value)
[h,w] = freqrespest(sysobj,L,opts)
[h,w] = freqrespest(sysobj,'Arithmetic',arithType)
freqrespest(sysobj, ___)
```

## Description

`[h,w] = freqrespest(sysobj)` computes the frequency response estimate of the input filter System object. The function estimates by running input data made up from sinusoids with uniformly distributed random frequencies through the filter and forming the ratio between output data and input data.

The `freqrespest` function computes the frequency response estimate of the input filter object that is close to the frequency response obtained by using only the quantized coefficients as long as:

- No overflow occurs when performing the fixed-point filtering
- There isn't significant quantization happening in the fixed-point additions and multiplications

`freqrespest` can be used as a diagnostic tool for fixed-point implementations. If `freqrespest` differs significantly from `freqz` (which only takes into account the quantization of the coefficients), it is an indication that at least one of the two conditions might be true.

`[h,w] = freqrespest(sysobj,L)` computes the frequency response estimate of the filter object by specifying `L` number of trials.

`[h,w] = freqrespest(sysobj,L,Name,Value)` uses the `Name,Value` pairs as input arguments to specify optional parameters for the test. Enter the parameter name as an input argument in single quotation marks followed by the possible value of the parameter.

`[h,w] = freqrespest(sysobj,L,opts)` uses an options object to specify the optional input parameters in lieu of specifying name-value pairs.

`[h,w] = freqrespest(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input.

`freqrespest(sysobj, ___)` with no output argument launches FVTool and shows the magnitude response estimate of the filter object.

## Examples

## Estimate the Frequency Response of Fixed-Point FIR Filter

Estimate the frequency response of a fixed-point FIR filter.

```
firFilt = design(fdesign.lowpass(.4,.5,1,60),'equiripple','Systemobject',true);
dataIn = fi(randn(16,15),1,16,15);
dataOut = firFilt(dataIn); %#ok
[h,w] = freqrespest(firFilt); %#ok % This should be about the same as freqz.
release(firFilt);
```

Continuing with the filter object `firFilt`, change the `FullPrecisionOverride` property to `false` and then specify the word lengths and precision (the fraction lengths) applied to the output from internal addition and multiplication operations. After you set the word and fraction lengths, use the `freqrespest` function to compute the frequency response estimate for the fixed-point filter.

```
firFilt.FullPrecisionOverride = false;
firFilt.ProductDataType = 'Custom';
firFilt.CustomProductDataType = numerictype(1,16,15);
firFilt.AccumulatorDataType = 'Custom';
firFilt.CustomAccumulatorDataType = numerictype(1,16,15);
firFilt.OutputDataType = 'Same as accumulator';
dataOut = firFilt(dataIn);
[h,w] = freqrespest(firFilt,2);
[h2,w2] = freqz(firFilt,512);
plot(w/pi,20*log10(abs([h,h2])))
legend('Frequency response estimated by filtering',...
'Freq. response computed by quantizing coefficients only');
xlabel('Normalized Frequency (\times\pi rad/sample)')
ylabel('Magnitude (dB)')
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FIRFilter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`

- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **L — Number of trials**

10 | positive integer

Number of trials used to compute the estimate, specified as a positive integer. If you do not specify this value, L defaults to 10. More the number of trials, the greater is the accuracy in the estimate of the response. However, when L is large, the function requires more time to compute the estimate.

Data Types: `single` | `double`

### **opts — Options object**

options object

Options object to specify the optional input parameters in lieu of specifying name-value pairs.

Create the `opts` object using the `freqrespopts` function.

```
opts = freqrespopts(sysobj);
```

Because `opts` is an object, you use the `set` function to change the property values in `opts` before you use it with `freqrespest`. For example, you could specify a new sample rate with:

```
set(opts, 'fs', 48e3); % Same as opts.fs = 48e3
```

### **arithType — Arithmetic type**

'double' | 'single' | 'fixed'

Analyze the filter System object, based on the arithmetic specified in the `arithType` input. `arithType` can be set to 'double', 'single', or 'fixed'. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

`freqrespest` requires knowledge of the input data type. Analysis cannot be performed if the input data type is not available. If you do not specify the `arithType` parameter, that is, use the syntax `[h,w] = freqrespest(sysobj)`, then these rules apply.

- The System object state is `Unlocked` — `freqrespest` performs double precision analysis.
- The System object state is `Locked` — `freqrespest` performs analysis based on the locked input data type.

When you do specify the `arithType` parameter, that is, use the syntax `[h,w] = freqrespest(sysobj, 'Arithmetic', arithType)`, the following rules apply:

| Value                             | System Object State   | Rule   |
|-----------------------------------|-----------------------|--|
| <code>arithType = 'double'</code> | <code>Unlocked</code> | <code>freqrespest</code> performs double-precision analysis. |
|                                   | <code>Locked</code>   | <code>freqrespest</code> performs double-precision analysis. |
| <code>arithType = 'single'</code> | <code>Unlocked</code> | <code>freqrespest</code> performs single-precision analysis. |

| Value                            | System Object State | Rule  |
|----------------------------------|---------------------|---|
|                                  | Locked              | <code>freqrespest</code> performs single-precision analysis.  |
| <code>arithType = 'fixed'</code> | Unlocked            | <code>freqrespest</code> produces an error because the fixed-point input data type is unknown.  |
|                                  | Locked              | If the input data type is double or single, then <code>freqrespest</code> produces an error because the fixed-point input data type is unknown. |
|                                  |                     | When the input data is of fixed-point type, <code>freqrespest</code> performs analysis based on the locked input data type.                     |

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

```
Example: firFilt =
design(fdesign.lowpass(.4,.5,1,60),'equiripple','Systemobject',true); [h,w] =
freqrespest(firFilt,10,'NFFT',1024);
```

### NFFT — Number of FFT points

512 (default) | positive integer

Number of FFT points used in computing the frequency response estimate, specified as a positive integer. This value determines the length of the frequency response vector `h` and the length of the frequency vector `w`. When not specified, `NFFT` defaults to 512.

Data Types: `single` | `double`

### NormalizedFrequency — Use normalized frequency

`true` (default) | `false`

Indicate whether to use normalized frequency or linear frequency, specified as either:

- `true` -- Use normalized frequency. When not specified, the function defaults to `true`.
- `false` -- Use linear frequency. When you specify `false`, you must supply the sampling frequency `Fs`.

### Fs — Sampling frequency

positive scalar

Sampling frequency to be specified when `NormalizedFrequency` is set to `false`. No default value. You must set `NormalizedFrequency` to `false` before setting a value for `Fs`.

Data Types: `single` | `double`

**SpectrumRange — Spectrum range**`half (default) | whole`

Spectrum range to be used while computing the frequency response estimate, specified as either:

- `half`
- `whole`

**CenterDC — Set center of spectrum to DC**`false (default) | true`

Specify whether to set the center of the spectrum to the DC value in the output plot. If you select `true`, both the negative and positive values appear in the plot. If you select `false`, DC appears at the origin of the axes.

**Output Arguments****h — Estimate of complex frequency response**

vector

Estimate of the complex frequency response, returned as a vector. The length of the vector equals the NFFT value. By default, this vector is of length 512.

Data Types: `double`

Complex Number Support: Yes

**w — Frequencies**

vector

Frequencies at which the complex frequency response `h` is estimated, returned as a vector. The length of the vector equals the NFFT value. By default, this vector is of length 512.

Data Types: `double`**Version History**

Introduced in R2011a

## freqrespopts

**Package:** dsp

Create an options object for frequency response estimate

### Syntax

```
opts = freqrespopts(sysobj)
```

### Description

`opts = freqrespopts(sysobj)` uses the current settings in the filter System object to create an options object. This object contains options for frequency response estimation. You pass the `opts` object as an input argument to the `freqrespest` function to specify values for the input parameters.

`freqrespopts` allows you to use the same settings for `freqrespest` with multiple filters without specifying all of the parameters as input arguments to `freqrespest`.

### Examples

#### Set Frequency Response Options

This example uses the `freqrespopts` function to set options which are used by the `freqrespest` function. `hd` and `hd2` are bandpass filters that use different design methods. The `opts` object makes it easier to set the same conditions for the frequency response estimate when using the `freqrespest` function with different filter objects..

```
d = fdesign.bandpass('fst1,fp1,fp2,fst2,ast1,ap,ast2',...
0.25,0.3,0.45,0.5,60,0.1,60);
hd = design(d,'butter','SystemObject',true)
```

```
hd =
```

```
  dsp.SOSFilter with properties:
```

    SpectrumRange: 'Whole'
        CenterDC: true

```

With the `opts` object configured as needed, use it as an input argument for the `freqrespest` function.

```
[h2,w2] = freqrespest(hd2,20,opts);
```

```
[h1,w1] = freqrespest(hd,20,opts);
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CoupledAllpassFilter`

- `dsp.Differentiator`
- `dsp.FIRFilter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

### **opts** — Options object

`pseudospectrum` object

Options object which contains the options for frequency response estimation, returned as a `pseudospectrum` object. You pass the `opts` object as an input argument to the `freqrespest` function to specify values for input parameters.

## Version History

**Introduced in R2011a**

### **See Also**

`freqrespest` | `noisepsd` | `noisepsdopts` | `scale`

# freqsamp

Real or complex frequency-sampled FIR filter from specification object

## Syntax

```
hd = design(d,'freqsamp','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
hd = design(...,'window',window,'SystemObject',true)
```

## Description

`hd = design(d,'freqsamp','SystemObject',true)` designs a frequency-sampled filter specified by the filter specifications object `d`.

`hd = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the filter structure you specify by the `structure` input argument. `structure` is `dffir` by default and can be any one of the following filter structures.

| Structure              | Description of Resulting Filter Structure |
|------------------------|---|
| <code>dffir</code>     | Direct-form FIR filter                    |
| <code>dffirt</code>    | Transposed direct-form FIR filter         |
| <code>dfsymfir</code>  | Symmetrical direct-form FIR filter        |
| <code>dfasymfir</code> | Asymmetrical direct-form FIR filter       |

`hd = design(...,'window',window,'SystemObject',true)` designs filters using the window specified by `window`. Provide the input argument `window` as

- A character vector for the window type. For example, use `'bartlett'`, or `'hamming'`. See `window` for the full list of windows available.
- A function handle that references the window function. When the window function requires more than one input, use a cell array to hold the required arguments. The first example shows a cell array input argument.
- The window vector itself.

## Examples

### Design a Frequency Sampled FIR Filter

These examples design FIR filters that have arbitrary magnitude responses. In the first filter, the response has three distinct sections and the resulting filter is real.

The second example creates a complex filter.

```
b1 = 0:0.01:0.18;
b2 = [.2 .38 .4 .55 .562 .585 .6 .78];
b3 = 0.79:0.01:1;
```

```

a1 = .5+sin(2*pi*7.5*b1)/4; % Sinusoidal response section.
a2 = [.5 2.3 1 1 -.2 -.2 1 1]; % Piecewise linear response section.
a3 = .2+18*(1-b3).^2; % Quadratic response section.
f = [b1 b2 b3];
a = [a1 a2 a3];
n = 300;
d = fdesign.arbmag('n,f,a',n,f,a); % First specifications object.
hd = design(d,'freqsamp','window',{@kaiser,.5},...
'SystemObject',true); % Filter.
fvtool(hd)

```

Now design the arbitrary-magnitude complex FIR filter. Recall that vector  $f$  contains frequency locations and vector  $a$  contains the desired filter response values at the locations specified in  $f$ .

```

f = [-1 -.93443 -.86885 -.80328 -.7377 -.67213 -.60656 -.54098 ...
-.47541,-.40984 -.34426 -.27869 -.21311 -.14754 -.081967 ...
-.016393 .04918 .11475,.18033 .2459 .31148 .37705 .44262 ...
.5082 .57377 .63934 .70492 .77049,.83607 .90164 1];
a = [.0095848 .021972 .047249 .099869 .23119 .57569 .94032 ...
.98084 .99707,.99565 .9958 .99899 .99402 .99978 .99995 .99733 ...
.99731 .96979 .94936,.8196 .28502 .065469 .0044517 .018164 ...
.023305 .02397 .023141 .021341,.019364 .017379 .016061];
n = 48;
d = fdesign.arbmag('n,f,a',n,f,a); % Second spec. object.
hdc = design(d,'freqsamp','window','rectwin','SystemObject',true); % Filter.
fvtool(hdc)

```

fvtool shows you the response for hdc from -1 to 1 in normalized frequency. `design(d,...)` returns a complex filter for hdc because the frequency vector includes negative frequency values.

# freqz

**Package:** dsp

Frequency response of discrete-time filter System object

## Syntax

```
[h,w] = freqz(sysobj)
[h,w] = freqz(sysobj,n)
[h,w] = freqz(sysobj,'Arithmetic',arithType)
freqz(sysobj)
```

## Description

`[h,w] = freqz(sysobj)` returns the complex frequency response  $h$  of the filter System object, `sysobj`. The vector  $w$  contains the frequencies (in radians/sample) at which the function evaluates the frequency response. The frequency response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[h,w] = freqz(sysobj,n)` returns the complex frequency response of the filter System object and the corresponding frequencies at  $n$  points equally spaced around the upper half of the unit circle.

`freqz` uses the transfer function associated with the filter to calculate the frequency response of the filter with the current coefficient values.

`[h,w] = freqz(sysobj,'Arithmetic',arithType)` analyzes the filter System object, based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

`freqz(sysobj)` uses `fvtool` to plot the magnitude and unwrapped phase of the frequency response of the filter System object `sysobj`.

For more input options, see `freqz` in Signal Processing Toolbox.

## Examples

### Frequency Response of the Filter

This examples plot the frequency response of the lowpass FIR filter using `freqz`.

```
b = fir1(80,0.5,kaiser(81,8));
firFilt = dsp.FIRFilter('Numerator',b);
freqz(firFilt);
```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`

- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**n — Number of points over which the frequency response is computed**

8192 (default) | positive integer

Number of points over which the frequency response is computed. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- **unlocked** -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- **locked** -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **h** — Frequency response

vector

Complex  $n$ -element frequency response vector. If  $n$  is not specified, the function uses a default value of 8192. The frequency response is evaluated at  $n$  points equally spaced around the upper half of the unit circle.

Data Types: double

### **w** — frequencies

vector

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

## Tips

There are several ways of analyzing the frequency response of filters. `freqz` accounts for quantization effects in the filter coefficients, but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, refer to function `noisepsd`.

## Algorithms

`freqz` calculates the frequency response for a filter from the filter transfer function  $Hq(z)$ . The complex-valued frequency response is calculated by evaluating  $Hq(e^{j\omega})$  at discrete values of  $w$  specified by the syntax you use. The integer input argument  $n$  determines the number of equally-spaced points around the upper half of the unit circle at which `freqz` evaluates the frequency response. The frequency ranges from 0 to  $\pi$  radians per sample when you do not supply a sampling frequency as an input argument. When you supply the scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to  $fs/2$  Hz.

# freqz

**Package:** dsp

Frequency response of filters in channelizer

## Syntax

```
[H,w] = freqz(obj)
[H,w] = freqz(obj,ind)
[H,f] = freqz(obj,ind,Name,Value)
```

## Description

`[H,w] = freqz(obj)` computes a matrix of complex frequency responses for each filter in the `dsp.Channelizer` System object. Each column of `H` corresponds to the frequency response for one of the filters in the channelizer. `w` is a vector of normalized frequencies at which the rows of `H` are computed.

`[H,w] = freqz(obj,ind)` computes the frequency response of the filters with indices corresponding to the elements in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where `N` is the number of frequency bands.

For example, to compute the frequency response of the first 4 filters, set `ind` to `[1:4]`.

```
channelizer = dsp.Channelizer;
[H,w] = freqz(channelizer,[1:4]);
```

`[H,f] = freqz(obj,ind,Name,Value)` computes the frequency response of the filters with additional options specified by one or more `Name,Value` pair arguments.

For example, to specify a sampling rate of 44100 Hz, set `'Fs'` to 44100. To compute the frequency response using 1024 frequency points, set `'NFFT'` to 1024. In addition, to compute the sum of the frequency response of the filters, set `'overall'` to `true`.

```
channelizer = dsp.Channelizer;
[H,f] = freqz(channelizer,[1:4],'Fs',44100,'NFFT',1024,'overall',true);
```

## Examples

### Frequency Response of Channelizer Filter Bank

Compute the frequency response of the filters in the channelizer using the `freqz` function.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. Compute the frequency response matrix, `H`, and the corresponding vector of frequency points, `w`.

```
channelizer = dsp.Channelizer;
[H,w] = freqz(channelizer); %#ok
whos H
```

| Name | Size   | Bytes   | Class  | Attributes |
|------|--------|---------|--------|------------|
| H    | 8192x8 | 1048576 | double | complex    |

The number of rows in  $H$  corresponds to the number of frequency points, and the number of columns in  $H$  corresponds to the number of frequency bands. To view only a portion of the filter bank, specify the indices.

```
[H,w] = freqz(channelizer,(1:4)); %#ok
```

Specifying the filter indices as  $[1:4]$  computes the individual frequency response of the first 4 filters. You can alternatively view the sum of the filter responses by setting the 'overall' to true.

```
[H,w] = freqz(channelizer,1:4,'overall',true);
plot(w/pi,20*log10(abs(H)))
xlabel('Normalized Frequency (\times \pi rad/sample)')
ylabel('Magnitude (dB)')
```

You can also compute the frequencies in Hz by passing a sampling frequency. Frequency in Hz,  $f$ , equals  $(w/2 * \pi) * F_s$ , where  $w$  is frequency in radians, and  $F_s$  is the sampling rate.

```
[H,f] = freqz(channelizer,'Fs',44100); %#ok
```

Specify the number of frequency points using the 'NFFT' argument.

```
[H,f] = freqz(channelizer,'Fs',44100,'NFFT',1024);
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

Example: `[H,w] = freqz(channelizer);`

### **ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range `[1 obj.NumFrequencyBands]`. By default, `ind` is set to `1:N`, where `N` is the number of frequency bands specified through the `obj.NumFrequencyBands` property.

Example: `freqz(channelizer,[1:4]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[H,f] = freqz(channelizer,[1:4],'Fs',44100,'NFFT',1024,'overall',true);`

### **Fs** — Sampling rate

scalar

Sampling rate, specified as a scalar. This value determines the frequencies in Hz at which `freqz` computes the frequency response.

Example: 44100

Example: 22050

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NFFT** — Number of frequency points used to compute frequency response

8192 (default) | positive scalar

Number of frequency points used to compute the frequency response, specified as a positive scalar.

Example: 8192

Example: 1024

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **overall** — Type of filter response

`false` (default) | `true`

The type of filter response, specified as either:

- `true` -- `freqz` computes the sum of the filter responses.
- `false` -- `freqz` computes the individual filter responses.

Data Types: `logical`

## Output Arguments

### **H** — Frequency response of filter

matrix (default) | vector

Complex frequency response of the filters in the channelizer. The dimensions of the output depend on the value of the `'overall'` argument:

- When the `'overall'` argument is `true`, the frequency response vector contains the sum of the frequency responses of all the filters. The vector is of size `[nfft 1]`, where `nfft` is the number of frequency points. For example, if `nfft` is 8192, `H` is a matrix of size `[8192 1]`.
- When the `'overall'` argument is `false`, the frequency response is a matrix of size `[nfft nFilters]`, where `nfft` is the number of frequency points and `nFilters` is the number of filters whose frequency response is computed. Suppose `nfft` is 8192 and `ind` is `[2:5]`, `H` is a matrix of size `[8192 4]`.

Data Types: `double`

### **w** — Normalized frequencies

vector

Normalized frequencies, specified in rad/sample, at which the frequency response is computed. The vector is of size `[nfft 1]`.

Data Types: `double`

### **f** — Frequencies

vector

Frequencies, specified in Hz, at which the frequency response is computed. The vector is of size `[nfft 1]`.

Data Types: `double`

## Version History

Introduced in R2017b

`dsp.Channelizer`

## freqz

**Package:** dsp

Frequency response of the multirate multistage filter

### Syntax

```
[h, f] = freqz(sysobj, n, range)
[h, f] = freqz(sysobj, f)
```

### Description

`[h, f] = freqz(sysobj, n, range)` returns the complex frequency response, `h`, of the multirate multistage filter System object and the frequency vector `f` at which `h` is computed. `n` is the number of frequency points, and `range` is the frequency range over which the response is computed.

For the sample rate converter object, the sample rate is the larger of `InputSampleRate` and `OutputSampleRate`.

`[h, f] = freqz(sysobj, f)` returns the complex frequency response `h` computed at the frequency points specified by vector `f`. The input vector `f` is in Hz.

### Examples

#### Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;
[H, f] = freqz(src);
plot(f, 20*log10(abs(H)))
```

Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;  
[H,f] = freqz(src,f);  
plot(f,20*log10(abs(H)))
```

### Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100);  
[h,f] = freqz(cbp);  
plot(f,20*log10(abs(h)))  
grid on  
xlabel('Frequency (Hz)')  
ylabel('h (dB)')
```

## Input Arguments

### **sysobj** — Filter System object

`dsp.ComplexBandpassDecimator` | `dsp.SampleRateConverter`

Filter System object, specified as a `dsp.ComplexBandpassDecimator` or a `dsp.SampleRateConverter` System object.

### **n** — Number of evaluation points

8192 (default) | positive integer

Number of frequency points for response evaluation, specified as a positive integer scalar. If `n` is not specified, the default is 8192.

Data Types: `single` | `double`

### **range** — Range of frequencies

'half' (default) | 'whole'

Range considered when computing the frequency response, specified as either 'half' (from 0 to  $\pi$ ) or 'whole' (from 0 to  $2\pi$ ). If range is not specified, the default is 'half'.

### **f** — Frequencies in Hz at which response is computed

vector

Frequencies in Hz at which the response is computed, specified as a vector.

Data Types: double

## Output Arguments

### **h** — Complex frequency response

vector

Complex frequency response, returned as a vector.

Data Types: double

### **f** — Frequencies at which response is computed

vector

Frequencies at which the response is computed, returned as a vector.

Data Types: double

# info

**Package:** dsp

Characteristic information about generated signal

## Syntax

```
S = info(nco)
```

## Description

`S = info(nco)` returns a structure containing the characteristic information, `S`, about the `dsp.NCO` System object, `nco`.

## Examples

### Obtain the Characteristic Information of the NCO Object

The characteristic information of the NCO object is defined by the following fields:

- `NumPointsLUT` — Number of data points in the lookup table.
- `SineLUTSize` — Quarter-wave sine lookup table size in bytes.
- `TheoreticalSFDR` — Theoretical spurious free dynamic range (SFDR) in dBc.
- `FrequencyResolution` — Frequency resolution of the NCO.

To obtain the above characteristics for a specific NCO object, call the `info` function on the object.

```
nco = dsp.NCO
```

```
nco =
    dsp.NCO with properties:
        PhaseIncrementSource: 'Input port'
        PhaseOffsetSource: 'Property'
        PhaseOffset: 0
        Dither: true
        NumDitherBits: 4
        PhaseQuantization: true
        NumQuantizerAccumulatorBits: 12
        PhaseQuantizationErrorOutputPort: false
        Waveform: 'Sine'
        SamplesPerFrame: 1
        OutputDataType: 'Custom'
```

Show all properties

```
info(nco)
```

```
ans = struct with fields:
    NumPointsLUT: 1025
```

```

        SineLUTSize: 2050
    TheoreticalSFDR: 84
    FrequencyResolution: 1.5259e-05

```

The fields and their corresponding values change depending on the settings of the object. For instance, if the `PhaseQuantization` property is set to `false`, the `TheoreticalSFDR` field does not appear.

```

nco.PhaseQuantization = false;
info(nco)

ans = struct with fields:
    NumPointsLUT: 16385
    SineLUTSize: 32770
    FrequencyResolution: 1.5259e-05

```

## Input Arguments

### **nco** — Numerically controlled oscillator

`dsp.NCO` System object

Numerically controlled oscillator, specified as a `dsp.NCO` System object.

## Output Arguments

### **S** — Characteristic information about signal

structure

Characteristic information about the `dsp.NCO` System object, returned as a structure, `S`. The number of fields of `S` and their values vary depending on the property value settings of `nco`. The possible fields and their values are:

| Field                            | Value   |
|----------------------------------|---|
| <code>NumPointsLUT</code>        | Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.   |
| <code>SineLUTSize</code>         | Quarter-wave sine lookup table size in bytes.   |
| <code>TheoreticalSFDR</code>     | Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the <code>PhaseQuantization</code> property to <code>true</code> . |
| <code>FrequencyResolution</code> | Frequency resolution of the NCO in Hz. The sample time of the output signal is assumed to be 1 second.  |

Data Types: `struct`

## Version History

Introduced in R2012a

## fvtool

**Package:** dsp

Visualize frequency response of DSP filters

### Syntax

```
fvtool(sysobj)
fvtool(sysobj,options)
fvtool(____,Name,Value)
```

### Description

`fvtool(sysobj)` displays the magnitude response of the filter System object.

`fvtool(sysobj,options)` displays the response that is specified by the options.

For example, to visualize the impulse response of an FIR filter System object, set options to 'impulse'.

```
Fs = 96e3; filtSpecs = fdesign.lowpass(20e3,22.05e3,1,80,Fs);
    fir1p2 = design(filtSpecs,'equiripple','SystemObject',true);
fvtool(fir1p2,'impulse');
```

`fvtool(____,Name,Value)` visualizes the response of the filter with each specified property set to the specified value.

For more input options, see **FVTool** in Signal Processing Toolbox.

### Examples

#### Impulse and Frequency Response of Halfband Decimation Filter

Create two lowpass halfband decimation filters for data sampled at 44.1 kHz. The design method in the first filter is set to "Equiripple" and in the second filter is set to "Kaiser".

The output data rate is 1/2 the input sample rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = "Filter order and transition width";
Order = 52;
TW = 4.1e3;
firhalfbanddecimEqui = dsp.FIRHalfbandDecimator(...
    Specification=filterspec,...
    FilterOrder=Order,...
    TransitionWidth=TW,...
    DesignMethod="Equiripple",...
    SampleRate=Fs);
firhalfbanddecimKaiser = dsp.FIRHalfbandDecimator(...
```

```

Specification=filterspec,...
FilterOrder=Order,...
TransitionWidth=TW,...
DesignMethod="Kaiser",...
SampleRate=Fs);

```

Plot the impulse response of both the filters. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```

hfvt = fvtool(firhalfbanddecimEqui,firhalfbanddecimKaiser,...
    Analysis="impulse");
legend(hfvt,{'Equiripple','Kaiser'})

```

Plot the magnitude and phase response.

If the filter specifications are tight, say a very high filter order with a very narrow transition width, the filter designed using the "Kaiser" method converges more effectively.

```

hvftMag = fvtool(firhalfbanddecimEqui,firhalfbanddecimKaiser,...
    Analysis="Magnitude");
legend(hvftMag,{'Equiripple','Kaiser'})

```

```
hvftPhase = fvtool(firhalfbanddecimEqui, firhalfbanddecimKaiser, ...  
    Analysis="Phase");  
legend(hvftPhase, {'Equiripple', 'Kaiser'})
```

### Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum-order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```

Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter(SampleRate=Fs,...
    FilterType=filtertype,...
    PassbandFrequency=Fpass,...
    StopbandFrequency=Fstop,...
    PassbandRipple=Rp,...
    StopbandAttenuation=Astop);

```

Design a minimum-order IIR lowpass filter with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to IIR.

```

IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';

```

Plot the impulse response of the FIR lowpass filter. The zeroth-order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,Analysis='impulse')
```

Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF,Analysis='impulse')
```

Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,Analysis='freq')
```

Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF,Analysis='freq')
```

Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than the FIR filter.

```
cost(IIRLPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```

Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`

- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

```
Example: firFilt = dsp.FIRFilter('Numerator', fir1(130, 2000/(8000/2)));
fvtool(firFilt)
```

### options — Filter analysis options

'magnitude' (default) | 'phase' | 'freq' | 'grpdelay' | 'phasedelay' | 'impulse' | 'step' | 'polezero' | 'coefficients' | 'info' | 'magestimate' | 'noisepower'

Filter analysis options, specified as one of the following:

- 'magnitude' -- Magnitude response
- 'phase' -- Phase response
- 'freq' -- Frequency response
- 'grpdelay' -- Group delay
- 'phasedelay' -- Phase delay
- 'impulse' -- Impulse response
- 'step' -- Step response
- 'polezero' -- Pole zero plot
- 'coefficients' -- Coefficients vector
- 'info' -- Filter information
- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

```
Example: fvtool(firFilt, 'freq')
```

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

```
Example: firFilt = dsp.FIRFilter('Numerator', fir1(130, 2000/(8000/2)));  
fvtool(firFilt, 'Arithmetic', 'single')
```

### **Fs — Sampling rate**

scalar

Sampling rate, specified as a scalar. This value determines the Nyquist interval  $[-Fs/2 \ Fs/2]$  in which the fvtool shows the frequency response of the filters in the channelizer.

Data Types: `single` | `double`

### **Arithmetic — Arithmetic type**

`'double'` (default) | `'single'` | `'Fixed'`

Specify the arithmetic used during analysis. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is unlocked. The `'Arithmetic'` property set to `'Fixed'` applies only to filter System objects with fixed-point properties.

When the `'Arithmetic'` property is set to `'Fixed'`, the tool shows both the double-precision reference filter and the quantized version of the filter. The `CoefficientsDataType` property in the respective filter System object is used in creating the quantized version of the filter for all the analyses options except for the two below:

- `'magestimate'` -- Magnitude response estimate.
- `'noisepower'` -- Round-off noise power spectrum

For these two analyses options, all the fixed-point settings are used in analyzing the quantized version of the filter.

## **Version History**

Introduced before R2006a

## **See Also**

### **Tools**

FVTool

### **Topics**

“Analysis Methods for Filter System Objects” on page 3-2

## fvtool

**Package:** dsp

Visualize the filters in the channelizer

### Syntax

```
fvtool(obj)
fvtool(obj,ind)
fvtool(obj,ind,Name,Value)
```

### Description

`fvtool(obj)` visualizes the filters in the `dsp.Channelizer System` object using the Filter Visualization Tool (FVTool).

`fvtool(obj,ind)` visualizes the filters corresponding to the indices in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where `N` is the smallest of `obj.NumFrequencyBands` and 64.

For example, to visualize the first 4 filters, set `ind` to `[1:4]`.

```
channelizer = dsp.Channelizer;
fvtool(channelizer,[1:4]);
```

`fvtool(obj,ind,Name,Value)` visualizes the filters with additional options specified by one or more `Name,Value` pair arguments.

For example, to visualize the first 4 filters in the channelizer over the Nyquist interval  $[-44100/2, 44100/2]$  Hz, set `'Fs'` to 44100. To compute the frequency response using 1024 frequency points, set `'NFFT'` to 1024. In addition, to visualize sum of the filter responses, set `'overall'` to `true`.

```
channelizer = dsp.Channelizer;
fvtool(channelizer,[1:4],'Fs',44100,'NFFT',1024,'overall',true);
```

### Examples

#### Visualize Filters in Channelizer

Using the `fvtool` function, you can visualize the individual filter responses or sum of all the filter responses in the channelizer filter bank.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. View the response of the filter bank.

```
channelizer = dsp.Channelizer;
fvtool(channelizer)
```

The `fvtool` shows the response of the lowpass prototype filter and all the modulated filters. To view only a portion of the filter bank, specify the indices in `ind`. To view the response of the first 4 filters, set `ind` to `[1:4]`.

```
fvtool(channelizer,(1:4));
```

You can change the Nyquist interval to [-22,050 22,050] Hz and the number of frequency points to 1024.

```
fvtool(channelizer,(1:4),'Fs',44100,'NFFT',1024);
```

To see the sum of the responses of all 4 filters, set the 'overall' argument to true.

```
fvtool(channelizer,(1:4),'Fs',44100,'NFFT',1024,'overall',true);
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as a `dsp.Channelizer` System object.

Example: `channelizer = dsp.Channelizer; fvtool(channelizer);`

### **ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range `[1 obj.NumFrequencyBands]`. By default, `ind` is set to `1:N`, where  $N$  is the smallest of `obj.NumFrequencyBands` and 64.

Example: `fvtool(channelizer,[1:4]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `fvtool(channelizer,'Fs',44100,'NFFT',1024,'overall',true);`

### **Fs — Sampling rate**

scalar

Sampling rate, specified as a scalar. This value determines the Nyquist interval  $[-Fs/2 \ Fs/2]$  in which the `fvtool` shows the frequency response of the filters in the channelizer.

Example: 44100

Example: 22050

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **NFFT — Number of frequency points used to compute the frequency response**

8192 (default) | positive scalar

Number of frequency points used to compute the frequency response, specified as a positive scalar.

Example: 8192

Example: 1024

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **overall — Type of filter response**

`false` (default) | `true`

Type of filter response, specified as either:

- `true` -- `fvtool` shows the sum of the filter responses.
- `false` -- `fvtool` shows the individual filter responses.

Data Types: `logical`

## fvtool

**Package:** dsp

Visualize frequency response of coupled allpass filter

### Syntax

```
fvtool(caf)
fvtool(caf,options)
fvtool(____,Name,Value)
```

### Description

`fvtool(caf)` displays the magnitude response of the coupled allpass filter System object.

`fvtool(caf,options)` displays the response that is specified by the options. For example, to visualize the impulse response of a coupled allpass filter System object, set options to 'impulse'.

```
caf = dsp.CoupledAllpassFilter;
fvtool(caf,'impulse');
```

`fvtool(____,Name,Value)` visualizes the response of the filter with each specified property set to the specified value.

For more input options, see **FVTool**.

### Examples

#### View Power Complementary Output of Coupled Allpass Filter

Design a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;    % in Hz
Fc = 12000;   % in Hz
frameLength = 1024;
[b,a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1,c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
```

Using the 'SubbandView' option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, the power complementary highpass filter output, or both using the `fvtool`.

To view the lowpass filter output, set 'SubbandView' to 1.

```
fvtool(caf,'SubbandView',1,'Fs',Fs)
```

To view the highpass filter output, set 'SubbandView' to 2.

```
fvtool(caf, 'SubbandView', 2, 'Fs', Fs)
```

To view both the outputs, set 'SubbandView' to 'all', [1 2] or [1;2].

```
fvtool(caf, 'SubbandView', 'all', 'Fs', Fs);
```

## Input Arguments

### caf — Input filter

filter System object

Input filter, specified as a `dsp.CoupledAllpassFilter` System object.

Example: `caf = dsp.CoupledAllpassFilter; fvtool(caf)`

### options — Filter analysis options

'magnitude' (default) | 'phase' | 'freq' | 'grpdelay' | 'phasedelay' | 'impulse' | 'step' | 'polezero' | 'coefficients' | 'info' | 'magestimate' | 'noisepower'

Filter analysis options, specified as one of the following:

- 'magnitude' -- Magnitude response
- 'phase' -- Phase response
- 'freq' -- Frequency response
- 'grpdelay' -- Group delay
- 'phasedelay' -- Phase delay
- 'impulse' -- Impulse response
- 'step' -- Step response

- 'polezero' -- Pole zero plot
- 'coefficients' -- Coefficients vector
- 'info' -- Filter information
- 'magemestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

Example: `fvtool(caf, 'freq')`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `caf = dsp.CoupledAllpassFilter;`  
`fvtool(caf, 'SubbandView', 'all', 'Arithmetic', 'single')`

### SubbandView — Subband view

1 (default) | 2 | 'all' | [1 2] | [1;2]

Specify the subband to be viewed. You can set this property to one of the following:

- 1 -- Display the lowpass filter output.
- 2 -- Display the power complimentary highpass filter output.
- 'all', [1 2], [1;2] -- Display both the outputs.

### Fs — Sampling rate

scalar

Sampling rate, specified as a scalar. This value determines the Nyquist interval  $[-Fs/2 \ Fs/2]$  in which FVTool shows the frequency response of the filters in the channelizer.

Data Types: `single` | `double`

### Arithmetic — Arithmetic type

'double' (default) | 'single'

Specify the arithmetic used during analysis. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is unlocked.

## Version History

#### Functions

`getBranches`

#### Tools

**FVTool**

**Objects**`dsp.CoupledAllpassFilter`

## gain

**Package:** dsp

Gain of CIC filter System object

### Syntax

```
g = gain(sysobj)
g = gain(sysobj,j)
```

### Description

`g = gain(sysobj)` returns the gain of the CIC filter System object.

When `sysobj` is a `dsp.CICDecimator` object, the `gain` function returns the gain for the overall CIC decimator.

When `sysobj` is a `dsp.CICInterpolator` object, the `gain` function returns the gain of the  $2N^{\text{th}}$  stage of the CIC interpolation filter, where  $N$  is the number of filter sections. For more details, see `g`.

`g = gain(sysobj,j)` returns the gain of the  $j^{\text{th}}$  section of a CIC interpolation filter. When you omit `j`, the function assumes that `j` is  $2N$ , and returns the gain of the last section of the filter. This syntax does not apply when `sysobj` is a `dsp.CICDecimator` object.

### Examples

#### Compare Performance of Interpolation Filters

To compare the performance of two interpolators, one a CIC filter and the other an FIR filter, use the `gain` function to adjust the CIC filter output amplitude to match the FIR filter output amplitude.

Start by creating an input data set, a sinusoidal signal `x`.

```
fs = 1000;           % Input sampling frequency.
t = (0:1/fs:1.5)';  % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
```

Design a cascade of two `dsp.FIRInterpolator` objects with an overall interpolation factor of 4.

```
l = 4; % Interpolation factor for FIR filter.
firInterp = designMultistageInterpolator(l)
```

```
firInterp =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    CloneStages: false
```

Run the data through the interpolator.

```
yfir = firInterp(x);
```

Design a `dsp.CICInterpolator` object with an interpolation factor set 4, differential delay set to 1, and the number of sections set to 4.

```
r = 4; % Interpolation factor for the CIC filter.
cicInterp = dsp.CICInterpolator(r,1,4);
```

Run the same data through the filter.

```
ycic = cicInterp(x);
```

Use the `gain` function to adjust the CIC filter output amplitude to match the FIR filter output amplitude.

```
gaincic = gain(cicInterp);
subplot(211);
plot([yfir; double(ycic)]);
subplot(212)
plot([yfir; double(ycic)/gain(cicInterp)]);
```

After correcting for the gain induced by the CIC interpolator, in the second subplot you can see that the FIR filter and the CIC filter provide nearly identical interpolation.

This gain equals the gain of the last section of the CIC filter. To confirm, correct the FIR filter amplitude using `gain(cicInterp,2N)`. If  $N$  is the number of integrator and comb sections of the CIC filter, then  $2N$  is the last section of the CIC filter.  $N$  is given by `cicInterp.NumSections`.

The second subplot shows that the FIR filter and CIC filter provide nearly identical interpolation when the correction gain equals the gain of the last section of the CIC filter.

```
subplot(212);
plot([yfir; double(ycic)/gain(cicInterp,2*cicInterp.NumSections)]);
```

## Input Arguments

### **sysobj** — Input CIC filter

CIC filter System object

Input CIC filter, specified as one of the following filter System objects:

- `dsp.CICDecimator`
- `dsp.CICInterpolator`

### **j** — Index of the CIC interpolator stage

positive scalar

Index of the CIC interpolator stage for which the gain is computed, specified as a positive scalar.

Data Types: `single` | `double`

## Output Arguments

### **g** — Gain of CIC filter

scalar

Gain of the CIC filter, returned a scalar. When the input `sysobj` is:

- `dsp.CICDecimator` -- The gain function returns the gain for the overall CIC decimator.
- `dsp.CICInterpolator` -- The CIC interpolator inserts zeros into the input data stream, reducing the filter overall gain by  $1/R$ , where  $R$  is the interpolation factor, to account for the added zero-valued samples. Therefore, the gain of a CIC interpolator is  $(RM)^N/R$ , where  $N$  is the number of filter sections and  $M$  is the filter differential delay. The gain function returns this value.

Data Types: `single` | `double`

## Version History

Introduced in R2011a

# generatehdl

**Package:** dsp

Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

## Syntax

```
generatehdl(filtS0, 'InputDataType', nt)
generatehdl(filtS0, 'InputDataType', nt, 'FractionalDelayDataType', fd)
generatehdl(filterObj)

generatehdl( ____, Name, Value)
```

## Description

`generatehdl(filtS0, 'InputDataType', nt)` generates HDL code for the specified filter System object and the input data type, `nt`.

The generated file is a single source file that includes the entity declaration and architecture code. You can find this file in your current working folder, inside the `hdlsrc` subfolder.

`generatehdl(filtS0, 'InputDataType', nt, 'FractionalDelayDataType', fd)` generates HDL code for a `dsp.VariableFractionalDelay` filter System object. Specify the input data type, `nt`, and the fractional delay data type, `fd`.

`generatehdl(filterObj)` generates HDL code for the specified `dfilt` filter object using default settings.

`generatehdl( ____, Name, Value)` uses optional name-value arguments, in addition to the input arguments in previous syntaxes. Use these properties to override default HDL code generation settings.

For more details, see the corresponding properties in the Filter Design HDL Coder documentation:

- To customize filter name, destination folder, and to specify target language, see Fundamental HDL Code Generation Properties.
- To configure coefficients, complex input ports, and optional ports for specific filter types, see HDL Filter Configuration Properties.
- To optimize the speed or area of generated HDL code, see HDL Optimization Properties.
- To customize ports, identifiers, and comments, see HDL Ports and Identifiers Properties.
- To customize HDL constructs, see HDL Constructs Properties.
- To generate and customize test bench, see HDL Test Bench Properties.
- To integrate third-party EDA tools into the filter design workflow, see Synthesis and Workflow Automation Properties.

## Examples

## Generate HDL Code for FIR Equiripple Filter

Design a direct form symmetric equiripple filter with these specifications:

- Normalized passband frequency of 0.2
- Normalized stopband frequency of 0.22
- Passband ripple of 1 dB
- Stopband attenuation of 60 dB

The design function returns a `dsp.FIRFilter` System object™ that implements the specification.

```
filtSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.22,1,60);
FIRe = design(filtSpecs,'equiripple','FilterStructure','dfsymfir','SystemObject',true)

FIRe =
    dsp.FIRFilter with properties:

        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [-0.0011 -0.0017 -0.0025 -0.0031 -0.0031 -0.0024 -9.7703e-04 0.0010 0.0031]
    InitialConditions: 0

    Show all properties
```

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input using the “InputDataType” (Filter Design HDL Coder) property. The coder generates the file `MyFilter.vhd` in the default target folder, `hdlsrc`.

```
generatehdl(FIRe,'InputDataType',numeric(1,16,15),'Name','MyFilter');

### Starting VHDL code generation process for filter: MyFilter
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex48836167\hdlsrc\
### Starting generation of MyFilter VHDL entity
### Starting generation of MyFilter VHDL architecture
### Successful completion of VHDL code generation process for filter: MyFilter
### HDL latency is 2 samples
```

## Generate HDL Code and Test Bench for FIR Equiripple Filter

Design a direct form symmetric equiripple filter with these specifications:

- Normalized passband frequency of 0.2
- Normalized stopband frequency of 0.22
- Passband ripple of 1 dB
- Stopband attenuation of 60 dB

The design function returns a `dsp.FIRFilter` System object™ that implements the specification.

```
filtSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.22,1,60);
FIRe = design(filtSpecs,'equiripple','FilterStructure','dfsymfir','SystemObject',true)

FIRe =
    dsp.FIRFilter with properties:
```

```

        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [-0.0011 -0.0017 -0.0025 -0.0031 -0.0031 -0.0024 -9.7703e-04 0.0010 0.0031]
    InitialConditions: 0

```

Show all properties

Generate VHDL code and a VHDL test bench for the FIR equiripple filter. When the filter is a System object, you must specify a fixed-point data type for the input data type. The coder generates the files `MyFilter.vhd` and `MyFilterTB.vhd` in the default target folder, `hdlsrc`.

```

generatehdl(FIR,'InputDataType',numerictype(1,16,15),'Name','MyFilter',...
    'GenerateHDLTestbench','on','TestBenchName','MyFilterTB')

### Starting VHDL code generation process for filter: MyFilter

```

### Generate HDL Code for Fully Parallel FIR Filter with Programmable Coefficients

Design a direct form symmetric equiripple filter with fully parallel (default) architecture and programmable coefficients. The `design` function returns a `dsp.FIRFilter` System object™ with default lowpass filter specification.

```
firfilt = design(fdesign.lowpass,'equiripple','FilterStructure','dfsymfir','SystemObject',true)
```

```

firfilt =
    dsp.FIRFilter with properties:
        Structure: 'Direct form symmetric'
    NumeratorSource: 'Property'
        Numerator: [-0.0024 -0.0021 0.0068 0.0167 0.0111 -0.0062 -0.0084 0.0093 0.0130 -0.0130]
    InitialConditions: 0

```

Show all properties

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data. To generate a processor interface for the coefficients, you must specify an additional name-value pair argument.

```

generatehdl(firfilt,'InputDataType',numerictype(1,16,15),'CoefficientSource','ProcessorInterface')

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex74213987\hdlsrc\

```

```

### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples

```

The coder generates this VHDL entity for the filter object.

```

ENTITY firfilt IS
  PORT( clk      : IN      std_logic;
        clk_enable : IN      std_logic;
        reset     : IN      std_logic;
        filter_in  : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En15
        write_enable : IN      std_logic;
        write_done  : IN      std_logic;
        write_address : IN      std_logic_vector(4 DOWNTO 0); -- ufix5
        coeffs_in   : IN      std_logic_vector(15 DOWNTO 0); -- sfix16_En16
        filter_out  : OUT     std_logic_vector(36 DOWNTO 0) -- sfix37_En31
        );
END firfilt;

```

### Generate Partly Serial FIR Filter with Programmable Coefficients

Create a direct form antisymmetric filter with coefficients:

```

coeffs = fir1(22,0.45);
firfilt = dsp.FIRFilter('Numerator',coeffs,'Structure','Direct form antisymmetric')

```

```

firfilt =
  dsp.FIRFilter with properties:
      Structure: 'Direct form antisymmetric'
      NumeratorSource: 'Property'
      Numerator: [3.6133e-04 0.0031 8.4473e-04 -0.0090 -0.0072 0.0203 0.0272 -0.0341 -0.07
      InitialConditions: 0

```

Show all properties

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data. To generate a partly serial architecture, specify a serial partition. To enable `CoefficientMemory` property, you must set `CoefficientSource` to `ProcessorInterface`.

```

generatehdl(firfilt,'InputDataType',numerictype(1,16,15), ...
  'SerialPartition',[7 4],'CoefficientMemory','DualPortRAMs', ...
  'CoefficientSource','ProcessorInterface')

```

```

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex21465785\hdlsrc\
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 7 times the input sample rate for this architecture.

```

```
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples
```

The generated code includes a dual-port RAM interface for the programmable coefficients.

```
ENTITY firfilt IS
  PORT ( clk          : IN      std_logic;
         clk_enable   : IN      std_logic;
         reset        : IN      std_logic;
         filter_in    : IN      std_logic_vector(15 DOWNT0 0); -- sfix16_En15
         write_enable  : IN      std_logic;
         write_done    : IN      std_logic;
         write_address : IN      std_logic_vector(3 DOWNT0 0); -- ufix4
         coeffs_in    : IN      std_logic_vector(15 DOWNT0 0); -- sfix16_En16
         filter_out    : OUT     std_logic_vector(35 DOWNT0 0) -- sfix36_En31
        );
END firfilt;
```

### Generate Serial Partitions for FIR Filter

Explore clock rate and latency for different serial implementations of the same filter. Using a symmetric structure also allows the filter logic to share multipliers for symmetric coefficients.

Create a direct form symmetric FIR filter with these specifications:

- Filter order 13
- Normalized cut-off frequency of 0.4 for the 6-dB point

The design function returns a `dsp.FIRFilter` System object™ that implements the specification.

```
FIR = design(fdesign.lowpass('N,Fc',13,.4), 'FilterStructure', 'dfsymfir', 'SystemObject', true)
```

```
FIR =
```

```
  dsp.FIRFilter with properties:
```

```
      Structure: 'Direct form symmetric'
      NumeratorSource: 'Property'
      Numerator: [0.0037 0.0045 -0.0115 -0.0417 1.0911e-17 0.1776 0.3674 0.3674 0.1776 1.0911e-17 -0.0417 -0.0115 0.0045 0.0037]
      InitialConditions: 0
```

```
Show all properties
```

To generate HDL code, call the `generatehdl` function. When the filter is a System object, you must specify a fixed-point data type for the input data.

For a baseline comparison, first generate a default fully parallel architecture.

```
generatehdl(FIR, 'Name', 'FullyParallel', ...
            'InputDataType', numerictype(1,16,15))

### Starting VHDL code generation process for filter: FullyParallel
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex94948885\hdlsrc\
```

```
### Starting generation of FullyParallel VHDL entity
### Starting generation of FullyParallel VHDL architecture
### Successful completion of VHDL code generation process for filter: FullyParallel
### HDL latency is 2 samples
```

Generate a fully serial architecture by setting the partition size to the effective filter length. The system clock rate is six times the input sample rate. The reported HDL latency is one sample greater than the default parallel implementation.

```
generatehdl(FIR, 'SerialPartition', 6, 'Name', 'FullySerial', ...
            'InputDataType', numeric_type(1, 16, 15))
```

```
### Starting VHDL code generation process for filter: FullySerial
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex94948885\hdlsrc\
### Starting generation of FullySerial VHDL entity
### Starting generation of FullySerial VHDL architecture
### Clock rate is 6 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: FullySerial
### HDL latency is 3 samples
```

Generate a partly serial architecture with three equal partitions. This architecture uses three multipliers. The clock rate is two times the input rate, and the latency is the same as the default parallel implementation.

```
generatehdl(FIR, 'SerialPartition', [2 2 2], 'Name', 'PartlySerial', ...
            'InputDataType', numeric_type(1, 16, 15))
```

```
### Starting VHDL code generation process for filter: PartlySerial
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex94948885\hdlsrc\
### Starting generation of PartlySerial VHDL entity
### Starting generation of PartlySerial VHDL architecture
### Clock rate is 2 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: PartlySerial
### HDL latency is 3 samples
```

Generate a cascade-serial architecture by enabling accumulator reuse. Specify the three partitions in descending order of size. Notice that the clock rate is higher than the rate in the partly serial (without accumulator reuse) example.

```
generatehdl(FIR, 'SerialPartition', [3 2 1], 'ReuseAccum', 'on', 'Name', 'CascadeSerial', ...
            'InputDataType', numeric_type(1, 16, 15))
```

```
### Starting VHDL code generation process for filter: CascadeSerial
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex94948885\hdlsrc\
### Starting generation of CascadeSerial VHDL entity
### Starting generation of CascadeSerial VHDL architecture
### Clock rate is 4 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: CascadeSerial
### HDL latency is 3 samples
```

You can also generate a cascade-serial architecture without specifying the partitions explicitly. The coder automatically selects partition sizes.

```
generatehdl(FIR, 'ReuseAccum', 'on', 'Name', 'CascadeSerial', ...
            'InputDataType', numeric_type(1, 16, 15))
```

```
### Starting VHDL code generation process for filter: CascadeSerial

```

### Generate Serial Partitions of Cascaded Filter

Create a two-stage cascaded filter with these specifications for each filter stage:

- Direct form symmetric FIR filter
- Filter order 8
- Normalized cut-off frequency of 0.4 for the 6-dB point

Each call of the `design` function returns a `dsp.FIRFilter` System object™ that implements the specification. The `cascade` function returns a two-stage cascaded filter.

```

lp = design(fdesign.lowpass('N,Fc',8,.4),'FilterStructure','dfsymfir','SystemObject',true)
lp =
    dsp.FIRFilter with properties:
        Structure: 'Direct form symmetric'
        NumeratorSource: 'Property'
        Numerator: [-0.0061 -0.0136 0.0512 0.2657 0.4057 0.2657 0.0512 -0.0136 -0.0061]
        InitialConditions: 0
    Show all properties

hp = design(fdesign.highpass('N,Fc',8,.4),'FilterStructure','dfsymfir','SystemObject',true)
hp =
    dsp.FIRFilter with properties:
        Structure: 'Direct form symmetric'
        NumeratorSource: 'Property'
        Numerator: [0.0060 0.0133 -0.0501 -0.2598 0.5951 -0.2598 -0.0501 0.0133 0.0060]
        InitialConditions: 0
    Show all properties

casc = cascade(lp, hp)
casc =
    dsp.FilterCascade with properties:
        Stage1: [1x1 dsp.FIRFilter]
        Stage2: [1x1 dsp.FIRFilter]
        CloneStages: true

```

To generate HDL code, call the `generatehdl` function for the cascaded filter. When the filter is a System object, you must specify a fixed-point data type for the input data.

Specify different partitions for each cascade stage as a cell array.

```
generatehdl(casc, 'InputDataType', numerictype(1,16,15), 'SerialPartition', {[3 2],[4 1]})
```

```
### Starting VHDL code generation process for filter: casfilt

### HDL latency is 2 samples
```

To explore the effective filter length and partitioning options for each filter stage of a cascade, call the `hdlfilterserialinfo` function. The function returns a partition vector corresponding to a desired number of multipliers. Request serial partition possibilities for the first stage, and choose a number of multipliers.

```
hdlfilterserialinfo(casc.Stage1, 'InputDataType', numerictype(1,16,15))
```

| Total Coefficients | Zeros | A/Symm | Effective |
|--------------------|-------|--------|-----------|
| 9                  | 0     | 4      | 5         |

Effective filter length for SerialPartition value is 5.

Table of 'SerialPartition' values with corresponding values of folding factor and number of multipliers for the given filter.

| Folding Factor | Multipliers | SerialPartition |
|----------------|-------------|-----------------|
| 1              | 5           | [1 1 1 1 1]     |
| 2              | 3           | [2 2 1]         |
| 3              | 2           | [3 2]           |
| 4              | 2           | [4 1]           |
| 5              | 1           | [5]             |

Select a serial partition vector for a target of two multipliers, and pass the vectors to the `generatehdl` function. Calling the function this way returns the first possible partition vector, but there are multiple partition vectors that achieve a two-multiplier architecture. Each stage uses a different clock rate based on the number of multipliers. The coder generates a timing controller to derive these clocks.

```

sp1 = hdlfilterserialinfo(casc.Stage1, 'InputDataType', numerictype(1,16,15), 'Multiplier', 2)
sp1 = 1×2
      3      2

sp2 = hdlfilterserialinfo(casc.Stage2, 'InputDataType', numerictype(1,16,15), 'Multiplier', 3)
sp2 = 1×3
      2      2      1

### Generate Serial Architectures for IIR Filter

Create a direct form I SOS filter with these specifications:

- Sampling frequency of 48 kHz
- Filter order 5
- Cut-off frequency of 10.8 kHz for the 3 dB point

The design function returns a `dsp.BiquadFilter` System object™ that implements the specification. The custom accumulator data type avoids quantization error.

```

Fs = 48e3;
Fc = 10.8e3;
N = 5;
lp = design(fdesign.lowpass('n,f3db',N,Fc,Fs), 'butter', ...
    'FilterStructure', 'df1sos', 'SystemObject', true, 'UseLegacyBiquadFilter', true)
lp =
    dsp.BiquadFilter with properties:

```

```

        Structure: 'Direct form I'
        SOSMatrixSource: 'Property'
        SOSMatrix: [3x6 double]
        ScaleValues: [4x1 double]
        NumeratorInitialConditions: 0
        DenominatorInitialConditions: 0
        OptimizeUnityScaleValues: true

```

Show all properties

```

nt_accum = numericitytype('Signedness','auto','WordLength',20, ...
    'FractionLength',15);
nt_input = numericitytype(1,16,15);
lp.NumeratorAccumulatorDataType = 'Custom';
lp.CustomNumeratorAccumulatorDataType = nt_accum;
lp.DenominatorAccumulatorDataType = 'Custom';
lp.CustomDenominatorAccumulatorDataType = nt_accum;

```

To list all possible serial architecture specifications for this filter, call the `hdlfilterserialinfo` function. When the filter is a System object, you must specify a fixed-point data type for the input data.

```
hdlfilterserialinfo(lp,'InputDataType',nt_input)
```

Table of folding factors with corresponding number of multipliers for the given filter.

| Folding factor | Multipliers |
|----------------|-------------|
| 6              | 3           |
| 9              | 2           |
| 18             | 1           |

To generate HDL code, call the `generatehdl` function with one of the serial architectures. Specify either the `NumMultipliers` or `FoldingFactor` property, but not both. For instance, using the `NumMultipliers` property:

```
generatehdl(lp,'NumMultipliers',2,'InputDataType',nt_input)
```

```

### Starting VHDL code generation process for filter: lp
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex90334139\hdlsrc\
### Starting generation of lp VHDL entity
### Starting generation of lp VHDL architecture
### Successful completion of VHDL code generation process for filter: lp
### HDL latency is 2 samples

```

Alternatively, specify the same architecture with the `FoldingFactor` property.

```
generatehdl(lp,'FoldingFactor',9,'InputDataType',nt_input)
```

```

### Starting VHDL code generation process for filter: lp
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex90334139\hdlsrc\
### Starting generation of lp VHDL entity
### Starting generation of lp VHDL architecture
### Successful completion of VHDL code generation process for filter: lp
### HDL latency is 2 samples

```

Both these commands generate a filter that uses a total of two multipliers, with a latency of nine clock cycles. This architecture uses less area than the parallel implementation, at the expense of latency.

### Distributed Arithmetic for Single Rate Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

Create a direct-form FIR filter and calculate the filter length, FL.

```
filtdes = fdesign.lowpass('N,Fc,Ap,Ast',30,0.4,0.05,0.03,'linear');
firfilt = design(filtdes,'FilterStructure','dffir','SystemObject',true);
FL = length(find(firfilt.Numerator ~= 0))
```

```
FL = 31
```

Specify a set of partitions such that the partition sizes add up to the filter length. This is just one partition option, you can specify other combinations of sizes.

```
generatehdl(firfilt,'InputDataType',numeric(1,16,15), ...
'DALUTPartition',[8 8 8 7])
```

```
### Structure fir has symmetric coefficients, consider converting to structure symmetricfir for
### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex00198568\hdlsrc\
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 16 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples
```

For comparison, create a direct-form symmetric FIR filter. The filter length is smaller in the symmetric case.

```
filtdes = fdesign.lowpass('N,Fc,Ap,Ast',30,0.4,0.05,0.03,'linear');
firfilt = design(filtdes,'FilterStructure','dfsymfir','SystemObject',true);
FL = ceil(length(find(firfilt.Numerator ~= 0))/2)
```

```
FL = 16
```

Specify a set of partitions such that the partition sizes add up to the filter length. This is just one partition option, you can specify other combinations of sizes. **Tip:** Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible DARadix values for a filter.

```
generatehdl(firfilt,'InputDataType',numeric(1,16,15), ...
'DALUTPartition',[8 8])
```

```
### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex00198568\hdlsrc\
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Clock rate is 17 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 3 samples
```

## Distributed Arithmetic for Multirate Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

Create a direct-form FIR polyphase decimator, and calculate the filter length.

```
d = fdesign.decimator(4);
filt = design(d, 'SystemObject', true);
FL = size(polyphase(filt), 2)
```

```
FL = 27
```

Specify distributed arithmetic LUT partitions that add up to the filter size. When you specify partitions as a vector for a polyphase filter, each subfilter uses the same partitions.

```
generatehdl(filt, 'InputDataType', numerictype(1, 16, 15), ...
    'DALUTPartition', [8 8 8 3])
```

```
### Starting VHDL code generation process for filter: firdecim
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex51670151\hdlsrc\
### Starting generation of firdecim VHDL entity
### Starting generation of firdecim VHDL architecture
### Clock rate is 4 times the input and 16 times the output sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firdecim
### HDL latency is 16 samples
```

You can also specify unique partitions for each subfilter. For the same filter, specify subfilter partitioning as a matrix. The length of the first subfilter is 1, and the other subfilters have length 26.

**Tip:** Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible DARadix values for a filter.

```
d = fdesign.decimator(4);
filt = design(d, 'SystemObject', true);
generatehdl(filt, 'InputDataType', numerictype(1, 16, 15), ...
    'DALUTPartition', [1 0 0 0; 8 8 8 2; 8 8 6 4; 8 8 8 2])
```

```
### Starting VHDL code generation process for filter: firdecim
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex51670151\hdlsrc\
### Starting generation of firdecim VHDL entity
### Starting generation of firdecim VHDL architecture
### Clock rate is 4 times the input and 16 times the output sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: firdecim
### HDL latency is 16 samples
```

## Distributed Arithmetic for Cascaded Filters

Use distributed arithmetic options to reduce the number of multipliers in the filter implementation.

### Create Cascaded Filter

Create a two-stage cascaded filter. Define different LUT partitions for each stage, and specify the partition vectors in a cell array.

```

lp = design(fdesign.lowpass('N,Fc',8,.4), 'filterstructure', 'dfsymfir', ...
  'SystemObject', true);
hp = design(fdesign.highpass('N,Fc',8,.4), 'filterstructure', 'dfsymfir', ...
  'SystemObject', true);
casc = cascade(lp, hp);
nt1 = numerictype(1,12,10);
generatehdl(casc, 'InputDataType', nt1, 'DALUTPartition', {[3 2],[2 2 1]})

### Starting VHDL code generation process for filter: casfilt
### Cascade stage # 1
### Starting VHDL code generation process for filter: casfilt_stage1
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex17169310\hdlsrc\
### Starting generation of casfilt_stage1 VHDL entity
### Starting generation of casfilt_stage1 VHDL architecture
### Clock rate is 13 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: casfilt_stage1
### Cascade stage # 2
### Starting VHDL code generation process for filter: casfilt_stage2
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex17169310\hdlsrc\
### Starting generation of casfilt_stage2 VHDL entity
### Starting generation of casfilt_stage2 VHDL architecture
### Clock rate is 29 times the input sample rate for this architecture.
### Successful completion of VHDL code generation process for filter: casfilt_stage2
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex17169310\hdlsrc\
### Starting generation of casfilt VHDL entity
### Starting generation of casfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: casfilt
### HDL latency is 4 samples

```

### Distributed Arithmetic Options

Use the `hdlfilterdainfo` function to display the effective filter length, LUT partitioning options, and possible DARadix values for each filter stage of a cascade. The function returns a LUT partition vector corresponding to a desired number of address bits.

Request LUT partition possibilities for the first stage.

```
hdlfilterdainfo(casc.Stage1, 'InputDataType', nt1);
```

| Total Coefficients | Zeros | A/Symm | Effective |
|--------------------|-------|--------|-----------|
| 9                  | 0     | 4      | 5         |

Effective filter length for SerialPartition value is 5.

Table of 'DARadix' values with corresponding values of folding factor and multiple for LUT sets for the given filter.

| Folding Factor | LUT-Sets Multiple | DARadix         |
|----------------|-------------------|-----------------|
| 1              | 12                | 2 <sup>12</sup> |
| 3              | 6                 | 2 <sup>6</sup>  |
| 4              | 4                 | 2 <sup>4</sup>  |
| 5              | 3                 | 2 <sup>3</sup>  |
| 7              | 2                 | 2 <sup>2</sup>  |
| 13             | 1                 | 2 <sup>1</sup>  |

Details of LUTs with corresponding 'DALUTPartition' values.

| Max Address Width | Size(bits) | LUT Details           | DALUTPartition |
|-------------------|------------|-----------------------|----------------|
| 5                 | 416        | 1x32x13               | [5]            |
| 4                 | 216        | 1x16x12, 1x2x12       | [4 1]          |
| 3                 | 124        | 1x4x13, 1x8x9         | [3 2]          |
| 2                 | 104        | 1x2x12, 1x4x12, 1x4x8 | [2 2 1]        |

Notes:

- LUT Details indicates number of LUTs with their sizes. e.g. 1x1024x18 implies 1 LUT of 1024 18-bit wide locations.

To request LUT partition possibilities for the second stage, you must first determine the input data type of the second stage.

```
y = casc.Stage1(fi(0,nt1));
nt2 = y.numericType;
hdlfilterdainfo(casc.Stage2,'InputDataType',nt2);
```

| Total Coefficients | Zeros | A/Symm | Effective |
|--------------------|-------|--------|-----------|
| 9                  | 0     | 4      | 5         |

Effective filter length for SerialPartition value is 5.

Table of 'DARadix' values with corresponding values of folding factor and multiple for LUT sets for the given filter.

| Folding Factor | LUT-Sets Multiple | DARadix         |
|----------------|-------------------|-----------------|
| 1              | 28                | 2 <sup>28</sup> |
| 3              | 14                | 2 <sup>14</sup> |
| 5              | 7                 | 2 <sup>7</sup>  |
| 8              | 4                 | 2 <sup>4</sup>  |
| 15             | 2                 | 2 <sup>2</sup>  |
| 29             | 1                 | 2 <sup>1</sup>  |

Details of LUTs with corresponding 'DALUTPartition' values.

| Max Address Width | Size(bits) | LUT Details            | DALUTPartition |
|-------------------|------------|------------------------|----------------|
| 5                 | 896        | 1x32x28                | [5]            |
| 4                 | 488        | 1x16x27, 1x2x28        | [4 1]          |
| 3                 | 304        | 1x4x28, 1x8x24         | [3 2]          |
| 2                 | 256        | 1x2x28, 1x4x23, 1x4x27 | [2 2 1]        |

Notes:

- LUT Details indicates number of LUTs with their sizes. e.g. 1x1024x18 implies 1 LUT of 1024 18-bit wide locations.

### Different LUT Partitions for Each Stage

Select address widths and folding factors to obtain LUT partition for each stage. The first stage uses LUTs with a maximum address size of five bits. The second stage uses LUTs with a maximum address size of three bits. They run at the same clock rate, and have different LUT partitions.

```
dp1 = hdlfilterdainfo(casc.Stage1,'InputDataType',nt1, ...
    'LUTInputs',5,'FoldingFactor',3);
```

```

dp2 = hdlfilterdainfo(casc.Stage2,'InputDataType',nt1, ...
    'LUTInputs',3,'FoldingFactor',5);
generatehdl(casc,'InputDataType',nt1,'DALUTPartition',{dp1,dp2});

### HDL latency is 4 samples

```

## Cascaded Filter with Multiple Architectures

Specify different filter architectures for the different stages of a cascaded filter. You can specify a mix of serial, distributed arithmetic (DA), and parallel architectures depending upon your hardware constraints.

### Create Cascaded Filter

Create a three-stage filter. Each stage is a different type.

```
h1 = dsp.FIRFilter('Numerator',[0.05 -.25 .88 0.9 .88 -.25 0.05]);
h2 = dsp.FIRFilter('Numerator',[-0.008 0.06 -0.44 0.44 -0.06 0.008], ...
    'Structure','Direct form antisymmetric');
h3 = dsp.FIRFilter('Numerator',[-0.008 0.06 0.44 0.44 0.06 -0.008], ...
    'Structure','Direct form symmetric');
casc = cascade(h1,h2,h3);
```

### Specify Architecture for Each Stage

Specify a DA architecture for the first stage, a serial architecture for the second stage, and a fully parallel (default) architecture for the third stage.

To obtain DARadix values for the first architecture, use `hdlfilterdainfo`, then pick a value from `dr`.

```
nt = numerictype(1,12,10);
[dp,dr,lutsize,ff] = hdlfilterdainfo(casc.Stage1, ...
    'InputDataType',numerictype(1,12,10));
dr

dr = 6x1 cell
    {'2^12'}
    {'2^6' }
    {'2^4' }
    {'2^3' }
    {'2^2' }
    {'2^1' }
```

Set the property values as cell arrays, where each cell applies to a stage. To disable a property for a particular stage, use default values (-1 for the partitions and 2 for DARadix).

```
generatehdl(casc,'InputDataType',nt, ...
    'SerialPartition',{-1,3,-1}, ...
    'DALUTPartition',{[4 3],-1,-1}, ...
    'DARadix',{2^6,2,2});

### Test Bench for FIR Filter with Programmable Coefficients

You can specify input coefficients to test a filter with programmable coefficients.

Create a direct-form symmetric FIR filter with a fully parallel (default) architecture. Define the coefficients for the filter object in the vector **b**. The coder generates test bench code to test the coefficient interface using a second set of coefficients, **c**. The coder trims **c** to the effective length of the filter.

```

b = [-0.01 0.1 0.8 0.1 -0.01];
c = [-0.03 0.5 0.7 0.5 -0.03];
c = c(1:ceil(length(c)/2));
filt = dsp.FIRFilter('Numerator',b,'Structure','Direct form symmetric');
generatehdl(filt,'InputDataType',numeric(1,16,15), ...
    'GenerateHDLTestbench','on', ...
    'CoefficientSource','ProcessorInterface','TestbenchCoeffStimulus',c)

        );
END filtiiir;

```

## Clock Ports for Multirate Filters

Explore various ways to specify clock ports for multirate filters.

### Default Setting

Create a polyphase sample rate converter. By default, the coder generates a single input clock (`clk`), an input clock enable (`clk_enable`), and a clock enable output signal named `ce_out`. The `ce_out` signal indicates when an output sample is ready. The `ce_in` output signal indicates when an input sample was accepted. You can use this signal to control the upstream data flow.

```

firrc = dsp.FIRRateConverter('InterpolationFactor',5,'DecimationFactor',3);
generatehdl(firrc,'InputDataType',numeric(1,16,15))

### Starting VHDL code generation process for filter: firrc
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex09049114\hdlsrc\
### Starting generation of firrc VHDL entity
### Starting generation of firrc VHDL architecture
### Successful completion of VHDL code generation process for filter: firrc
### HDL latency is 2 samples

```

The generated entity has the following signals:

```
ENTITY firrc IS
  PORT( clk           : IN    std_logic;
        clk_enable    : IN    std_logic;
        reset         : IN    std_logic;
        filter_in     : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En15
        filter_out    : OUT   std_logic_vector(35 DOWNTO 0); -- sfix36_En31
        ce_in         : OUT   std_logic;
        ce_out        : OUT   std_logic
        );
END firrc;
```

### Custom Clock Names

You can provide custom names for the input clock enable and the output clock enable signals. You cannot rename the ce\_in signal.

```
firrc = dsp.FIRRateConverter('InterpolationFactor',5,'DecimationFactor',3)
```

```
firrc =
  dsp.FIRRateConverter with properties:
```

```
  Main
```

```
  InterpolationFactor: 5
```

```
  DecimationFactor: 3
```

```
  NumeratorSource: 'Property'
```

```
  Numerator: [0 -6.6976e-05 -1.6044e-04 -2.2552e-04 -1.8884e-04 0 3.2095e-04 6.5785e-05]
```

```
  Show all properties
```

```
generatehdl(firrc,'InputDataType',numerictype(1,16,15),...
            'ClockEnableInputPort','clk_en1', ...
            'ClockEnableOutputPort','clk_en2')
```

```
### Starting VHDL code generation process for filter: firrc
```

```
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex09049114\hdlsrc\
```

```
### Starting generation of firrc VHDL entity
```

```
### Starting generation of firrc VHDL architecture
```

```
### Successful completion of VHDL code generation process for filter: firrc
```

```
### HDL latency is 2 samples
```

The generated entity has the following signals:

```

ENTITY firrc IS
  PORT( clk           : IN    std_logic;
        clk_en1      : IN    std_logic;
        reset        : IN    std_logic;
        filter_in    : IN    std_logic_vector(15 DOWNTO 0); -- sfix16_En15
        filter_out   : OUT   std_logic_vector(35 DOWNTO 0); -- sfix36_En31
        ce_in       : OUT   std_logic;
        clk_en2     : OUT   std_logic
        );

END firrc;

```

### Multiple Clock Inputs

To generate multiple clock input signals for a supported multirate filter, set the `ClockInputs` property to 'Multiple'. In this case, the coder does not generate any output clock enable ports.

```

decim = dsp.CICDecimator(7,1,4);
generatehdl(decim, 'InputDataType', numerictype(1,16,15), ...
    'ClockInputs', 'Multiple')

```

```

### Starting VHDL code generation process for filter: cicDec0rIntFilt

```

The generated entity has the following signals:

```

ENTITY cicdecimfilt IS
  PORT( clk           : IN    std_logic;
        clk_enable   : IN    std_logic;
        reset        : IN    std_logic;
        filter_in    : IN    std_logic_vector(15 DOWNT0 0); -- sfix16_En15
        clk1         : IN    std_logic;
        clk_enable1  : IN    std_logic;
        reset1       : IN    std_logic;
        filter_out   : OUT   std_logic_vector(27 DOWNT0 0) -- sfix28_En15
        );

END cicdecimfilt;

```

### Generate Default Altera Quartus II Synthesis Script

Create a filter object. Then call `generatehdl`, and specify a synthesis tool.

```

lpf = fdesign.lowpass('fp,fst,ap,ast',0.45,0.55,1,60);
firfilt = design(lpf,'equiripple','FilterStructure','dfsymfir', ...
  'SystemObject',true);
generatehdl(firfilt,'InputDataType',numerictype(1,14,13), ...
  'HDLSynthTool','Quartus');

```

```

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex92219095\hdlsrc\
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples

```

The coder generates a script file named `firfilt_quartus.tcl`, using the default script properties for the Altera® Quartus II synthesis tool.

```
type hdlsrc/firfilt_quartus.tcl
```

```

load_package flow
set top_level firfilt
set src_dir "./hdlsrc"
set prj_dir "q2dir"
file mkdir ../$prj_dir
cd ../$prj_dir
project_new $top_level -revision $top_level -overwrite
set_global_assignment -name FAMILY "Stratix II"
set_global_assignment -name DEVICE EP2S60F484C3
set_global_assignment -name TOP_LEVEL_ENTITY $top_level
set_global_assignment -name vhdl_FILE "../$src_dir/firfilt.vhd"
execute_flow -compile
project_close

```

## Construct Customized Synthesis Script

You can set the script automation properties to dummy values to illustrate how the coder constructs the synthesis script from the properties.

Design a filter and generate HDL. Specify a synthesis tool and custom text to include in the synthesis script.

```
lpf = fdesign.lowpass('fp,fst,ap,ast',0.45,0.55,1,60);
firfilt = design(lpf,'equiripple','FilterStructure','dfsymfir', ...
    'Systemobject',true);
generatehdl(firfilt,'InputDataType',numerictype(1,14,13), ...
    'HDLSynthTool','ISE', ...
    'HDLSynthInit','init line 1 : module name is %s\ninit line 2\n', ...
    'HDLSynthCmd','command : HDL filename is %s\n', ...
    'HDLSynthTerm','term line 1\nterm line 2\n');

### Starting VHDL code generation process for filter: firfilt
### Generating: C:\TEMP\Bdoc23a_2213998_3568\ib570499\33\tp913ae594\hdlfilter-ex64737676\hdlsrc\
### Starting generation of firfilt VHDL entity
### Starting generation of firfilt VHDL architecture
### Successful completion of VHDL code generation process for filter: firfilt
### HDL latency is 2 samples
```

The coder generates a script file named `firfilt_ise.tcl`. Note the locations of the custom text you specified. You can use this feature to add synthesis instructions to the generated script.

```
type hdlsrc/firfilt_ise.tcl

init line 1 : module name is firfilt
init line 2
command : HDL filename is firfilt.vhd
term line 1
term line 2
```

## Input Arguments

### `filtS0` — Filter

filter System object

Filter from which to generate HDL code, specified as a filter System object. To create a filter System object, use the `design` function or see the reference page of the object. You can use the following System objects from DSP System Toolbox:

### Single Rate Filters

- `dsp.FIRFilter`
- `dsp.BiquadFilter`
- `dsp.HighpassFilter`
- `dsp.LowpassFilter`
- `dsp.FilterCascade`
- `dsp.VariableFractionalDelay`

### Multirate Filters

- `dsp.FIRDecimator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FarrowRateConverter`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.FilterCascade`
- `dsp.DigitalDownConverter`
- `dsp.DigitalUpConverter`

#### **nt** — Input data type

`numericType` object

Input data type, specified as a `numericType` object. This argument applies only when the input filter is a System object. Call `numericType(s,w,f)`, where `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits.

#### **fd** — Fractional delay data type

`numericType` object

Fractional delay data type, specified as a `numericType` object. This argument applies only when the input filter is a `dsp.VariableFractionalDelay` System object. Call `numericType(s,w,f)`, where `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits.

#### **filterObj** — Filter

`dfilt` object

Filter from which to generate HDL code, specified as a `dfilt` object. You can create this object by using the `design` function. For an overview of supported filter features, see “Filter Configuration Options” (Filter Design HDL Coder).

### Alternatives

You can use the `fdhdltool` function to generate HDL code instead (requires Filter Design HDL Coder). Specify the input and fractional delay data types as arguments, and then set additional properties in the Generate HDL dialog box.

## Version History

# getPolynomialCoefficients

**Package:** dsp

Get polynomial coefficients of farrow rate conversion filter

## Syntax

```
[C] = getPolynomialCoefficients(frc)
```

## Description

[C] = getPolynomialCoefficients(frc) returns the polynomial coefficients that the dsp.FarrowRateConverter System object, frc, uses to implement the specified sample rate conversion.

## Examples

### Return Polynomial Coefficients of dsp.FarrowRateConverter

Create a default dsp.FarrowRateConverter System object™ that converts a signal from 44.1 kHz to 48 kHz.

```
frc = dsp.FarrowRateConverter()
```

```
frc =
  dsp.FarrowRateConverter with properties:
```

```
  Main
    InputSampleRate: 44100
    OutputSampleRate: 48000
    OutputRateTolerance: 0
    Specification: 'Polynomial order'
    PolynomialOrder: 3
```

```
Show all properties
```

Return the self-designed polynomial coefficients that the object uses to implement the specified rate conversion.

```
c = getPolynomialCoefficients(frc)
```

```
c = 4x4

   -0.1667    0.5000   -0.3333         0
    0.5000   -1.0000   -0.5000    1.0000
   -0.5000    0.5000    1.0000         0
    0.1667         0   -0.1667         0
```

## Input Arguments

### **frc** — Polynomial sample rate conversion filter

`dsp.FarrowRateConverter` System object

Polynomial sample rate conversion filter, specified as a `dsp.FarrowRateConverter` System object.

## Output Arguments

### **C** — Polynomial coefficients of Farrow rate conversion filter

real-valued square matrix

Polynomial coefficients of Farrow rate conversion filter, returned as a  $M$ -by- $M$  matrix, where  $M$  is the polynomial order.

Data Types: `double`

## Version History

**Introduced in R2014b**

## See Also

### Functions

`getActualOutputRate` | `getRateChangeFactors`

### Objects

`dsp.FarrowRateConverter`

# getActualOutputRate

**Package:** dsp

Get actual output rate

## Syntax

```
fsout = getActualOutputRate(rateConverter)
```

## Description

`fsout = getActualOutputRate(rateConverter)` returns the actual output sample rate of the `rateConverter` object, taking into account the `OutputRateTolerance` property. The rate converter object can be a `dsp.FarrowRateConverter System` object or a `dsp.SampleRateConverter System` object.

## Examples

### Specify Tolerance and Confirm Output Sample Rate of `dsp.FarrowRateConverter`

Set the tolerance of the filter to 1%, then return the actual output sample rate for the default conversion between 44.1 kHz and 48 kHz.

```
frc = dsp.FarrowRateConverter();  
frc.OutputRateTolerance = 0.01;  
FsOut = getActualOutputRate(frc)
```

```
FsOut = 4.8109e+04
```

The actual output rate can differ from the requested `OutputSampleRate`, within the configured tolerance.

### Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```
src = dsp.SampleRateConverter;  
src.OutputRateTolerance = 0.01;  
FsOut = getActualOutputRate(src)
```

```
FsOut = 4.4308e+04
```

## Input Arguments

**rateConverter** — Sample rate conversion filter

`dsp.FarrowRateConverter` | `dsp.SampleRateConverter`

Polynomial sample rate conversion filter, specified as a `dsp.FarrowRateConverter` or a `dsp.SampleRateConverter` System object.

## Output Arguments

### **fsout** — Actual output sample rate

scalar

Actual output sample rate of the filter, returned as a scalar in Hz.

Data Types: `double`

## Version History

**Introduced in R2014b**

## See Also

### Functions

`getRateChangeFactors` | `getPolynomialCoefficients`

### Objects

`dsp.FarrowRateConverter` | `dsp.SampleRateConverter`

# getRateChangeFactors

**Package:** dsp

Get overall interpolation and decimation factors

## Syntax

```
[L,M] = getRateChangeFactors(rateConverter)
```

## Description

`[L,M] = getRateChangeFactors(rateConverter)` returns the overall interpolation factor, L, and the overall decimation factor, M, corresponding to the `rateConverter`. The rate converter object can be a `dsp.FarrowRateConverter` System object or a `dsp.SampleRateConverter` System object. The rate change factors computed take into account the `OutputRateTolerance` property.

In the case of `dsp.SampleRateConverter`, the overall decimation factor affects the allowable frame size of the input to the object. The row length of the input vector or matrix to the `dsp.SampleRateConverter` object must be an integer multiple of M.

This function supports C and C++ code generation.

## Examples

### Return Resampling Factors of `dsp.FarrowRateConverter`

Create a default `dsp.FarrowRateConverter` object that converts a signal from 44.1 kHz to 48 kHz.

```
frc = dsp.FarrowRateConverter
frc =
  dsp.FarrowRateConverter with properties:
    Main
      InputSampleRate: 44100
      OutputSampleRate: 48000
      OutputRateTolerance: 0
      Specification: 'Polynomial order'
      PolynomialOrder: 3
    Show all properties
```

Return the overall interpolation (L) and decimation (M) factors of the filter object.

```
[L,M] = getRateChangeFactors(frc)
```

```
L = 160
```

```
M = 147
```

### Default Resampling Factors

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```
src = dsp.SampleRateConverter;  
[L,M] = getRateChangeFactors(src)
```

```
L = 147
```

```
M = 640
```

### Input Arguments

#### **rateConverter** — Sample rate conversion filter

`dsp.FarrowRateConverter` | `dsp.SampleRateConverter`

Polynomial sample rate conversion filter, specified as a `dsp.FarrowRateConverter` or a `dsp.SampleRateConverter` System object.

### Output Arguments

#### **L** — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

Data Types: `double`

#### **M** — Overall decimation factor

scalar

Overall decimation factor, returned as a scalar. In the case of `dsp.SampleRateConverter`, the overall decimation factor affects the allowable frame size of the input to the object. The row length of the input vector or matrix to the `dsp.SampleRateConverter` object must be an integer multiple of `M`.

Data Types: `double`

### Version History

Introduced in R2014b

### Extended Capabilities

#### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

## getBandwidth

**Package:** dsp

Get 3 dB bandwidth

### Syntax

```
BW = getBandwidth(npFilter)
```

### Description

`BW = getBandwidth(npFilter)` returns the 3 dB bandwidth for the notch peak filter. If the `Specification` property is set to 'Quality factor and center frequency', the 3 dB bandwidth is determined from the quality factor value. If the `Specification` property is set to 'Coefficients', the 3 dB bandwidth is determined from the `BandwidthCoefficient` value and the sample rate.

### Examples

#### Get 3 dB Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to 'Quality factor and center frequency'. The default quality factor  $Q$  is 5, and the center frequency  $F_c$  is 11,025 Hz.

```
np = dsp.NotchPeakFilter('Specification',...  
    'Quality factor and center frequency')
```

```
np =  
dsp.NotchPeakFilter with properties:  
  
    Specification: 'Quality factor and center frequency'  
    QualityFactor: 5  
    CenterFrequency: 11025  
    SampleRate: 44100
```

Compute the 3 dB bandwidth of the notch peak filter using the `getBandwidth` function. The bandwidth is computed as the ratio of the center frequency and the quality factor,  $\frac{F_c}{Q}$ .

```
getBandwidth(np)
```

```
ans = 2205
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

## Input Arguments

**npFilter — Notch peak filter**  
`dsp.NotchPeakFilter`

Notch peak filter whose 3 dB bandwidth is measured, specified as a `dsp.NotchPeakFilter` object.

## Output Arguments

**BW — 3 dB bandwidth**  
scalar

3 dB bandwidth of the filter, returned as a scalar.

Data Types: `double`

## Version History

Introduced in R2014a

dsp.NotchPeakFilter

# getBranches

**Package:** dsp

Return internal allpass branches

## Syntax

```
s = getBranches(caf)
```

## Description

`s = getBranches(caf)` returns copies of the internal allpass branches as a two-field structure, `s`. Each branch is an instance of `dsp.AllpassFilter`.

## Examples

### Get Branches of `dsp.CoupledAllpassFilter`

Get the internal allpass branches of the `dsp.CoupledAllpassFilter` System object™.

#### Minimum Multiplier

Create a `dsp.CoupledAllpassFilter` object with filter structure set to 'Minimum multiplier'. Use the `getBranches` function to get the internal allpass filter objects.

```
caf = dsp.CoupledAllpassFilter
```

```
caf =
  dsp.CoupledAllpassFilter with properties:
      Structure: 'Minimum multiplier'
  PureDelayBranch: 0
  AllpassCoefficients1: {[0 0.5000]}
  AllpassCoefficients2: {[[]]}
      Gain1: '1'
      Gain2: '1'
```

```
s = getBranches(caf)
```

```
s = struct with fields:
  Branch1: [1x1 dsp.internal.LegacyAllpassFilter]
  Branch2: [1x1 dsp.internal.LegacyAllpassFilter]
```

```
s.Branch1
```

```
ans =
  dsp.internal.LegacyAllpassFilter with properties:
      AllpassCoefficients: {[0 0.5000]}
      Structure: 'Minimum multiplier'
```

```
InitialConditions: 0
```

```
s.Branch2
```

```
ans =  
dsp.internal.LegacyAllpassFilter with properties:  
  
AllpassCoefficients: {}  
    Structure: 'Minimum multiplier'  
InitialConditions: 0
```

### Wave Digital Filter

Change the filter structure to 'Wave Digital Filter'. The internal allpass filters display WDF coefficients.

```
caf.Structure = 'Wave Digital Filter'
```

```
caf =  
dsp.CoupledAllpassFilter with properties:  
  
    Structure: 'Wave Digital Filter'  
PureDelayBranch: 0  
WDFCoefficients1: {[0.5000 0]}  
WDFCoefficients2: {}  
    Gain1: '1'  
    Gain2: '1'
```

```
s = getBranches(caf)
```

```
s = struct with fields:  
Branch1: [1x1 dsp.internal.LegacyAllpassFilter]  
Branch2: [1x1 dsp.internal.LegacyAllpassFilter]
```

```
s.Branch1
```

```
ans =  
dsp.internal.LegacyAllpassFilter with properties:  
  
WDFCoefficients: {[0.5000 0]}  
    Structure: 'Wave Digital Filter'  
InitialConditions: 0
```

```
s.Branch2
```

```
ans =  
dsp.internal.LegacyAllpassFilter with properties:  
  
WDFCoefficients: {}  
    Structure: 'Wave Digital Filter'  
InitialConditions: 0
```

## Lattice

When the filter structure is set to 'Lattice', the internal allpass filters display the lattice coefficients.

```
caf.Structure = 'Lattice'
```

```
caf =
  dsp.CoupledAllpassFilter with properties:
      Structure: 'Lattice'
      PureDelayBranch: 0
      LatticeCoefficients1: {[0 0.5000]}
      LatticeCoefficients2: {[]}
      Beta: 1
      Gain1: '1'
      Gain2: '1'
      ComplexConjugateCoefficients: 0
```

```
s = getBranches(caf)
```

```
s = struct with fields:
  Branch1: [1x1 dsp.internal.LegacyAllpassFilter]
  Branch2: [1x1 dsp.internal.LegacyAllpassFilter]
```

```
s.Branch1
```

```
ans =
  dsp.internal.LegacyAllpassFilter with properties:
      LatticeCoefficients: {[0 0.5000]}
      Structure: 'Lattice'
      InitialConditions: 0
```

```
s.Branch2
```

```
ans =
  dsp.internal.LegacyAllpassFilter with properties:
      LatticeCoefficients: {[]}
      Structure: 'Lattice'
      InitialConditions: 0
```

## Input Arguments

### caf — Input filter object

dsp.CoupledAllpassFilter

Input filter object, specified as a dsp.CoupledAllpassFilter System object.

## Output Arguments

### s — Internal allpass branches

structure

Internal allpass branches, returned as a two-field structure. The two fields contain instances of the `dsp.AllpassFilter` System objects representing the two individual branches of the `dsp.CoupledAllpassFilter` object.

## **Version History**

**Introduced in R2013b**

#### **Functions**

`fvtool`

#### **Objects**

`dsp.CoupledAllpassFilter`

# getCenterFrequency

**Package:** dsp

Get center frequency

## Syntax

```
CF = getCenterFrequency(npFilter)
```

## Description

`CF = getCenterFrequency(npFilter)` returns the center frequency of the notch peak filter. If the `Specification` property is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

## Examples

### Get Center Frequency of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object with the `Specification` property set to `'Coefficients'`.

```
np = dsp.NotchPeakFilter('Specification','Coefficients')
```

```
np =
```

```
    dsp.NotchPeakFilter with properties:
```

```
        Specification: 'Coefficients'
    BandwidthCoefficient: 0.7265
    CenterFrequencyCoefficient: 0
        SampleRate: 44100
```

Determine the center frequency of the notch peak filter using the `getCenterFrequency` function. When the `Specification` is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

```
getCenterFrequency(np)
```

```
ans = 11025
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

## Input Arguments

**npFilter** — Notch peak filter  
`dsp.NotchPeakFilter`

Notch peak filter whose center frequency is measured, specified as `dsp.NotchPeakFilter` object.

## Output Arguments

**CF** — Center frequency  
scalar

Center frequency of the filter, returned as a scalar.

Data Types: `double`

## Version History

Introduced in R2014a

## See Also

### Functions

getBandwidth | getOctaveBandwidth | getQualityFactor | tf

### Objects

dsp.NotchPeakFilter

## getCursorInfo

**Package:** dsp

Return settings for Logic Analyzer cursor

### Syntax

```
cursorInfo = getCursorInfo(scope, 'CursorTag', tag)
```

### Description

`cursorInfo = getCursorInfo(scope, 'CursorTag', tag)` returns the settings for the cursor or cursors specified by the input tag.

### Examples

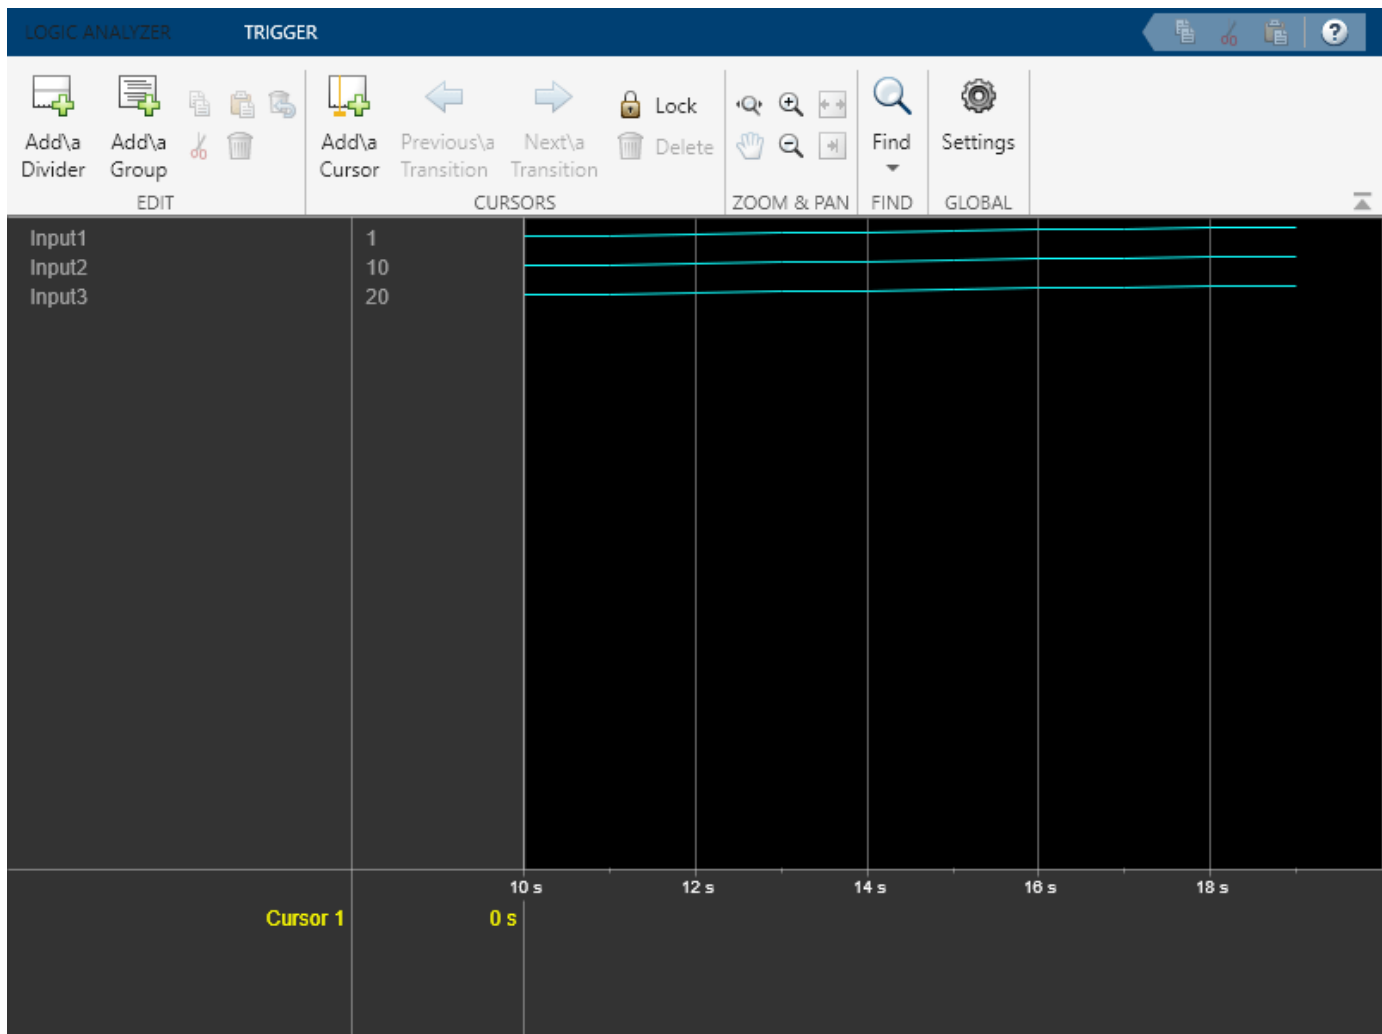

#### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

#### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

Add a cursor at 15 seconds and show the cursor information.

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
  Location: 15
  Color: [0 1 1]
  Locked: 0
  Tag: 'C2'
```

### Modify Cursor

Change the cursor color to magenta.

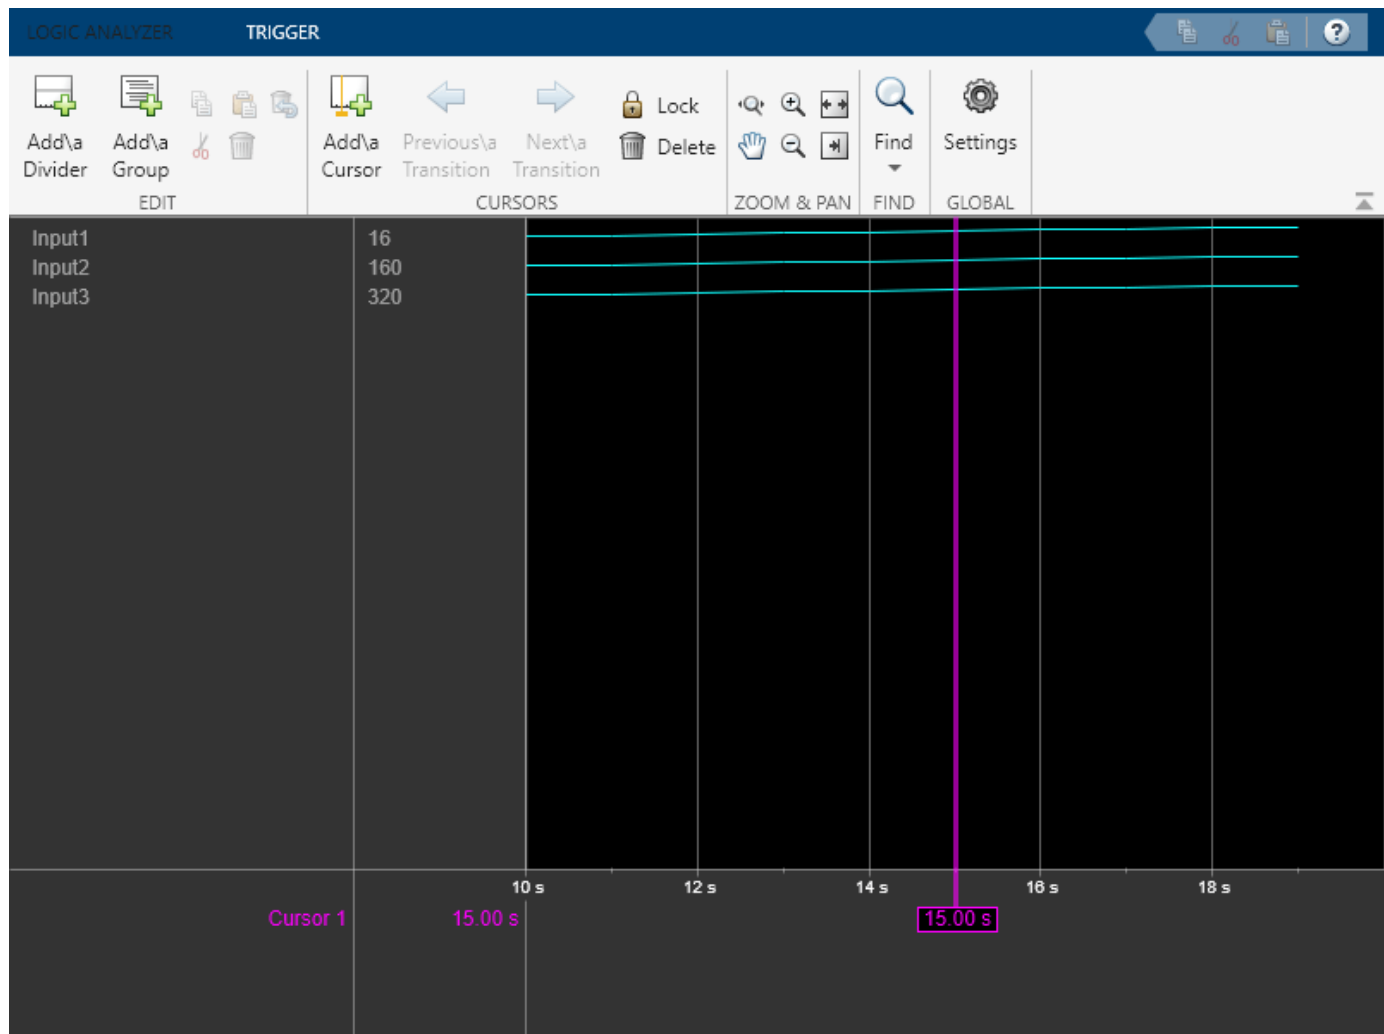

```
hide(scope)
modifyCursor(scope, cursor, 'Color', 'Magenta')
show(scope)
```

### Remove Cursor

Delete the yellow cursor at 0 seconds.

```
hide(scope)
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
show(scope)
```

## Input Arguments

**scope** — The Logic Analyzer object from which you want to return cursor settings

`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return cursor settings, specified as a handle to the `dsp.LogicAnalyzer` object.

**tag** — identifying tag or tags

character vector | string scalar | cell array of character vectors | string array

The tag or tags identifying the cursor or cursors about which to get information, specified as the randomly assigned cursor tag or tags.

Example: 'C5'

Example: {'C4', 'C5'}

Example: ["C4", "C5"]

Data Types: char | cell | string

## Output Arguments

**cursorInfo** — Information about settings for the cursor or cursors

struct

The `cursorInfo` struct contains the following fields:

- `Location` — Location of the cursors
- `Color` — Color of the cursors
- `Locked` — Locked status of the cursors
- `Tag` — Tag identifying cursors

## Version History

Introduced in R2013a

### See Also

`dsp.LogicAnalyzer` | `getCursorTags` | `modifyCursor` | `getDisplayChannelInfo`

# getCursorTags

**Package:** dsp

Return all Logic Analyzer cursor tags

## Syntax

```
cursorTags = getCursorTags(scope)
```

## Description

`cursorTags = getCursorTags(scope)` returns all the cursor tags for the Logic Analyzer. You can use these tags to get information about a cursor using the `getCursorInfo` method, to modify a cursor using the `modifyCursor` method, or to delete a cursor using the `deleteCursor` method.

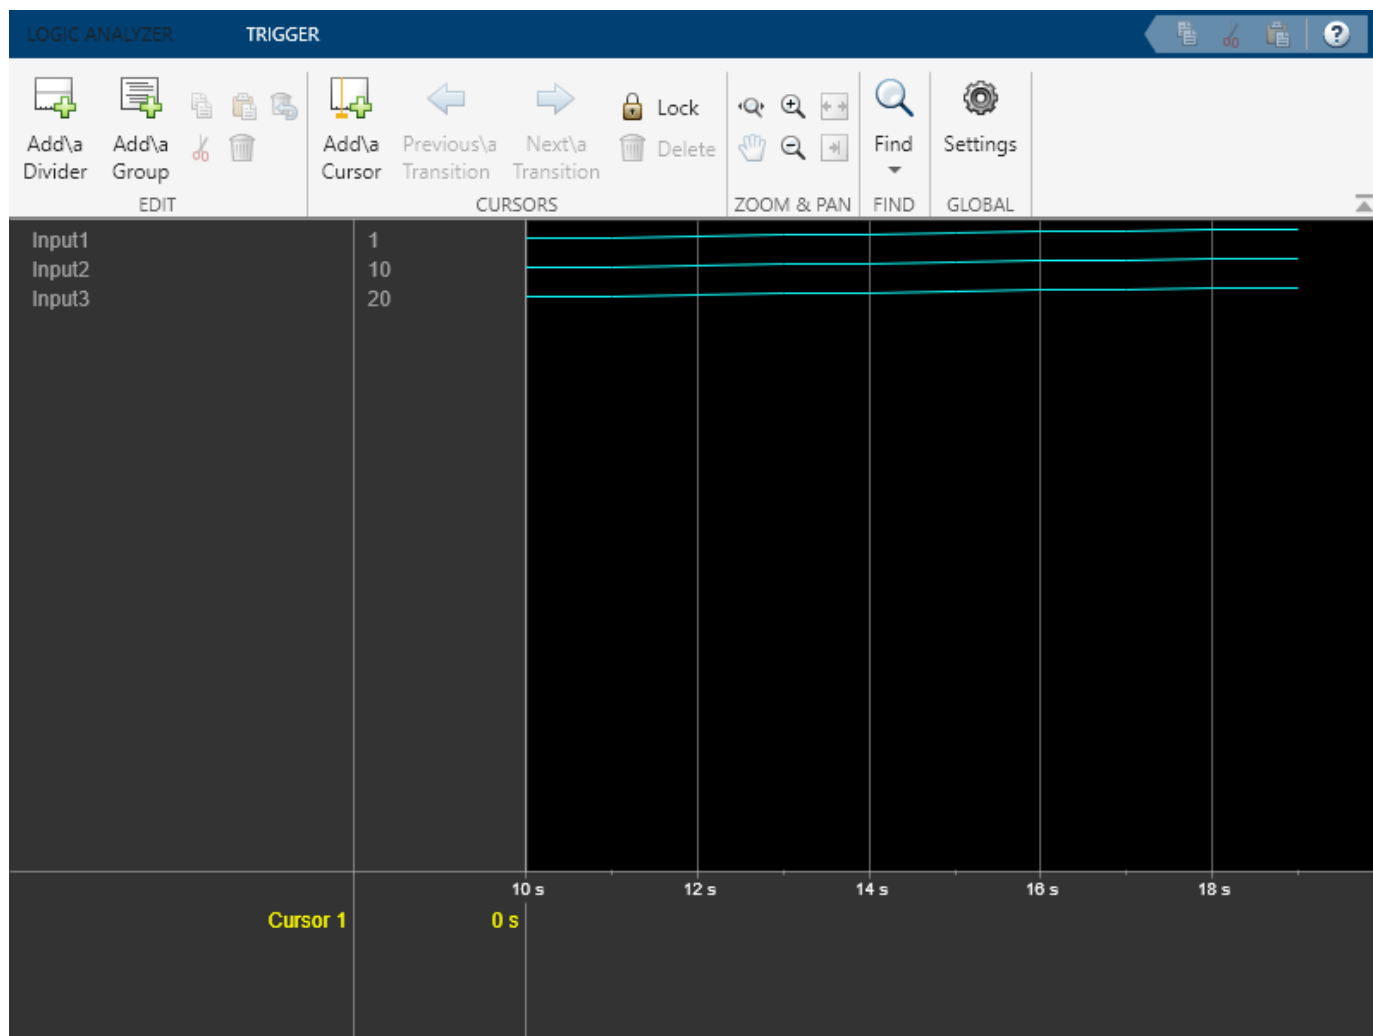

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

Add a cursor at 15 seconds and show the cursor information.

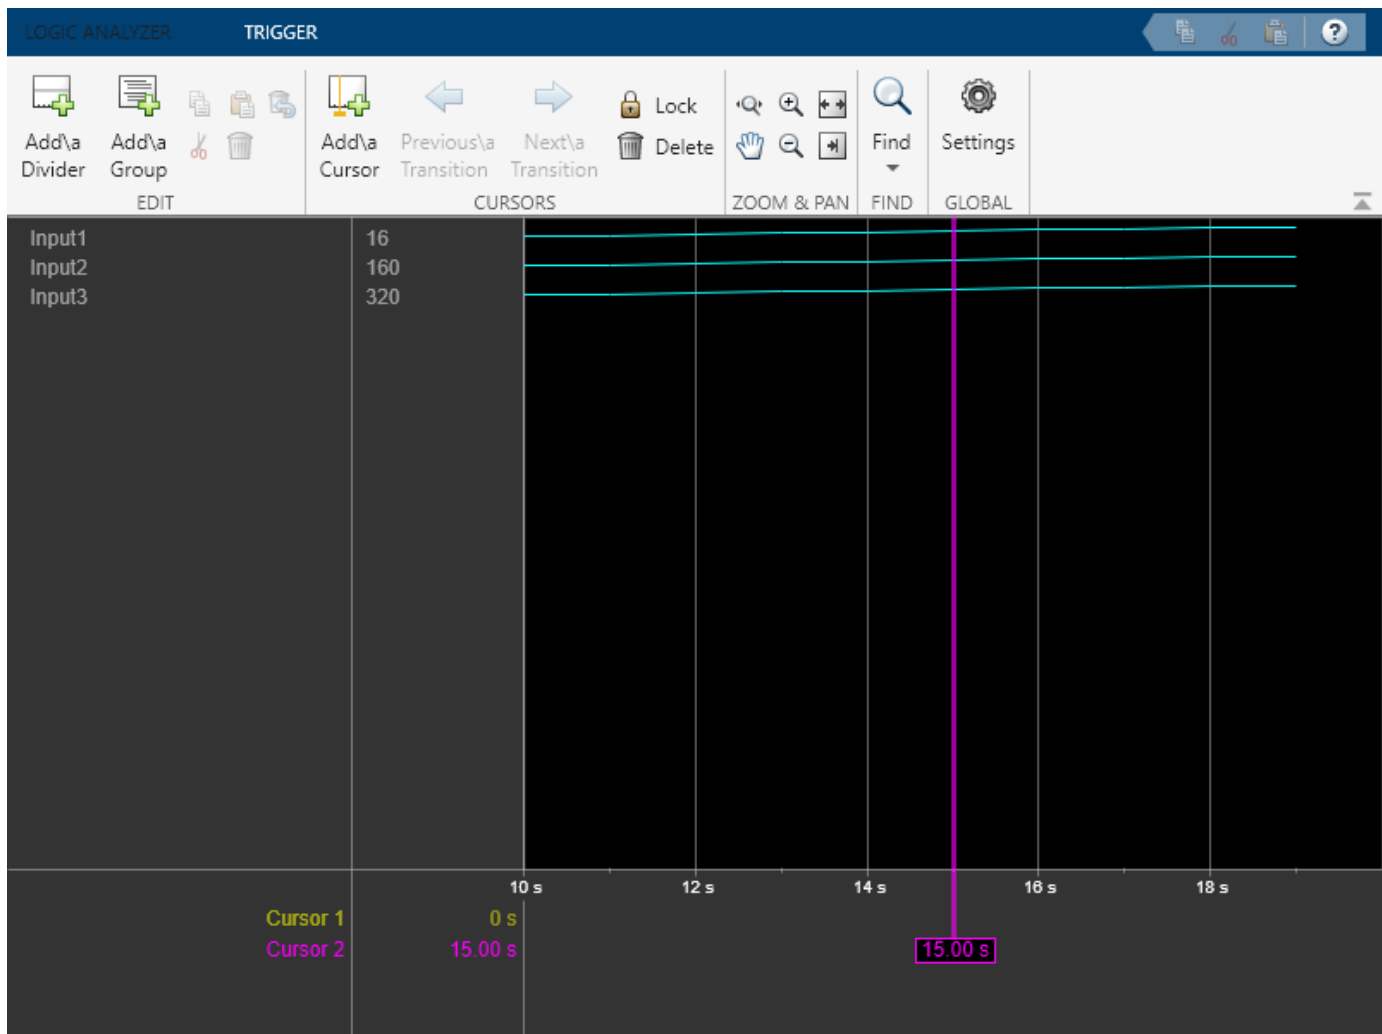

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
    Location: 15
    Color: [0 1 1]
    Locked: 0
    Tag: 'C2'
```

### Modify Cursor

Change the cursor color to magenta.

```
hide(scope)
modifyCursor(scope, cursor, 'Color', 'Magenta')
show(scope)
```

### Remove Cursor

Delete the yellow cursor at 0 seconds.

```
hide(scope)
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
show(scope)
```

## Input Arguments

### scope — Logic analyzer object

`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return all cursor tags, specified as a handle to the `dsp.LogicAnalyzer` object.

## Output Arguments

### cursorTags — All cursor tags

cell array of character vectors

The cursor tags, specified as a cell array of character vectors.

Example: `{ 'C1' }`

Example: `{ 'C1', 'C2', 'C3' }`

Data Types: `cell`

## **Version History**

**Introduced in R2013a**

### **See Also**

`dsp.LogicAnalyzer` | `getDisplayChannelTags` | `getCursorInfo` | `modifyCursor`

## getDecimationFactors

**Package:** dsp

Get decimation factors of each filter stage of a digital down converter

### Syntax

```
M = getDecimationFactors(dwnConv)
```

### Description

`M = getDecimationFactors(dwnConv)` returns a vector, `M`, with the decimation factors of each filter stage of the digital down converter, `dwnConv`. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages. If the third filter stage is not bypassed, then `M` is a 1-by-3 vector containing the decimation factors of the first, second, and third filter stages.

### Examples

#### Get Decimation Factors

Get decimation factors of each filter stage of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `getDecimationFactors` function, obtain the decimation factors of each stage of the object.

```
dwnConv = dsp.DigitalDownConverter

dwnConv =
    dsp.DigitalDownConverter with properties:

        DecimationFactor: 100
    MinimumOrderDesign: true
           Bandwidth: 200000
StopbandFrequencySource: 'Auto'
      PassbandRipple: 0.1000
StopbandAttenuation: 60
      Oscillator: 'Sine wave'
    CenterFrequency: 14000000
      SampleRate: 30000000

Show all properties

M = getDecimationFactors(dwnConv) %#ok

M = 1×3

    25     2     2
```

The `DecimationFactor` property of the object is set to 100. The output `M` is by default a 1-by-3 vector, where each element in the vector is a factor of the overall decimation factor.

When you set the `DecimationFactor` to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively.

```
dwnConv.DecimationFactor = [10 10]
```

```
dwnConv =
  dsp.DigitalDownConverter with properties:

    DecimationFactor: [10 10]
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv)
```

```
M = 1×2
    10    10
```

The output of the `getDecimationFactors` function is now a 1-by-2 vector.

## Input Arguments

### **dwnConv** — Digital down converter

`dsp.DigitalDownConverter`

Digital down converter, specified as a `dsp.DigitalDownConverter` System object.

## Output Arguments

### **M** — Decimation factors

vector

Decimation factors of each filter stage, returned as a 1-by-2 or a 1-by-3 vector. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages. If the third filter stage is not bypassed, then `M` is a 1-by-3 vector containing the decimation factors of the first, second, and third filter stages.

Data Types: `double`

# getDisplayChannelInfo

**Package:** dsp

Return settings for Logic Analyzer display channel

## Syntax

```
channelInfo = getDisplayChannelInfo(scope, 'DisplayChannelTag', tag)
```

## Description

`channelInfo = getDisplayChannelInfo(scope, 'DisplayChannelTag', tag)` returns the settings for the display channel or channels, specified by the input tag.

## Examples

### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

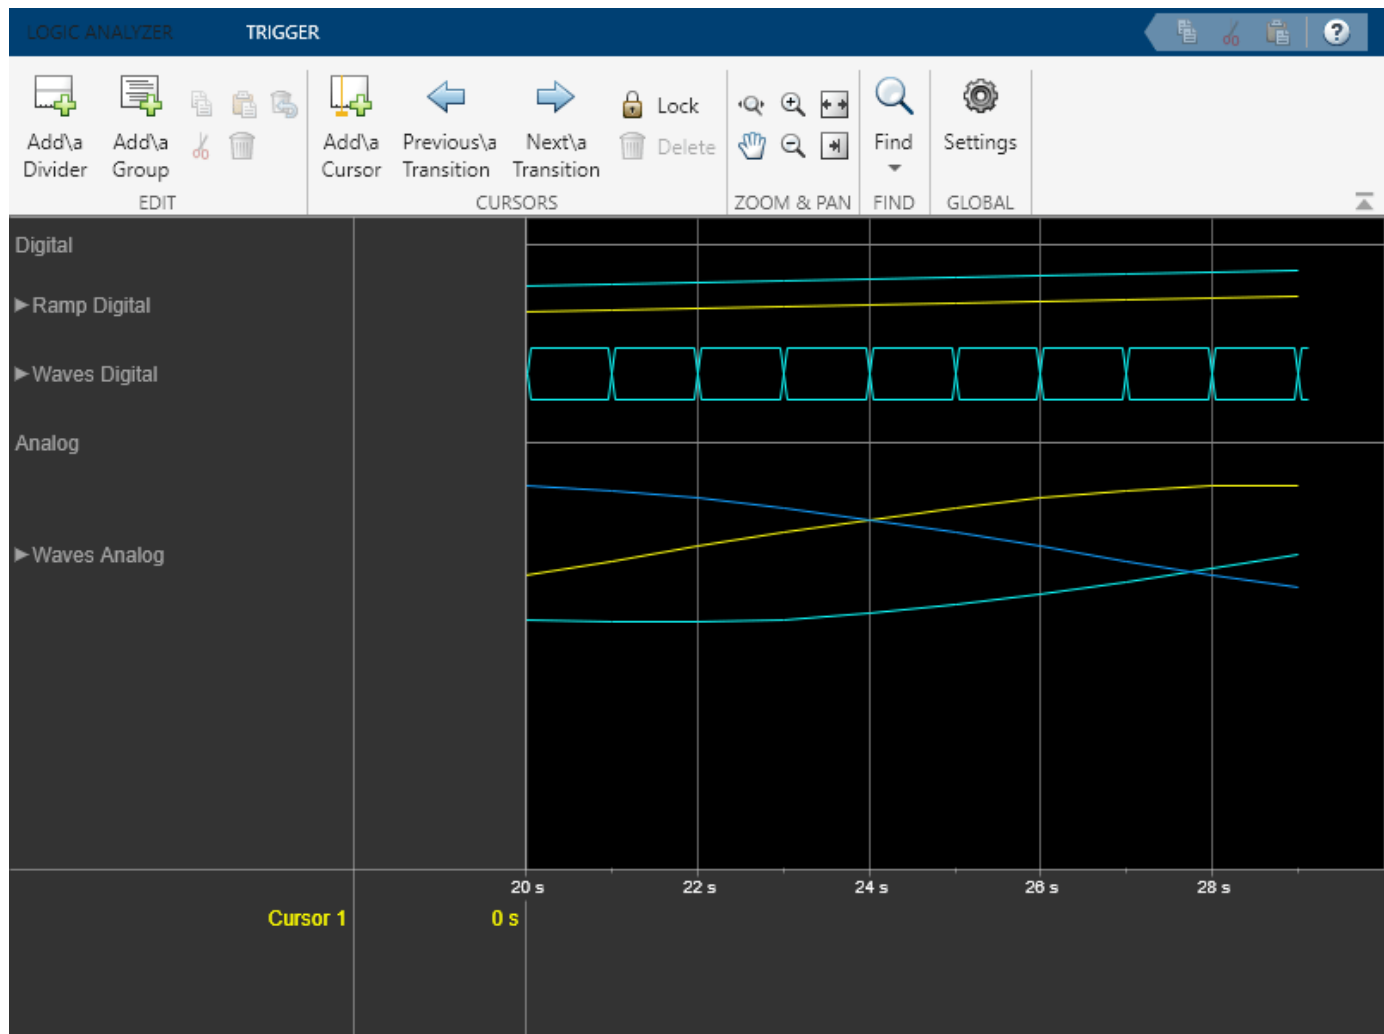

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

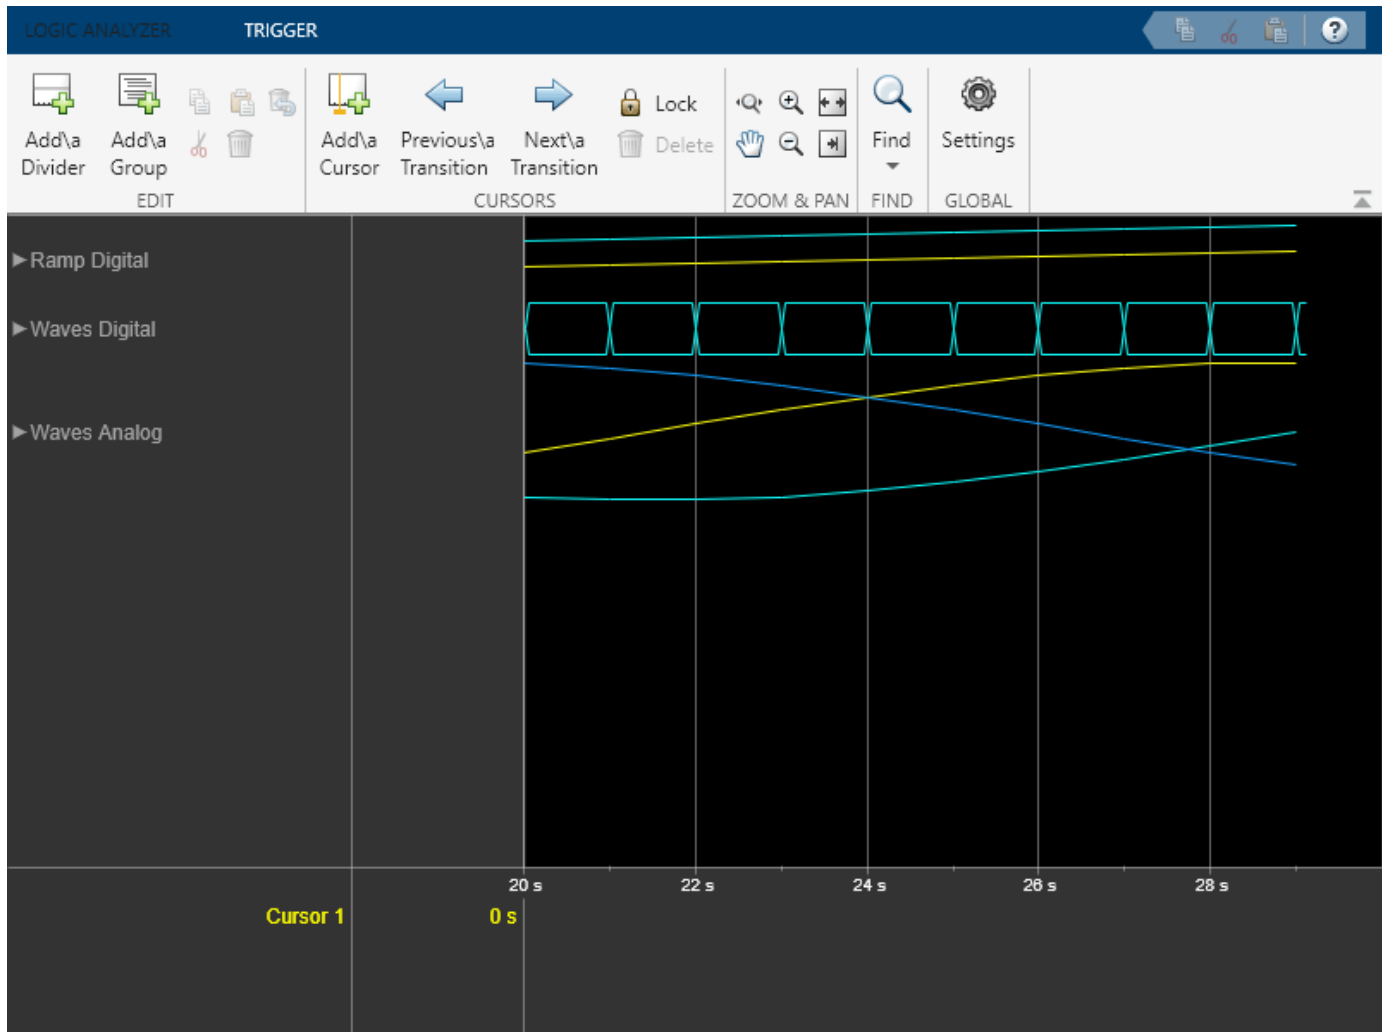

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return display channel settings, specified as a handle to the dsp.LogicAnalyzer object.

### tag — Tag or tags identifying the display channel or channels about which to get information

character vector | string scalar | cell array of character vectors | string array

The tag or tags identifying the display channel or channels about which to get information.

Example: 'DisplayChannelTag', 'W5'

Example: 'DisplayChannelTag', {'W4', 'W5'}

Example: 'DisplayChannelTag', ["W4", "W5"]

Data Types: char | string

## Output Arguments

**channelInfo** — Information about settings for the display channel or channels  
struct

The `channelInfo` struct contains the following fields:

- `Color` — Color of the waves.
- `InputChannel` — Channel on the display that corresponds to the specified waves.
- `Radix` — Radix for the waves.
- `FontSize` — Font size for values in the waves. A value of 0 indicates that the waves inherit `FontSize` from the global `DisplayChannelColor` property.
- `Name` — The name or label for the waves.
- `Height` — Height of the wave. A value of 0 indicates that the waves inherit `Height` from the global `DisplayChannelHeight` property.
- `Tag` — Tag for the channel.

# getDisplayChannelTags

**Package:** dsp

Return all Logic Analyzer display channel tags

## Syntax

```
displayChannelTags = getDisplayChannelTags(scope)
```

## Description

`displayChannelTags = getDisplayChannelTags(scope)` returns all the tags for waves or dividers in a Logic Analyzer. You use these tags to

- Get information about a wave or divider using `getDisplayChannelInfo`
- Modify a wave or divider using `modifyDisplayChannel`
- Delete a wave or divider using `deleteDisplayChannel`

## Examples

### Manipulate Logic Analyzer Programatically

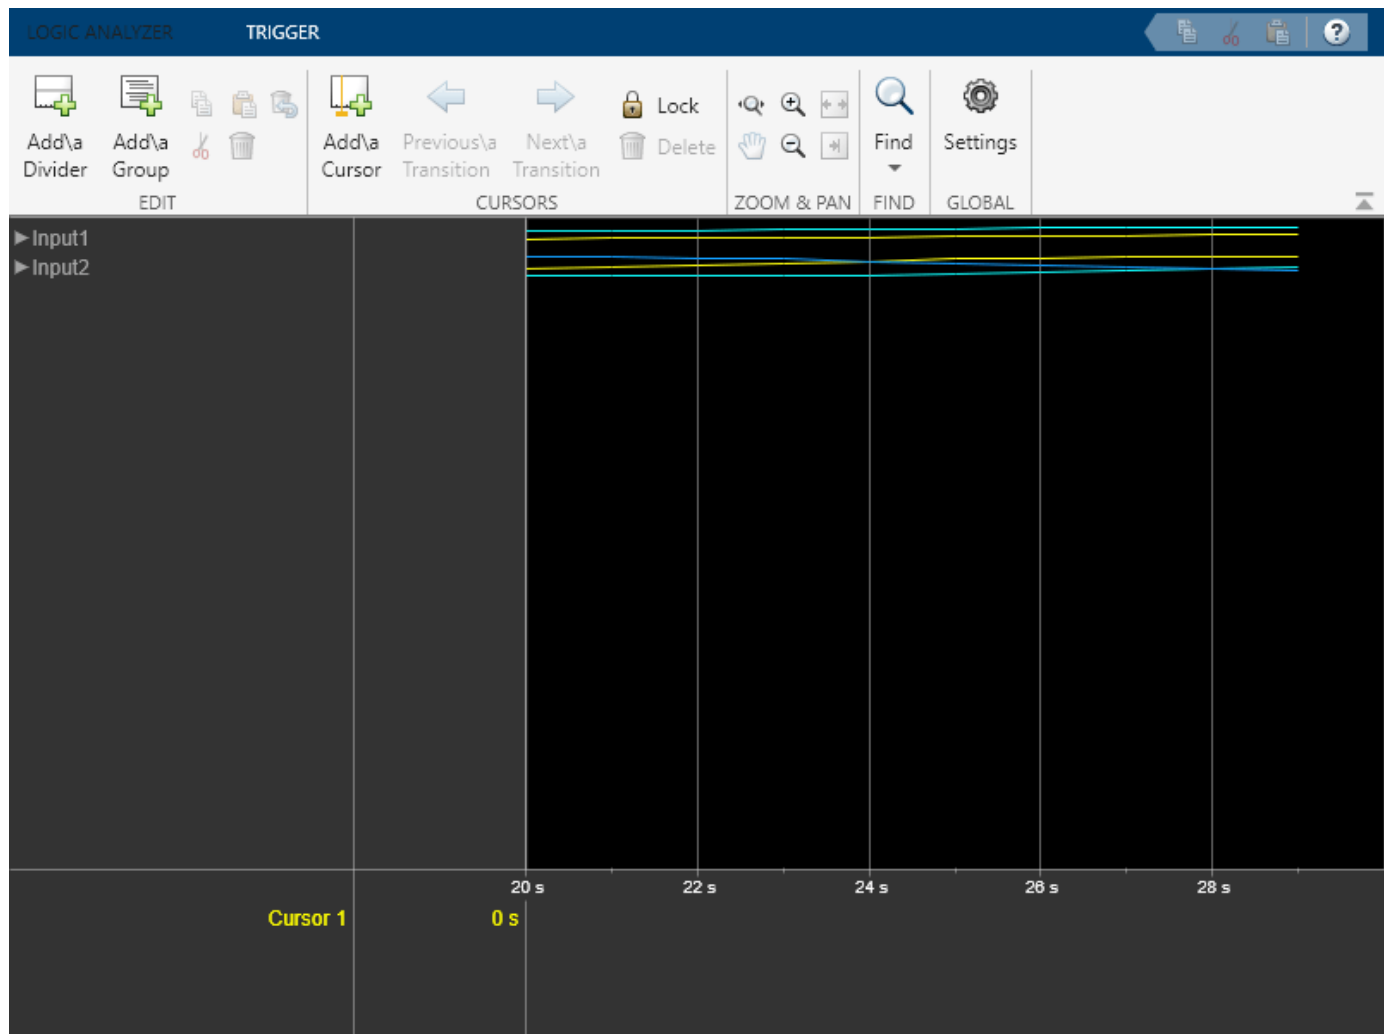

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

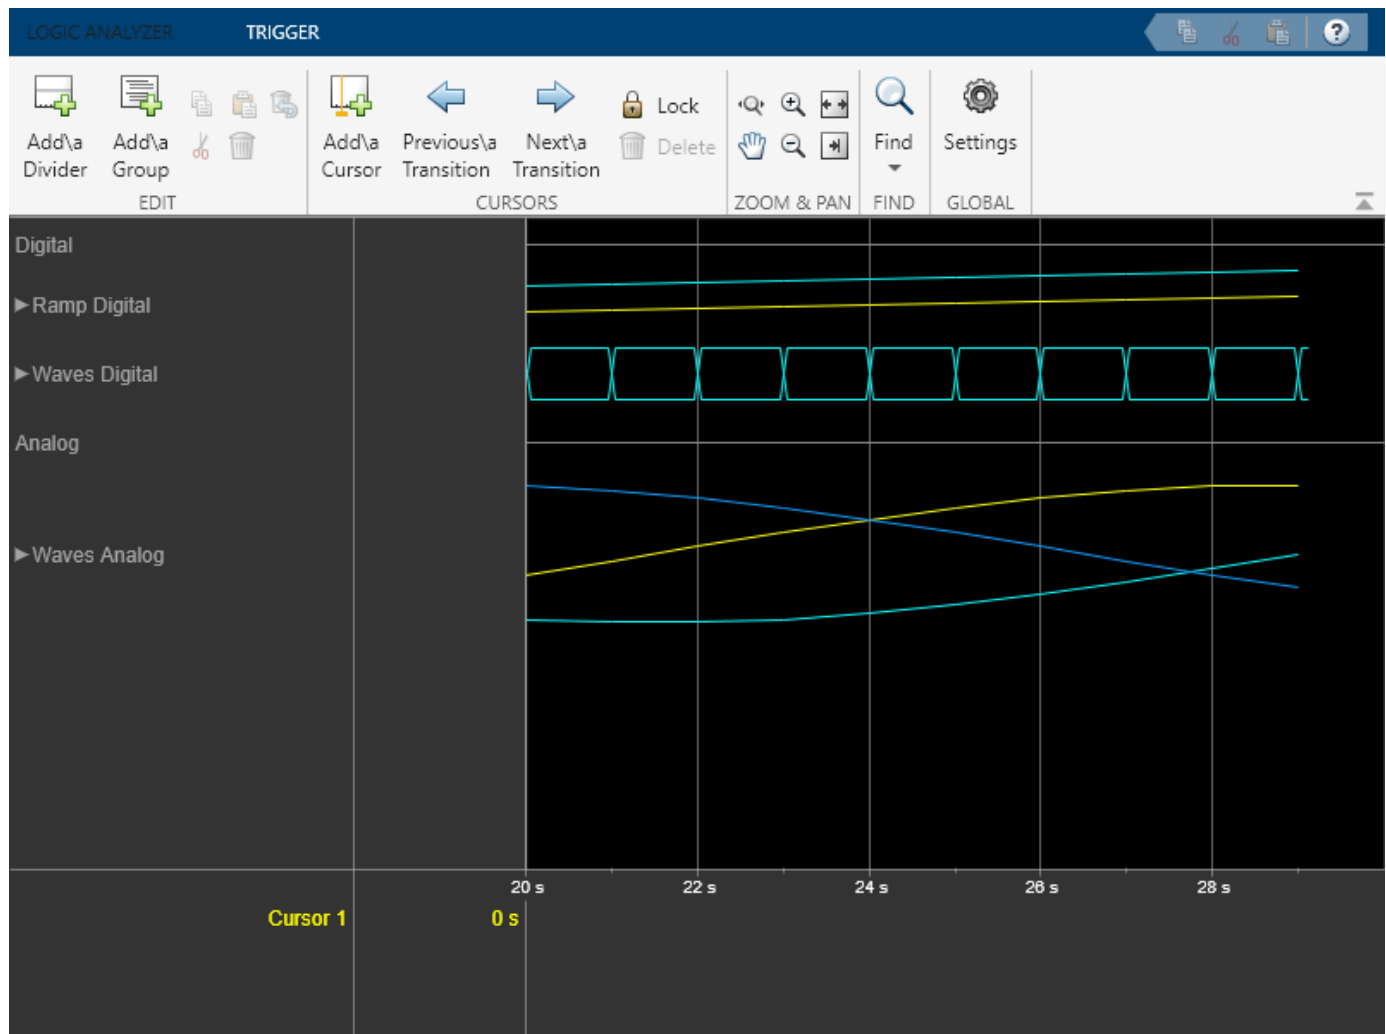

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

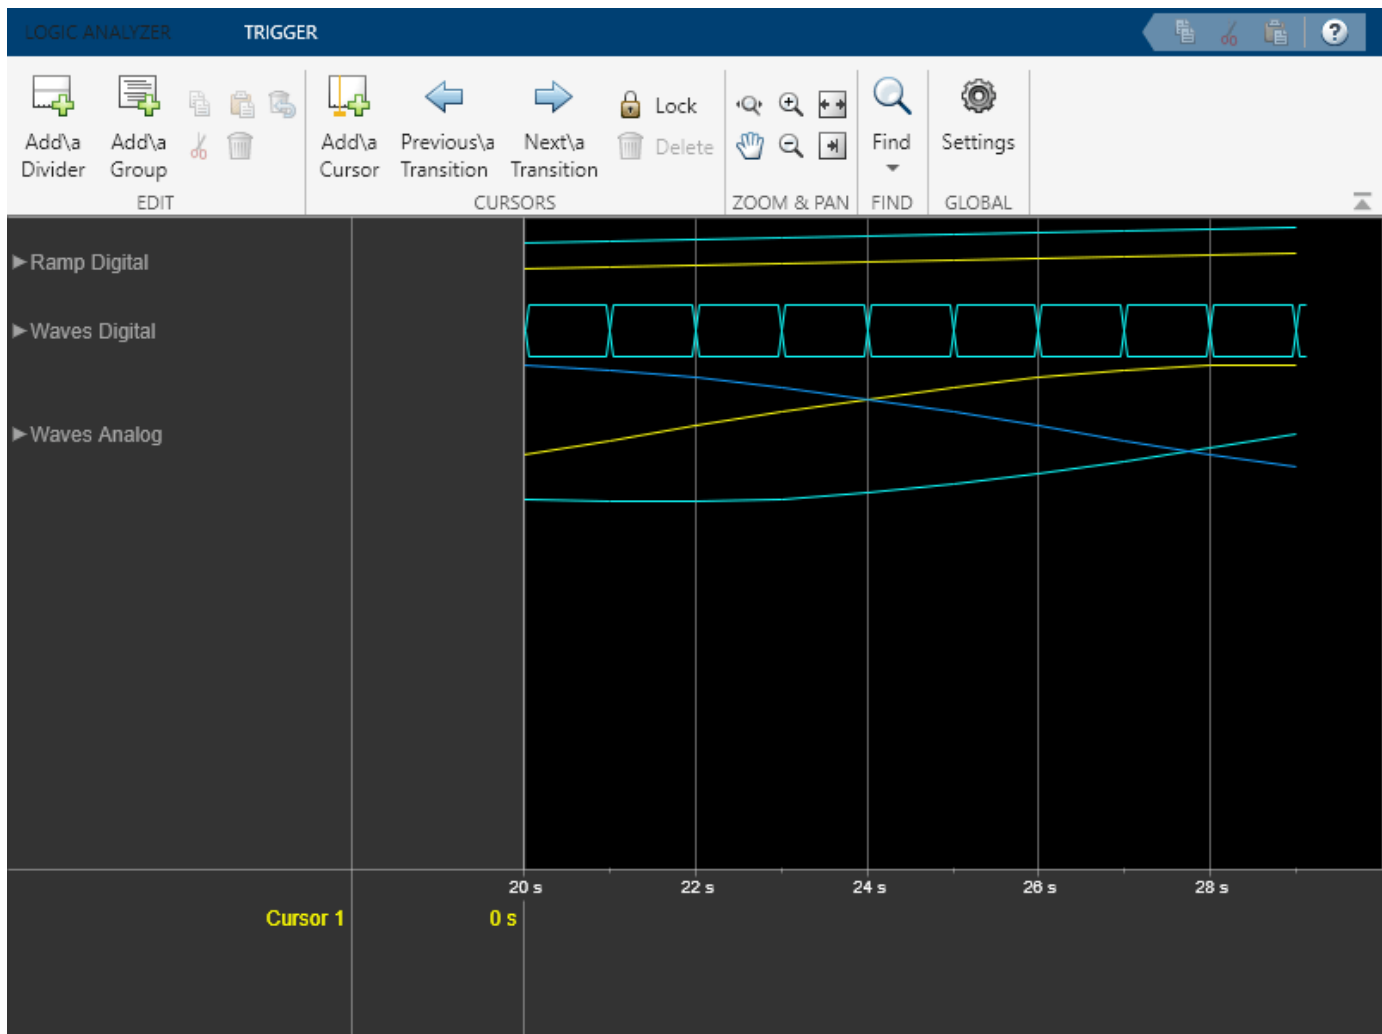

### Duplicate Wave and Check Information

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
    'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

### Input Arguments

**scope** — The Logic Analyzer object from which you want to return all display channel tags  
 dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return all display channel tags, specified as a handle to the dsp.LogicAnalyzer object.

### Output Arguments

**displayChannelTags** — The display channel tags  
 cell array of character vectors

The display channel tags, returned as a cell array of character vectors.

Example: { 'W1' }

Example: { 'W1', 'W2', 'W3' }

Data Types: cell

## **Version History**

# getFilterOrders

**Package:** dsp

Get orders of digital down converter or digital up converter filter cascade

## Syntax

```
S = getFilterOrders(Conv)
```

## Description

`S = getFilterOrders(Conv)` returns a structure, `S`, that contains the number of CIC filter sections and the orders of the FIR filter stages of a digital down converter or digital up converter, `Conv`. The converter usually implements the conversion using three filter stages. Sometimes, one of the stages is bypassed and the order of that filter stage is returned as an empty field.

## Examples

### Get Filter Orders of Digital Up Converter

Get orders of each decimation filter stage of the `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings.

```
upConv = dsp.DigitalUpConverter
upConv =
    dsp.DigitalUpConverter with properties:
        InterpolationFactor: 100
        MinimumOrderDesign: true
        Bandwidth: 200000
        StopbandFrequencySource: 'Auto'
        PassbandRipple: 0.1000
        StopbandAttenuation: 60
        Oscillator: 'Sine wave'
        CenterFrequency: 14000000
        SampleRate: 300000
```

Show all properties

Using the `getFilterOrders` function, obtain the number of CIC decimator sections, order of the CIC compensation filter stage, and order of the third filter stage.

```
S = getFilterOrders(upConv)
S = struct with fields:
    FirstFilterOrder: 24
    SecondFilterOrder: 12
    NumCICSections: 4
```

The first filter order field is empty when the object bypasses the first filter stage.

### Get Filter Orders of Digital Up Converter

Get orders of each decimation filter stage of the `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings.

```
upConv = dsp.DigitalUpConverter

upConv =
  dsp.DigitalUpConverter with properties:

    InterpolationFactor: 100
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 300000
```

Show all properties

Using the `getFilterOrders` function, obtain the number of CIC decimator sections, order of the CIC compensation filter stage, and order of the third filter stage.

```
S = getFilterOrders(upConv)

S = struct with fields:
    FirstFilterOrder: 24
    SecondFilterOrder: 12
    NumCICSections: 4
```

The first filter order field is empty when the object bypasses the first filter stage.

## Input Arguments

### Conv — Digital down converter or digital up converter

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

Digital down converter or digital up converter, specified as a `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` System object.

## Output Arguments

### S — Filter order information

structure

Filter order information, returned as a structure containing the number of CIC sections, and the orders of the two FIR filter stages. For a digital down converter object, the structure contains these fields:

- `NumCICSections` -- Number of sections of the CIC decimator. The default is 4.
- `SecondFilterOrder` -- Order of the CIC compensation filter stage. The default is 12.
- `ThirdFilterOrder` -- Order of the third filter stage. The default is 24. The `ThirdFilterOrder` structure field is empty if the third filter stage has been bypassed.

For a digital up converter object, the structure contains these fields:

- `FirstFilterOrder` -- Order of the first filter stage. The default is 24. The `FirstFilterOrder` structure field is empty if the first filter stage has been bypassed.
- `SecondFilterOrder` -- Order of the CIC compensation filter stage. The default is 12.
- `NumCICSections` -- Number of sections of the CIC interpolator. The default is 4.

## Version History

Introduced in R2012a

## getFilters

**Package:** dsp

Get handles to digital down converter or digital up converter filter cascade objects

### Syntax

```
S = getFilters(Conv)
S = getFilters(Conv, 'Arithmetic', arithType)
```

### Description

`S = getFilters(Conv)` returns a structure, `S`, that contains copies of the filter System objects and the CIC normalization factor that form a digital down converter or digital up converter, `Conv`. The CIC normalization factor equals the inverse of the CIC filter gain. This gain can include a correction factor to ensure that the cascade response meets the ripple specifications.

The converter usually implements the conversion using three filter stages. Sometimes, one of the stages is bypassed and that filter stage is returned as an empty field.

`S = getFilters(Conv, 'Arithmetic', arithType)` specifies the arithmetic type of the filter stages. Set `arithType` to `'double'`, `'single'`, or `'Fixed-point'`. When the `Conv` object is in an unlocked state, you must specify the arithmetic input. When the `Conv` object is in a locked state, it ignores the arithmetic input argument.

### Examples

#### Get Filters of Digital Down Converter

Get handles to decimation filter objects of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings.

```
dwnConv = dsp.DigitalDownConverter

dwnConv =
  dsp.DigitalDownConverter with properties:

    DecimationFactor: 100
  MinimumOrderDesign: true
    Bandwidth: 200000
  StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
  StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 30000000
```

Show all properties

Use the `getFilters` function to obtain the filter System objects and the CIC normalization factor that form the decimation filter cascade.

To use the `getFilters` function on an unlocked System object, you must specify the filter arithmetic through the 'Arithmetic' input of the `getFilters` function.

```
S = getFilters(dwnConv, 'Arithmetic', 'Fixed-point')

S = struct with fields:
    CICDecimator: [1x1 dsp.CICDecimator]
    CICNormalizationFactor: 2.5600e-06
    SecondFilterStage: [1x1 dsp.FIRDecimator]
    ThirdFilterStage: [1x1 dsp.FIRDecimator]
```

Alternatively, you can lock the System object by passing a valid input to the object algorithm. In this case, you can use the `getFilters` function without specifying the filter arithmetic.

### Get Filters of Digital Up Converter

Get handles to decimation filter objects of the `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings.

```
upConv = dsp.DigitalUpConverter

upConv =
    dsp.DigitalUpConverter with properties:

        InterpolationFactor: 100
        MinimumOrderDesign: true
        Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
        PassbandRipple: 0.1000
    StopbandAttenuation: 60
        Oscillator: 'Sine wave'
        CenterFrequency: 14000000
        SampleRate: 300000
```

Show all properties

Use the `getFilters` function to obtain the filter System objects and the CIC normalization factor that form the decimation filter cascade.

To use the `getFilters` function on an unlocked System object, you must specify the filter arithmetic through the 'Arithmetic' input of the `getFilters` function.

```
S = getFilters(upConv, 'Arithmetic', 'Fixed-point')

S = struct with fields:
    FirstFilterStage: [1x1 dsp.FIRInterpolator]
    CICNormalizationFactor: 6.4000e-05
    SecondFilterStage: [1x1 dsp.FIRInterpolator]
    CICInterpolator: [1x1 dsp.CICInterpolator]
```

The first filter field is empty when the object bypasses the first filter stage.

Alternatively, you can lock the System object by passing a valid input to the object algorithm. In this case, you can use the `getFilters` function without specifying the filter arithmetic.

## Input Arguments

### Conv — Digital down converter or digital up converter

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

Digital down converter or digital up converter, specified as a `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` System object.

### arithType — Arithmetic type

'double' (default) | 'single' | 'fixed-point'

When the Conv object is in an unlocked state, you must specify the arithmetic type. When the Conv object is in a locked state, it ignores the arithmetic input argument.

When Conv is in an unlocked state, and you specify the arithmetic type as 'fixed-point', the `getFilters` function returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` objects use to process data when you call the object. All other fixed-point properties are set to their default values.

When Conv is in a locked state, and the input to the object algorithm is of a fixed-point data type, the `getFilters` function returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` objects use to process the data.

## Output Arguments

### S — Handles to decimation or interpolation filter objects

structure

The output is a structure, S, containing three filter object handles and the `CICNormalizationFactor`. For a digital down converter object, the structure contains these fields:

- `CICDecimator` -- Handle to the `dsp.CICDecimator` object.
- `CICNormalizationFactor` -- Inverse of the CIC filter gain.
- `SecondFilterStage` -- Handle to the CIC compensation filter stage.
- `ThirdFilterStage` -- Handle to the third filter stage. This field is empty if the third filter stage has been bypassed.

For a digital up converter object, the structure contains these fields:

- `FirstFilterStage` -- Handle to the first filter stage. This field is empty if the first filter stage has been bypassed.
- `CICNormalizationFactor` -- Inverse of the CIC filter gain.
- `SecondFilterStage` -- Handle to the CIC compensation filter stage.

- `CICInterpolator` -- Handle to the `dsp.CICInterpolator` object.

## Version History

Introduced in R2012a

#### Objects

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

## groupDelay

**Package:** dsp

Group delay of digital down converter or digital up converter filter cascade

### Syntax

```
D = groupDelay(Conv,N)
[D,F] = groupDelay(Conv,N)
```

### Description

`D = groupDelay(Conv,N)` returns a vector of group delays, `D`, of a digital down converter or digital up converter, `Conv`, evaluated at `N` frequency points. The frequency points are equally spaced around the upper half of the unit circle.

`[D,F] = groupDelay(Conv,N)` returns a vector of frequencies, `F`, at which the group delay has been computed.

### Examples

#### Group Delays of Digital Down Converter

Compute the group delays of the digital down converter using the `groupDelay` function.

Create a `dsp.DigitalDownConverter` System object with the default settings.

```
dwnConv = dsp.DigitalDownConverter

dwnConv =
    dsp.DigitalDownConverter with properties:

        DecimationFactor: 100
        MinimumOrderDesign: true
            Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
        PassbandRipple: 0.1000
    StopbandAttenuation: 60
        Oscillator: 'Sine wave'
        CenterFrequency: 14000000
        SampleRate: 30000000

    Show all properties
```

Use the `groupDelay` function to compute the vector of group delays. By default, the function evaluates the group delays at 8192 frequency points equally spaced around the upper half of the unit circle.

```
D = groupDelay(dwnConv);
```

Plot the vector of group delays.

```
plot(D)
xlabel('Number of frequency points')
ylabel('Group delay')
```

Determine the vector of frequencies over which the group delays are computed and plot them.

```
[D,F] = groupDelay(dwnConv);
plot(F,D)
xlabel('Frequencies')
ylabel('Group delay')
```

## Input Arguments

### Conv — Digital down converter or digital up converter

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

Digital down converter or digital up converter, specified as a `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` System object.

### N — Number of frequency points

8192 (default) | positive scalar

Number of frequency points over which the group delays are evaluated, specified as a positive scalar. These points are equally spaced around the upper half of the unit circle.

Data Types: `double` | `single`

## Output Arguments

### D — Vector of group delays

column vector

Vector of group delays of the digital down converter or digital up converter, evaluated at `N` frequency points equally spaced around the upper half of the unit circle.

Data Types: `double`

**F — Vector of frequencies**

column vector

Frequencies at which the group delays are evaluated, returned as a column vector.

Data Types: double

**Version History**

Introduced in R2012a

**See Also****Functions**[getDecimationFactors](#) | [getInterpolationFactors](#) | [getFilterOrders](#) | [getFilters](#) | [fvtool](#) | [visualizeFilterStages](#)**Objects**[dsp.DigitalDownConverter](#) | [dsp.DigitalUpConverter](#)

## getFixedPointInfo

**Package:** dsp

Get fixed-point word and fraction lengths

### Syntax

```
[WLs, FLs] = getFixedPointInfo(cicObj,nt)
```

### Description

[WLs, FLs] = getFixedPointInfo(cicObj,nt) returns all the word lengths and fraction lengths of the fixed-point sections and the output of the CIC filter System objects, dsp.CICDecimator and dsp.CICInterpolator, based on the input numeric type, nt. For locked objects or when the FixedPointDataType property of the unlocked CIC filter object is set to 'Specify word and fraction lengths', the input numeric type argument, nt, is optional.

### Examples

#### Determine the Section and Output Word Lengths and Fraction Lengths

Using the getFixedPointInfo function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the dsp.CICDecimator and dsp.CICInterpolator System objects. The data types of the filter sections and the output depend on the FixedPointDataType property of the filter System object™.

#### Full precision

Create a dsp.CICDecimator object. The default value of the NumSections property is 2. This value indicates that there are two integrator and comb sections. The WLs and FLs vectors returned by the getFixedPointInfo function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

By default, the FixedPointDataType property of the object is set to 'Full precision'. Calling the getFixedPointInfo function on this object with the input numeric type, nt, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)
```

```

nt =

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

```

```
[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok
```

```

WLs = 1x5

    18    18    18    18    18

```

```

FLs = 1x5

    15    15    15    15    15

```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```

input = int64(randn(8,1))

input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

```

```
output = cicD(input)
```

```

output =

     0
     1
     3
     0

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 66
    FractionLength: 0

```

```
[WLs,FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5

    66    66    66    66    66

```

```
FLs = 1x5
      0      0      0      0      0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

### Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'
```

```
cicD =
  dsp.CICDecimator with properties:

    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32
```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
  3.5784   -0.1241
  2.7694    1.4897
 -1.3499    1.4090
  3.0349    1.4172
  0.7254    0.6715
 -0.0630   -1.2075
  0.7148    0.7172
 -0.2050    1.6302

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
      26      26      26      26      32
```

```
FLs = 1x5
      15      15      15      15      21
```

### Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Specify word and fraction lengths'
        SectionWordLengths: [16 16 16 16]
        SectionFractionLengths: 0
        OutputWordLength: 32
        OutputFractionLength: 0
```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
```

```
    16    16    16    16    32
```

```
FLs = 1x5
```

```
     0     0     0     0     0
```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```
WLs = 1x5
```

```
    16    16    16    16    32
```

```
FLs = 1x5
```

```
     0     0     0     0     0
```

### Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to 'Specify word lengths'.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```
cicD =
    dsp.CICDecimator with properties:
```

```
        DecimationFactor: 2
```

```

    DifferentialDelay: 1
      NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD, numerictype(inputF))
```

```
WLs = 1x5
```

```
    16    16    16    16    32
```

```
FLs = 1x5
```

```
     5     5     5     5    21
```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

## Input Arguments

### **cicObj** — CIC filter System object

`dsp.CICDecimator` | `dsp.CICInterpolator`

CIC filter System object, specified as either a `dsp.CICDecimator` or `dsp.CICInterpolator` System object.

### **nt** — Input numeric type

`numerictype`

Input data numeric type, specified as a `numerictype` object. Specify this input when the System object is unlocked and the `FixedPointDataType` property of the CIC filter is set to 'Full precision', 'Minimum section word lengths', or 'Specify word lengths'. If the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the word and fraction lengths of the filter sections and the output are specified through the object parameters. In this case, the `nt` input is optional. Alternatively, if the object is locked, the fixed-point data input to the object specifies the input word length and fraction length. The `nt` argument in this case is also optional.

Example: `numerictype(1,16,15)`

Example: `input = fi(randn(16,1),1,32,30); numerictype(input)`

## Output Arguments

### **WLs** — Section and output word lengths

row vector

Section and output word lengths, returned as a row vector. The first  $2 \times \text{NumSections}$  elements in the row vector correspond to the word lengths of the integrator and comb sections of the CIC filter.

The value of the `NumSections` property specifies the number of sections in either the integrator part or the comb part of the filter. The last element in the vector corresponds to the word length of the object output.

The word length of the CIC filter sections and the object output depend on the `FixedPointDataType` property of the CIC filter object.

### Full precision

When the `FixedPointDataType` property of the CIC filter object is set to 'Full precision', the section and output word lengths are computed using the following equation:

$$WL_{\text{section}} = WL_{\text{input}} + NumSect$$

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$

where,

- $WL_{\text{section}}$  -- Word length of the CIC filter section.
- $WL_{\text{output}}$  -- Word length of the output data.
- $WL_{\text{input}}$  -- Word length of the input data.
- $NumSect$  -- Number of CIC filter sections specified through the `NumSections` property.

For locked objects,  $WL_{\text{input}}$  is inherited from the data input you pass to the object algorithm. For unlocked objects, the  $WL_{\text{input}}$  is inherited from the `nt` argument.

### Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the section word length is given by the following equation:

$$WL_{\text{section}} = WL_{\text{input}} + NumSect$$

The output word length is the value you specify in `OutputWordLength` property of the CIC filter object.

### Specify word and fraction lengths

When the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the section word lengths and output word length are the values you specify in the `SectionWordLengths` and `OutputWordLength` properties of the CIC filter object.

### Specify word lengths

When the `FixedPointDataType` property is set to 'Specify word lengths', the section word lengths and the output word length are the values you specify in the `SectionWordLengths` and `OutputWordLength` properties of the CIC filter object.

Example: [20 20 20 20 20]

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### FLs — Section and output fraction lengths

row vector

Section and output fraction lengths, returned as a row vector. The first  $2 \times NumSections$  elements in the row vector correspond to the fraction lengths of the integrator and comb sections of the CIC filter.

The value of `NumSections` property specifies the number of sections in either the integrator part or the comb part of the filter. The last element in the vector corresponds to the fraction length of the object output.

The fraction length of the CIC filter sections and the object output depend on the `FixedPointDataType` property of the CIC filter object.

### Full precision

When the `FixedPointDataType` property of the CIC filter object is set to 'Full precision', the section and output fraction lengths are computed using the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

For inputs of built-in integer data types, the section and output fraction lengths are 0.

### Minimum section word lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Minimum section word lengths', the section and output fraction lengths,  $FL_{\text{section}}$  and  $FL_{\text{output}}$  are given by the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

For inputs of built-in integer data types, the section and output fraction lengths are 0.

### Specify word and fraction lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Specify word and fraction lengths', the section and output fraction lengths are the values you specify in the `SectionFractionLengths` and `OutputFractionLength` properties.

### Specify word lengths

When the `FixedPointDataType` property of the CIC filter object is set to 'Specify word lengths', the section and output fraction lengths,  $FL_{\text{section}}$  and  $FL_{\text{output}}$  are given by the following equation:

$$FL_{\text{section}} = WL_{\text{section}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + NumSect)$$

Example: [12 12 12 12 12]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## getFilters

**Package:** dsp

Return matrix of channelizer FIR filters

### Syntax

```
B = getFilters(obj)
B = getFilters(obj,ind)
```

### Description

`B = getFilters(obj)` returns a matrix `B` of filter coefficients corresponding to each filter in the `dsp.Channelizer` System object filter bank. Each row contains the coefficients for the corresponding bandpass filter. The channelizer does not actually use all these filters in the implementation. It only uses the prototype lowpass filter (the first row of matrix `B`) and an FFT to implement the filter bank. The combination of polyphase implementation of the prototype lowpass and the FFT effectively implements all the filters in `B`, but does so in a very efficient manner.

`B = getFilters(obj,ind)` returns the filters with indices corresponding to the elements in the vector `ind`. `ind` is a row vector of indices between 1 and `obj.NumFrequencyBands`. By default, this vector is `[1:N]`, where `N` is the number of frequency bands specified in the `obj.NumFrequencyBands` property.

### Examples

#### Coefficients of Channelizer Filters

Using the `getFilters` function, you can access the coefficients of the lowpass prototype filter and the modulated bandpass filters of the channelizer.

```
channelizer = dsp.Channelizer;
B = getFilters(channelizer);
```

The first row corresponds to the coefficients of the prototype filter. The subsequent rows correspond to the coefficients of the respective modulated filters. Compare the first row with the coefficients returned by the `tf` function.

```
b = tf(channelizer);
isequal(b,B(1,:))
```

```
ans = logical
     1
```

The output of the `tf` function and the first row of the `B` matrix are equal.

Visualize the frequency response of the first 4 filters of the channelizer.

```
fvtool(B(1,:),1, B(2,:),1, B(3,:),1, B(4,:),1);
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer`

Input filter, specified as `dsp.Channelizer` System object. The `getFilters` function returns a matrix of filter coefficients corresponding to each filter in the channelizer filter bank.

### **ind** — Filter indices

row vector

Filter indices, specified as a row vector in the range  $[1 \text{ obj}.\text{NumFrequencyBands}]$ . If not specified, `ind` is  $1:N$ , where  $N$  is the number of frequency bands specified through the `obj.NumFrequencyBands` property.

Example: `getFilters(channelizer,[1:4]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **B** — Matrix of channelizer FIR filter coefficients

matrix

Matrix of channelizer finite impulse response (FIR) filter coefficients, returned as a matrix. Each row in the matrix corresponds to a filter in the filter bank. The first row corresponds to the prototype filter as returned by  $b = \text{tf}(\text{obj})$ . The remaining rows in  $B$  are given by:

$$b_k = b \times e^{jw_k n/N}$$

$N$  is the number of frequency bands, and  $k$  is the row index - 1.

# generateScript

## Package:

Generate MATLAB script to create scope with current settings

## Syntax

```
generateScript(scope)
```

## Description

`generateScript(scope)` generates a MATLAB script that can recreate a scope object with the current settings in the scope.

## Examples

### Generate Script from spectrumAnalyzer

- 1 Create a spectrumAnalyzer object.

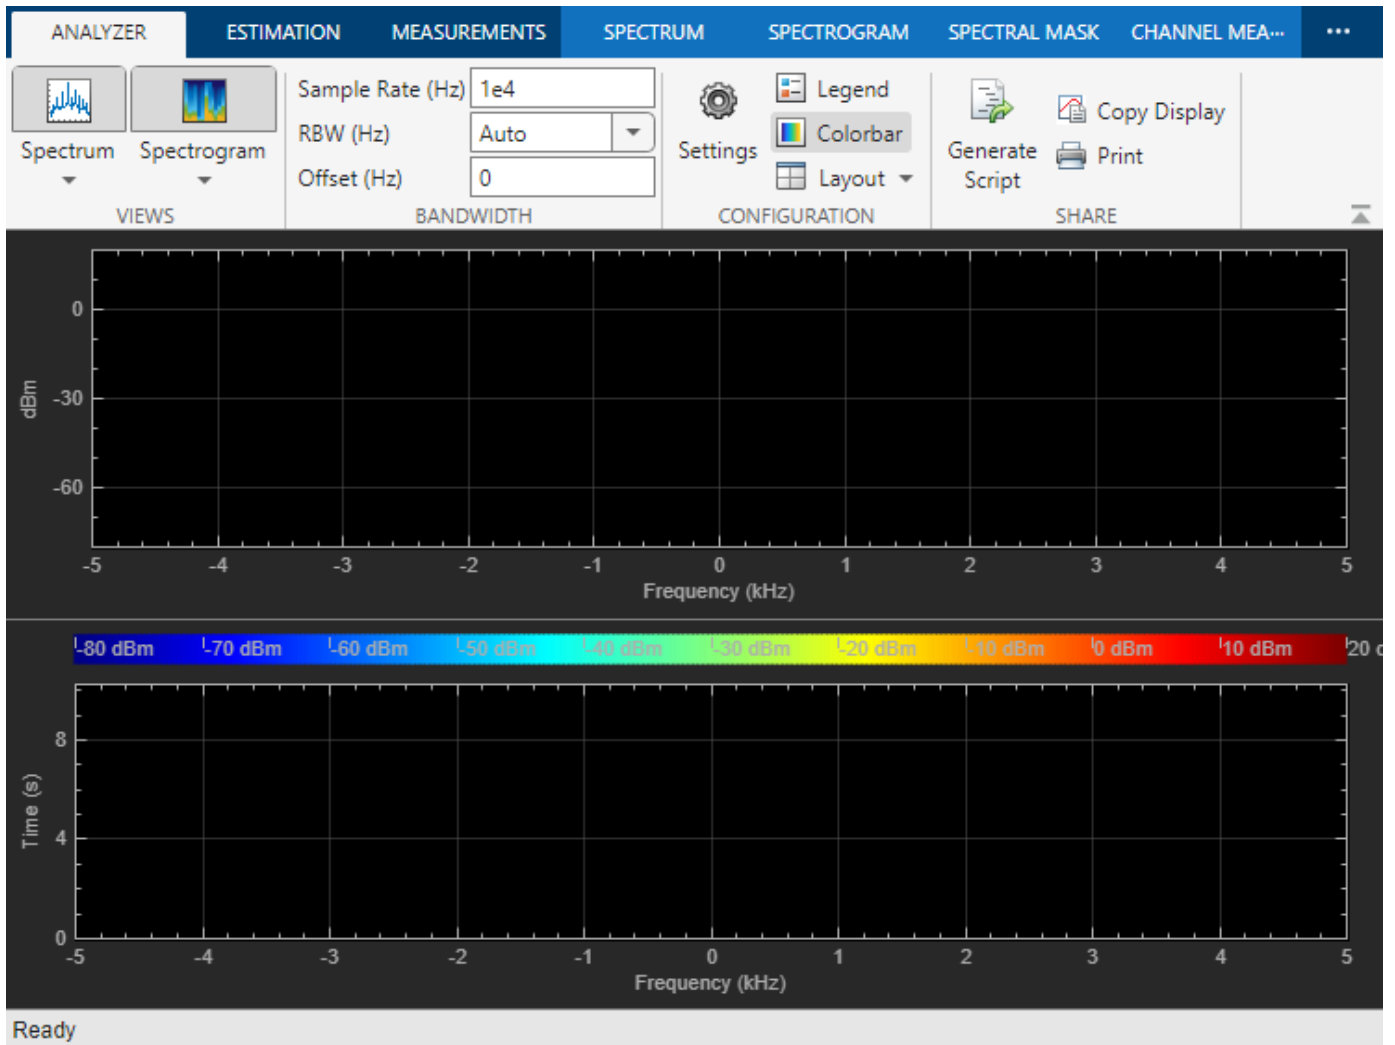

```
scope = spectrumAnalyzer();  
show(scope);
```

- 2 Set options in the Spectrum Analyzer. For this example, enable both **Spectrum** and **Spectrogram** to be shown in the **Analyzer** tab of the Spectrum Analyzer toolstrip.

In addition, enable **Max-Hold Trace** and **Min-Hold Trace** in the **Spectrum** tab.

- 3 Generate a script to recreate the `spectrumAnalyzer` with the modified settings. Either click **Generate Script** from the **Analyzer** tab, or enter this command in the MATLAB command prompt.

```
generateScript(scope);
```

A new editor window opens with code to regenerate the same scope.

```
% Generated by MATLAB(R) 9.12 (R2022a) and DSP System Toolbox 9.14 (R2022a).
% Generated on 15-Nov-2021 15:24:16 -0500.

% Construct a spectrumAnalyzer object
specScope = spectrumAnalyzer(ViewType="spectrum-and-spectrogram", ...
    PlotMaxHoldTrace=true, ...
    PlotMinHoldTrace=true, ...
    Position=[184 190 742 563]);
```

### Generate Script from `dsp.ArrayPlot`

- 1 Create a `dsp.ArrayPlot` object.

```
scope = dsp.ArrayPlot();
show(scope);
```

- Set options in the Array Plot. For this example, from the **Measurements** tab, turn on the **Data Cursors**. From the **Plot** tab, turn on **Legend** and **Magnitude and Phase**. Click **Settings** and give the plot an XLabel and Title.

- Generate a script to recreate the `dsp.ArrayPlot` with the same modified settings. Either select **Generate Script** from the **Plot** tab, or enter the following in the MATLAB command prompt:

```
generateScript(scope);
```

A new editor window opens with code to regenerate the same scope.

```
% Generated by MATLAB(R) 9.12 (R2022a) and DSP System Toolbox 9.14 (R2022a).
% Generated on 8-Dec-2021 15:37:21 -0500.

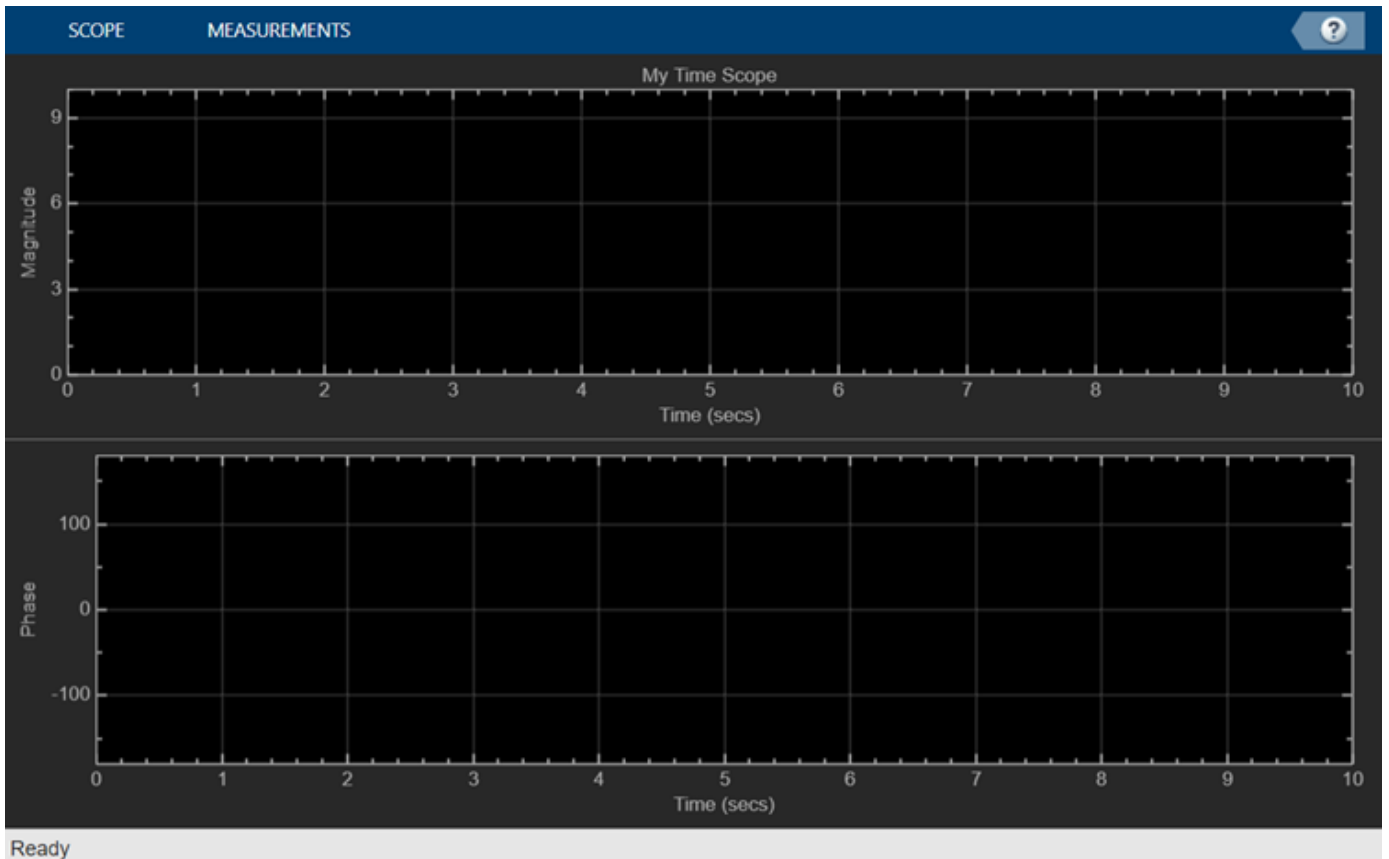

% Construct a dsp.ArrayPlot object
arrayPlot = dsp.ArrayPlot(PlotAsMagnitudePhase=true, ...
    Title="My Array Plot", ...
    XLabel="Frequency", ...
    ShowLegend=true);
% Cursor Measurements Configuration
arrayPlot.CursorMeasurements.Enabled = true;
```

## Generate Script from timescope

- Create a `timescope` object.

```
scope = timescope;
show(scope)
```

- 2 Set options in the Time Scope. For this example, on the **Scope** tab, click **Settings**. Under **Display and Labels**, select **Show Legend** and **Magnitude Phase Plot**. Set the **Title** as well.

- 3 Generate a script to recreate the `timescope` with the same modified settings. Either select **Generate Script** from the **Scope** tab, or enter the following in the MATLAB command prompt:

```
generateScript(scope);
```

A new editor window opens with code to regenerate the same scope.

```
% Generated by MATLAB(R) 9.14 (R2023a) and DSP System Toolbox 9.15 (R2023a).
% Generated on 1-Dec-2022 12:33:51 -0500.

% Construct a timescope object
timeScope = timescope(Position=[2672 404 800 500], ...
    PlotAsMagnitudePhase=true, ...
    Title="My Time Scope", ...
    ShowLegend=true);
```

## Input Arguments

### `scope` — Scope object

scope object

Scope object whose settings you want to recreate with a script, specified as one of the following:

- `spectrumAnalyzer` object

- dsp.ArrayPlot object
- timescope object
- dsp.DynamicFilterVisualizer object

## Version History

Introduced in R2019a

### R2022a: Support for dsp.SpectrumAnalyzer object will be removed

*Not recommended starting in R2022a*

The generateScript function will stop supporting the dsp.SpectrumAnalyzer object in a future release. Use the spectrumAnalyzer object instead.

### Update Code

No updates to your code are required except replacing instances of dsp.SpectrumAnalyzer with spectrumAnalyzer.

This table shows how the generateScript function typically uses the dsp.SpectrumAnalyzer System object and explains how to update existing code to use the spectrumAnalyzer object.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <pre>scope = dsp.SpectrumAnalyzer; show(scope)</pre> <p>Make changes in the UI. Generate script.</p> <pre>generateScript(scope);</pre> <p>A new editor window opens with code to regenerate the same scope.</p> <pre>% Creation Code for 'dsp.SpectrumAnalyzer'. % Generated by Spectrum Analyzer on 16-Nov-2021 11:35:13 -0500. specScope = dsp.SpectrumAnalyzer('ViewType','Spectrum and spectrogram', ...     'PlotMaxHoldTrace',true, ...     'PlotMinHoldTrace',true);</pre> | <pre>scope = spectrumAnalyzer; show(scope)</pre> <p>Make changes in the UI. Generate script.</p> <pre>generateScript(scope);</pre> <p>A new editor window opens with code to regenerate the same scope.</p> <pre>% Generated by MATLAB(R) 9.12 (R2022a) and DSP System Toolbox 9.14 (R2022a) % Generated on 16-Nov-2021 11:36:19 -0500. % Construct a spectrumAnalyzer object specScope = spectrumAnalyzer(ViewType="spectrum-and-spectrogram", ...     PlotMaxHoldTrace=true, ...     PlotMinHoldTrace=true);</pre> |

### R2022b: New support for dsp.DynamicFilterVisualizer object

Starting in R2022b, the generateScript function supports the dsp.DynamicFilterVisualizer object.

## Topics

“Configure Spectrum Analyzer”

## getSpectralMaskStatus

Get test results of current spectral mask

### Syntax

```
results = getSpectralMaskStatus(scope)
```

### Description

`results = getSpectralMaskStatus(scope)` returns the current status of the spectral mask on the spectrum analyzer, `scope`, in a structure, `results`.

### Examples

#### Get Spectral Mask Status

Add a spectral mask to an existing `spectrumAnalyzer` object. Use the `getSpectralMaskStatus` function to get the spectral mask status.

```
sine = dsp.SineWave(Frequency=[98 100],SampleRate=1000);
sine.SamplesPerFrame = 1024;
scope = spectrumAnalyzer(SampleRate=sine.SampleRate,...
    PlotAsTwoSidedSpectrum=false,ShowLegend=true,YLimits=[-60 40]);
hide(scope);

scope.SpectralMask.EnabledMasks = "upper-and-lower";
upperMask = [0 -10; 90 -10; 90 30; 110 30; 110 -10; 500 -10];
set(scope.SpectralMask,UpperMask=upperMask,LowerMask=-55);

for i=1:100
    scope(sine() + 0.05*randn(1024,2));
end

res = getSpectralMaskStatus(scope)

res = struct with fields:
    IsCurrentlyPassing: 1
    NumPassedTests: 44
    NumTotalTests: 50
    SuccessRate: 88
    FailingMasks: ''
    FailingChannels: [1x0 double]
    SimulationTime: 102.3990
```

You can also view the status in the **Spectral Mask** tab on the Spectrum Analyzer toolstrip.

```
show(scope);
release(scope);
```

## Input Arguments

### scope — Spectrum Analyzer

object name | block configuration

Spectrum Analyzer with spectral masks, specified as one of the following:

- spectrumAnalyzer object
- SpectrumAnalyzerConfiguration object for a Spectrum Analyzer block

## Output Arguments

### results — Current status of spectral mask

structure

Current status of the spectral mask, returned as a structure with these fields.

| Field              | Description   |
|--------------------|---|
| IsCurrentlyPassing | Pass status of one or more masks.<br>1 — All masks have passed<br>0 — One or more masks have failed |
| NumPassedTests     | Number of mask tests that have passed   |
| NumTotalTests      | Total number of mask tests  |
| SuccessRate        | Percentage of tests that have passed  |
| FailingChannels    | Array of channel numbers that have currently failed the mask test                                   |
| FailingMasks       | Masks that have currently failed: "none", "upper", "lower", or "upper-and-lower"                    |
| SimulationTime     | Simulation time   |

## Version History

Introduced in R2017a

### **R2022a: Support for `dsp.SpectrumAnalyzer` object will be removed**

*Not recommended starting in R2022a*

The `getSpectralMaskStatus` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

### **Update Code**

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `getSpectralMaskStatus` function typically uses the `dsp.SpectrumAnalyzer` System object and explains how to update existing code to use the `spectrumAnalyzer` object.

## getSpectrumData

Save spectrum data shown in spectrum analyzer

### Syntax

```
spectrumTable = getSpectrumData(scope)
```

### Description

`spectrumTable = getSpectrumData(scope)` returns the spectrum and spectrogram displayed on the spectrum analyzer along with additional statistics about the spectrum.

### Examples

#### Save Spectrum Data

Create a Spectrum Analyzer object and generate data.

```
scope = spectrumAnalyzer;  
scope(randn(6000,3))
```

Save data from the last spectrum shown in the Spectrum Analyzer to a table.

```
specTable = getSpectrumData(scope)
```

```
specTable =
```

```
1x3 table
```

| SimulationTime | Spectrum        | FrequencyVector |
|----------------|-----------------|-----------------|
| {[0.5999]}     | {1024x3 double} | {1024x1 double} |

## Input Arguments

### scope — Spectrum analyzer

object name | block configuration

Spectrum Analyzer you want to query, specified as one of the following:

- spectrumAnalyzer object
- SpectrumAnalyzerConfiguration object for a Spectrum Analyzer block

## Output Arguments

### spectrumTable — Data about current spectrum estimation

table

A spectrum table is returned containing the following fields:

| Field           | Description                                |
|-----------------|--|
| SimulationTime  | Simulation time                            |
| Spectrum        | Power, power density, or RMS spectrum data |
| Spectrogram     | Spectrogram data                           |
| MinHoldTrace    | Minimum hold trace data                    |
| MaxHoldTrace    | Maximum hold trace data                    |
| FrequencyVector | Frequency vector                           |

## Version History

### Introduced in R2017b

### R2022a: Support for dsp.SpectrumAnalyzer object will be removed

*Not recommended starting in R2022a*

The getSpectrumData function will stop supporting the dsp.SpectrumAnalyzer object in a future release. Use the spectrumAnalyzer object instead.

### Update Code

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `getSpectrumData` function typically uses the `dsp.SpectrumAnalyzer` System object and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre>scope = dsp.SpectrumAnalyzer;<br/>scope(randn(100000,1))<br/>specTable = getSpectrumData(scope)</pre> | <pre>scope = spectrumAnalyzer;<br/>scope(randn(100000,1))<br/>specTable = getSpectrumData(scope)</pre> |

# getMeasurementsData

Get the current measurement data displayed on the spectrum analyzer

## Syntax

```
data = getMeasurementsData(scope)
data = getMeasurementsData(scope,"all")
```

## Description

`data = getMeasurementsData(scope)` returns a data table about the current spectrum analyzer measurements in use.

`data = getMeasurementsData(scope,"all")` returns a data table about all spectrum analyzer measurements for the current time step.

## Examples

### Obtain Measurements Data Programmatically for spectrumAnalyzer object

Compute and display the power spectrum of a noisy sinusoidal input signal using the `spectrumAnalyzer` MATLAB® object. Measure the peaks, cursor placements, adjacent channel power ratio, and distortion values in the spectrum by enabling these properties:

- `PeakFinder`
- `CursorMeasurements`
- `ChannelMeasurements`
- `DistortionMeasurements`

### Initialization

The input sine wave has two frequencies: 1000 Hz and 5000 Hz. Create two `dsp.SineWave` System objects to generate these two frequencies. Create a `spectrumAnalyzer` object to compute and display the power spectrum.

```
Fs = 44100;
Sineobject1 = dsp.SineWave(SamplesPerFrame=1024,PhaseOffset=10,...
    SampleRate=Fs,Frequency=1000);
Sineobject2 = dsp.SineWave(SamplesPerFrame=1024,...
    SampleRate=Fs,Frequency=5000);
SA = spectrumAnalyzer(SampleRate=Fs,SpectrumType="power",...
    PlotAsTwoSidedSpectrum=false,ChannelNames={'Power spectrum of the input'},...
    YLimits=[-120 40],ShowLegend=true);
```

### Enable Measurements Data

To obtain the measurements, set the `Enabled` property to `true`.

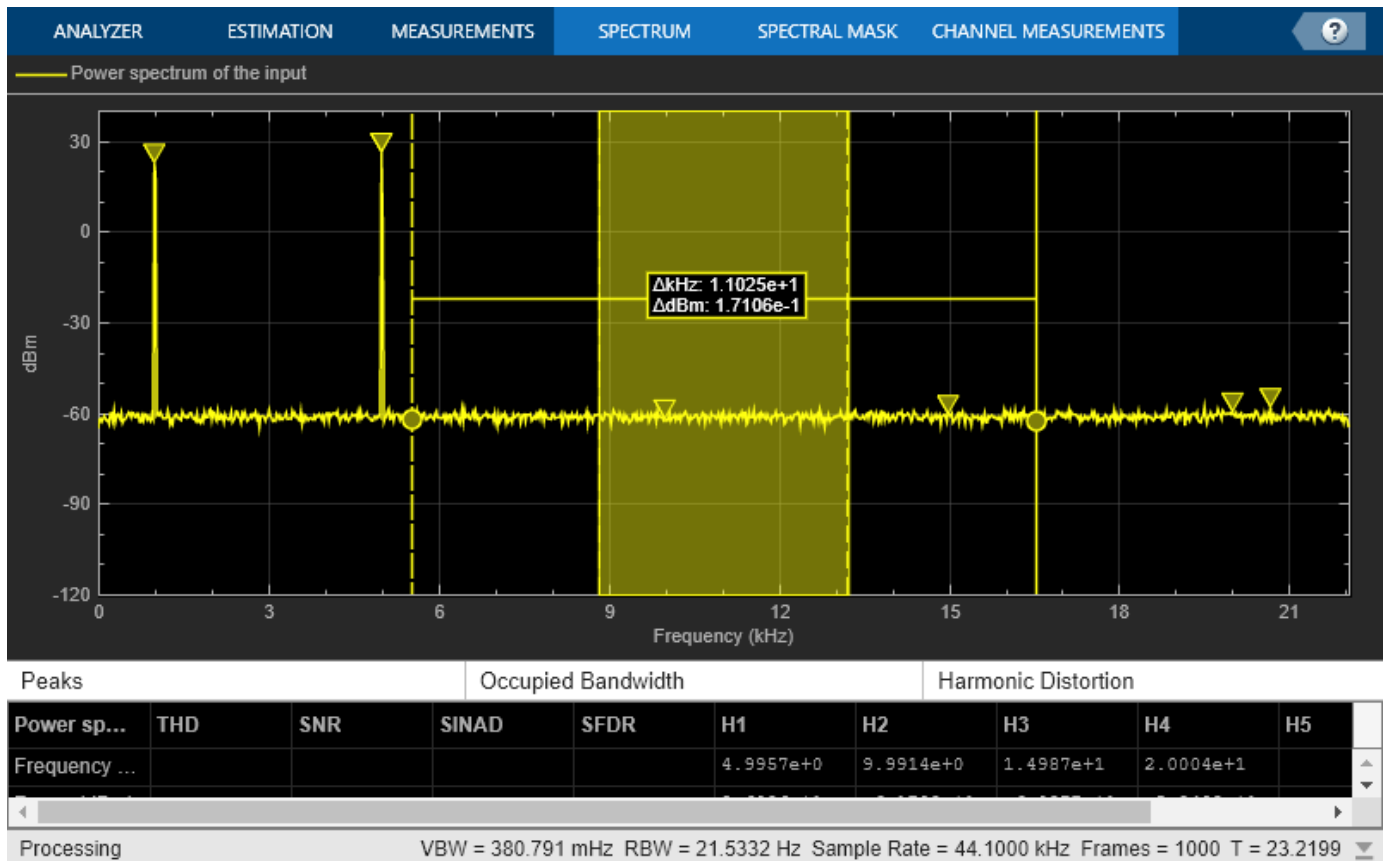

```
SA.CursorMeasurements.Enabled = true;
SA.ChannelMeasurements.Enabled = true;
```

```
SA.PeakFinder.Enabled = true;
SA.DistortionMeasurements.Enabled = true;
```

### Use getMeasurementsData

Stream in the noisy sine wave input signal and estimate the power spectrum of the signal using the spectrumAnalyzer object. Measure the characteristics of the spectrum. Use the getMeasurementsData function to obtain these measurements programmatically. The isNewDataReady function returns true when there is new spectrum data. Store the measured data in the variable data.

```
data = [];
for Iter = 1:1000
    Sinewave1 = Sineobject1();
    Sinewave2 = Sineobject2();
    Input = Sinewave1 + Sinewave2;
    NoisyInput = Input + 0.001*randn(1024,1);
    SA(NoisyInput);
    if SA.isNewDataReady
        data = [data;getMeasurementsData(SA)];
    end
end
```

The panes at the bottom of the scope window display the measurements that you have enabled. The values in these panes match the values in the last time step of the data variable. You can access the individual fields of data to obtain the various measurements programmatically.

## Compare Peak Values

Use the `PeakFinder` property to obtain peak values. Verify that the peak values in the last time step of `data` match the values in the spectrum analyzer plot.

```
peakvalues = data.PeakFinder(end).Value
```

```
peakvalues = 3×1
```

```
    26.3957  
    22.7830  
   -57.9977
```

```
frequencieskHz = data.PeakFinder(end).Frequency/1000
```

```
frequencieskHz = 3×1
```

```
    4.9957  
    0.9905  
   20.6719
```

## Obtain Measurements Data Programmatically for Spectrum Analyzer Block

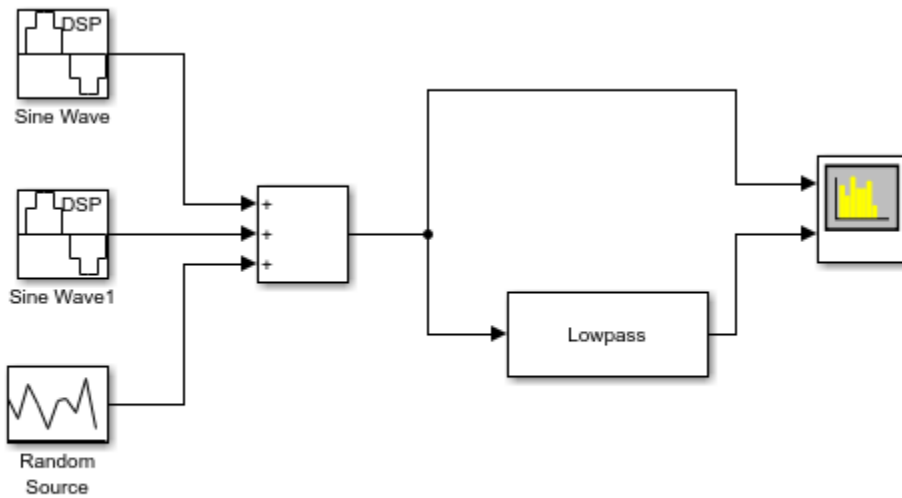

Compute and display the power spectrum of a noisy sinusoidal input signal using the Spectrum Analyzer block. Measure the cursor placements, adjacent channel power ratio, distortion, and peak values in the spectrum by enabling these block configuration properties:

- `CursorMeasurements`
- `ChannelMeasurements`
- `DistortionMeasurements`
- `PeakFinder`

## Open and Inspect the Model

Filter a streaming noisy sinusoidal input signal using a Lowpass Filter block. The input signal consists of two sinusoidal tones: 1 kHz and 15 kHz. The noise is white Gaussian noise with a mean of 0 and a variance of 0.05. The sampling frequency is 44.1 kHz. Open the model and inspect the parameter values in the blocks.

```
model = 'spectrumanalyzer_measurements.slx';  
open_system(model)
```

Copyright 2018-2022 The MathWorks, Inc.

Access the configuration properties of the Spectrum Analyzer block using the `get_param` function.

```
sablock = 'spectrumanalyzer_measurements/Spectrum Analyzer';  
cfg = get_param(sablock, 'ScopeConfiguration');
```

### Enable Measurements Data

To obtain the measurements, set the Enabled property to `true`.

```
cfg.CursorMeasurements.Enabled = true;  
cfg.ChannelMeasurements.Enabled = true;  
cfg.DistortionMeasurements.Enabled = true;  
cfg.PeakFinder.Enabled = true;
```

### Simulate the Model

Run the model. The Spectrum Analyzer block compares the original spectrum with the filtered spectrum.

```
sim(model)
```

The panes at the bottom of the spectrum analyzer window display the measurements that you have enabled.

### Use getMeasurementsData function

Use the `getMeasurementsData` function to obtain the measurements programmatically.

```
data = getMeasurementsData(cfg)
```

```
data =
```

```
1x5 table
```

```
SimulationTime
```

```
9.9962
```

```
PeakFinder
```

```
1x1 struct
```

```
CursorMeasurements
```

```
1x1 struct
```

```
ChannelMeasurements
```

```
1x1 struct
```

```
DistortionMeasurements
```

```
1x1 struct
```

The values shown in the measurement panels match the values shown in `data`. You can access the individual fields of `data` to obtain the various measurements programmatically.

### Compare Peak Values

As an example, compare the peak values. Verify that the peak values obtained by `data.PeakFinder` match with the values in the spectrum analyzer window.

```
peakvalues = data.PeakFinder.Value
frequencieskHz = data.PeakFinder.Frequency/1000
```

```
peakvalues =
```

```
    26.8653
    26.2638
    -3.4329
```

```
frequencieskHz =
```

```
    15.0015
     1.0049
     3.7755
```

## Input Arguments

### scope — Spectrum Analyzer

object name | block configuration

Spectrum Analyzer you want to query, specified as one of the following:

- spectrumAnalyzer object
- SpectrumAnalyzerConfiguration object for a Spectrum Analyzer block

## Output Arguments

### data — Measurements data

table

Measurements data, returned as a table. When you specify "all", the function returns a measurements table containing the following fields.

| Field  | Description                  |
|--|------------------------------|
| SimulationTime   | Simulation time              |
| PeakFinder   | Peak finder data             |
| CursorMeasurements   | Cursor measurements data     |
| ChannelMeasurements  | Channel measurements data    |
| DistortionMeasurements   | Distortion measurements data |
| CCDFMeasurements (applies only for SpectrumAnalyzerConfiguration object) | CCDF measurements data       |

When you do not specify "all", the data table contains only the Spectrum Analyzer measurements currently in use.

## Version History

Introduced in R2018b

**R2022a: Support for dsp.SpectrumAnalyzer object will be removed***Not recommended starting in R2022a*

The `getMeasurementsData` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

**Update Code**

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `getMeasurementsData` function typically uses the `dsp.SpectrumAnalyzer` System object and explains how to update existing code to use the `spectrumAnalyzer` object.

## getOctaveBandwidth

**Package:** dsp

Bandwidth in number of octaves

### Syntax

```
N = getOctaveBandwidth(npFilter)
```

### Description

`N = getOctaveBandwidth(npFilter)` returns the bandwidth of the notch peak filter, measured in number of octaves.

### Examples

#### Get Octave Bandwidth of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration.

```
np = dsp.NotchPeakFilter
```

```
np =  
    dsp.NotchPeakFilter with properties:
```

```
    Specification: 'Bandwidth and center frequency'  
    Bandwidth: 2205  
    CenterFrequency: 11025  
    SampleRate: 44100
```

Determine the octave bandwidth of the filter using the `getOctaveBandwidth` function.

```
getOctaveBandwidth(np)
```

```
ans = 0.2881
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

## Input Arguments

**npFilter** — Notch peak filter  
`dsp.NotchPeakFilter`

Notch peak filter whose bandwidth is measured in octaves, specified as a `dsp.NotchPeakFilter` object.

## Output Arguments

**N** — Number of octaves  
scalar

Bandwidth of the filter measured in number of octaves, returned as a scalar.

Data Types: `double`

## Version History

Introduced in R2014a

### **Functions**

getBandwidth | getCenterFrequency | getQualityFactor | tf

### **Objects**

dsp.NotchPeakFilter

# getQualityFactor

**Package:** dsp

Get quality factor

## Syntax

```
Q = getQualityFactor(npFilter)
```

## Description

`Q = getQualityFactor(npFilter)` returns the quality factor (Q factor) of the notch peak filter. The Q factor is defined as the center frequency divided by the bandwidth.

## Examples

### Compute Quality Factor of Notch Peak Filter

Create a `dsp.NotchPeakFilter` object in the default configuration, where the `Specification` property is set to 'Bandwidth and center frequency'.

```
np = dsp.NotchPeakFilter
```

```
np =  
    dsp.NotchPeakFilter with properties:
```

```
    Specification: 'Bandwidth and center frequency'  
    Bandwidth: 2205  
    CenterFrequency: 11025  
    SampleRate: 44100
```

Determine the quality factor of the filter using the `getQualityFactor` function. The quality factor is given by the ratio of the center frequency to the bandwidth.

```
getQualityFactor(np)
```

```
ans = 5
```

Visualize the filter response using `fvtool`.

```
fvtool(np)
```

## Input Arguments

**npFilter** — Notch peak filter  
`dsp.NotchPeakFilter`

Notch peak filter whose quality factor is computed, specified as a `dsp.NotchPeakFilter` object.

## Output Arguments

**Q** — Quality factor  
scalar

Quality factor of the filter, returned as a scalar. The Q factor is defined as the center frequency divided by the bandwidth.

Data Types: `double`

[dsp.NotchPeakFilter](#)

## tf

**Package:** dsp

Transfer function

### Syntax

```
[B,A] = tf(npFilter)
[B,A,B2,A2] = tf(npFilter)
```

### Description

`[B,A] = tf(npFilter)` returns the vector of numerator coefficients, B, and the vector of denominators, A, for the equivalent transfer function corresponding to the notch filter.

`[B,A,B2,A2] = tf(npFilter)` also returns the vector of numerator coefficients, B2, and the vector of denominator coefficients, A2, for the equivalent transfer function corresponding to the peak filter.

### Examples

#### Determine Transfer Function of Notch Peak Filter

Create a `dsp.NotchPeakFilter` System object™. Obtain the coefficients of the transfer function corresponding to the notch and peak filters.

```
notchpeak = dsp.NotchPeakFilter;
[Bnotch,Anotch,Bpeak,Apeak] = tf(notchpeak)
```

```
Bnotch = 1×3
```

```
    0.8633    -0.0000    0.8633
```

```
Anotch = 1×3
```

```
    1.0000    -0.0000    0.7265
```

```
Bpeak = 1×3
```

```
    0.1367         0    -0.1367
```

```
Apeak = 1×3
```

```
    1.0000    -0.0000    0.7265
```

**Bnotch** and **Anotch** are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the notch filter. **Bpeak** and **Apeak** are the vectors of numerator and denominator coefficients for the equivalent transfer function corresponding to the peak filter.

## Input Arguments

### **npFilter** — Notch peak filter object

`dsp.NotchPeakFilter`

Notch peak filter object, specified as a `dsp.NotchPeakFilter` object.

## Output Arguments

### **B** — Numerator coefficients of notch filter

vector

Numerator coefficients for the equivalent transfer function corresponding to the notch filter, specified as a vector.

Data Types: `double`

### **A** — Denominator coefficients of notch filter

vector

Denominator coefficients for the equivalent transfer function corresponding to the notch filter, specified as a vector.

Data Types: `double`

### **B2** — Numerator coefficients of peak filter

vector

Numerator coefficients for the equivalent transfer function corresponding to the peak filter, specified as a vector.

Data Types: `double`

### **A2** — Denominator coefficients of peak filter

vector

Denominator coefficients for the equivalent transfer function corresponding to the peak filter, specified as a vector.

Data Types: `double`

**Objects**

dsp.NotchPeakFilter

# grpdelay

**Package:** dsp

Group delay response of discrete-time filter System object

## Syntax

```
[gd,w] = grpdelay(sysobj)
[gd,w] = grpdelay(sysobj,n)
[gd,w] = grpdelay(sysobj,'Arithmetic',arithType)
grpdelay(sysobj)
```

## Description

`[gd,w] = grpdelay(sysobj)` returns the group delay `gd` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the group delay is evaluated. The group delay is defined as:

$$-\frac{d}{dw}(\text{angle}(w))$$

The group delay is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,n)` returns the group delay of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[gd,w] = grpdelay(sysobj,'Arithmetic',arithType)` computes the group delay of the filter System object, based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

`grpdelay(sysobj)` plots the group delay of the filter System object in the `fvtool`.

For more input options, see `grpdelay` in Signal Processing Toolbox.

## Examples

### Group Delay of Discrete-Time Multirate Filter

```
CICComp = dsp.CICCompensationDecimator;
```

`grpdelay` computes the group delay of the filter and displays it using `fvtool`.

```
grpdelay(CICComp);
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`

- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

#### **n — Number of samples**

8192 (default) | positive integer

Number of samples, specified as a positive integer. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

#### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- **unlocked** -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- **locked** -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **gd** — Group delay

vector

Group delay vector of length  $n$ . If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

### **w** — Frequencies

vector

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

## Version History

Introduced in R2011a

grpdelay

### Topics

"Analysis Methods for Filter System Objects" on page 3-2

# help

Help for design method with filter specification

## Syntax

```
help(d, 'designmethod')
```

## Description

`help(d, 'designmethod')` displays help in the command window for the design algorithm `designmethod` for the current specifications of the filter specification object `d`. `designmethod` must be one of the design algorithms returned by `designmethods` for `d`, the design object.

## Examples

### Get Help for Designing Butterworth Filters

Get specific help for designing lowpass Butterworth filters.

The first lowpass filter uses the default specification 'Fp,Fst,Ap,Ast' and returns help text specific to the specification.

```
d = fdesign.lowpass;
designmethods(d, 'Systemobject', true)
```

Design Methods that support System objects for class `fdesign.lowpass` (Fp,Fst,Ap,Ast):

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

```
help(d, 'butter')
```

DESIGN Design a Butterworth IIR filter.

`HD = DESIGN(D, 'butter')` designs a Butterworth filter specified by the `FDESIGN` object `D`, and returns the `DFILT/MFILT` object `HD`.

`HD = DESIGN(D, ..., 'SystemObject', true)` implements the filter, `HD`, using a System object instead of a `DFILT/MFILT` object.

`HD = DESIGN(..., 'FilterStructure', STRUCTURE)` returns a filter with the structure `STRUCTURE`. `STRUCTURE` is 'df2sos' by default and can be any of the following:

```
'df1sos'
```

```
'df2sos'
'dfltsos'
'df2tsos'
'cascadeallpass'
'cascadewdfallpass'
```

Some of the listed structures may not be supported by System object filters. Type `validstructures(D, 'butter', 'SystemObject', true)` to get a list of structures supported by System objects.

`HD = DESIGN(..., 'MatchExactly', MATCH)` designs a Butterworth filter and matches the frequency and magnitude specification for the band MATCH exactly. The other band will exceed the specification. MATCH can be 'stopband' or 'passband' and is 'stopband' by default.

`HD = DESIGN(..., 'SOSScaleNorm', NORM)` designs an SOS filter and scales the coefficients using the P-Norm NORM. NORM can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'. Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting `SOSScaleNorm = ''`.

`HD = DESIGN(..., 'SOSScaleOpts', OPTS)` designs an SOS filter and scales the coefficients using an `FDOPTS.SOSSCALING` object OPTS. Scaling options are:

| Property               | Default    | Description/Valid values   |
|------------------------|------------|--|
| 'sosReorder'           | 'auto'     | Reorder section prior to scaling.<br>{'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'} |
| 'MaxNumerator'         | 2          | Maximum value for numerator coefficients   |
| 'NumeratorConstraint'  | 'none'     | {'none', 'unit', 'normalize', 'po2'}   |
| 'OverflowMode'         | 'wrap'     | {'wrap', 'saturate'}   |
| 'ScaleValueConstraint' | 'unit'     | {'unit', 'none', 'po2'}  |
| 'MaxScaleValue'        | 'Not used' | Maximum value for scale values   |

When `sosReorder` is set to 'auto', the sections will be automatically reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint' is set to something other than 'unit'. If 'MaxScaleValue' is set to a number, the 'ScaleValueConstraint' will be changed to 'none'. Further, if `SOSScaleNorm` is off (as it is by default), then all the `SOSScaleOpts` will be ignored.

For more information about P-Norm and scaling options see help for `DFILT\SCALE`.

```
% Example #1 - Compare passband and stopband MatchExactly.
```

```

h      = fdesign.lowpass('Fp,Fst,Ap,Ast', .1, .3, 1, 60);
Hd     = design(h, 'butter', 'MatchExactly', 'passband');
Hd(2) = design(h, 'butter', 'MatchExactly', 'stopband');

% Compare the passband edges in FVTool.
fvtool(Hd);
axis([.09 .11 -2 0]);

```

Note the discussion of the `MatchExactly` input option. When you use a design object that uses a different specification, such as `'N,F3dB'`, the help content for the `butter` design method changes.

In this case, the `MatchExactly` option does not appear in the help because it is not an available input argument for the specification `'N,F3dB'`.

```

d = fdesign.lowpass('N,F3dB')

d =
  lowpass with properties:

      Response: 'Lowpass'
  Specification: 'N,F3dB'
  Description: {2x1 cell}
  NormalizedFrequency: 1
      FilterOrder: 10
          F3dB: 0.5000

```

```
designmethods(d, 'SystemObject', true)
```

Design Methods that support System objects for class `fdesign.lowpass (N,F3dB)`:

```
butter
maxflat
```

```
help(d, 'butter')
```

DESIGN Design a Butterworth IIR filter.

`HD = DESIGN(D, 'butter')` designs a Butterworth filter specified by the `FDESIGN` object `D`, and returns the `DFILT/MFILT` object `HD`.

`HD = DESIGN(D, ..., 'SystemObject', true)` implements the filter, `HD`, using a System object instead of a `DFILT/MFILT` object.

`HD = DESIGN(..., 'FilterStructure', STRUCTURE)` returns a filter with the structure `STRUCTURE`. `STRUCTURE` is `'df2sos'` by default and can be any of the following:

```

'df1sos'
'df2sos'
'df1tsos'
'df2tsos'
'cascadeallpass'
'cascadewdfallpass'

```

Some of the listed structures may not be supported by System object filters. Type `validstructures(D, 'butter', 'SystemObject', true)` to get a list of structures supported by System objects.

`HD = DESIGN(..., 'SOSScaleNorm', NORM)` designs an SOS filter and scales the coefficients using the P-Norm `NORM`. `NORM` can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'. Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

Scaling is turned off by default, which is equivalent to setting `SOSScaleNorm = ''`.

`HD = DESIGN(..., 'SOSScaleOpts', OPTS)` designs an SOS filter and scales the coefficients using an `FDOPTS.SOSSCALING` object `OPTS`. Scaling options are:

| Property               | Default    | Description/Valid values   |
|------------------------|------------|--|
| 'sosReorder'           | 'auto'     | Reorder section prior to scaling.<br>{'auto', 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', 'bandstop'} |
| 'MaxNumerator'         | 2          | Maximum value for numerator coefficients   |
| 'NumeratorConstraint'  | 'none'     | {'none', 'unit', 'normalize', 'po2'}   |
| 'OverflowMode'         | 'wrap'     | {'wrap', 'saturate'}   |
| 'ScaleValueConstraint' | 'unit'     | {'unit', 'none', 'po2'}  |
| 'MaxScaleValue'        | 'Not used' | Maximum value for scale values   |

When `sosReorder` is set to 'auto', the sections will be automatically reordered depending on the response type of the design (lowpass, highpass, etc.).

Note that 'MaxScaleValue' will only be used when 'ScaleValueConstraint' is set to something other than 'unit'. If 'MaxScaleValue' is set to a number, the 'ScaleValueConstraint' will be changed to 'none'. Further, if `SOSScaleNorm` is off (as it is by default), then all the `SOSScaleOpts` will be ignored.

For more information about P-Norm and scaling options see help for `DFILT\SCALE`.

```
% Example #1 - Design a lowpass Butterworth filter in the DF2TSOS structure.
h = fdesign.lowpass('N,F3dB');
Hd = design(h, 'butter', 'FilterStructure', 'df2tsos');
```

# hide

## Package:

Hide scope window

## Syntax

```
hide(scope)
```

## Description

hide(scope) hides the window of the scope.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sample rate
signal = dsp.SineWave(Frequency=50, SampleRate=Fs, ...
    SamplesPerFrame=100);
scope = timescope(SampleRate=Fs, TimeSpanSource="property", ...
    TimeSpan=0.25, YLimits=[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

### **scope** — Scope object

scope object

Scope object, specified as one of the following:

- spectrumAnalyzer object
- dsp.ArrayPlot object
- dsp.LogicAnalyzer System object
- timescope object
- dsp.DynamicFilterVisualizer object

Example: `myScope = timescope; hide(myScope)`

## Version History

Introduced in R2011a

**R2022a: Support for `dsp.SpectrumAnalyzer` object will be removed**

*Not recommended starting in R2022a*

The `hide` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

**Update Code**

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `hide` function typically uses the `dsp.SpectrumAnalyzer System` object and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| <pre>scope = dsp.SpectrumAnalyzer;<br/>scope(randn(100000,1))<br/>hide(scope)</pre> | <pre>scope = spectrumAnalyzer;<br/>scope(randn(100000,1))<br/>hide(scope)</pre> |

**See Also****Functions**

# ifir

Interpolated FIR filter design

## Syntax

```
[h,g] = ifir(l,type,f,dev)
[h,g,d] = ifir(l,type,f,dev)
[...] = ifir(...,str)
```

## Description

`[h,g] = ifir(l,type,f,dev)` designs a periodic filter  $h(z^l)$ , where  $l$  is the interpolation factor. It also finds an image-suppressor filter  $g(z)$ , such that the cascade of the two filters represents the optimal minimax FIR approximation of the desired response. This response is specified by `type`, with band edge frequencies contained in vector `f`. This is done while not exceeding the maximum deviations or ripples (linear) specified in vector `dev`.

When `type` is set to 'low', the filter design is a lowpass design. When `type` is set to 'high', the filter design is a highpass design. `f` is a two-element vector with passband and stopband edge frequency values. For narrowband lowpass filters and wideband highpass filters,  $l \times f(2)$  is less than 1. For wideband lowpass filters and narrowband highpass filters, specify `f` so that  $l \times (1 - f(1))$  is less than 1.

`dev` is a two-element vector that contains the peak ripple or deviation (in linear units) allowed for both the passband and the stopband.

The `ifir` design algorithm achieves an efficient design in the sense that it reduces the total number of multipliers required. To do this, the design problem is broken into two stages. In the first stage, the filter is upsampled to achieve the stringent specifications without using many multipliers. In the second stage, the filter removes the images created when upsampling the previous filter.

`[h,g,d] = ifir(l,type,f,dev)` returns a delay `d` that is connected in parallel with the cascade of  $h(z^l)$  and  $g(z)$  for both wideband lowpass and highpass filters. This is necessary to obtain the desired response.

`[...] = ifir(...,str)` uses `str` to choose the algorithm level of optimization used. Possible values for `str` are 'simple', 'intermediate' (default) or 'advanced'. `str` provides for a tradeoff between design speed and filter order optimization. The 'advanced' option can result in substantial filter order reduction, especially for  $g(z)$ .

## Examples

### Narrowband lowpass design using an interpolation factor of 6

This example shows how to use the function `ifir` to design a narrowband lowpass filter.

```
[h,g] = ifir(6,'low',[.12 .14],[.01 .001]);
H = dsp.FIRFilter('Numerator',h);
G = dsp.FIRFilter('Numerator',g);
```

```
hfv = fvtool(H,G);  
legend(hfv, 'Periodic Filter', 'Image Suppressor Filter')
```

```
Hcas = cascade(H,G);  
hfv2 = fvtool(Hcas);  
legend(hfv2, 'Overall Filter')
```

### Wideband highpass design using an interpolation factor of 6

This example shows how to use `ifir` to design a wideband highpass filter.

```
[h,g,d]=ifir(6,'high',[.12 .14],[.001 .01]);
H = dsp.FIRFilter('Numerator',h); G = dsp.FIRFilter('Numerator',g);
b1 = cascade(H,G); % Branch 1
b2 = dsp.FIRFilter('Numerator',d); % Branch 2
Hoverall = freqz(b1) + freqz(b2); % Overall wideband highpass
plot(linspace(0,1,length(Hoverall)),20*log10(abs(Hoverall)))
xlabel('Normalized frequency (\times \pi) rad/s')
ylabel('Magnitude (dB)')
title('Overall Filter');
grid on
```

### Design a cascade of lowpass filters

This example shows how to use `fdesign.lowpass` to design a cascade of lowpass filters. After designing the filter, use `fvtool` to plot the response curve.

```
fpass = 0.2;  
fstop = 0.24;  
d1 = fdesign.lowpass(fpass, fstop);  
lowpassCascade = design(d1, 'ifir', 'Systemobject', true);  
fvtool(lowpassCascade)
```

## iirbpc2bpc

Transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirbpc2bpc(B,A,Wo,Wt)` transform IIR complex bandpass filter to IIR complex bandpass filter with different characteristics.

The `iirbpc2bpc` function returns the numerator and denominator vectors, `Num` and `Den`, respectively of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation. For more details, see IIR Complex Bandpass Frequency Transformation on page 5-910.

The function also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is specified with the numerator `B` and a denominator `A`.

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

### Examples

#### Shift Complex Bandpass

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
```

Create a complex passband from  $0.25\pi$  to  $0.75\pi$ .

```
[bc,ac] = iirlp2bpc(b,a,0.5,[0.25 0.75]);
```

Move the bandpass to between  $-0.3\pi$  and  $0.1\pi$ .

```
[num,den] = iirbpc2bpc(bc,ac,[0.25 0.75],[-0.3 0.1]);
```

Compare the three filters in FVTool.

```
hvft = fvtool(b,a,bc,ac,num,den);
legend(hvft,'Prototype','Positive complex band','Target')
```

## Input Arguments

### **B** — Numerator of prototype lowpass filter

row vector

Numerator of the prototype lowpass filter, specified as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

### **A** — Denominator of prototype lowpass filter

row vector

Denominator of the prototype lowpass filter, specified as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

### **Wo** — Frequency values to be transformed from prototype filter

two-element vector

Frequency values to be transformed from the prototype filter, specified as a two-element vector. Frequencies in **Wo** must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**Wt — Desired frequency locations in transformed target filter**

two-element vector

Desired frequency locations in the transformed target filter, specified as a two-element vector. Frequencies in **Wt** must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Data Types: single | double

**Output Arguments****Num — Numerator of target filter**

row vector

Numerator of the target filter, returned as a row vector.

Data Types: single | double

Complex Number Support: Yes

**Den — Denominator of target filter**

row vector

Denominator of the target filter, returned as a row vector.

Data Types: single | double

Complex Number Support: Yes

**AllpassNum — Numerator of mapping filter**

row vector

Numerator of the mapping filter, returned as a row vector.

Data Types: single | double

Complex Number Support: Yes

**AllpassDen — Denominator of mapping filter**

row vector

Denominator of the mapping filter, returned as a row vector.

Data Types: single | double

**More About****IIR Complex Bandpass Frequency Transformation**

IIR Complex Bandpass Frequency transformation effectively places two features of the original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations,  $W_{t1}$ , and  $W_{t2}$  respectively. It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

IIR complex bandpass frequency transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle for example in the adaptive system.

## **Version History**

## iircomb

IIR comb notch or peak filter

### Syntax

```
[num,den] = iircomb(n,bw)
[num,den] = iircomb(n,bw,ab)
[num,den] = iircomb( ____,type)
```

### Description

`[num,den] = iircomb(n,bw)` returns a digital notching filter with order  $n$  and with the width of the filter notch at -3 dB set to  $bw$ , the filter bandwidth.

For the notching filter, the transfer function takes the form:

$$H(z) = b \frac{1 - z^{-n}}{1 - \alpha z^{-n}}$$

where  $\alpha$  and  $b$  are positive scalars and  $n$  is the filter order or the number of notches in the filter minus 1.

`[num,den] = iircomb(n,bw,ab)` returns a digital notching filter whose bandwidth,  $bw$ , is specified at a level of  $-ab$  decibels.

`[num,den] = iircomb( ____,type)` returns either a digital notch filter or a digital peaking filter as specified by `type`.

The transfer function for peaking filters is:

$$H(z) = b \frac{1 - z^{-n}}{1 + az^{-n}}$$

### Examples

#### Design IIR Notch Filter

Design and plot an IIR notch filter with 11 notches (equal to filter order plus 1) that removes a 60 Hz tone ( $f_0$ ) from a signal at 600 Hz( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
fs = 600;
fo = 60;
q = 35;
bw = (fo/(fs/2))/q;
[b,a] = iircomb(fs/fo,bw,'notch'); % Note type flag 'notch'
```

Use the Filter Visualization Tool (`fvtool`) to generate the plot showing the filter notches.

```
fvtool(b,a);
```

Note that the notches are evenly spaced and one falls at exactly 60 Hz.

## Input Arguments

### **n** — Order of digital filter

positive integer

Order of the digital filter, specified as a positive integer.  $n$  also defines the number of notches (or peaks) in the filter across the frequency range 0 to  $2\pi$ . The number of notches (or peaks) equals  $n+1$ .

Data Types: `single` | `double`

### **bw** — Bandwidth of filter

positive scalar in the range  $(0, 1)$

Bandwidth of the filter at a level of  $-ab$  decibels, specified as a positive scalar in the range  $(0, 1)$ .

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = \omega_0/bw$  where  $\omega_0$  is the frequency to remove from the signal.

Data Types: `single` | `double`

### **ab** — Magnitude response at filter bandwidth

-3 (default) | scalar

Magnitude response at the filter bandwidth `bw`, specified as a scalar in dB. You can include the optional input argument `ab` to specify the magnitude response at a level other than the default -3 dB, for example, -6 dB or 0 dB. If you do not include the argument `ab`, the function sets the magnitude response at the default -3 dB level.

Data Types: `single` | `double`

### **type** — Type of digital filter

'notch' (default) | 'peak'

Type of the digital filter, specified as either:

- 'notch' — Design an IIR notch filter. Notch filters attenuate the response at the specified frequencies. This is the default type. When you omit the `type` input argument, `iircomb` function returns a notch filter.
- 'peak' — Design an IIR peaking filter. Peaking filters boost the signal at the specified frequencies.

## **Output Arguments**

### **num** — Numerator coefficients

real-valued row vector

Numerator coefficients of the IIR filter transfer function, returned as a real-valued row vector. For an  $n$ th-order filter, the number of elements in the row vector is  $n+1$ .

Data Types: `single` | `double`

### **den** — Denominator coefficients

real-valued row vector

Denominator coefficients of the IIR filter transfer function, returned as a real-valued row vector. For an  $n$ th-order filter, the number of elements in the row vector is  $n+1$ .

Data Types: `single` | `double`

# iirftansf

IIR frequency transformation of digital filter

## Syntax

```
[num,den] = iirftansf(b,a,allpassNum,allpassDen)
```

## Description

`[num,den] = iirftansf(b,a,allpassNum,allpassDen)` returns the numerator and the denominator coefficients of the transformed filter.

The `iirftansf` function transforms a prototype filter, specified by the numerator `b` and denominator `a`, by using an allpass mapping filter, specified by the numerator `allpassNum` and the denominator `allpassDen`. If you do not specify an allpass mapping filter, then the function returns an original filter.

## Examples

### Transform Lowpass Filter Using Allpass Mapping Filter

Using the `iirftansf` function, extend the passband of a lowpass IIR filter by using an allpass mapping filter.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirftransf`

Extend the passband of the real prototype filter by specifying the allpass mapping filter as a vector of numerator and denominator coefficients, `alpnum` and `alpden` respectively. Use the `allpasslp2lp` function to generate the allpass mapping filter coefficients.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[b,a] = ellip(3,0.1,30,0.409);
[alpnum,alpden] = allpasslp2lp(0.5,0.25);
[num,den] = iirftransf(b,a,alpnum,alpden);
```

Compare the magnitude response of the filters using FVTool.

```
fvt = fvtool(b,a,num,den);
legend(fvt,"Prototype Filter (TF Form)",...
       "Transformed Filter")
```

You can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The numerator and the denominator coefficients of the transformed filter are given by `num2` and `den2`, respectively.

```
ss = tf2sos(b,a);
[num2,den2] = iirftansf(ss(:,1:3),ss(:,4:6),...
    alpnum,alpden);
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(ss,[num2 den2]);
legend(hvft,"Prototype Filter (SOS Form)",...
    "Transformed Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see **a**.
- *k* -- Row index.
- *i* -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections) *Q*.

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where *n* is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an *P*-by- $(Q+1)$  matrix, where *P* is the number of filter sections and *Q* is the order of each filter section. If *Q* = 2, the filter is a second-order section filter. For higher-order sections, make *Q* > 2.

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see **b**.
- *k* -- Row index.
- *i* -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections) *P*.

Data Types: `single` | `double`

**allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, specified as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

**allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, specified as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

**num — Numerator coefficients of transformed filter**

row vector | matrix

Numerator coefficients of the transformed filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `num` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `num` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`**den — Denominator coefficients of transformed filter**

row vector | matrix

Denominator coefficients of the transformed filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

## iirgrpdelay

Optimal IIR filter with prescribed group-delay

### Syntax

```
[num,den] = iirgrpdelay(n,f,edges,a)
[num,den] = iirgrpdelay(n,f,edges,a,w)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)
[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)
[num,den,tau] = iirgrpdelay(n,f,edges,a,w)
```

### Description

`[num,den] = iirgrpdelay(n,f,edges,a)` returns an allpass IIR filter of order  $n$  ( $n$  must be even) which is the best approximation to the relative group-delay response described by  $f$  and  $a$  in the least- $p$ th sense.  $f$  is a vector of frequencies between 0 and 1 and  $a$  is specified in samples. The vector  $edges$  specifies the band-edge frequencies for multi-band designs. `iirgrpdelay` uses a constrained Newton-type algorithm. Always check your resulting filter using `grpdelay` or `freqz`.

`[num,den] = iirgrpdelay(n,f,edges,a,w)` uses the weights in  $w$  to weight the error.  $w$  has one entry per frequency point and must be the same length as  $f$  and  $a$ ). Entries in  $w$  tell `iirgrpdelay` how much emphasis to put on minimizing the error in the vicinity of each specified frequency point relative to the other points.

$f$  and  $a$  must have the same number of elements.  $f$  and  $a$  can contain more elements than the vector  $edges$  contains. This lets you use  $f$  and  $a$  to specify a filter that has any group-delay contour within each band.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius)` returns a filter having a maximum pole radius equal to `radius`, where  $0 < \text{radius} < 1$ . `radius` defaults to 0.999999. Filters whose pole radius you constrain to be less than 1.0 can better retain transfer function accuracy after quantization.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p)`, where  $p$  is a two-element vector  $[p_{\min} \ p_{\max}]$ , lets you determine the minimum and maximum values of  $p$  used in the least- $p$ th algorithm.  $p$  defaults to  $[2 \ 128]$  which yields filters very similar to the L-infinity, or Chebyshev, norm.  $p_{\min}$  and  $p_{\max}$  should be even. If  $p$  is 'inspect', no optimization occurs. You might use this feature to inspect the initial pole/zero placement.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization process. The number of grid points is  $(\text{dens} * (n+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden)` allows you to specify the initial estimate of the denominator coefficients in vector `initden`. This can be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initden`.

`[num,den] = iirgrpdelay(n,f,edges,a,w,radius,p,dens,initden,tau)` allows the initial estimate of the group delay offset to be specified by the value of `tau`, in samples.

`[num,den,tau] = iirgrpdelay(n,f,edges,a,w)` returns the resulting group delay offset. In all cases, the resulting filter has a group delay that approximates `[a + tau]`. Allpass filters can have only positive group delay and a non-zero value of `tau` accounts for any additional group delay that is needed to meet the shape of the contour specified by `(f,a)`. The default for `tau` is `max(a)`.

Hint: If the zeros or poles cluster together, your filter order may be too low or the pole radius may be too small (overly constrained). Try increasing `n` or `radius`.

For group-delay equalization of an IIR filter, compute `a` by subtracting the filter's group delay from its maximum group delay. For example,

```
[be,ae] = ellip(4,1,40,0.2);
f = 0:0.001:0.2;
g = grpdelay(be,ae,f,2); % Equalize only the passband.
a = max(g)-g;
[num,den]=iirgrpdelay(8, f, [0 0.2], a);
```

## iirlinphase

Quasi-linear phase IIR filter from halfband filter specification

### Syntax

```
iirlinFilter= design(d,'iirlinphase','SystemObject',true)
hd = design(...,'filterstructure',structure,'SystemObject',true)
```

### Description

`iirlinFilter= design(d,'iirlinphase','SystemObject',true)` designs a quasi-linear phase filter `iirlinFilter` specified by the filter specification object `d`.

`hd = design(...,'filterstructure',structure,'SystemObject',true)` returns a filter with the structure specified by `structure`. By default, the filter structure is a cascade structure. The following table lists all the structures `design` supports for the IIR linear phase response.

| Structure                      | Filter Structure                               |
|--------------------------------|--|
| <code>cascadeallpass</code>    | Cascade of allpass filters                     |
| <code>cascadewdfallpass</code> | Cascade of allpass wave digital filters        |
| <code>iirdecim</code>          | IIR polyphase decimator                        |
| <code>iirwdfdecim</code>       | IIR wave digital filter polyphase decimator    |
| <code>iirinterp</code>         | IIR polyphase interpolator                     |
| <code>iirwdfinterp</code>      | IIR wave digital filter polyphase interpolator |

To get a list of all the structures the specific `fdesign` method supports, type the following in the MATLAB command prompt.

```
d = fdesign.halfband;
strucs = validstructures(d,'SystemObject',true);
```

To get a list of structures `iirlinphase` supports, type the following in the MATLAB command prompt.

```
iirlinphaseStrucs = strucs.iirlinphase;
```

### Examples

#### Design a Minimum-order Halfband IIR Filter

Design a quasi-linear phase, minimum-order halfband IIR filter with transition width of 0.36 and stopband attenuation of at least 80 dB.

```
tw = 0.36;
ast = 80;
d = fdesign.halfband('tw,ast',tw,ast); % Transition width,
                                     % stopband attenuation.
```

```
halfbandIIR = design(d,'iirlinphase','SystemObject',true);
fvtool(halfbandIIR)
```

Notice the characteristic halfband nature of the ripple in the stopband. If you measure the resulting filter, you see it meets the specifications.

```
measure(halfbandIIR)
```

```
ans =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.32
3-dB Point       : 0.5
6-dB Point       : 0.51911
Stopband Edge    : 0.68
Passband Ripple  : 4.0866e-08 dB
Stopband Atten.  : 80.2642 dB
Transition Width  : 0.36
```

## iirlp2bp

Transform IIR lowpass filter to IIR bandpass filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2bp(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2bp(b,a,wo,wt)` transforms an IIR lowpass filter to an IIR bandpass filter.

The `iirlp2bp` function returns the numerator and denominator coefficients of the transformed bandpass filter. The function transforms the real lowpass prototype filter, specified by the numerator coefficients `b` and denominator coefficients `a`, by applying a second-order real lowpass to real bandpass frequency mapping. For more information, see “IIR Lowpass to IIR Bandpass Transformation” on page 5-933.

The function also returns the numerator and the denominator coefficients of the allpass mapping filter, `allpassNum` and `allpassDen` respectively.

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

### Examples

#### Transform Lowpass Filter to Bandpass Filter

Transform a lowpass IIR filter to a bandpass filter using the `iirlp2bp` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter using the `ellip` function. The filter has a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2bp`

Transform the prototype lowpass filter into a bandpass filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2bp(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)","Transformed Bandpass Filter")
```

You can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The transformed filter is a fourth-order section filter given by the numerator and the denominator coefficients `num2` and `den2`.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2bp(ss(:,1:3),ss(:,4:6),0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

To visualize the magnitude response of the fourth-order section filter, first pass the filter coefficients to the `dsp.FourthOrderSectionFilter` object. Then, use this object as an input to the `FVTool`.

```
fos = dsp.FourthOrderSectionFilter(Numerator=num2,...
    Denominator=den2);
hvft = fvtool(ss, fos);
legend(hvft, "Prototype Filter (SOS Form)", ...
    "Transformed Bandpass Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo** — **Frequency value to be transformed from prototype filter**

scalar

Frequency value to transform from the prototype filter, specified as a scalar. Frequency **wo** must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**wt** — **Desired frequency locations in transformed target filter**

two-element vector

Desired frequency locations in the transformed target filter, specified as a two-element vector. Frequencies in **wt** must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

## Output Arguments

**num** — **Numerator coefficients of transformed bandpass filter**

row vector | matrix

Numerator coefficients of the transformed bandpass filter, returned as one of the following:

- Row vector of length  $2n+1$ , where  $n$  is the order of the input filter. The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(2Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**den** — **Denominator coefficients of transformed bandpass filter**

row vector | matrix

Denominator coefficients of the transformed bandpass filter, returned as one of the following:

- Row vector of length  $2n+1$ , where  $n$  is the order of the input filter. The **den** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(2Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **den** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**allpassNum** — **Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

**allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

**More About****IIR Lowpass to IIR Bandpass Transformation**

IIR lowpass to IIR bandpass transformation effectively places one feature of the original filter, located at frequency  $-w_0$ , at the required target frequency location  $w_{t1}$ , and the second feature, originally at  $+w_0$ , at the new location  $w_{t2}$ . It is assumed that  $w_{t2}$  is greater than  $w_{t1}$ . This transformation implements the “*DC Mobility*,” meaning that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $w_{ts}$ .

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others.

Real lowpass to bandpass transformation can also be used to transform other types of filters, for example, real notch filters or resonators can be doubled and positioned at two distinct desired frequencies.

`iirftransf` | `allpasslp2bp` | `zpklp2bp`

## iirlp2bpc

Transform IIR lowpass filter to complex bandpass filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2bpc(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2bpc(b,a,wo,wt)` transforms an IIR lowpass filter to a complex bandpass filter.

The function transforms a real lowpass prototype filter, specified as the numerator and denominator coefficients `b` and `a` respectively, to a complex bandpass filter by applying a first-order real lowpass to complex bandpass frequency transformation.

The function returns the numerator and denominator coefficients of the transformed complex bandpass filter. The function also returns the numerator and denominator coefficients of the allpass mapping filter, `allpassNum` and `allpassDen` respectively.

For more details on the transformation, see “IIR Lowpass to Complex Bandpass Transformation” on page 5-941.

### Examples

#### Transform Lowpass Filter to Complex Bandpass Filter

Transform a lowpass IIR filter to a complex bandpass filter using the `iirlp2bpc` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2bpc`

Transform the prototype lowpass filter into a complex bandpass filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2bpc(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)",...
       "Transformed Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second order section coefficient matrices as inputs.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2bpc(ss(:,1:3),ss(:,4:6),0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using FVTool.

```
hvft = fvtool(ss,[num2 den2]);
legend(hvft,"Prototype Filter (Matrix Form)", ...
       "Transformed Filter")
```

Copyright 2012-2021 The MathWorks, Inc.

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo — Frequency value to transform from prototype filter**

scalar

Frequency value to transform from the prototype filter, specified as a real scalar. Frequency  $w_0$  should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**wt — Desired frequency locations in transformed target filter**

two-element vector

Desired frequency locations in the transformed target filter, specified as a two-element vector. Frequencies in  $w_t$  should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

## Output Arguments

**num — Numerator coefficients of transformed complex bandpass filter**

row vector | matrix

Numerator coefficients of the transformed complex bandpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `num` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `num` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

**den — Denominator coefficients of transformed complex bandpass filter**

row vector | matrix

Denominator coefficients of the transformed complex bandpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

**allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator of the mapping filter, returned as a row vector.

Data Types: single | double

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator of the mapping filter, returned as a row vector.

Data Types: single | double

Complex Number Support: Yes

## **More About**

### **IIR Lowpass to Complex Bandpass Transformation**

IIR lowpass to complex bandpass transformation effectively places one feature of the original filter, located at frequency  $-w_o$ , at the required target frequency location,  $w_{t1}$ , and the second feature, originally at  $w_o$ , at the new location,  $w_{t2}$ . It is assumed that  $w_{t2}$  is greater than  $w_{t1}$ .

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others.

Lowpass to bandpass transformation can also be used to transform other types of filters, for example real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle, forming a pair of complex notches or resonators. You can use this transformation to design bandpass filters for radio receivers from the high-quality prototype lowpass filter.

## iirlp2bs

Transform IIR lowpass filter to IIR bandstop filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2bs(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2bs(b,a,wo,wt)` transforms an IIR lowpass filter to an IIR bandstop filter.

The lowpass filter is specified using the numerator and denominator coefficients `b` and `a` respectively. The function returns the numerator and denominator coefficients of the transformed bandstop digital filter. The function also returns the numerator and denominator coefficients of the allpass mapping filter, `allpassNum` and `allpassDen` respectively.

For more details on the transformation, see “IIR Lowpass Filter to IIR Bandstop Filter Transformation” on page 5-948.

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

### Examples

#### Transform Lowpass Filter to Bandstop Filter

Transform a lowpass IIR filter to a bandstop filter using the `iirlp2bs` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2bs`

Transform the prototype lowpass filter into a bandstop filter by placing the cutoff frequencies of the prototype filter at  $0.25\pi$  and  $0.75\pi$ .

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2bs(b,a,0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

```
hfvt = fvtool(b,a,num,den);
legend(hfvt,"Prototype Filter (TF Form)",...
       "Transformed Bandstop Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The transformed filter is a fourth-order section filter given by the numerator and the denominator coefficients `num2` and `den2`.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2bs(ss(:,1:3),ss(:,4:6),0.5,[0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

To visualize the magnitude response of the fourth-order section filter, first pass the filter coefficients to the `dsp.FourthOrderSectionFilter` object. Then, use this object as an input to the `FVTool`.

```
fos = dsp.FourthOrderSectionFilter(Numerator=num2,...
    Denominator=den2);
hvft = fvtool(ss,fos);
legend(hvft,"Prototype Filter (SOS Form)",...
    "Transformed Bandstop Filter")
```

Copyright 2012-2021 The MathWorks, Inc.

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo** — **Frequency value to transform from prototype filter**

scalar

Frequency value to transform from the prototype filter, specified as a real scalar. Frequency  $\omega_0$  must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**wt** — **Desired frequency locations in transformed target filter**

two-element vector

Desired frequency locations in the transformed target filter, specified as a two-element vector. Frequencies in  $\omega_t$  must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

## Output Arguments

**num** — **Numerator coefficients of transformed bandstop filter**

row vector | matrix

Numerator coefficients of the transformed bandstop filter, returned as one of the following:

- Row vector of length  $2n+1$ , where  $n$  is the order of the input filter. The `num` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(2Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `num` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

**den** — **Denominator coefficients of transformed bandstop filter**

row vector | matrix

Denominator coefficients of the transformed bandstop filter, returned as one of the following:

- Row vector of length  $2n+1$ , where  $n$  is the order of the input filter. The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(2Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

**allpassNum** — **Numerator coefficients of mapping filter**

row vector

Numerator of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

**allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator of the mapping filter, returned as a row vector.

Data Types: `single` | `double`**More About****IIR Lowpass Filter to IIR Bandstop Filter Transformation**

IIR lowpass filter to IIR bandstop filter transformation effectively places one feature of the original filter, located at frequency  $-w_o$ , at the required target frequency location,  $w_{t1}$ , and the second feature, originally at  $w_o$ , at the new location,  $w_{t2}$ . Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others. It is assumed that  $w_{t2}$  is greater than  $w_{t1}$ . Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $w_o$  and  $w_{ts}$ .

Relative positions of other features of the original filter change in the target filter. This means that it is possible to select two features of the original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. In addition, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

For more details on the lowpass to bandstop frequency transformation, see "Digital Frequency Transformations".

## iirlp2bsc

Transform IIR lowpass filter to complex bandstop filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2bsc(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2bsc(b,a,wo,wt)` transform an IIR lowpass filter to a complex bandstop filter.

The prototype lowpass filter is specified with the numerator `b` and the denominator `a`. The function returns the numerator and denominator coefficients of the transformed complex bandstop filter. The function also returns the numerator, `allpassNum`, and the denominator, `allpassDen`, of the allpass mapping filter.

The function transforms a real lowpass prototype filter to a complex bandstop filter by applying a first-order real lowpass to complex bandstop frequency transformation. For more details, see “IIR Lowpass Filter to IIR Complex Bandstop Filter Transformation” on page 5-956.

### Examples

#### Transform Lowpass Filter to Complex Bandstop Filter

Transform a lowpass IIR filter to a complex bandstop filter using the `iirlp2bsc` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2bsc`

Transform the prototype lowpass filter into a complex bandstop filter by placing the cutoff frequencies of the prototype filter at  $-0.25\pi$  and  $0.75\pi$ .

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2bsc(b,a,0.5,[-0.25 0.75]);
```

Compare the magnitude response of the filters using `FVTool`.

```
fvt = fvtool(b,a,num,den);
legend(fvt,"Prototype Filter (TF Form)",...
       "Transformed Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second order section coefficient matrices as inputs.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2bsc(ss(:,1:3),ss(:,4:6),0.5,[-0.25 0.75]);
```

Compare the magnitude response of the filters using FVTool.

```
hvft = fvtool(ss,[num2 den2]);
legend(hvft,"Prototype Filter (Matrix Form)", ...
       "Transformed Filter")
```

Copyright 2012-2021 The MathWorks, Inc.

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

#### **wo** — Frequency value to transform from prototype filter

real scalar

Frequency value to transform from the prototype filter, specified as a scalar. Frequency  $\omega_0$  should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

#### **wt** — Desired frequency locations in transformed target filter

two-element vector

Desired frequency locations in the transformed target filter, specified as a two-element vector. Frequencies in  $\omega_t$  should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

## Output Arguments

#### **num** — Numerator coefficients of transformed complex bandstop filter

row vector | matrix

Numerator coefficients of the transformed complex bandstop filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `num` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `num` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

#### **den** — Denominator coefficients of transformed complex bandstop filter

row vector | matrix

Denominator coefficients of the transformed complex bandstop filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

#### **allpassNum** — Numerator coefficients of mapping filter

row vector

Numerator of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **More About**

### **IIR Lowpass Filter to IIR Complex Bandstop Filter Transformation**

IIR Lowpass Filter to IIR Complex Bandstop Filter transformation effectively places one feature of the original filter, located at frequency  $-w_o$ , at the required target frequency location,  $w_{t1}$ , and the second feature, originally at  $w_o$ , at the new location,  $w_{t2}$ . It is assumed that  $w_{t2}$  is greater than  $w_{t1}$ . Additionally, the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others.

Lowpass to bandpass transformation can also be used to transform other types of filters, for example. real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

## iirlp2hp

Transform lowpass IIR filter to highpass filter

### Syntax

```
[num,den] = iirlp2hp(b,a,wo,wt)
[num,den,allpassNum,allpassDen] = iirlp2hp(b,a,wo,wt)
```

### Description

`[num,den] = iirlp2hp(b,a,wo,wt)` transforms a lowpass IIR filter to a highpass IIR filter.

The `iirlp2hp` function returns the numerator and denominator coefficients of the transformed highpass filter. The function accepts `wo`, frequency value to be transformed from the prototype filter, and `wt`, desired frequency in the transformed highpass filter, and applies the lowpass to highpass frequency transformation on the input prototype filter. The input prototype lowpass filter is specified with the numerator and denominator coefficients, `b` and `a` respectively. For more details on the transformation, see “IIR Lowpass to Highpass Frequency Transformation” on page 5-963.

`[num,den,allpassNum,allpassDen] = iirlp2hp(b,a,wo,wt)` additionally returns the numerator and the denominator coefficients of the mapping filter.

### Examples

#### Transform Lowpass Filter to Highpass Filter

Transform an IIR filter from lowpass to highpass by moving the magnitude response at one frequency in the source filter to a new location in the transformed filter.

#### Input Lowpass IIR Filter

Generate a least P-norm optimal IIR lowpass filter with varying attenuation levels in the stopband. Specify a numerator order of 10 and a denominator order of 6. The function returns the coefficients both in the vector form and in the second-order sections (SOS) form. The output argument `g` specifies the overall gain of the filter when expressed in the second-order sections form.

```
[b,a,~,sos,g] = iirlpnorm(10,6,[0 0.0175 0.02 0.0215 0.025 1], ...
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...
    [1 1 1 1 20 20]);
```

Visualize the magnitude response of the filter.

```
fvtool(b,a)
```

### Transform Filter Using `iirlp2hp`

Transform the lowpass IIR filter using the `iirlp2hp` function. Specify the filter as a vector of numerator and denominator coefficients.

To generate a highpass filter whose passband flattens out at  $0.4\pi$  rad/sample, select the frequency in the lowpass filter at  $0.0175\pi$ , the frequency where the passband starts to roll off, and move it to the new location.

```
wc = 0.0175;
wd = 0.4;
[num,den] = iirlp2hp(b,a,wc,wd);
```

Compare the magnitude responses of the filters using FVTool. The transition band for the highpass filter is essentially the mirror image of the transition for the lowpass filter from  $0.0175\pi$  to  $0.025\pi$ , stretched out over a wider frequency range. In the passbands, the filter share common ripple characteristics and magnitude.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)",...
       "Transformed Highpass Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the scaled second order section coefficient matrices as inputs. Apply the scaling factor  $g$  to the first section of the filter.

```
sosg = sos;
sosg(1,1:3) = g*sosg(1,1:3);
[num2,den2] = iirlp2hp(sosg(:,1:3),sosg(:,4:6),wc,wd);
```

Compare the magnitude response of the filters using FVTool.

```
hvft = fvtool(sosg,[num2 den2]);
legend(hvft,"Prototype Filter (SOS Form)",...
       "Transformed Highpass Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo** — Frequency value to be transformed from prototype filter

positive scalar in  $(0, 1)$

Frequency value to transform from the prototype filter, specified as a real positive scalar in the range  $(0, 1)$ .

Data Types: `single` | `double`

**wt** — Desired frequency location in transformed highpass filter

positive scalar in  $(0, 1)$

Desired frequency location in the transformed highpass filter, specified as a real positive scalar in the range  $(0, 1)$ .

Data Types: `single` | `double`

## Output Arguments

**num** — Numerator coefficients of transformed highpass filter

row vector | matrix

Numerator coefficients of the transformed highpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**den** — Denominator coefficients of transformed highpass filter

row vector | matrix

Denominator coefficients of the transformed highpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The **den** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **den** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**allpassNum** — Numerator coefficients of mapping filter

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **aIIPassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **More About**

### **IIR Lowpass to Highpass Frequency Transformation**

IIR lowpass to highpass frequency transformation takes a selected frequency from the lowpass filter,  $\omega_0$ , and maps the corresponding magnitude response value onto the desired frequency location in the highpass filter,  $\omega_t$ . Note that all frequencies are normalized between 0 and 1 and that the filter order does not change when you transform to a highpass filter.

When you select  $\omega_0$  and designate  $\omega_t$ , the transformation algorithm sets the magnitude response at the  $\omega_t$  values of your bandstop filter to be the same as the magnitude response of your lowpass filter at  $\omega_0$ . Filter performance between the values in  $\omega_t$  is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as  $\omega_0$ . Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features, but in a highpass version without designing the highpass filter from the beginning.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the highpass filter. Use `fvtool` to verify the response of your converted filter.

`iirlp2bp` | `iirlp2bs` | `iirlp2lp` | `firlp2lp` | `firlp2hp`

## iirlp2lp

Transform lowpass IIR filter to different lowpass filter

### Syntax

```
[num,den] = iirlp2lp(b,a,wo,wt)
[num,den,allpassNum,allpassDen] = iirlp2lp(b,a,wo,wt)
```

### Description

`[num,den] = iirlp2lp(b,a,wo,wt)` transforms lowpass IIR filter to different lowpass filter.

The prototype lowpass filter is specified with the numerator and denominator coefficients, `b` and `a` respectively. The function returns the numerator and denominator coefficients of the transformed lowpass digital filter.

The function transforms the magnitude response from lowpass to a different lowpass. For more details, see “Lowpass IIR Filter to Different Lowpass Filter Transformation” on page 5-971.

`[num,den,allpassNum,allpassDen] = iirlp2lp(b,a,wo,wt)` in addition returns the numerator and the denominator coefficients of the allpass mapping filter.

### Examples

#### Extend Passband of Lowpass Filter

Transform the passband of a lowpass IIR filter by moving the magnitude response from one frequency in the source filter to a new location in the transformed filter.

#### Input Lowpass IIR Filter

Generate a least P-norm optimal IIR lowpass filter using the `iirlpnorm` function. Specify a numerator order of 10 and a denominator order of 6. The function returns the coefficients both in the vector form and in the second-order sections (SOS) form. The output argument `g` specifies the overall gain of the filter when expressed in the second-order sections form.

```
[b,a,~,sos,g] = iirlpnorm(10,6, ...
    [0 0.0175 0.02 0.0215 0.025 1], ...
    [0 0.0175 0.02 0.0215 0.025 1],[1 1 0 0 0 0], ...
    [1 1 1 1 10 10]);
```

Visualize the magnitude response of the filter.

```
fvtool(b,a)
```

### Transform Filter Using `iirlp2lp`

Transform the passband of the lowpass IIR filter using the `iirlp2lp` function. Specify the filter as a vector of numerator and denominator coefficients.

To generate a lowpass filter whose passband extends out to  $0.2\pi$  rad/sample, select the frequency in the lowpass filter at  $0.0175\pi$ , the frequency where the passband starts to roll off, and move it to the new location.

Moving the edge of the passband from  $0.0175\pi$  to  $0.2\pi$  results in a new lowpass filter whose peak response in-band is the same as in the original filter, with the same ripple and the same absolute magnitude. The rolloff is slightly less steep and the stopband profiles are the same for both filters. The new filter stopband is a "stretched" version of the original, as is the passband of the new filter.

```
wc = 0.0175;
wd = 0.2;
[num,den] = iirlp2lp(b,a,wc,wd);
```

Compare the magnitude response of the filters using FVTool.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)", ...
      "Transformed Lowpass Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the scaled second order section coefficient matrices as inputs. Apply the scaling factor  $g$  to the first section of the filter.

```
sosg = sos;
sosg(1,1:3) = g*sosg(1,1:3);
[num2,den2] = iirlp2lp(sosg(:,1:3),sosg(:,4:6),wc,wd);
```

Compare the magnitude response of the filters using FVTool.

```
hvft = fvtool(sosg,[num2 den2]);
legend(hvft,"Prototype Filter (Matrix Form)",...
        "Transformed Lowpass Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo** — **Frequency value to transform from prototype filter**

positive scalar

Frequency value to transform from the prototype filter, specified as a real positive scalar. Frequency **wo** must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**wt** — **Desired frequency location in transformed target filter**

positive scalar

Desired frequency location in the transformed target filter, specified as a real positive scalar. Frequency **wt** must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

## Output Arguments

**num** — **Numerator coefficients of transformed lowpass filter**

row vector | matrix

Numerator coefficients of the transformed lowpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**den** — **Denominator coefficients of transformed lowpass filter**

row vector | matrix

Denominator coefficients of the transformed lowpass filter, returned as one of the following:

- Row vector of length  $n+1$ , where  $n$  is the order of the input filter. The **den** output is a row vector when the input coefficients **b** and **a** are row vectors.
- $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each section of the transformed filter. The **den** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**allpassNum** — **Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **aIIRpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **More About**

### **Lowpass IIR Filter to Different Lowpass Filter Transformation**

Lowpass IIR filter to different lowpass filter transformation takes a selected frequency from your lowpass filter,  $\omega_0$ , and maps the corresponding magnitude response value onto the desired frequency location in the transformed lowpass filter,  $\omega_t$ . Note that all frequencies are normalized between zero and one and that the filter order does not change when you transform to the target lowpass filter.

When you select  $\omega_0$  and designate  $\omega_t$ , the transformation algorithm sets the magnitude response at the  $\omega_t$  values of your bandstop filter to be the same as the magnitude response of your lowpass filter at  $\omega_0$ . Filter performance between the values in  $\omega_t$  is not specified, except that the stopband retains the ripple nature of your original lowpass filter and the magnitude response in the stopband is equal to the peak response of your lowpass filter. To accurately specify the filter magnitude response across the stopband of your bandpass filter, use a frequency value from within the stopband of your lowpass filter as  $\omega_c$ . Then your bandstop filter response is the same magnitude and ripple as your lowpass filter stopband magnitude and ripple.

The fact that the transformation retains the shape of the original filter is what makes this function useful. If you have a lowpass filter whose characteristics, such as rolloff or passband ripple, particularly meet your needs, the transformation function lets you create a new filter with the same characteristic performance features.

In some cases transforming your filter may cause numerical problems, resulting in incorrect conversion to the target filter. Use `fvtool` to verify the response of your converted filter.

# iirlp2mb

Transform IIR lowpass filter to IIR multiband filter

## Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2mb(b,a,wo,wt)
[num,den,allpassNum,allpassDen] = iirlp2mb(b,a,wo,wt,pass)
```

## Description

`[num,den,allpassNum,allpassDen] = iirlp2mb(b,a,wo,wt)` transforms an IIR lowpass filter to an IIR multiband filter.

The `iirlp2mb` function returns the numerator and denominator coefficients of the transformed IIR multiband filter. The function also returns the numerator, `allpassNum`, and the denominator, `allpassDen`, of the  $M^{\text{th}}$  order allpass mapping filter. The prototype lowpass filter is specified with the numerator `b` and the denominator `a`.

The function transforms a real lowpass prototype filter to a multiband filter by applying an  $M^{\text{th}}$ -order real lowpass to real multiple bandpass frequency mapping. Parameter  $M$  is the number of times an original feature is replicated in the transformed filter. By default the DC feature is kept at its original location. For more details, see “IIR Lowpass Filter to IIR Multiband Filter Transformation” on page 5-979.

`[num,den,allpassNum,allpassDen] = iirlp2mb(b,a,wo,wt,pass)` allows you to specify an additional parameter, `pass` as 'pass' or 'stop', which chooses between using the “*Nyquist Mobility*” and the “*DC Mobility*”, respectively. In the case of “*Nyquist Mobility*”, the DC feature is kept at an original frequency and the Nyquist feature is free to move. In the case of “*DC Mobility*”, the Nyquist feature stays at its original location and the DC feature is free to move.

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Examples

### Transform Lowpass Filter to Multiband Filter

Transform a lowpass IIR filter to a multiband IIR filter using the `iirlp2mb` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
fvtool(b,a)
```

### Transform Filter Using `iirlp2mb`

Transform the real prototype lowpass filter into a real multiband filter with two passbands.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num1,den1] = iirlp2mb(b,a,0.5,[2 4 6 8]/10);
```

Transform the prototype filter into a real multiband filter with two stopbands.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num2,den2] = iirlp2mb(b,a,0.5,[2 4 6 8]/10,"stop");
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(b,a,num1,den1,num2,den2);
legend(hvft,"Prototype Filter (TF Form)",...
       "Two passbands","Two stopbands")
```

You can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. Change the desired frequency locations to be [0.5 0.6] in normalized frequency units. The transformed 2-band filter is a fourth-order section filter given by the numerator and the denominator coefficients num3 and den3.

```
ss = tf2sos(b,a);
[num3, den3] = iirlp2mb(ss(:,1:3), ss(:,4:6), ...
    0.5, [5 6]/10);
```

Compare the magnitude response of the filters using FVTool.

To visualize the magnitude response of the fourth-order section filter, first pass the filter coefficients to the `dsp.FourthOrderSectionFilter` object. Then, use this object as an input to the FVTool.

```
fos = dsp.FourthOrderSectionFilter(Numerator=num3, ...
    Denominator=den3);
hvft = fvtool(ss, fos);
legend(hvft, "Prototype Filter (SOS Form)", ...
    "Transformed Multiband Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo — Frequency value to transform from prototype filter**

positive scalar

Frequency value to transform from the prototype filter, specified as a real scalar. Frequency  $\omega_0$  must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

**wt — Desired frequency locations in transformed target filter**

row vector

Desired frequency locations in the transformed target filter, specified as a row vector. Frequencies in **wt** must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate. The value of  $M$  which is equal to the number of times an original feature is replicated in the transformed filter equals the length of the **wt** vector.

Data Types: `single` | `double`

**pass — Choice of passband or stopband at DC**

"pass" (default) | "stop"

Choice of passband or stopband at DC, specified as either:

- "pass" -- "Nyquist Mobility". The DC feature is kept at an original frequency and the Nyquist feature is free to move.
- "stop" -- "DC Mobility". The Nyquist feature stays at its original location and the DC feature is free to move.

## Output Arguments

**num — Numerator coefficients of transformed multiband filter**

row vector | matrix

Numerator coefficients of the transformed multiband filter, returned as one of the following:

- Row vector of length  $Mn+1$ , where  $M$  is the number of times an original feature is replicated in the transformed filter and  $n$  is the order of the input filter. The value of  $M$  equals the length of the **wt** vector.

The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QM+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $M$  is the number of times an original feature is replicated in the transformed filter.

The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**den — Denominator coefficients of transformed multiband filter**

row vector | matrix

Denominator coefficients of the transformed multiband filter, returned as one of the following:

- Row vector of length  $Mn+1$ , where  $M$  is the number of times an original feature is replicated in the transformed filter and  $n$  is the order of the input filter. The value of  $M$  equals the length of the `wt` vector.

The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.

- $P$ -by- $(QM+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $M$  is the number of times an original feature is replicated in the transformed filter.

The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

### **allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **More About**

### **IIR Lowpass Filter to IIR Multiband Filter Transformation**

IIR lowpass filter to IIR multiband filter transformation effectively places one feature of the original filter, located at frequency  $w_o$ , at the required target frequency locations,  $w_{t1}, \dots, w_{tM}$ .

Relative positions of other features of the original filter do not change in the target filter. It is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others.

The IIR lowpass filter to IIR multiband filter transformation can also be used to transform other types of filters, for example, notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## iirlp2mbc

Transform IIR lowpass filter to IIR complex multiband filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2mbc(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2mbc(b,a,wo,wt)` transform an IIR lowpass filter to an IIR complex multiband filter.

The `iirlp2mbc` returns the numerator and denominator coefficients of the transformed complex IIR multiband filter. The function also returns the numerator, `allpassNum`, and the denominator, `allpassDen`, of the  $M^{\text{th}}$  order allpass mapping filter. The prototype lowpass filter is specified with the numerator `b` and the denominator `a`.

The function transforms a real lowpass prototype filter to a multiband filter by applying an  $M^{\text{th}}$ -order real lowpass to complex multiple bandpass frequency mapping. Parameter  $M$  is the number of times an original feature is replicated in the transformed filter. For more details, see “IIR Lowpass Filter to IIR Complex Multiband Filter Transformation” on page 5-987.

### Examples

#### Transform Lowpass Filter to Complex Multiband Filter

Transform a real lowpass IIR filter to a complex multiband IIR filter using the `iirlp2mbc` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2mbc`

Transform the real prototype lowpass filter into a complex multiband filter with two passbands.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2mbc(b,a,0.5,[-7 -5 6 8]/10);
```

Compare the magnitude response of the filters using `FVTool`. `iirlp2mbc` replicates the desired feature at 0.5 in the lowpass filter at four locations in the multiband filter.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)",...
       "Transformed Multiband Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The transformed filter is a fourth-order section filter given by the numerator and the denominator coefficients `num2` and `den2`.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2mbc(ss(:,1:3),ss(:,4:6),0.5,[-7 -5 6 8]/10);
```

Compare the magnitude response of the filters using FVTool.

To visualize the magnitude response of the fourth-order section filter, first pass the filter coefficients to the `dsp.FourthOrderSectionFilter` object. Then, use this object as an input to the FVTool.

```
fos = dsp.FourthOrderSectionFilter(Numerator=num2,...
    Denominator=den2);
hvft = fvtool(ss,fos);
legend(hvft,"Prototype Filter (SOS Form)",...
    "Transformed Multiband Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

### **wo — Frequency value to transform from prototype filter**

positive scalar

Frequency value to transform from the prototype filter, specified as a positive scalar. Frequency  $w_0$  should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Data Types: `single` | `double`

### **wt — Desired frequency locations in transformed target filter**

row vector

Desired frequency locations in the transformed target filter, specified as a row vector. Frequencies in **wt** should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. The value of  $M$  which is equal to the number of times an original feature is replicated in the transformed filter equals the length of the **wt** vector.

Data Types: `single` | `double`

## **Output Arguments**

### **num — Numerator coefficients of transformed multiband filter**

row vector | matrix

Numerator coefficients of the transformed multiband filter, returned as one of the following:

- Row vector of length  $Mn/2+1$ , where  $M$  is the number of times an original feature is replicated in the transformed filter and  $n$  is the order of the input filter. The value of  $M$  equals the length of the **wt** vector.

The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QM/2+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $M$  is the number of times an original feature is replicated in the transformed filter.

The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

### **den — Denominator coefficients of transformed multiband filter**

row vector | matrix

Denominator coefficients of the transformed multiband filter, returned as one of the following:

- Row vector of length  $Mn/2+1$ , where  $M$  is the number of times an original feature is replicated in the transformed filter and  $n$  is the order of the input filter. The value of  $M$  equals the length of the **wt** vector.

The **den** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QM/2+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $M$  is the number of times an original feature is replicated in the transformed filter.

The den output is a matrix when the input coefficients  $b$  and  $a$  are matrices.

Data Types: `single` | `double`

### **allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

## **More About**

### **IIR Lowpass Filter to IIR Complex Multiband Filter Transformation**

IIR lowpass filter to IIR complex multiband filter transformation effectively places one feature of the original filter, located at frequency  $w_o$ , at the required target frequency locations,  $w_{t1}, \dots, w_{tM}$ .

Relative positions of other features of the original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. You can choose to transform any feature of the original filter like stopband edge, DC, deep minimum in the stopband, or others.

## iirlp2xc

Transform IIR lowpass filter to IIR complex  $N$ -point filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2xc(b,a,wo,wt)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2xc(b,a,wo,wt)` transforms an IIR lowpass filter to an IIR complex  $N$ -point filter.

The prototype lowpass filter is specified with the numerator `b` and the denominator `a`. The function returns the numerator and the denominator coefficients of the transformed IIR complex  $N$ -point filter. The function also returns the numerator, `allpassNum`, and the denominator, `allpassDen`, of the allpass mapping filter.

The function transforms a real lowpass prototype filter to an  $N$ -point complex filter by applying an  $N^{\text{th}}$ -order real lowpass to complex multipoint frequency transformation, where  $N$  is the number of features being mapped and is given by the length of the vector `wo`. For more details, see “IIR Lowpass Filter to IIR Complex  $N$ -Point Filter Transformation” on page 5-995.

### Examples

#### Transform Lowpass Filter to IIR Complex $N$ -Point Filter

Transform a lowpass IIR filter to an  $N$ -point IIR complex filter using the `iirlp2xc` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);  
fvtool(b,a)
```

### Transform Filter Using `iirlp2xc`

Transform the real prototype lowpass filter to an IIR complex  $N$ -point filter.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2xc(b,a,[-0.5 0.5],[-0.25 0.25]);
```

Compare the magnitude response of the filters using `FVTool`. The transformed filter has complex coefficients and is indeed a bandpass filter.

```
fvt = fvtool(b,a,num,den);
legend(fvt,"Prototype Filter (TF Form)",...
      "Transformed Complex Multipoint Filter")
```

Alternatively, you can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The numerator and the denominator coefficients of the transformed filter are given by `num2` and `den2`, respectively.

```
ss = tf2sos(b,a);
[num2,den2] = iirlp2xc(ss(:,1:3),ss(:,4:6),...
    [-0.5 0.5],[-0.25 0.25]);
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(ss,[num2 den2]);
legend(hvft,"Prototype Filter (SOS Form)",...
    "Transformed Complex Multipoint Filter")
```

Copyright 2012-2021 The MathWorks, Inc.

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

**wo** — Frequency values to transform from prototype filter

row vector

Frequency values to transform from the prototype filter, specified as a row vector with even number of elements. Frequencies in **wo** should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate. The value of  $N$  equals the length of the **wo** vector. Length of vectors **wo** and **wt** must be the same.

Data Types: `single` | `double`

**wt** — Desired frequency locations in transformed target filter

row vector

Desired frequency locations in the transformed target filter, specified as a row vector with even number of elements. Frequencies in **wt** should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

---

**Note** Length of **wo** and **wt** vectors must be the same.

---

Data Types: `single` | `double`

## Output Arguments

**num** — Numerator coefficients of transformed multipoint filter

row vector | matrix

Numerator coefficients of the transformed multipoint filter, returned as one of the following:

- Row vector of length  $Nn/2+1$ , where  $n$  is the order of the input filter and  $N$  is the number of features being mapped. The value of  $N$  equals the length of the **wo** vector.

The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QN/2+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $N$  is the number of features being mapped and is given by the length of the vector **wo**.

The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

**den** — Denominator coefficients of transformed multipoint filter

row vector | matrix

Denominator coefficients of the transformed multipoint filter, returned as one of the following:

- Row vector of length  $Nn/2+1$ , where  $n$  is the order of the input filter and  $N$  is the number of features being mapped. The value of  $N$  equals the length of the **wo** vector.

The **den** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QN/2+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $N$  is the number of features being mapped and is given by the length of the vector  $w_0$ .

The den output is a matrix when the input coefficients  $b$  and  $a$  are matrices.

Data Types: `single` | `double`

### **allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

Complex Number Support: Yes

## **More About**

### **IIR Lowpass Filter to IIR Complex $N$ -Point Filter Transformation**

IIR lowpass filter to IIR complex  $N$ -point filter transformation effectively places  $N$  features of the original filter, located at frequencies  $w_{o1}, \dots, w_{oN}$ , at the required target frequency locations,  $w_{t1}, \dots, w_{tM}$ . The function `iirlp2xc` requires that  $N$  and  $M$  are equal.

Relative positions of other features of the original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., a stopband edge, DC, the deep minimum in the stopband, or other ones. Select features such that there is no band overlap when creating  $N$  bands around the unit circle.

IIR lowpass filter to IIR complex  $N$ -point filter transformation can also be used to transform other types of filters, for example, notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

## **Version History**

### Functions

`iirfttransf` | `allpasslp2xc` | `zpklp2xc`

## iirlp2xn

Transform IIR lowpass filter to IIR real  $N$ -point filter

### Syntax

```
[num,den,allpassNum,allpassDen] = iirlp2xn(b,a,wo,wt)
[num,den,allpassNum,allpassDen] = iirlp2xn(b,a,wo,wt,pass)
```

### Description

`[num,den,allpassNum,allpassDen] = iirlp2xn(b,a,wo,wt)` transforms an IIR lowpass filter to an IIR real  $N$ -point filter.

The `iirlp2xn` function returns the numerator and denominator coefficients of the transformed IIR  $N$ -point filter. The function also returns the numerator, `allpassNum`, and the denominator, `allpassDen`, of the  $N^{\text{th}}$  order allpass mapping filter. The prototype lowpass filter is specified with the numerator `b` and the denominator `a`.

The function transforms a real lowpass prototype filter to an  $N$ -point filter by applying an  $N^{\text{th}}$ -order real lowpass to real multipoint frequency transformation, where  $N$  is the number of features being mapped and is given by the length of the vector `wo`. By default, the DC feature is kept at its original location. For more details, see “IIR Lowpass to IIR Real  $N$ -Point Filter Transformation” on page 5-1003.

`[num,den,allpassNum,allpassDen] = iirlp2xn(b,a,wo,wt,pass)` allows you to specify an additional parameter, `pass` as 'pass' or 'stop', which chooses between using the “*Nyquist Mobility*” and the “*DC Mobility*”, respectively. In the case of “*Nyquist Mobility*”, the DC feature is kept at an original frequency and the Nyquist feature is free to move. In the case of “*DC Mobility*”, the Nyquist feature stays at its original location and the DC feature is free to move.

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

### Examples

#### Transform Lowpass Filter to IIR Real $N$ -Point Filter

Transform a lowpass IIR filter to an  $N$ -point IIR filter using the `iirlp2xn` function.

#### Input Lowpass IIR Filter

Design a prototype real IIR lowpass elliptic filter with a gain of about -3 dB at  $0.5\pi$  rad/sample.

```
[b,a] = ellip(3,0.1,30,0.409);
fvtool(b,a)
```

### Transform Filter Using `iirlp2xn`

Transform the real prototype lowpass filter to an IIR real  $N$ -point filter with one passband.

Specify the prototype filter as a vector of numerator and denominator coefficients, `b` and `a` respectively.

```
[num,den] = iirlp2xn(b,a,[-0.5 0.5],[0.3 0.6],"pass");
```

Compare the magnitude response of the filters using `FVTool`.

```
hvft = fvtool(b,a,num,den);
legend(hvft,"Prototype Filter (TF Form)",...
       "Transformed Multipoint Filter");
```

You can also specify the input lowpass IIR filter as a matrix of coefficients. Pass the second-order section matrices as inputs. The transformed filter is a fourth-order section filter with one stopband. The numerator and the denominator coefficients of the transformed filter are given by `num2` and `den2`, respectively.

```
ss = tf2sos(b,a);
[num2, den2] = iirlp2xn(ss(:,1:3),ss(:,4:6),[-0.5 0.5],...
    [0.3 0.6],"stop");
```

Compare the magnitude response of the filters using FVTool.

To visualize the magnitude response of the fourth-order section filter, first pass the filter coefficients to the `dsp.FourthOrderSectionFilter` object. Then, use this object as an input to the FVTool.

```
fos = dsp.FourthOrderSectionFilter(Numerator=num2,...
    Denominator=den2);
hvft = fvtool(ss,fos);
legend(hvft,"Prototype Filter (SOS Form)",...
    "Transformed Multipoint Filter")
```

## Input Arguments

### **b** — Numerator coefficients of prototype lowpass IIR filter

row vector | matrix

Numerator coefficients of the prototype lowpass IIR filter, specified as either:

- Row vector -- Specifies the values of  $[b_0, b_1, \dots, b_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}}$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the numerator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{b} = \begin{bmatrix} b_{01} & b_{11} & b_{21} & \dots & b_{Q1} \\ b_{02} & b_{12} & b_{22} & \dots & b_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{0P} & b_{1P} & b_{2P} & \dots & b_{QP} \end{bmatrix}$$

In the transfer function form, the numerator coefficient matrix  $b_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **a** -- Denominator coefficients matrix. For more information on how to specify this matrix, see [a](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **b** and **a** matrices must have the same number of rows (filter sections)  $Q$ .

Data Types: `single` | `double`

### **a** — Denominator coefficients of prototype lowpass IIR filter

row vector | matrix

Denominator coefficients for a prototype lowpass IIR filter, specified as one of these options:

- Row vector -- Specifies the values of  $[a_0, a_1, \dots, a_n]$ , given this transfer function form:

$$H(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1z^{-1} + \dots + b_nz^{-n}}{a_0 + a_1z^{-1} + \dots + a_nz^{-n}},$$

where  $n$  is the order of the filter.

- Matrix -- Specifies the denominator coefficients in the form of an  $P$ -by- $(Q+1)$  matrix, where  $P$  is the number of filter sections and  $Q$  is the order of each filter section. If  $Q = 2$ , the filter is a second-order section filter. For higher-order sections, make  $Q > 2$ .

$$\mathbf{a} = \begin{bmatrix} a_{01} & a_{11} & a_{21} & \dots & a_{Q1} \\ a_{02} & a_{12} & a_{22} & \dots & a_{Q2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{0P} & a_{1P} & a_{2P} & \dots & a_{QP} \end{bmatrix}$$

In the transfer function form, the denominator coefficient matrix  $a_{ik}$  of the IIR filter can be represented using the following equation:

$$H(z) = \prod_{k=1}^P H_k(z) = \prod_{k=1}^P \frac{b_{0k} + b_{1k}z^{-1} + b_{2k}z^{-2} + \dots + b_{Qk}z^{-Q}}{a_{0k} + a_{1k}z^{-1} + a_{2k}z^{-2} + \dots + a_{Qk}z^{-Q}},$$

where,

- **b** -- Numerator coefficients matrix. For more information on how to specify this matrix, see [b](#).
- $k$  -- Row index.
- $i$  -- Column index.

When specified in the matrix form, **a** and **b** matrices must have the same number of rows (filter sections)  $P$ .

Data Types: `single` | `double`

#### **wo** — Frequency values to transform from prototype filter

row vector

Frequency values to transform from the prototype filter, specified as a row vector. Frequencies in **wo** should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

The value of  $N$  equals the length of the **wo** vector. Length of vectors **wo** and **wt** must be the same.

Data Types: `single` | `double`

#### **wt** — Desired frequency locations in transformed target filter

row vector

Desired frequency locations in the transformed target filter, specified as a row vector. Frequencies in **wt** should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Length of vectors **wo** and **wt** must be the same.

Data Types: `single` | `double`

#### **pass** — Choice of passband or stopband at DC

`"pass"` (default) | `"stop"`

Choice of passband or stopband at DC, specified as either:

- `"pass"` -- *"Nyquist Mobility"*. The DC feature is kept at an original frequency and the Nyquist feature is free to move.
- `"stop"` -- *"DC Mobility"*. The Nyquist feature stays at its original location and the DC feature is free to move.

## Output Arguments

#### **num** — Numerator coefficients of transformed multipoint filter

row vector | matrix

Numerator coefficients of the transformed multipoint filter, returned as one of the following:

- Row vector of length  $Nn+1$ , where  $n$  is the order of the input filter and  $N$  is the number of features being mapped. The value of  $N$  equals the length of the **wo** vector.

The **num** output is a row vector when the input coefficients **b** and **a** are row vectors.

- $P$ -by- $(QN+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $N$  is the number of features being mapped and is given by the length of the vector **wo**.

The **num** output is a matrix when the input coefficients **b** and **a** are matrices.

Data Types: `single` | `double`

#### **den** — Denominator coefficients of transformed multipoint filter

row vector | matrix

Denominator coefficients of the transformed multipoint filter, returned as one of the following:

- Row vector of length  $Nn+1$ , where  $n$  is the order of the input filter and  $N$  is the number of features being mapped. The value of  $N$  equals the length of the `wo` vector.

The `den` output is a row vector when the input coefficients `b` and `a` are row vectors.

- $P$ -by- $(QN+1)$  matrix, where  $P$  is the number of filter sections,  $Q$  is the order of each section of the transformed filter, and  $N$  is the number of features being mapped and is given by the length of the vector `wo`.

The `den` output is a matrix when the input coefficients `b` and `a` are matrices.

Data Types: `single` | `double`

### **allpassNum — Numerator coefficients of mapping filter**

row vector

Numerator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

### **allpassDen — Denominator coefficients of mapping filter**

row vector

Denominator coefficients of the mapping filter, returned as a row vector.

Data Types: `single` | `double`

## **More About**

### **IIR Lowpass to IIR Real $N$ -Point Filter Transformation**

IIR Lowpass to IIR Real  $N$ -Point Filter transformation effectively places  $N$  features of the original filter, located at frequencies  $w_{o1}, \dots, w_{oN}$ , at the required target frequency locations,  $w_{t1}, \dots, w_{tM}$ . The function `iirlp2xn` requires that  $N$  and  $M$  are equal.

Relative positions of other features of the original filter are the same in the target filter for the Nyquist mobility and are reversed in DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. Select features such that there is no band overlap when creating  $N$  bands around the unit circle.

IIR lowpass to IIR real  $N$ -point filter transformation can also be used to transforming other types of filters, for example, notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Functions

`iirlp2xc` | `iirftransf` | `allpasslp2xn` | `zpklp2xn`

# iirlpnorm

Least P-norm optimal IIR filter

## Syntax

```
[num,den] = iirlpnorm(n,d,f,edges,a)
[num,den] = iirlpnorm(n,d,f,edges,a,w)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)
[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)
[num,den,err] = iirlpnorm(...)
[num,den,err,sos,g] = iirlpnorm(...)
```

## Description

`[num,den] = iirlpnorm(n,d,f,edges,a)` returns a filter having a numerator order  $n$  and denominator order  $d$  which is the best approximation to the desired frequency response described by  $f$  and  $a$  in the least- $p$ th sense. The vector `edges` specifies the band-edge frequencies for multi-band designs. An unconstrained quasi-Newton algorithm is employed and any poles or zeros that lie outside of the unit circle are reflected back inside.  $n$  and  $d$  should be chosen so that the zeros and poles are used effectively. See the “Hints” on page 5-1007 section. Always use `freqz` to check the resulting filter.

`[num,den] = iirlpnorm(n,d,f,edges,a,w)` uses the weights in  $w$  to weight the error.  $w$  has one entry per frequency point (the same length as  $f$  and  $a$ ) which tells `iirlpnorm` how much emphasis to put on minimizing the error in the vicinity of each frequency point relative to the other points.  $f$  and  $a$  must have the same number of elements, which may exceed the number of elements in `edges`. This allows for the specification of filters having any gain contour within each band. The frequencies specified in `edges` must also appear in the vector  $f$ . For example,

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

is a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p)` where  $p$  is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of  $p$  used in the least- $p$ th algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm.  $p_{min}$  and  $p_{max}$  should be even. If  $p$  is 'inspect', no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is  $(dens*(n+d+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnorm(n,d,f,edges,a,w,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors `initnum` and `initden`. `initnum` should be of length  $n+1$ , and `initden` should be of length  $d+1$ . This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnorm(...)` returns the least- $p^{\text{th}}$  approximation error, `err`.

`[num,den,err,sos,g] = iirlpnorm(...)` returns the second-order section representation in the matrix `sos` and gain `g`. For numerical reasons it may be beneficial to use `sos` and `g` in some cases.

## Examples

“Least Pth-Norm Optimal IIR Filter Design”

### Design a Lowpass Filter with a Peak of 4.015 dB in Passband

```
[num,den] = iirlpnorm(5,12,[0 .15 .4 .5 1],[0 .4 .5 1],...  
[1 1.6 1 0 0],[1 1 1 10 10])
```

```
num = 1×6
```

```
    -0.0128    0.0041   -0.0068    0.0048    0.0056   -0.0001
```

```
den = 1×13
```

```
    1.0000   -6.0264   18.6845  -38.7635   59.2365  -69.7345   64.5556  -47.2403   27.1100  -11.9
```

Display the magnitude response in `fvtool`

```
fvtool(num,den)
```

## Hints

- This is a weighted least- $p^{\text{th}}$  optimization.
- Check the radii and locations of the poles and zeros for your filter. If the zeros are on the unit circle and the poles are well inside the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radii and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weighting in the passband.

[num,den] = iirlpnormc(5,5,[0 .15 .4 .5 1],[0 .4 .5 1],...
[1 1.6 1 0 0],[1 1 1 10 10])
```

designs a lowpass filter with a peak of 1.6 within the passband.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius)` returns a filter having a maximum pole radius of `radius` where  $0 < \text{radius} < 1$ . `radius` defaults to 0.999999. Filters that have a reduced pole radius may retain better transfer function accuracy after you quantize them.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p)` where  $p$  is a two-element vector `[pmin pmax]` allows for the specification of the minimum and maximum values of  $p$  used in the least- $p$ th algorithm. Default is `[2 128]` which essentially yields the L-infinity, or Chebyshev, norm. `pmin` and `pmax` should be even. If  $p$  is 'inspect', no optimization will occur. This can be used to inspect the initial pole/zero placement.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens)` specifies the grid density `dens` used in the optimization. The number of grid points is  $(\text{dens} * (n+d+1))$ . The default is 20. `dens` can be specified as a single-element cell array. The grid is not equally spaced.

`[num,den] = iirlpnormc(n,d,f,edges,a,w,radius,p,dens,initnum,initden)` allows for the specification of the initial estimate of the filter numerator and denominator coefficients in vectors

`initnum` and `initden`. This may be useful for difficult optimization problems. The pole-zero editor in Signal Processing Toolbox software can be used for generating `initnum` and `initden`.

`[num,den,err] = iirlpnormc(...)` returns the least-Pth approximation error `err`.

`[num,den,err,sos,g] = iirlpnormc(...)` returns the second-order section representation in the matrix `SOS` and gain `G`. For numerical reasons you may find `SOS` and `G` beneficial in some cases.

## Hints

- This is a weighted least-pth optimization.
- Check the radii and location of the resulting poles and zeros.
- If the zeros are all on the unit circle and the poles are well inside of the unit circle, try increasing the order of the numerator or reducing the error weighting in the stopband.
- Similarly, if several poles have a large radius and the zeros are well inside of the unit circle, try increasing the order of the denominator or reducing the error weight in the passband.
- If you reduce the pole radius, you might need to increase the order of the denominator.

The message

Poorly conditioned matrix. See the "help" file.

indicates that `iirlpnormc` cannot accurately compute the optimization because either:

- a The approximation error is extremely small (try reducing the number of poles or zeros — refer to the hints above).
- b The filter specifications have huge variation, such as `a=[1 1e9 0 0]`.

## Examples

### Magnitude Response of Constrained Least Pth-norm Optimal IIR Filter

This example returns a lowpass filter whose pole radius is constrained to 0.8.

```
[b,a,err,s,g] = iirlpnormc(6,6,[0 .4 .5 1],[0 .4 .5 1],...  
[1 1 0 0],[1 1 1 1],.8);  
fvtool(b,a);
```

The magnitude response shows the lowpass nature of the filter. The pole/zero plot following shows that the poles are constrained to 0.8 as specified in the command.

```
fvtool(b,a,'polezero');
```

## Version History

Introduced in R2011a

## References

## iirls

Least-squares IIR filter from specification object

### Syntax

```
hd = design(d,'iirls','SystemObject',true)
hd =
design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true)
```

### Description

`hd = design(d,'iirls','SystemObject',true)` designs a least-squares filter specified by the filter specification object `d`.

---

**Note** The `iirls` algorithm might not be well behaved in all cases. Experience is your best guide to determining if the resulting filter meets your needs. When you use `iirls` to design a filter, review the filter carefully to ensure that it is appropriate for your use.

---

`hd = design(d,'iirls',designoption,value,designoption,value,...,'SystemObject',true)` returns a least-squares IIR filter where you specify design options as input arguments.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `iirls`, refer to the command line help system. For example, to get specific information about using `iirls` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'iirls')
```

### Examples

#### Design a Complex Bandpass Filter

Starting from an arbitrary magnitude and phase design object `d`, generate a complex bandpass filter of order = 5. To make the example a little easier to do, use the default values for `F`, and `H`, the frequency vector and the complex desired frequency response.

```
d = fdesign.arbmagnphase('N,F,H',5)
```

```
d =
arbmagnphase with properties:
```

```
Response: 'Arbitrary Magnitude and Phase'
```

```

Specification: 'N,F,H'
Description: {3x1 cell}
NormalizedFrequency: 1
FilterOrder: 5
Frequencies: [-1 -0.9969 -0.9939 -0.9908 -0.9878 -0.9847 -0.9817 -0.9786 -0.9755 -0.9725]
FreqResponse: [-0.0030 - 0.0105i -0.0031 - 0.0107i -0.0032 - 0.0108i -0.0032 - 0.0110i]

```

```

filtObj = design(d,'iirls','SystemObject',true);
hvft = fvtool(filtObj,'freq');
legend(hvft,'Frequency Response')

```

## iirnotch

Second-order IIR notch filter

### Syntax

```
[num,den] = iirnotch(w0,bw)
[num,den] = iirnotch(w0,bw,ab)
```

### Description

`[num,den] = iirnotch(w0,bw)` returns the numerator coefficients, `num`, and the denominator coefficients, `den`, of the digital notching filter with the notch located at  $w_0$  and the bandwidth at the -3 dB point set to `bw`. To design the filter,  $w_0$  must meet the condition  $0.0 < w_0 < 1.0$ , where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w_0/bw$ , where  $w_0$  is the notch frequency.

`[num,den] = iirnotch(w0,bw,ab)` returns the digital notching filter whose bandwidth, `bw`, is specified at a level of `-ab` decibels.

### Examples

#### Design IIR Notch Filter Using iirnotch

Design and plot an IIR notch filter that removes a 60 Hz tone ( $f_0$ ) from a signal at 300 Hz ( $f_s$ ). For this example, set the Q factor for the filter to 35 and use it to specify the filter bandwidth.

```
w0 = 60/(300/2);
bw = w0/35;
[b,a] = iirnotch(w0,bw);
```

The notch filter has the desired bandwidth with the notch located at 60 Hz, or  $0.4\pi$  radians per sample. Compare this plot to the comb filter plot shown for `iircomb`.

```
fvtool(b,a)
```

## Input Arguments

### **w0** — Notch frequency

positive scalar

Notch frequency, specified as a positive scalar in the range (0.0, 1.0), where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

Data Types: `single` | `double`

### **bw** — 3 dB bandwidth

positive scalar

Bandwidth at the -3 dB point, specified as a positive scalar in the range (0.0, 1.0).

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = w0/bw$ , where  $w0$  is the notch frequency.

Data Types: `single` | `double`

### **ab** — Custom decibel level

real scalar

Custom decibel level,  $-ab$ , at which the filter has a bandwidth of  $bw$ . Including the optional input argument  $ab$  lets you specify the magnitude response bandwidth at a level that is not the default -3 dB point, such as -6 dB or 0 dB. If not specified,  $ab$  defaults to the -3 dB width ( $10\log_{10}(1/2)$ ).

Data Types: `single` | `double`

## Output Arguments

### **num** — Numerator coefficients

row vector

Numerator coefficients of the designed notch filter, returned as a row vector.

Data Types: `double`

### **den** — Denominator coefficients

row vector

Denominator coefficients of the designed notch filter, returned as a row vector.

Data Types: `double`

# iirparameq

(To be removed) IIR biquad digital parametric equalizer filter

---

**Note** The `iirparameq` function will be removed in a future release. Existing code using the function continues to run. For new code, use the `designParamEQ` function instead. For more information on how to update your existing code, see “Compatibility Considerations”.

---

## Syntax

```
[SOS,SV] = iirparameq(N,G,Wo,BW)
```

```
[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)
```

## Description

`[SOS,SV] = iirparameq(N,G,Wo,BW)` returns the coefficients of an  $N$ th order IIR biquad digital parametric equalizer with gain  $G$ , center frequency  $W_o$ , and bandwidth  $BW$ . The coefficients are returned in a second-order section matrix,  $SOS$ , and a vector of scale values between each biquad stage,  $SV$ .

`[SOS,SV,B,A] = iirparameq(N,G,Wo,BW)` additionally returns a matrix of numerator fourth-order sections,  $B$ , and a matrix  $A$  of denominator fourth-order sections,  $A$ . These can be used in lieu of a biquad implementation and are useful for the case  $W_o = 0.5$ .

## Examples

### Second-order section matrices of the parametric equalizer

Compute the second-order section matrix and scale values of a parametric equalizer.

```
[SOS,SV] = iirparameq(6,5,0.0042,0.0028)
```

SOS =

```

    1.0000    -1.9892     0.9894     1.0000    -1.9911     0.9912
    1.0000    -1.9926     0.9929     1.0000    -1.9941     0.9944
    1.0000    -1.9964     0.9965     1.0000    -1.9967     0.9968

```

SV =

```

    1.0009
    1.0000
    1.0009
    1.0000

```

### Fourth-order section matrices of the parametric equalizer

Compute the numerator and denominator coefficients of the fourth-order sections of the parametric equalizer.

```
[SOS,SV,B,A] = iirparameq(6,5,0.0042,0.0028)
```

SOS =

```
    1.0000    -1.9892    0.9894    1.0000    -1.9911    0.9912
    1.0000    -1.9926    0.9929    1.0000    -1.9941    0.9944
    1.0000    -1.9964    0.9965    1.0000    -1.9967    0.9968
```

SV =

```
    1.0009
    1.0000
    1.0009
    1.0000
```

B =

```
    1.0009    -1.9911    0.9903         0         0
    1.0009    -3.9927    5.9729    -3.9715    0.9903
```

A =

```
    1.0000    -1.9911    0.9912         0         0
    1.0000    -3.9908    5.9729    -3.9733    0.9912
```

### Two Equalizers Centered at Different Frequencies

Design two equalizers centered at 100 Hz and 1000 Hz respectively, both with a gain of 5 dB and a Q-factor of 1.5, for a system running at 48 kHz.

```
Fs = 48e3;
N = 6;
G = 5;
Q = 1.5;
Wo1 = 100/(Fs/2);
Wo2 = 1000/(Fs/2);
% Obtain the bandwidth of the equalizers from the center frequencies and
% Q-factors.
BW1 = Wo1/Q;
BW2 = Wo2/Q;
% Design the equalizers and obtain their SOS and SV values.
[SOS1,SV1] = iirparameq(N,G,Wo1,BW1);
[SOS2,SV2] = iirparameq(N,G,Wo2,BW2);
```

Design biquad filters using the obtained SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2,'ScaleValues',SV2);
```

Plot the magnitude response of both filters using a log scale.

```
fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');
legend('Equalizer centered at 100 Hz','Equalizer centered at 1000 Hz');
```

## Compare Notch Filters Designed with Different Orders

Design an eighth-order notch filter and compare it to a traditional second-order notch filter designed with IIRNOTCH.

```
Fs = 44.1e3;
N = 8;
G = -inf;
Q = 1.8;
Wo = 60/(Fs/2); % Notch at 60 Hz
BW = Wo/Q; % Bandwidth occurs at -3 dB for this special case
[SOS1,SV1] = iirparameq(N,G,Wo,BW);
[NUM,DEN] = iirnotch(Wo,BW);
SOS2 = [NUM,DEN];
```

Design the notch filters using the SOS and SV values.

```
BQ1 = dsp.BiquadFilter('SOSMatrix',SOS1,'ScaleValues',SV1);
BQ2 = dsp.BiquadFilter('SOSMatrix',SOS2);
```

Plot the magnitude response of both filters. The filters intersect at -3 dB point.

```
FVT = fvtool(BQ1,BQ2,'Fs',Fs,'FrequencyScale','Log');
legend(FVT,'8th order notch filter','2nd order notch filter');
```

## Input Arguments

### N — Order of the parametric equalizer

even positive integer

Order of the parametric equalizer, specified as an even positive integer.

Example: 6

Example: 10

Data Types: single | double

### G — Gain of the parametric equalizer

real scalar

Gain of the parametric equalizer in dB, specified as a real scalar.

Example: 2

Example: -2.2

Data Types: single | double

### Wo — Center frequency of the parametric equalizer

real scalar

Center frequency of the parametric equalizer, specified as a real scalar in the range [0.0 1.0]. A value of 1.0 corresponds to  $\pi$  radians/sample.

Example: 0.0

Example: 1.0

Data Types: single | double

### **BW — Bandwidth of the parametric equalizer**

real scalar

Bandwidth of the parametric equalizer, specified as a real scalar in the range [0.0 1.0]. A value of 1.0 corresponds to  $\pi$  radians/sample.

Example: 0.0

Example: 1.0

Data Types: single | double

## **Output Arguments**

### **SOS — Second-order section matrix**

real-valued matrix

Second-order section matrix, returned as a real-valued  $L$ -by-6 matrix, where  $L$  is the number of second-order sections of the filter.

### **SV — Scale values between each biquad stage**

real-valued vector

Scale values between each biquad stage, returned as a real-valued vector of length  $L + 1$ .

### **B — Numerator coefficients of the fourth-order sections of the parametric equalizer**

real-valued matrix

Numerator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued  $M$ -by-5 matrix.  $M$  is the number of fourth-order sections of the filter.

### **A — Denominator coefficients of the fourth-order sections of the parametric equalizer**

real-valued matrix

Denominator coefficients of the fourth-order sections of the parametric equalizer, returned as a real-valued  $M$ -by-5 matrix.  $M$  is the number of fourth-order sections of the filter.

## **Algorithms**

### **High-order Parametric Equalizer**

Parametric equalizers are digital filters used in audio processing for adjusting the frequency content of a sound signal. Parametric equalizers provide capabilities beyond those of graphic equalizers by allowing the adjustment of gain, center frequency, and bandwidth of each filter. In contrast, graphic equalizers allow for the adjustment of the gain of each filter only. Digital parametric audio equalizers are commonly implemented as biquadratic (second-order IIR) filters. Due to low order, biquadratic filters can present relatively large ripple or transition regions. When several filters are connected in cascade, they can overlap with each other. In such circumstances, high-order filters are preferred. High-order filters provide flatter passbands, sharper band edges, and more control over the shape of

each filter. In addition, if the order of the filter is set to two, the design changes to a special case: a traditional second-order parametric equalizer.

The figure shows the magnitude response of a second-order parametric equalizer compared with a high-order parametric equalizer.

$W_0 = 0.3 \times \pi$  radians/sample is the center frequency of the equalizer,  $BW = 0.2$  radians/sample is the bandwidth of the equalizer,  $G = 10$  is the peak gain of the equalizer,  $G_0 = 1$ , and  $G_B = (G_0^2 + G^2) / 2$ .

### Algorithm

The first step in the filter design is to design a high-order analog lowpass shelving filter that meets the specified gain and bandwidth. A high-order Butterworth filter is used for this purpose. The analog Butterworth filter is then transformed into a digital lowpass shelving filter, and finally into a peaking equalizer that is centered at the specified peak frequency.

The design specifications for the digital equalizer are the order of the equalizer,  $N$ , the gain of the equalizer,  $G$ , the center frequency of the equalizer,  $W_0$ , and the bandwidth of the equalizer,  $BW$ .

The transfer function of the high-order parametric equalizer is given by:

$$H(z) = \left[ \frac{b_{00} + b_{01}z^{-1} + b_{02}z^{-2}}{1 + a_{01}z^{-1} + a_{02}z^{-2}} \right]^r \times \prod_{i=1}^L \left[ \frac{b_{i0} + b_{i1}z^{-1} + b_{i2}z^{-2} + b_{i3}z^{-3} + b_{i4}z^{-4}}{1 + a_{i1}z^{-1} + a_{i2}z^{-2} + a_{i3}z^{-3} + a_{i4}z^{-4}} \right]$$

where  $b_{00}$ ,  $b_{01}$ ,  $b_{02}$ ,  $a_{01}$ , and  $a_{02}$  are coefficients of the second-order section of the equalizer.  $b_{i0}$ ,  $b_{i1}$ ,  $b_{i2}$ ,  $b_{i3}$ ,  $b_{i4}$ ,  $a_{i1}$ ,  $a_{i2}$ , and  $a_{i3}$  are coefficients of the fourth-order sections of the equalizer.  $L = (N - r) / 2$ ,

where  $r = 1$  when  $N$  is odd, and  $r = 0$  when  $N$  is even. The fourth-order sections are factored into second-order sections so that you can implement them using biquad filters.

For more information on how coefficients are computed in terms of the design specifications, see the "Butterworth Designs" section in [1].

## Version History

### Introduced in R2015a

#### R2022a: `iirparameq` will be removed

*Warns starting in R2022a*

The `iirparameq` function will be removed in a future release. Existing instances of the function continue to run. For new code, use the `designParamEQ` function instead.

#### Update Code

This table shows how the function is typically used and explains how to update the existing code to use the `designParamEQ` function.

# iirpeak

Second-order IIR peak or resonator filter

## Syntax

```
[num,den] = iirpeak(w0,bw)  
[num,den] = iirpeak(w0,bw,ab)
```

## Description

`[num,den] = iirpeak(w0,bw)` returns a second-order digital peaking filter with the peak located at  $w_0$ , and with the bandwidth at the +3 dB point set to  $bw$ .

`[num,den] = iirpeak(w0,bw,ab)` returns a digital peaking filter whose bandwidth,  $bw$ , is specified at a level of  $+ab$  decibels.

## Examples

### Design IIR Peaking Filter

Design and plot an IIR peaking filter that boosts the frequency at 1.75 KHz in a signal and has a bandwidth of 500 Hz at the -3 dB point.

```
fs = 10000;  
wo = 1750/(fs/2);  
bw = 500/(fs/2);  
[b,a] = iirpeak(wo,bw);  
fvtool(b,a,Fs=fs)
```

The peak filter has the desired gain and bandwidth at 1.75 KHz.

## Input Arguments

### **w0 — Peak frequency**

positive scalar in the range (0.0, 1.0)

Peak frequency of the IIR filter, specified as a positive scalar in the range (0.0, 1.0), where 1.0 corresponds to  $\pi$  radians per sample in the frequency range.

Data Types: single | double

### **bw — Bandwidth of filter**

positive scalar in the range (0.0, 1.0)

Bandwidth of the filter at a level of +ab decibels, specified as a positive scalar in the range (0.0, 1.0).

The quality factor (Q factor)  $q$  for the filter is related to the filter bandwidth by  $q = \omega_0 / bw$  where  $\omega_0$  is the signal frequency to boost.

Data Types: single | double

### **ab — Magnitude response at filter bandwidth**

3 (default) | scalar

Magnitude response at the filter bandwidth `bw`, specified as a scalar in dB. Including the optional input argument `ab` lets you specify the magnitude response bandwidth at a level that is not the default +3 dB point, such as +6 dB or 0 dB.

Data Types: `single` | `double`

## Output Arguments

### **num** — Numerator coefficients

real-valued three-element row vector

Numerator coefficients of the second order IIR peak filter transfer function, returned as a real-valued three-element row vector.

Data Types: `single` | `double`

### **den** — Denominator coefficients

real-valued three-element row vector

Denominator coefficients of the second order IIR peak filter transfer function, returned as a real-valued three-element row vector.

Data Types: `single` | `double`

## Version History

## iirpowcomp

Power complementary IIR filter

### Syntax

```
[bp,ap] = iirpowcomp(b,a)
[bp,ap] = iirpowcomp(b,a,c)
```

### Description

`[bp,ap] = iirpowcomp(b,a)` returns the coefficients vectors `bp` and `ap`, of the power complementary IIR filter  $g(z) = bp(z) / ap(z)$ , given the coefficients vectors `b` and `a` of the IIR filter  $h(z) = b(z) / a(z)$  in `.` The vector `b` must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as the vector `a`. The two power complementary filters satisfy the relation

$$|H(w)|^2 + |G(w)|^2 = 1.$$

`[bp,ap] = iirpowcomp(b,a,c)` allow you to specify a complex scalar of unity magnitude, `c`, which forces `bp` to satisfy the generalized Hermitian property:

$$\text{conj}(bp(\text{end}:-1:1)) = c*bp$$

### Examples

#### Power Complementary IIR Filter

Calculate the coefficients of the power complementary IIR filter.

```
[b,a]=cheby1(10,.5,.4);
[bp,ap]=iirpowcomp(b,a);
```

Compare the magnitude responses of the filters using FVTool.

```
hvft = fvtool(b,a,bp,ap,'MagnitudeDisplay','Magnitude squared');
legend(hvft,'Original Filter','Power Complementary Version');
```

## Input Arguments

### **b** — Numerator of IIR filter

row vector

Numerator coefficients of the IIR filter, specified as a row vector. The vector **b** must be symmetric (Hermitian) or antisymmetric (antihermitian) and of the same length as the vector **a**.

Data Types: `single` | `double`

### **a** — Denominator of IIR filter

row vector

Denominator coefficients of the IIR filter, specified as a row vector.

Data Types: `single` | `double`

### **c** — Complex scalar of unity magnitude

complex scalar

Complex scalar of unity magnitude, which forces the **bp** to satisfy generalized Hermitian property.

The generalized Hermitian property is given by:

$$\text{conj}(\text{bp}(\text{end}:-1:1)) = \text{c}*\text{bp}$$

When *c* is omitted, the function chooses *c* as follows:

- When *b* is real, the function chooses *c* as 1 or -1, whichever yields *bp* as real.
- When *b* is complex, *c* defaults to 1.

*ap* is always equal to *a*.

Data Types: `single` | `double`

## Output Arguments

### **bp — Numerator of power complementary IIR filter**

row vector

Numerator coefficients of the power complementary IIR filter, returned as a row vector.

Data Types: `single` | `double`

### **ap — Denominator of power complementary IIR filter**

row vector

Denominator coefficients of the power complementary IIR filter, returned as a row vector.

Data Types: `single` | `double`

# iirrateup

Upsample IIR filter by integer factor

## Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)
```

## Description

`[Num,Den,AllpassNum,AllpassDen] = iirrateup(B,A,N)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter being transformed from any prototype by applying an `N`th-order rateup frequency transformation, where `N` is the upsample ratio. Transformation creates `N` equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with a numerator specified by `B` and a denominator specified by `A`.

The relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);  
[num, den] = iirrateup(b, a, 4);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

As shown in the figure produced by FVTool, the transformed filter appears as expected.

## Arguments

| Variable     | Description                                 |
|--------------|---|
| $B$          | Numerator of the prototype lowpass filter   |
| $A$          | Denominator of the prototype lowpass filter |
| $N$          | Frequency multiplication ratio              |
| $Num$        | Numerator of the target filter              |
| $Den$        | Denominator of the target filter            |
| $AllpassNum$ | Numerator of the mapping filter             |
| $AllpassDen$ | Denominator of the mapping filter           |

## Version History

Introduced in R2011a

## iirshift

Shift frequency response of IIR filter

### Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)
```

### Description

`[Num,Den,AllpassNum,AllpassDen] = iirshift(B,A,Wo,Wt)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a second-order real shift frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator of the allpass mapping filter, `AllpassDen`. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

This transformation places one selected feature of an original filter located at frequency  $W_0$  to the required target frequency location,  $W_t$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_0$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them from the beginning.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Perform the real frequency shift by defining where the selected feature of the prototype filter, originally at  $W_0=0.5$ , should be placed in the target filter,  $W_t=0.75$ :

```
Wo = 0.5; Wt = 0.75;
[num, den] = iirshift(b, a, Wo, Wt);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

Shifting the specified feature from the prototype to the target generates the response shown in the figure.

## Arguments

| Variable     | Description   |
|--------------|---|
| $B$          | Numerator of the prototype lowpass filter                   |
| $A$          | Denominator of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Num$        | Numerator of the target filter                              |
| $Den$        | Denominator of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## Version History

# iirshiftc

Shift frequency response of IIR complex filter

## Syntax

```
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)
```

## Description

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,Wo,Wc)` returns the numerator and denominator vectors, `Num` and `Den` respectively, of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with the numerator specified by `B` and the denominator specified by `A`.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,0.5)` calculates the allpass filter for doing the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = iirshiftc(B,A,0,-0.5)` calculates the allpass filter for doing an inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

## Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
```

Rotate all features of the prototype filter in the frequency domain by the same amount by specifying where the selected feature of an original filter,  $W_o = 0.5$ , should appear in the target filter,  $W_t = 0.25$ :

```
[num, den] = iirshiftc(b, a, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, num, den);
```

After applying the shift, the selected feature from the original filter is just where it should be, at  $W_t = 0.25$ .

## Arguments

| Variable     | Description   |
|--------------|---|
| $B$          | Numerator of the prototype lowpass filter                   |
| $A$          | Denominator of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Num$        | Numerator of the target filter                              |
| $Den$        | Denominator of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# impz

**Package:** dsp

Impulse response of discrete-time filter System object

## Syntax

```
[impResp,t] = impz(sysobj)
[impResp,t] = impz(sysobj,n)
[impResp,t] = impz(sysobj,n,fs)
[impResp,t] = impz(sysobj,[],fs)
[impResp,t] = impz(sysobj,'Arithmetic',arithType)
impz(sysobj)
```

## Description

`[impResp,t] = impz(sysobj)` computes the impulse response of the filter System object and returns the response in column vector `impResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[impResp,t] = impz(sysobj,n)` computes the impulse response at `floor(n)` one-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[impResp,t] = impz(sysobj,n,fs)` computes the impulse response at `floor(n)` `1/fs`-second intervals. The time vector `t` equals `(0:floor(n)-1)/fs`.

`[impResp,t] = impz(sysobj,[],fs)` computes the impulse response at `k` `1/fs`-second intervals. `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)/fs`.

`[impResp,t] = impz(sysobj,'Arithmetic',arithType)` computes the impulse response based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

`impz(sysobj)` uses `fvtool` to plot the impulse response of the filter System object `sysobj`.

You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

For more input options, refer to `impz` in Signal Processing Toolbox.

## Examples

### Plot the Impulse Response of a Lowpass Elliptic Filter

Create a discrete-time filter for a fourth-order, lowpass elliptic filter with a cutoff frequency of 0.4 times the Nyquist frequency. Use a second-order sections structure to resist quantization errors. Plot the first 50 samples of the impulse response, along with the reference impulse response.

```
d = fdesign.lowpass(.4,.5,1,80);
```

Create a design object for the prototype filter. Use `ellip` to design a minimum order discrete-time SOS filter.

```
sosFilt = design(d,'ellip','Systemobject',true)
```

```
sosFilt =  
  dsp.SOSFilter with properties:  
    Structure: 'Direct form II'  
  CoefficientSource: 'Property'  
    Numerator: [4x3 double]  
    Denominator: [4x3 double]  
  HasScaleValues: true  
    ScaleValues: [0.7277 0.8290 1.3494 0.0048 1]
```

Show all properties

Plot the impulse response.

```
impz(sosFilt);
```

## Input Arguments

**sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**n — Number of filter coefficients**

positive integer

Length of the impulse response vector, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**fs — Sampling frequency**

1 (default) | positive scalar

Sampling frequency used in computing the impulse response, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **impResp** — Impulse response

vector

Impulse response, returned as an n-element vector. If n is not specified, the length of the impulse response vector equals the number of coefficients in the filter.

Data Types: double

### **t** — Time vector

vector

Time vector of length n, in seconds. **t** consists of n equally spaced points in the range  $(0:\text{floor}(n)-1)/f_s$ . If n is not specified, the function uses the number of coefficients of the filter.

Data Types: double

# impzlength

**Package:** dsp

Length of impulse response of discrete-time filter System object

## Syntax

```
len = impzlength(sysobj)
len = impzlength(sysobj,tol)
len = impzlength( ____, 'Arithmetic', arithType)
```

## Description

`len = impzlength(sysobj)` returns the length of the impulse response of the filter System object.

`len = impzlength(sysobj,tol)` specifies the tolerance to increase or decrease the length accuracy.

`len = impzlength( ____, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

For more input options, see `impzlength` in Signal Processing Toolbox.

## Examples

### Impulse Response Length of Filter System object

This example requires DSP System Toolbox™ software.

Design a 4th-order lowpass elliptic filter with a cutoff frequency of  $0.4\pi$  rad/sample. Specify 1 dB of passband ripple and 60 dB of stopband attenuation. Design the filter in pole-zero-gain form and obtain the second order section matrix using the `zp2sos` function. Create an SOS filter object and input the object to `impzlength`.

```
[z,p,k] = ellip(4,1,60,.4);
[sos,g] = zp2sos(z,p,k);
hSosFilt = dsp.SOSFilter(Structure='Direct form I',...
    Numerator=sos(:,1:3),Denominator=sos(:,4:6),...
    HasScaleValues=true,ScaleValues=g);
len = impzlength(hSosFilt)
```

```
len = 80
```

### Impulse Response Length for Filter System Objects

Design an IIR Butterworth and an FIR equiripple filter for data sampled at 1 kHz. Set the passband frequency to 100 Hz and the stopband frequency to 150 Hz. Set the passband ripple to 0.5 dB and the

stopband attenuation to 60 dB. Create System objects for the filters and compare the filter impulse response sequence lengths.

```
d = fdesign.lowpass('Fp,Fst,Ap,Ast',100,150,0.5,60,1000);
Hd1 = design(d,'butter',SystemObject=true)
```

```
Hd1 =
  dsp.SOSFilter with properties:
    Structure: 'Direct form II'
    CoefficientSource: 'Property'
    Numerator: [9x3 double]
    Denominator: [9x3 double]
    HasScaleValues: true
    ScaleValues: [0.1020 0.0927 0.0852 0.0793 0.0748 0.0713 0.0689 0.0673 0.0665 1]
```

Show all properties

```
Hd2 = design(d,'equiripple',SystemObject=true)
```

```
Hd2 =
  dsp.FIRFilter with properties:
    Structure: 'Direct form'
    NumeratorSource: 'Property'
    Numerator: [-7.9808e-04 -2.8559e-04 0.0011 0.0036 0.0064 0.0079 0.0063 0.0012 -0.0055]
    InitialConditions: 0
```

Show all properties

```
len = [impzlength(Hd1) impzlength(Hd2)]
```

```
len = 1×2
    183    49
```

## Input Arguments

### **sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`

- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **tol — Tolerance for IIR filter effective impulse response length**

5e-5 (default) | positive scalar

Tolerance for IIR filter effective impulse response length, specified as a positive number. The tolerance determines the term in the absolutely summable sequence after which subsequent terms are considered to be 0. Increasing the tolerance returns a shorter effective impulse response sequence length. Decreasing the tolerance returns a longer effective impulse response sequence length.

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **len** — Length of impulse response

positive integer

Length of the impulse response, specified as a positive integer. For stable IIR filters with absolutely summable impulse responses, `impzlength` returns an effective length for the impulse response beyond which the coefficients are essentially zero. You can control this cutoff point by specifying the optional `tol` input argument.

## Syntax

```
s = info(sysobj)
s = info(sysobj,infoType)
s = info( ____, 'Arithmetic', arithType)
```

## Description

`s = info(sysobj)` returns very basic information about the filter System object. The particulars depend on the filter type and structure.

`s = info(sysobj,infoType)` returns the amount of filter information as specified by the `infoType`.

`s = info( ____, 'Arithmetic', arithType)` analyzes the filter System object, based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

For more input options, see `info` in Signal Processing Toolbox.

## Examples

### Obtain Filter Information

Obtain short-format and long-format information about a filter.

```
d = fdesign.lowpass;
f = design(d,'SystemObject',true);
info(f)

ans = 6x35 char array
'Discrete-Time FIR Filter (real)      '
'-----'
'Filter Structure   : Direct-Form FIR'
'Filter Length     : 43              '
'Stable            : Yes             '
'Linear Phase      : Yes (Type 1)    '
```

```
info(f,'long')
```

```
ans = 45x45 char array
'Discrete-Time FIR Filter (real)      '
'-----'
'Filter Structure   : Direct-Form FIR'
'Filter Length     : 43              '
'Stable            : Yes             '
'Linear Phase      : Yes (Type 1)    '
```

### Decimate a Signal Using a CICDecimator Object

Create a `dsp.CICDecimator` System object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```

cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;

```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```

Fs = 44.1e3;
% 0.0232 sec signal

```

```
n = (0:1023)';  
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create a `dsp.SignalSource` object.

```
src = dsp.SignalSource(x,64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16,16);  
for ii = 1:16  
    y(ii,:) = cicdec(src());  
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
D = cicdec.DecimationFactor;  
diffDelay = cicdec.DifferentialDelay;  
NumSect = cicdec.NumSections;  
gainCIC = ...  
    (D*diffDelay)^NumSect;  
stem(n(1:56)/Fs,double(x(4:59)))  
hold on;  
stem(n(1:14)/(Fs/D),double(y(1,3:end))/gainCIC,...  
    'r','filled')  
xlabel('Time (sec)')  
ylabel('Signal Amplitude')  
legend('Original signal',...  
    'Decimated signal',...  
    'Location','north')  
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Decimator

```

## Interpolate Signal Using CICInterpolator System object

Create a `dsp.CICInterpolator System` object™ with `InterpolationFactor` set to 2. Interpolate a fixed-point signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2)

cicint =
  dsp.CICInterpolator with properties:

    InterpolationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

Create a `dsp.SinWave` object with `SampleRate` set to 22.05 kHz, `SamplesPerFrame` set to 32, and `OutputDataType` set to 'Custom'. To generate a fixed-point signal, set the `CustomOutputDataType` property to a `numericType` object. For the purpose of this example, set the value to `numericType([], 16)`. The fraction length is computed based on the values of the generated sinusoidal signal to give the best possible precision.

To generate a fixed-point signal, set the `Method` property of the `dsp.SinWave` object to 'Table lookup'. This method of generating the sinusoidal signal requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is,  $1/f_i T_s = k_i$  must be an integer value for every channel  $i = 1, 2, \dots, N$ . The value of  $T_s$  equals  $1/F_s$ , the variable  $f_i$  is the frequency of the sinusoidal signal, and  $F_s$  is the sample rate of the signal. In other words, the ratio  $F_s/f_i$  must be an integer. For more details, see the "Algorithms" on page 4-1009 section on the `dsp.SinWave` object page.

In this example,  $F_s$  is set to 22050 Hz and  $f_i$  is set to 1050 Hz.

```
Fs = 22.05e3;
sine = dsp.SinWave('Frequency', 1050, ...
    'SampleRate', Fs, ...
    'SamplesPerFrame', 32, ...
    'Method', 'Table lookup', ...
    'OutputDataType', 'Custom')

sine =
  dsp.SinWave with properties:

    Amplitude: 1
    Frequency: 1050
    PhaseOffset: 0
    ComplexOutput: false
    Method: 'Table lookup'
    TableOptimization: 'Speed'
    SamplesPerFrame: 32
    SampleRate: 22050
```

```
OutputDataType: 'Custom'
```

```
Show all properties
```

In each loop of the iteration, stream in a frame of the fixed-point sinusoidal signal sampled at 22.05 kHz. Interpolate the streamed signal by a factor of 2. The interpolated output has 64 samples per frame.

```
for i = 1:16
    x = sine();
    y = cicint(x);
end
```

The output of the CIC interpolation filter is amplified by a specific gain value. You can determine this value using the `gain` function. This gain equals the gain of the  $2N^{\text{th}}$  stage of the CIC interpolation filter and equals  $(I \times D)^N / I$ , where  $I$  is the interpolation factor,  $D$  is the differential delay, and  $N$  is the number of sections of the CIC interpolator.

```
gainCIC = gain(cicint)
```

```
gainCIC = 2
```

To adjust this amplified output and to match it to the amplitude of the original signal, divide the CIC interpolated signal with the computed gain value.

Compare the last frames of the original and the interpolated signals. While plotting, account for the output latency of 2 samples.

```
n = (0:63)';
stem(n(1:31)/Fs, double(x(1:31)), 'r', 'filled')
hold on;
I = cicint.InterpolationFactor;
stem(n(1:61)/(Fs*I), ...
     double(y(4:end))/gainCIC, 'b')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original Signal', ...
       'Interpolated Signal', ...
       'location', 'north')
hold off;
```

Using the `info` function in the 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Interpolator

```

## Input Arguments

### **sysobj** — Input filter

filter System object

One of the following types of filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.ComplexBandpassDecimator`
- `dsp.CoupledAllpassFilter`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **infoType** — Amount of information to display

'short' (default) | 'long'

Amount of filter information to be displayed. When this property is set to:

- 'short' -- The function displays the same information as `info(sysobj)`, which is the basic filter information.
- 'long' -- The function returns the following information about the filter:
  - Specifications such as the filter structure and filter order.
  - Information about the design method and options.
  - Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the `measure` method
  - .
  - Cost of implementing the filter in terms of operations required to apply the filter to data, included in the `cost` method.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

Data Types: `char` | `string`

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## **Output Arguments**

### **s — store filter information**

character array

Filter information, returned as a character array.

When the `infoType` is 'short', the function displays basic filter information. When the `infoType` is 'long', the function displays the following information:

- Specifications such as the filter structure and filter order
- Information about the design method and options
- Performance measurements for the filter response, such as the passband cutoff or stopband attenuation, included in the `measure` method
- Cost of implementing the filter in terms of operations required to apply the filter to data, included in the `cost` method

When the filter uses fixed-point arithmetic, the function returns additional information about the filter, including the arithmetic setting and details about the filter internals.

# info

**Package:** dsp

Characteristic information about valid delay range

## Syntax

```
S = info(obj)
```

## Description

`S = info(obj)` returns a structure that contains the valid delay range values of the `dsp.VariableFractionalDelay` object.

## Examples

### Obtain the Valid Delay Range

Create a `dsp.VariableFractionalDelay` object. Set the interpolation method to 'Farrow', and the maximum delay to 9. Obtain the valid delay range for these settings using the `info` method.

```
vfd = dsp.VariableFractionalDelay('InterpolationMethod','Farrow','MaximumDelay',9);
info(vfd)
```

```
ans = struct with fields:
    ValidDelayRange: '[1, 9]'
```

Specify the delay vector to have two taps - [0.95 10]. These values are out of the valid range. The object clips these values to [1 9] and concurrently applies the delay values to the input channel.

```
in = randn(10,1)
```

```
in = 10×1
    0.5377
    1.8339
   -2.2588
    0.8622
    0.3188
   -1.3077
   -0.4336
    0.3426
    3.5784
    2.7694
```

```
delayVec = [0.95 10]
```

```
delayVec = 1×2
```

```
0.9500    10.0000
```

```
vfdout = vfd(in,delayVec)
```

```
vfdout = 10x2
```

```
         0         0
    0.5377         0
    1.8339         0
   -2.2588         0
    0.8622         0
    0.3188         0
   -1.3077         0
   -0.4336         0
    0.3426         0
    3.5784    0.5377
```

The output contains two channels, each being a delayed version of the input channel. The first channel is delayed by 1 sample and the second channel is delayed by 9 samples.

## Input Arguments

### **obj** — Input System object

`dsp.VariableFractionalDelay`

Input object, specified as a `dsp.VariableFractionalDelay` System object.

Example: `vfd = dsp.VariableFractionalDelay; info(vfd);`

## Output Arguments

### **S** — Valid delay range information

structure

Valid delay range information of the input `dsp.VariableFractionalDelay` object, returned as the `ValidDelayRange` field in the output structure `S`. `ValidDelayRange` contains the possible range of delay values based on the current property values of the object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

`dsp.VariableFractionalDelay`

# info

Characteristic information about audio device writer

## Syntax

```
S = info(adw)
```

## Description

`S = info(adw)` returns a structure, `S`, containing characteristic information of the audio device writer object, `adw`.

## Examples

### Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` object with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3')

fileInfo = struct with fields:
    Filename: 'B:\matlab\toolbox\dsp\samples\speech_dft.mp3'
    CompressionMethod: 'MP3'
    NumChannels: 1
    SampleRate: 22050
    TotalSamples: 112893
    Duration: 5.1199
    Title: []
    Comment: []
    Artist: []
    BitRate: 64
```

Create an `audioDeviceWriter` object and specify the sample rate.

```
deviceWriter = audioDeviceWriter('SampleRate', fileInfo.SampleRate);
```

Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
setup(deviceWriter, zeros(fileReader.SamplesPerFrame, ...
    fileInfo.NumChannels))
```

Use the `info` function to obtain the characteristic information about the device writer.

```
info(deviceWriter)

ans = struct with fields:
    Driver: 'DirectSound'
```

```
        DeviceName: 'Primary Sound Driver'  
MaximumOutputChannels: 2
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)  
    audioData = fileReader();  
    deviceWriter(audioData);  
end
```

Close the input file and release the device.

```
release(fileReader)  
release(deviceWriter)
```

## Input Arguments

**adw** — Audio device writer object

audioDeviceWriter

Audio device writer object, specified as audioDeviceWriter System object.

## Output Arguments

**S** — Characteristic information

struct

Characteristic information of the audio device writer object, returned as a structure. The fields of the structure vary depending on the System object.

getAudioDevices

### Objects

audioDeviceWriter

# info

**Package:** dsp

Information about specific audio file

## Syntax

```
S = info(afr)
```

## Description

`S = info(afr)` returns a MATLAB structure, `S`, with information about the audio file specified in the `Filename` property.

## Examples

### Obtain Information About Audio File

Read an audio file using the `dsp.AudioFileReader` object. Obtain information related to the audio content of the file.

The `dsp.AudioFileReader` objects reads the default shipped file 'speech\_dft.mp3'.

```
afr = dsp.AudioFileReader
```

```
afr =  
dsp.AudioFileReader with properties:  
  
    Filename: 'B:\matlab\toolbox\dsp\samples\speech_dft.mp3'  
    PlayCount: 1  
    ReadRange: [1 Inf]  
    SamplesPerFrame: 1024  
    SampleRate: 22050  
    OutputDataType: 'double'
```

```
Show all properties
```

The output structure displays the sample rate of the audio signal in Hz, number of bits used to encode the audio stream, and the number of audio channels.

```
S = info(afr)
```

```
S = struct with fields:  
    SampleRate: 22050  
    NumBits: 32  
    NumChannels: 1
```

## Input Arguments

### **afr** — File reader

`dsp.AudioFileReader` (default)

File reader, specified as a `dsp.AudioFileReader` System object.

## Output Arguments

### **S** — Audio file information

structure

Information about the audio file specified in the `Filename` property, returned as a structure. The number of fields in the structure `S` varies depending on the audio content of the file. This table shows some of the fields that can appear in the structure `S`.

| Field                    | Value   |
|--------------------------|---|
| <code>SampleRate</code>  | Audio sampling rate of the audio file in Hz.    |
| <code>NumBits</code>     | Number of bits used to encode the audio stream. |
| <code>NumChannels</code> | Number of audio channels.                       |

### Functions

`isDone`

### Objects

`dsp.AudioFileReader`

# isDone

**Package:** dsp

End-of-file status (logical)

## Syntax

```
STATUS = isDone(afr)
```

## Description

`STATUS = isDone(afr)` returns a logical value, `STATUS`. The value of `STATUS` is true when the file has been read `PlayCount` number of times. The `PlayCount` property of the `dsp.AudioFileReader` System object determines the number of times the audio file plays.

## Examples

### Read and Play Back Audio File

Read and play back an audio file using the standard audio output device.

You can choose to read the entire data or specify a range of data to read from using the `ReadRange` property. By default, `ReadRange` is set to `[1 inf]`, indicating the file reader to read the entire data from the source. In this example, set `ReadRange` to `3Fs`, indicating the file reader to read the first 3 seconds of the data.

```
afr = dsp.AudioFileReader('speech_dft.mp3','ReadRange',[1 3*22050]);  
adw = audioDeviceWriter('SampleRate', afr.SampleRate);
```

```
while ~isDone(afr)  
    audio = afr();  
    adw(audio);  
end  
release(afr);  
release(adw);
```

## Input Arguments

**afr — Audio file reader**

`dsp.AudioFileReader`

Audio file reader, specified as a `dsp.AudioFileReader` System object.

## Output Arguments

**STATUS — Indicates EOF**

false | true

Logical value that indicates if the reader has reached the EOF, returned as:

- `true` -- The `STATUS` is `true` when the EOF is reached. If the `PlayCount` property is set to a value greater than 1, `STATUS` is returned as `true` only once the reader reaches the EOF `PlayCount` number of times.
- `false` -- The `STATUS` is `false` when the EOF has not reached. If `PlayCount` property is greater than 1, `STATUS` is returned as `false` until the EOF has reached `PlayCount` number of times.

Data Types: `logical`

#### **Functions**

`info`

#### **Objects**

`dsp.AudioFileReader`

# info

**Package:** dsp

Get cumulative overrun and underrun

## Syntax

```
S = info(asyncBuff)
```

## Description

`S = info(asyncBuff)` returns a structure, `S`, containing the cumulative overrun and underrun information of the `dsp.AsyncBuffer` System object, `asyncBuff`.

## Examples

### Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;  
input = randn(512,1);  
write(asyncBuff,input);  
plot(input)  
hold on
```

Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```
outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
end
plot(outTotal,'r')
hold off
```

Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
    CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

## Input Arguments

### **asyncBuff** — Async buffer

`dsp.AsyncBuffer` System object

Async buffer, specified as a `dsp.AsyncBuffer` System object.

## Output Arguments

### **S** — Cumulative overrun and underrun information

structure

Cumulative overrun and underrun information, returned as a structure. The fields for `S` are described in the table.

| <b>Field</b>                    | <b>Value</b>   |
|---------------------------------|--|
| <code>CumulativeOverrun</code>  | Number of samples overrun per channel since last call to <code>reset</code> . The number of samples overrun is the number of unread samples overwritten. |
| <code>CumulativeUnderrun</code> | Number of samples underrun per channel since last call to <code>reset</code> . Underrun occurs if you attempt to read more samples than available.       |

The `CumulativeOverrun` and `CumulativeUnderrun` properties are data type `int32`.

Read data from buffer

## Syntax

```
out = read(asyncBuff)
out = read(asyncBuff, NumRows)
out = read(asyncBuff, NumRows, Overlap)
[out, nUnderrun] = read( ___ )
```

## Description

`out = read(asyncBuff)` returns all unread samples from the buffer, `asyncBuff`.

`out = read(asyncBuff, NumRows)` returns `NumRows` samples from each channel (column) of the buffer.

`out = read(asyncBuff, NumRows, Overlap)` returns `NumRows` samples from each channel and overlaps previously read samples by `Overlap`.

`[out, nUnderrun] = read( ___ )` also returns the number of rows zero-padded if underrun occurred, using any of the previous arguments.

## Examples

### Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer System` object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer System` object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;
input = randn(512,1);
write(asyncBuff,input);
plot(input)
hold on
```

Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```
outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
end
plot(outTotal,'r')
hold off
```

Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
    CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

## Input Arguments

### **asyncBuff** — Async buffer

`dsp.AsyncBuffer` System object

Async buffer, specified as a `dsp.AsyncBuffer` System object.

### **NumRows** — Number of samples read from each channel

positive integer

Number of samples read from each channel (column) of the buffer, specified as a positive integer. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

**Overlap — Number of samples overlapped**

integer

The function returns `NumRows` samples from each channel and overlaps previously read samples by `Overlap`. The total number of samples read is  $\text{NumRows} \times \text{NumChann}$ , where *NumChann* is the number of channels in the buffer. The total number of new samples read is  $(\text{NumRows} - \text{Overlap}) \times \text{NumChann}$ . If the overlap portion contains samples that are overwritten, and are therefore not contiguously written, the output is zero-padded.

**Output Arguments****out — Data read from buffer**

vector | matrix

Data read from the buffer, returned as an array of  $\text{NumRows} \times \text{NumChann}$  samples. If `Overlap` is specified, the function returns  $(\text{NumRows} - \text{Overlap}) \times \text{NumChann}$  samples. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

Data Types: double

**nUnderrun — Number of samples zero-padded in each channel**

vector | matrix

Number of samples zero-padded in each channel (column) if underrun occurred. Underrun occurs if you attempt to read more samples than available. Samples that are zero-padded in overlapped portions are not counted as underrun.

Data Types: int32

**Version History**

Introduced in R2017a

**See Also****Functions**

info | write | peek

**Objects**

dsp.AsyncBuffer

# write

**Package:** dsp

Write data to buffer

## Syntax

```
nOverrun = write(asyncBuff,x)
```

## Description

`nOverrun = write(asyncBuff,x)` writes the input array, `x`, to the buffering object, `asyncBuff`, and returns the number of samples overrun, `nOverrun`.

## Examples

### Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT System` objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLenghSource', 'Property', 'FFTLengh', 256);
```

The sine wave is generated using the `sin` function in MATLAB. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;
for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fftObj(x));
        plotter(log(X));
    end
end
```

## Input Arguments

### **asyncBuff** — Async buffer

`dsp.AsyncBuffer` System object

Async buffer, specified as a `dsp.AsyncBuffer` System object.

### **x** — Data input

vector | matrix

Data written to the buffer, specified as a vector or a matrix. The maximum number of rows in the buffer is determined by the `Capacity` property of `asyncBuff`. The number of channels in the buffer is determined by the second dimension of the first data written to the buffer. Successive data inputs can vary in the number of rows, but the number of channels must remain fixed. To change the number of channels, you must call `release` on the buffer.

For example, the following is accepted:

```
asyncBuff = dsp.AsyncBuffer;
% First call to write
write(asyncBuff, randn(15,5));
% Add more data with a different number of rows
write(asyncBuff, randn(25,5));
write(asyncBuff, randn(5,5));
```

The following is not accepted and errors out:

```
asyncBuff = dsp.AsyncBuffer;  
% First call to write  
write(asyncBuff,randn(15,5));  
% Add more data with a different number of columns  
write(asyncBuff,randn(15,15));
```

To change the number of channels, call `release` on the buffer.

```
asyncBuff = dsp.AsyncBuffer;  
% First call to write  
write(asyncBuff,randn(15,5));  
release(asyncBuff)  
% Add more data with a different number of columns  
write(asyncBuff,randn(15,15));
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

## Output Arguments

### **nOverrun** — Number of samples overrun

scalar

Number of samples overrun in the current call to `write`. The number of samples overrun is the number of unread samples overwritten. If `x` is a multichannel input, then `nOverrun` is the number of rows of data overrun.

Data Types: `int32`

## Version History

Introduced in R2017a

### Functions

`info` | `read` | `peek`

### Objects

`dsp.AsyncBuffer`

## peek

**Package:** dsp

Read data from buffer without changing number of unread samples

### Syntax

```
out = peek(asyncBuff)
out = peek(asyncBuff,numRows)
out = peek(asyncBuff,numRows,overlap)
[out,nUnderrun] = peek( ___ )
```

### Description

`out = peek(asyncBuff)` returns all unread samples from the buffer, `asyncBuff`, without changing the number of unread samples in the buffer.

`out = peek(asyncBuff,numRows)` returns `numRows` samples from each channel (column) of the buffer.

`out = peek(asyncBuff,numRows,overlap)` returns `numRows` samples from each channel and overlaps previously read samples by `overlap`.

`[out,nUnderrun] = peek( ___ )` also returns the number of zero-padded rows if underrun occurred, using any of the previous arguments.

### Examples

#### Peek Data from Async Buffer

Read data from the async buffer without changing the number of unread samples using the `peek` function.

Create a `dsp.AsyncBuffer` System object™. The input is a column vector of 100 samples, 1 to 100. Write the data to the buffer.

```
asyncBuff = dsp.AsyncBuffer
asyncBuff =
  AsyncBuffer with properties:
      Capacity: 192000
  NumUnreadSamples: 0
```

```
input = (1:100)';
write(asyncBuff,input);
```

Peek at the first three samples. The output is `[1 2 3]'`.

```
out1 = peek(asyncBuff,3)
```

```
out1 = 3×1
```

```
 1
 2
 3
```

The `NumUnreadSamples` is 100, indicating that the `peek` function has not changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
     100
```

After peeking, read 50 samples using the `read` function. The output is `[1:50]'`.

```
out2 = read(asyncBuff,50)
```

```
out2 = 50×1
```

```
 1
 2
 3
 4
 5
 6
 7
 8
 9
10
 ⋮
```

The `NumUnreadSamples` is 50, indicating that the `read` function has changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
     50
```

Now peek again at the first three samples. The output is `[51 52 53]'`. Verify that the `NumUnreadSamples` is still 50.

```
out3 = peek(asyncBuff,3)
```

```
out3 = 3×1
```

```
51
52
53
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
     50
```

Read 50 samples again. The output now contains the sequence [51:100]'. Verify that `NumUnreadSamples` is 0.

```
out4 = read(asyncBuff)
```

```
out4 = 50×1
```

```
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
⋮
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32  
0
```

## Input Arguments

### **asyncBuff** — Async buffer

`dsp.AsyncBuffer` System object

Async buffer, specified as a `dsp.AsyncBuffer` System object.

### **numRows** — Number of samples peeked from each channel

positive integer

Number of samples peeked from each channel (column) of the buffer, specified as a positive integer. This operation does not change the number of unread samples in the buffer. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

### **overlap** — Number of samples overlapped

integer

Number of samples overlapped, specified as an integer. The function returns `numRows` samples from each channel and overlaps previously read samples by `overlap`. The total number of samples peeked is  $\text{numRows} \times \text{NumChann}$ , where `NumChann` is the number of channels in the buffer. The total number of new samples peeked is  $(\text{numRows} - \text{overlap}) \times \text{NumChann}$ . If the overlap portion contains samples that are overwritten, and are therefore not contiguously written, the output is zero-padded.

## Output Arguments

### **out** — Data peeked from buffer

vector | matrix

Data peeked from the buffer, returned as an array of  $\text{numRows} \times \text{NumChann}$  samples. If `overlap` is specified, the function returns  $(\text{numRows} - \text{overlap}) \times \text{NumChann}$  samples. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

Data Types: `double`

#### **nUnderrun — Number of zero-padded samples in each channel**

`vector` | `matrix`

Number of zero-padded samples in each channel (column) if underrun occurred. Underrun occurs if you attempt to peek more samples than available. Samples that are zero-padded in overlapped portions are not counted as underrun.

Data Types: `int32`

## **Version History**

`dsp.AsyncBuffer`

## readHeader

**Package:** dsp

Read file header

### Syntax

```
header = readHeader(reader)
```

### Description

`header = readHeader(reader)` returns the header structure, `header`, from the file specified by the binary file reader, `reader`.

### Examples

#### Read Header Data

Read the header data from a binary file using the `readHeader` function.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```
fid = fopen('myfile.dat','w');  
fwrite(fid,[1 2 3 4],'double');  
fwrite(fid,single((1:5).'),'single');  
fwrite(fid,(1:1000).'),'double');  
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');  
s = struct('A',zeros(1,4),'B',ones(5,1,'single'));  
reader.HeaderStructure = s;
```

Read the header using the `readHeader` function.

```
H = readHeader(reader);  
fprintf('H.A: ')
```

H.A:

```
fprintf('%d ',H.A);
```

1 2 3 4

```
fprintf('\nH.A datatype: %s\n',class(H.A))
```

H.A datatype: double

```
fprintf('H.B: ')
H.B:
fprintf('%d ',H.B);
1 2 3 4 5
fprintf('\nH.B datatype: %s\n',class(H.B))
H.B datatype: single
```

## Input Arguments

### **reader** — Binary file reader

`dsp.BinaryFileReader` System object

Binary file reader object, specified as a `dsp.BinaryFileReader` System object.

## Output Arguments

### **header** — Header structure

structure

Header structure of the binary file, returned as a structure. Each field of the structure is a real matrix of a built-in type. For example, if you specify the `HeaderStructure` property of the `dsp.BinaryFileReader` object to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, (1:10), followed by one single precision value, `single(1)`. If you do not specify a header, the object returns an empty structure, `struct([])`.

Data Types: `struct`

## getFrequencyVector

**Package:** dsp

Vector of frequencies at which estimation is done

### Syntax

```
freq = getFrequencyVector(estimator)
freq = getFrequencyVector(estimator,Fs)
```

### Description

`freq = getFrequencyVector(estimator)` returns the vector of frequencies at which the estimation is done.

`freq = getFrequencyVector(estimator,Fs)` returns the frequency vector assuming an input sample rate, `Fs`.

### Examples

#### Power Spectrum of Multichannel Sinusoidal Signal

Compute the power spectrum of a multichannel sinusoidal signal using the `dsp.SpectrumEstimator` System object™. You can get the vector of frequencies at which the spectrum is estimated using the `getFrequencyVector` function. To compute the resolution bandwidth of the estimate (RBW), use the `getRBW` function.

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by  $\pi/2$  and  $\pi/4$ , respectively.

```
sineSignal = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the `dsp.SpectrumEstimator` object for the computation and the `dsp.ArrayPlot` for the plotting.

```
estimator = dsp.SpectrumEstimator('FrequencyRange','onesided');
plotter = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = sineSignal();
pxx = estimator(y);
plotter(pxx)
```

Get the vector of frequencies at which the spectrum is estimated in Hz, using the `getFrequencyVector` function.

```
f = getFrequencyVector(estimator);
```

Compute the resolution bandwidth (RBW) of the estimate using the `getRBW` function.

```
rbw = getRBW(estimator)
```

```
rbw =
```

```
0.0015
```

The resolution bandwidth of the signal power spectrum is 0.0015 Hz. This frequency is the smallest frequency that can be resolved on the spectrum.

## Input Arguments

**estimator** — Estimator object

`dsp.SpectrumEstimator` | `dsp.CrossSpectrumEstimator` | `dsp.TransferFunctionEstimator`

Estimator object, specified as one of the following:

- `dsp.SpectrumEstimator` -- Estimates the power spectrum of the input signal.
- `dsp.CrossSpectrumEstimator` -- Estimates the cross-power spectrum of the input signal.
- `dsp.TransferFunctionEstimator` -- Estimates the transfer function of the system.

**Fs — Input sample rate**

positive scalar

Input sample rate, specified as a real positive scalar.

**Output Arguments****freq — Spectrum frequencies**

vector

Spectrum frequencies, returned as a column vector.

The length of the frequency vector is determined by the `FrequencyRange` and the FFT length.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length  $NFFT/2+1$ , and covers the interval  $[0, SampleRate/2]$ .

If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length  $(NFFT+1)/2$  and covers the interval  $[0, SampleRate/2]$ .

If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval  $[0, SampleRate]$ .

If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range  $[-SampleRate/2, SampleRate/2]$  and  $[-SampleRate/2, SampleRate/2]$  for even and odd length `NFFT`, respectively.

Data Types: `single` | `double`

“Fractional Delay Filters Using Farrow Structures”

# getFrequencyVector

**Package:** dsp

Get the vector of frequencies at which the short-time FFT is computed

## Syntax

```
freq = getFrequencyVector(stf)
freq = getFrequencyVector(stf,Fs)
```

## Description

`freq = getFrequencyVector(stf)` returns the frequency vector at which the short-time FFT is computed. The input sample rate used is  $2\pi$ .

`freq = getFrequencyVector(stf,Fs)` returns the frequency vector assuming an input sample rate,  $F_s$ .

## Examples

### Get Short-time FFT Frequencies

Get the frequency vector at which the short-time FFT is computed.

Create a `dsp.STFT` object. The STFT object is defined with a 'twosided' frequency range. The frequency vector is defined by the interval  $[0 F_s]$  and has the same length as the FFT length, where  $F_s$  is the input sample rate.

```
stf = dsp.STFT
stf =
  STFT with properties:
      Window: [512x1 double]
  OverlapLength: 256
      FFTLength: 512
  FrequencyRange: 'twosided'
```

When the input sample rate  $F_s$  is not defined, the frequencies are computed in the interval  $[0, 2\pi]$ .

Using the `getFrequencyVector` function, get the vector of frequencies at which the STFT is computed.

```
freq = getFrequencyVector(stf)
freq = 512x1
      0
  0.0123
  0.0245
```

```
0.0368
0.0491
0.0614
0.0736
0.0859
0.0982
0.1104
⋮
```

When the input sample rate  $F_s$  is defined, the frequency vector is defined by the interval  $[0 F_s]$ .

```
Fs = 44100;
freqFs = getFrequencyVector(stf,Fs)
```

```
freqFs = 512×1
104 ×
```

```
0
0.0086
0.0172
0.0258
0.0345
0.0431
0.0517
0.0603
0.0689
0.0775
⋮
```

## Input Arguments

### **stf** — STFT object

`dsp.STFT`

Short-time FFT object whose frequency vector is computed, specified as `dsp.STFT` object.

### **Fs** — Input sample rate

positive scalar

Input sample rate, specified as a real positive scalar. The STFT frequencies are computed in the interval determined by  $F_s$ . For more details, see `freq`.

Data Types: `single` | `double`

## Output Arguments

### **freq** — Frequencies

vector

Frequencies at which the short-time FFT is computed, returned as a column vector.

The length of the frequency vector is determined by the `FrequencyRange` property and the `FFTLlength`.

If you set `FrequencyRange` to `'onesided'` and `FFTlength` is even, the frequency vector is of length  $(\text{FFTlength}/2)+1$ . If you set the `FrequencyRange` to `'onesided'` and `FFTlength` is odd, the frequency vector is of length  $(\text{FFTlength}+1)/2$ .

The frequencies cover the interval  $[0, F_s/2]$ . When  $F_s$  is not specified, the frequencies range from  $[0, \pi]$ .

If you set the `FrequencyRange` property to `'twosided'`, the length of the frequency vector is equal to the value you specify in the `FFTlength` property. The frequencies cover the interval  $[0, F_s]$ . When  $F_s$  is not specified, the frequencies range from  $[0, 2\pi]$ .

Data Types: `single` | `double`

## getRBW

**Package:** dsp

Resolution bandwidth of spectrum

### Syntax

```
RBW = getRBW(estimator)
RBW = getRBW(estimator,Fs)
```

### Description

`RBW = getRBW(estimator)` returns the resolution bandwidth of the spectral estimate.

`RBW = getRBW(estimator,Fs)` returns the resolution bandwidth assuming an input sample rate of `Fs`.

### Examples

#### Power Spectrum of Multichannel Sinusoidal Signal

Compute the power spectrum of a multichannel sinusoidal signal using the `dsp.SpectrumEstimator` System object™. You can get the vector of frequencies at which the spectrum is estimated using the `getFrequencyVector` function. To compute the resolution bandwidth of the estimate (RBW), use the `getRBW` function.

Generate a three-channel sinusoid sampled at 1 kHz. Specify sinusoidal frequencies of 100, 200, and 300 Hz. The second and third channels have their phases offset from the first by  $\pi/2$  and  $\pi/4$ , respectively.

```
sineSignal = dsp.SineWave('SamplesPerFrame',1000,'SampleRate',1000, ...
    'Frequency',[100 200 300],'PhaseOffset',[0 pi/2 pi/4]);
```

Estimate and plot the one-sided spectrum of the signal. Use the `dsp.SpectrumEstimator` object for the computation and the `dsp.ArrayPlot` for the plotting.

```
estimator = dsp.SpectrumEstimator('FrequencyRange','onesided');
plotter = dsp.ArrayPlot('PlotType','Line','YLimits',[0 0.75], ...
    'YLabel','Power Spectrum (watts)','XLabel','Frequency (Hz)');
```

Step through to obtain the data streams and display the spectra of the three channels.

```
y = sineSignal();
pxx = estimator(y);
plotter(pxx)
```

Get the vector of frequencies at which the spectrum is estimated in Hz, using the `getFrequencyVector` function.

```
f = getFrequencyVector(estimator);
```

Compute the resolution bandwidth (RBW) of the estimate using the `getRBW` function.

```
rbw = getRBW(estimator)
```

```
rbw =
```

```
0.0015
```

The resolution bandwidth of the signal power spectrum is 0.0015 Hz. This frequency is the smallest frequency that can be resolved on the spectrum.

## Input Arguments

**estimator** — Estimator object

`dsp.SpectrumEstimator` | `dsp.CrossSpectrumEstimator` |  
`dsp.TransferFunctionEstimator`

Estimator object, specified as one of the following:

- `dsp.SpectrumEstimator` -- Estimates the power spectrum of the input signal.
- `dsp.CrossSpectrumEstimator` -- Estimates the cross-power spectrum of the input signal.
- `dsp.TransferFunctionEstimator` -- Estimates the transfer function of the system.

**Fs — Input sample rate**

positive scalar

Input sample rate, specified as a real positive scalar.

**Output Arguments****RBW — Resolution bandwidth**

scalar

Resolution bandwidth of the estimate, returned as a scalar.

The resolution bandwidth, RBW, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to  $NENBW * SampleRate / L$ , where  $L$  is the input length, and  $NENBW$  is the normalized effective noise bandwidth of the window.

The data type of RBW matches the data type of the input.

Data Types: `single` | `double`**Version History**

“Generate a Multithreaded MEX File from a MATLAB Function Using Unfolding”

# int

States from CIC filter

## Compatibility

`mfilt` will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

## Syntax

```
integerstates = int(hm.states)
```

## Description

`integerstates = int(hm.states)` returns the states of a CIC filter in matrix form, rather than as the native `filtstates` object. An important point about `int` is that it quantizes the state values to the smallest number of bits possible while maintaining the values accurately.

## Examples

For many users, the states of multirate filters are most useful as a matrix, but the CIC filters store the states as objects. Here is how you get the states from you CIC filter as a matrix.

```
hm = mfilt.cicinterp;  
hs = hm.states; % Returns a FILTSTATES.CIC object hs.  
states = int(hs); % Convert object hs to a signed integer matrix.
```

After using `int` to convert the states object to a matrix, here is what you get.

Before converting:

```
hm.states  
ans =  
    Integrator: [2x1 States]  
    Comb: [2x1 States]
```

After the conversion and assigning the states to `states`:

```
states  
states =  
     0     0  
     0     0
```

## Version History

Introduced in R2011a

# isallpass

**Package:** dsp

Verify that discrete-time filter System object is allpass

## Syntax

```
flag = isallpass(sysobj)
flag = isallpass(sysobj,tol)
flag = isallpass( ____, 'Arithmetic', arithType)
```

## Description

`flag = isallpass(sysobj)` returns `true` if the filter System object is allpass.

`flag = isallpass(sysobj,tol)` uses the tolerance `tol` to determine when two numbers are close enough to be considered equal.

`flag = isallpass( ____, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

For more input options, see `isallpass` in Signal Processing Toolbox.

## Examples

### Verify if Filter is Allpass

Create an allpass filter using the `dsp.AllpassFilter` object.

```
apass = dsp.AllpassFilter
```

```
apass =
```

```
  dsp.AllpassFilter with properties:
```

```
          Structure: 'Minimum multiplier'
    AllpassCoefficients: [-0.7071 0.5000]
    TrailingFirstOrderSection: false
```

Verify that the filter is an allpass filter by visualizing the magnitude response in `fvtool`.

```
fvtool(apass)
```

Now verify that the filter is an allpass filter using the `isallpass` function.

```
isallpass(apass)
```

```
ans = logical  
     1
```

## Input Arguments

### **sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`

- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.FrequencyDomainFIRFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

#### **tol — Tolerance value**

`eps^(2/3)` (default) | positive scalar

Tolerance value to determine when two numbers are close enough to be considered equal, specified as a positive scalar. If not specified, `tol`, defaults to `eps^(2/3)`. Specifying a tolerance may be most helpful in fixed-point allpass filters.

#### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **`flag` — Flag to determine if filter is allpass**

`true` or `1` | `false` or `0`

Flag to determine if the filter is allpass, returned as a logical:

- `1` -- Filter is allpass.
- `0` -- Filter is not allpass.

Data Types: `logical`

## Version History

**Introduced in R2013a**

### **See Also**

`isallpass`

# isfir

**Package:** dsp

Verify if filter System object is FIR

## Syntax

```
flag = isfir(sysobj)
```

## Description

`flag = isfir(sysobj)` determines whether the filter System object is an FIR filter. If the filter is an FIR filter, `isfir` returns 1.

To determine whether `sysobj` is an FIR filter, the `isfir` function inspects if the filter in the transfer function form has a scalar denominator. If it does, it is an FIR filter.

## Examples

### Determine if Filter is FIR

Design a Lowpass FIR Filter.

```
d = fdesign.lowpass;
h = design(d,'Systemobject',true)
```

```
h =
dsp.FIRFilter with properties:
```

```
    Structure: 'Direct form'
  NumeratorSource: 'Property'
    Numerator: [-0.0024 -0.0021 0.0068 0.0167 0.0111 -0.0062 -0.0084 0.0093 0.0130 -0.0130]
  InitialConditions: 0
```

Show all properties

Determine if the filter is an FIR filter using the `isfir` function.

```
isfir(h)
```

```
ans = logical
     1
```

`isfir` returns 1 to indicate that the filter is an FIR filter.

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

### **flag** — Flag to determine whether filter is FIR

1 | 0

Flag to determine whether the filter is FIR, returned as a logical scalar. If the filter is FIR, `isfir` returns a logical 1, else it returns a logical 0.

Data Types: `logical`

## **Version History**

**Introduced in R2011a**

## **See Also**

### **Functions**

`isallpass` | `islinphase` | `ismaxphase` | `isminphase` | `isreal` | `issos` | `isstable`

## isDone

**Package:** dsp

End-of-file status for signal reader object

### Syntax

```
isDone(src)
```

### Description

`isDone(src)` returns a logical value indicating whether or not the `SignalSource` object, `src`, has reached the end of the imported signal. If the `SignalEndAction` property of `src` is set to `Cyclic` repetition, this method returns `true` every time the reader reaches the end.

### Examples

#### Create Signal Source

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;  
src1.Signal = randn(1024,1);  
y1 = zeros(1024,1);  
idx = 1;  
while(~isDone(src1))  
    y1(idx) = src1();  
    idx = idx + 1;  
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024,1),128);  
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

### Input Arguments

#### **src** — Signal reader object

`dsp.SignalReader` System object

Signal reader object, specified as a `dsp.SignalSource` System object.

### Version History

**Introduced in R2012b**

### Objects

`dsp.SignalSource`

# islinphase

**Package:** dsp

Verify that discrete-time filter System object is linear phase

## Syntax

```
flag = islinphase(sysobj)
flag = islinphase(sysobj,tol)
flag = islinphase( ____, 'Arithmetic', arithType)
```

## Description

`flag = islinphase(sysobj)` returns `true` if the filter System object has linear phase.

`flag = islinphase(sysobj,tol)` uses the tolerance `tol` to determine when two numbers are close enough to be considered equal. If not specified, `tol` defaults to  $\text{eps}^{(2/3)}$ .

`flag = islinphase( ____, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input using either of the previous syntaxes.

For more input options, see `islinphase` in Signal Processing Toolbox.

## Examples

### Linear and Nonlinear Phase Filters

Use the window method to design a 10th order lowpass FIR filter with the normalized cutoff frequency of 0.55. Verify that the filter has linear phase.

```
firSpecs = fdesign.lowpass('N,Fc',10,0.55);
lpFIR = design(firSpecs,'window','SystemObject',true);

flag = islinphase(lpFIR)

flag = logical
     1
```

Plot the phase response of the filter and verify that it is linear.

```
[phs,w] = phasez(lpFIR);
plot(w/pi,phs)
xlabel('Frequency \omega/\pi')
ylabel('Phase')
```

IIR filters in general do not have linear phase. Verify this by constructing Butterworth, Chebyshev, and elliptic filters with similar specifications. Set the passband frequency to 0.35, stopband frequency to 0.4, passband ripple to 1 dB, and stopband attenuation to 20 dB.

```
Wp = 0.35;
Wst = 0.4;
atten = 20;
rippl = 1;
```

```
buttSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
buttIIR = design(buttSpecs,'butter','SystemObject',true);
```

```
chb1Specs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
chb1IIR = design(chb1Specs,'cheby1','SystemObject',true);
```

```
chb2Specs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
chb2IIR = design(chb2Specs,'cheby2','SystemObject',true);
```

```
ellpSpecs = fdesign.lowpass('Fp,Fst,Ap,Ast',Wp,Wst,rippl,atten);
ellpIIR = design(ellpSpecs,'ellip','SystemObject',true);
```

Plot the phase responses of the filters. Determine whether they have linear phase.

```
fv = fvtool(buttIIR,chb1IIR,chb2IIR,ellpIIR,'Analysis','phase');
legend(fv,'Butterworth','Chebyshev I','Chebyshev II','Elliptic')
```

```
phs = [islinphase(buttIIR) islinphase(chb1IIR) ...
       islinphase(chb2IIR) islinphase(ellpIIR)]
```

*phs = 1x4 logical array*

```
0 0 0 0
```

## Input Arguments

### **sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`

- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

#### **tol — Tolerance value**

`eps^(2/3)` (default) | positive scalar

Tolerance value to determine when two numbers are close enough to be considered equal, specified as a positive scalar. If not specified, `tol`, defaults to `eps^(2/3)`.

#### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is

signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **flag** — Flag to determine if filter has linear phase

`true` or `1` | `false` or `0`

Flag to determine if the filter has linear phase, returned as a logical:

- `1` -- Filter has linear phase.
- `0` -- Filter has nonlinear phase.

Data Types: `logical`

## Version History

**Introduced in R2013a**

### **See Also**

`islinphase`

# ismaxphase

**Package:** dsp

Verify that discrete-time filter System object is maximum phase

## Syntax

```
flag = ismaxphase(sysobj)
flag = ismaxphase(sysobj,tol)
flag = ismaxphase( ____, 'Arithmetic', arithType)
```

## Description

`flag = ismaxphase(sysobj)` returns `true` if the filter System object has maximum phase.

`flag = ismaxphase(sysobj,tol)` uses the tolerance `tol` to determine when two numbers are close enough to be considered equal. If not specified, `tol` defaults to  $\text{eps}^{(2/3)}$ .

`flag = ismaxphase( ____, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input using either of the previous syntaxes.

For more input options, see `ismaxphase` in Signal Processing Toolbox.

## Examples

### Determine if Filter has Maximum Phase

Design an allpass filter and determine if the filter has maximum phase.

Using the `dsp.AllpassFilter` System object™, design an allpass filter that uses the minimum multiplier structure.

```
a = dsp.AllpassFilter
a =
    dsp.AllpassFilter with properties:
        Structure: 'Minimum multiplier'
        AllpassCoefficients: [-0.7071 0.5000]
        TrailingFirstOrderSection: false
```

Using the `ismaxphase` function, determine if the filter has maximum phase.

```
ismaxphase(a)
ans = logical
     1
```

Verify the location of poles and zeros of the filter transfer function on the z-plane. By definition, the zeros of the maximum phase filter must be outside the unit circle.

`zplane(a)`

## Input Arguments

### **sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`

- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

#### **tol — Tolerance**

`eps^(2/3)` (default) | positive scalar

Tolerance value to determine when two numbers are close enough to be considered equal, specified as a positive scalar. If not specified, `tol` defaults to `eps^(2/3)`.

#### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **flag** — Flag to determine if filter has maximum phase

true or 1 | false or 0

Flag to determine if the filter has maximum phase, returned as a logical:

- 1 -- Filter has maximum phase.
- 0 -- Filter has non maximum phase.

Data Types: logical

## More About

### Maximum Phase Filters

A causal and stable discrete-time system is said to be *strictly maximum-phase* when all its zeros are outside the unit circle. A causal and stable LTI system is a *maximum-phase* system if its inverse is causal and unstable.

Such a system is called a *maximum-phase system* because it has the maximum group delay (`grpdelay`) of the set of systems that have the same magnitude response.

## Version History

Introduced in R2013a

### See Also

`ismaxphase` | `isminphase`

# isminphase

**Package:** dsp

Verify that discrete-time filter System object is minimum phase

## Syntax

```
flag = isminphase(sysobj)
flag = isminphase(sysobj,tol)
flag = isminphase( ____, 'Arithmetic', arithType)
```

## Description

`flag = isminphase(sysobj)` returns `true` if the filter System object has minimum phase.

`flag = isminphase(sysobj,tol)` uses the tolerance `tol` to determine when two numbers are close enough to be considered equal. If not specified, `tol` defaults to  $\text{eps}^{(2/3)}$ .

`flag = isminphase( ____, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input using either of the previous syntaxes.

For more input options, see `isminphase` in Signal Processing Toolbox.

## Examples

### Determine if Filter Has Minimum Phase and is Stable

Design a Chebyshev Type I IIR filter and determine if the filter has minimum phase and is stable.

Using the `fdesign.lowpass` and `design` functions, design a Chebyshev Type I IIR filter with a passband ripple of 0.5 dB and a 3 dB cutoff frequency at 9600 Hz.

```
Fs = 48000; % Sampling frequency of input signal
d = fdesign.lowpass('N,F3dB,Ap', 10, 9600, .5, Fs);
filt = design(d, 'cheby1', 'Systemobject', true)

filt =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II'
        CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
        HasScaleValues: true
        ScaleValues: [0.3318 0.2750 0.1876 0.0904 0.0225 0.9441]
```

Show all properties

Using the `isminphase` function, determine if the filter has minimum phase.

```
isminphase(filt)
```

```
ans = logical
      1
```

Verify the location of poles and zeros of the filter transfer function on the z-plane. By definition, the poles and zeros of the minimum phase filter must be on or inside the unit circle.

```
zplane(filt)
```

All minimum phase filters are stable. To verify if the designed filter is stable, use the `isstable` function.

```
isstable(filt)
```

```
ans = logical
      1
```

## Input Arguments

**sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`

- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**tol — Tolerance value**

`eps^(2/3)` (default) | positive scalar

Tolerance value to determine when two numbers are close enough to be considered equal, specified as a positive scalar. If not specified, `tol` defaults to `eps^(2/3)`.

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **flag** — Flag to determine if filter has minimum phase

true or 1 | false or 0

Flag to determine if the filter has minimum phase, returned as a logical:

- 1 -- Filter has minimum phase.
- 0 -- Filter has non minimum phase.

Data Types: logical

## More About

### Minimum Phase Filters

A causal and stable discrete-time system is said to be *strictly minimum-phase* when all its zeros are inside the unit circle. A causal and stable LTI system is a *minimum-phase* system if its inverse is causal and stable as well.

Such a system is called a *minimum-phase system* because it has the minimum group delay (`grpdelay`) of the set of systems that have the same magnitude response.

## Version History

Introduced in R2013a

### See Also

`isminphase` | `ismaxphase`

# isNewDataReady

Check spectrum analyzer for new data

## Syntax

```
flag = isNewDataReady(scope)
```

## Description

`flag = isNewDataReady(scope)` indicates whether the spectrum analyzer `scope` displays new spectral estimates. When logging spectrum analyzer data from the `spectrumAnalyzer` scope, use this function to ignore duplicate spectra from the `getSpectrumData` function.

## Examples

### Log Spectrum Data

Generate a discrete sine wave. Then display the sine wave signal using the Spectrum Analyzer. While the Spectrum Analyzer is running, save the spectrum data to a table. The Spectrum Analyzer does not update at every time step. To avoid saving that redundant spectrum data, use the `isNewDataReady` function.

```
wave = dsp.SineWave(Frequency=100,SampleRate=1000);  
wave.SamplesPerFrame = 1000;  
scope = spectrumAnalyzer(SampleRate=wave.SampleRate,...  
    ViewType="spectrum-and-spectrogram");  
data = [];  
  
for ii = 1:250  
    x = wave() + 0.05*randn(1000,1);  
    scope(x);  
    if scope.isNewDataReady  
        data = [data;getSpectrumData(scope)];  
    end  
end  
  
release(scope);
```

Show the first five rows in the table. You can see gaps in the simulation time in the data table. The missing rows indicate times where the Spectrum Analyzer was waiting for additional samples to update the spectrum. The `isNewDataReady` function prevented the script from saving that redundant data.

```
data(1:5, :)
```

ans =

5x4 table

| SimulationTime | Spectrum        | Spectrogram       | FrequencyVector |
|----------------|-----------------|-------------------|-----------------|
| {[1.9990]}     | {1024x1 double} | {100x1024 double} | {1024x1 double} |
| {[2.9990]}     | {1024x1 double} | {100x1024 double} | {1024x1 double} |
| {[3.9990]}     | {1024x1 double} | {100x1024 double} | {1024x1 double} |
| {[4.9990]}     | {1024x1 double} | {100x1024 double} | {1024x1 double} |
| {[5.9990]}     | {1024x1 double} | {100x1024 double} | {1024x1 double} |

## Input Arguments

**scope** — Spectrum analyzer  
object name

Spectrum analyzer from which you want to save data, specified as a `spectrumAnalyzer` object.

## Output Arguments

### flag — Flag indicating new data

true | false

Flag indicating new data, returned as one of these:

- true -- The Spectrum Analyzer shows new data.
- false -- The Spectrum Analyzer shows the same spectrum and no new data is available.

## Version History

### Introduced in R2017b

### R2022a: Support for `dsp.SpectrumAnalyzer` object will be removed

*Not recommended starting in R2022a*

The `isNewDataReady` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

### Update Code

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `isNewDataReady` function typically uses the `dsp.SpectrumAnalyzer` System object and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre> wave = dsp.SineWave('Frequency',100,'SampleRate',1000); wave.SamplesPerFrame = 1000; scope = dsp.SpectrumAnalyzer('SampleRate',wave.SampleRate,     'ReducePlotRate',false,...     'ViewType','Spectrum and spectrogram'); data = [];  for ii = 1:250     x = wave() + 0.05*randn(1000,1);     scope(x);     if scope.isNewDataReady         data = [data;getSpectrumData(scope)];     end end  release(scope); </pre> | <pre> wave = spectrumAnalyzer(SineWave(Frequency=100,SampleRate=1000); wave.SamplesPerFrame = 1000; scope = spectrumAnalyzer(SampleRate=wave.SampleRate,     ViewType="spectrum-and-spectrogram"); data = [];  for ii = 1:250     x = wave() + 0.05*randn(1000,1);     scope(x);     if scope.isNewDataReady         data = [data;getSpectrumData(scope)];     end end  release(scope); </pre> |

`spectrumAnalyzer` | `getSpectrumData` | `getMeasurementsData`

## isreal

**Package:** dsp

Verify that discrete-time filter System object is real

### Syntax

```
flag = isreal(sysobj)
```

### Description

`flag = isreal(sysobj)` determines if the filter coefficients are real. If the filter coefficients are real, `isreal` returns a logical 1. If the filter coefficients are complex, `isreal` returns a logical 0. Complex filters have one or more coefficients with nonzero imaginary parts.

### Examples

#### Check if Filter Coefficients Are Real

Create a `dsp.SOSFilter` System object™. Pass a fixed-point input to the object. Test the coefficients of the fixed-point filter to see if they are strictly real.

```
d = fdesign.lowpass('n,fp,ap,ast',5,0.4,0.5,20);  
sosFilter = design(d,'ellip',SystemObject=true)
```

```
sosFilter =  
  dsp.SOSFilter with properties:  
  
      Structure: 'Direct form II'  
CoefficientSource: 'Property'  
      Numerator: [3x3 double]  
      Denominator: [3x3 double]  
HasScaleValues: true  
ScaleValues: [0.6252 0.5432 0.4861 1]
```

Show all properties

```
IsRealBefore = isreal(sosFilter)
```

```
IsRealBefore = logical  
             1
```

Pass a fixed-point input to the object.

```
fiInput = fi(randn(1000,2),1,32,16);  
fiOutput = sosFilter(fiInput);  
IsRealAfter = isreal(sosFilter)
```

```
IsRealAfter = logical  
1
```

The `isreal` function returns a value of 1, indicating that the filter coefficients are real.

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

**flag** — Flag to determine whether filter coefficients are real

1 | 0

Flag to determine whether the filter coefficients are real, returned as a logical scalar. If the filter coefficients are real, `isreal` returns a logical 1, else it returns a logical 0.

Data Types: `logical`

## Version History

Introduced in R2011a

# issos

**Package:** dsp

Verify if discrete-time System object filter is in second-order sections form

## Syntax

```
flag = issos(sysobj)
```

## Description

`flag = issos(sysobj)` determines whether the filter System object is in second-order sections (SOS) form, returning a logical 1 if true and a logical 0 if false.

## Examples

### Design Lowpass SOS Filter

By default, `fdesign` and `design` functions return SOS filters when possible. This example designs a lowpass SOS filter that uses fixed-point arithmetic.

```
d = fdesign.lowpass('n,fp,ap,ast',40,0.55,0.1,60);
hd = design(d,'ellip','SystemObject',true);
```

Using the `issos` function, verify whether the designed filter is in SOS form.

```
IsSOS = issos(hd)
```

```
IsSOS = logical
       1
```

The filter is in second-order section form.

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`

- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

**flag** — Flag to determine if filter is in SOS form

1 | 0

Flag to determine whether the filter is in second-order sections (SOS) form, returned as a logical scalar. If the filter is in SOS form, `issos` returns a logical 1, else it returns a logical 0.

Data Types: `logical`

## Version History

Introduced in R2011a

# isVisible

## Package:

Determine visibility of scope

## Syntax

```
visibility = isVisible(scope)
```

## Description

`visibility = isVisible(scope)` returns the visibility of the scope as logical, with 1 (true) for visible.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sample rate
signal = dsp.SineWave(Frequency=50, SampleRate=Fs, ...
    SamplesPerFrame=100);
scope = timescope(SampleRate=Fs, TimeSpanSource="property", ...
    TimeSpan=0.25, YLimits=[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

### scope — Scope object

scope object

Scope object, specified as one of the following:

- spectrumAnalyzer object
- dsp.ArrayPlot object
- dsp.LogicAnalyzer System object
- timescope object
- dsp.DynamicFilterVisualizer object

Example: myScope = spectrumAnalyzer; visibility = isVisible(myScope)

Example: myTS = timescope; visibility = isVisible(myTS)

## Output Arguments

### visibility — Scope visibility

1 | 0

Scope visibility, returned as a logical 1 or a logical 0. If the scope display is showing, the `isVisible` function returns 1 (true). Otherwise, the function returns 0 (false).

## Version History

### Introduced in R2016b

#### R2022a: Support for `dsp.SpectrumAnalyzer` object will be removed

*Not recommended starting in R2022a*

The `isVisible` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

#### Update Code

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `isVisible` function typically uses the `dsp.SpectrumAnalyzer` System object and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre>scope = dsp.SpectrumAnalyzer; scope(randn(100000,1)) if(isVisible(scope))     hide(scope) end</pre> | <pre>scope = spectrumAnalyzer; scope(randn(100000,1)) if(isVisible(scope))     hide(scope) end</pre> |

#### R2022b: New support for `dsp.DynamicFilterVisualizer` object

Starting in R2022b, the `isVisible` function supports the `dsp.DynamicFilterVisualizer` object.

# isstable

**Package:** dsp

Verify that discrete-time filter System object is stable

## Syntax

```
flag = isstable(sysobj)
flag = isstable(sysobj,'Arithmetic',arithType)
```

## Description

`flag = isstable(sysobj)` returns `true` if filter System object is stable. The function returns `false` if filter System object is not stable.

`flag = isstable(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input.

For more input options, see `isstable` in Signal Processing Toolbox.

## Examples

### Determine if Filter Has Minimum Phase and is Stable

Design a Chebyshev Type I IIR filter and determine if the filter has minimum phase and is stable.

Using the `fdesign.lowpass` and `design` functions, design a Chebyshev Type I IIR filter with a passband ripple of 0.5 dB and a 3 dB cutoff frequency at 9600 Hz.

```
Fs = 48000; % Sampling frequency of input signal
d = fdesign.lowpass('N,F3dB,Ap', 10, 9600, .5, Fs);
filt = design(d,'cheby1','Systemobject',true)

filt =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II'
        CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
        HasScaleValues: true
        ScaleValues: [0.3318 0.2750 0.1876 0.0904 0.0225 0.9441]

    Show all properties
```

Using the `isminphase` function, determine if the filter has minimum phase.

```
isminphase(filt)
```

```
ans = logical
      1
```

Verify the location of poles and zeros of the filter transfer function on the z-plane. By definition, the poles and zeros of the minimum phase filter must be on or inside the unit circle.

```
zplane(filt)
```

All minimum phase filters are stable. To verify if the designed filter is stable, use the `isstable` function.

```
isstable(filt)
```

```
ans = logical
      1
```

## Input Arguments

### **sysobj** — Filter System object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### `flag` — Flag to determine if filter is stable

1 | 0

Flag to determine if the filter is stable, returned as a logical:

- 1 -- Filter is stable.
- 0 -- Filter is not stable.

Data Types: `logical`

## Version History

**Introduced in R2013a**

`isstable`

# kaiserwin

Kaiser window filter from specification object

## Syntax

```
kFilter = design(d,'kaiserwin','SystemObject',true)
kFilter = design(d,'kaiserwin',designoption,value,designoption,...
value,'SystemObject',true)
```

## Description

`kFilter = design(d,'kaiserwin','SystemObject',true)` designs a digital filter `kFilter` that uses a Kaiser window. For `kaiserwin` to work properly, the filter order in the specifications object must be even. In addition, higher order filters (filter order greater than 120) tend to be more accurate for smaller transition widths. `kaiserwin` returns a warning when your filter order may be too low to design your filter accurately.

`kFilter = design(d,'kaiserwin',designoption,value,designoption,... value,'SystemObject',true)` returns a filter where you specify design options as input arguments and the design process uses the Kaiser window technique.

To determine the available design options, use `designopts` with the specification object and the design method as input arguments as shown.

```
designopts(d,'method')
```

For complete help about using `kaiserwin`, refer to the command line help system. For example, to get specific information about using `kaiserwin` with `d`, the specification object, enter the following at the MATLAB prompt.

```
help(d,'kaiserwin')
```

## Examples

### Design a Direct Form FIR Filter

This example designs a direct form FIR filter from a halfband filter specification object.

```
d = fdesign.halfband('n,tw',200,0.01);
hbFilter = design(d,'kaiserwin','filterstructure','dffir',...
'SystemObject',true)

hbFilter =
  dsp.FIRFilter with properties:

    Structure: 'Direct form'
  NumeratorSource: 'Property'
    Numerator: [0 -0.0028 0 0.0029 0 -0.0030 0 0.0030 0 -0.0031 0 0.0032 0 -0.0033 0 0.0034 0 -0.0035 0 0.0036 0 -0.0037 0 0.0038 0 -0.0039 0 0.0040 0 -0.0041 0 0.0042 0 -0.0043 0 0.0044 0 -0.0045 0 0.0046 0 -0.0047 0 0.0048 0 -0.0049 0 0.0050 0 -0.0051 0 0.0052 0 -0.0053 0 0.0054 0 -0.0055 0 0.0056 0 -0.0057 0 0.0058 0 -0.0059 0 0.0060 0 -0.0061 0 0.0062 0 -0.0063 0 0.0064 0 -0.0065 0 0.0066 0 -0.0067 0 0.0068 0 -0.0069 0 0.0070 0 -0.0071 0 0.0072 0 -0.0073 0 0.0074 0 -0.0075 0 0.0076 0 -0.0077 0 0.0078 0 -0.0079 0 0.0080 0 -0.0081 0 0.0082 0 -0.0083 0 0.0084 0 -0.0085 0 0.0086 0 -0.0087 0 0.0088 0 -0.0089 0 0.0090 0 -0.0091 0 0.0092 0 -0.0093 0 0.0094 0 -0.0095 0 0.0096 0 -0.0097 0 0.0098 0 -0.0099 0 0.0100 0]
  InitialConditions: 0
```

Show all properties

```
fvtool(hbFilter);
```

In this example, `kaiserwin` uses an interpolating filter specification object.

```
d = fdesign.interpolator(4,'lowpass');
interpFilter= design(d,'kaiserwin','SystemObject',true)
```

```
interpFilter =
  dsp.FIRInterpolator with properties:
```

```
    InterpolationFactor: 4
```

```
    NumeratorSource: 'Property'
```

```
    Numerator: [3.4579e-04 2.6057e-04 -4.2478e-05 -4.6005e-04 -7.6928e-04 -7.3242e-04
```

Show all properties

```
fvtool(interpFilter);
```

## Version History

# lagrange

Fractional delay filter from `fdesign.fracdelay` specification object

## Syntax

```
Hd = design(d,'lagrange')
hd = design(d,'lagrange',FilterStructure,structure)
```

## Description

`Hd = design(d,'lagrange')` designs a fractional delay filter using the Lagrange method based on the specifications in `d`.

`hd = design(d,'lagrange',FilterStructure,structure)` specifies the Lagrange design method and the `structure` filter structure for `hd`. The only valid filter structure is `fd`, describing the fractional delay structure.

## Examples

This example uses a fractional delay of 0.30 samples. The `help` and `designopts` commands provide the details about designing fractional delay filters.

```
d=fdesign.fracdelay(.30)

d =

    Response: 'Fractional Delay'
  Specification: 'N'
    Description: {'Filter Order'}
      FracDelay: 0.3
  NormalizedFrequency: true
      FilterOrder: 3

designmethods(d)

Design Methods for class fdesign.fracdelay (N):

lagrange

help(d,'lagrange')

DESIGN Design a Lagrange fractional delay filter.
HD = DESIGN(D, 'lagrange') designs a Lagrange filter specified by the
  FDESIGN object D, and returns the DFILT object HD.

HD = DESIGN(..., 'FilterStructure', STRUCTURE) returns a filter with the
  structure STRUCTURE. STRUCTURE is 'farrowfd' by default and can be any of
  the following:

'farrowfd'
'fd'

% Example #1 - Design a linear Lagrange fractional delay filter of 0.2 samples.
h = fdesign.fracdelay(0.2,'N',2);
Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd')

% Example #2 - Design a cubic Lagrange fractional delay filter
Fs = 8000; % Sampling frequency of 8kHz
fdelay = 50e-6; % Fractional delay of 50 microseconds.
h = fdesign.fracdelay(fdelay,'N',3,Fs);
Hd = design(h, 'lagrange', 'FilterStructure', 'farrowfd');
```

This example designs a linear Lagrange fractional delay filter where you set the delay to 0.2 seconds and the filter order `N` to 2.

```
h = fdesign.fracdelay(0.2,'N',2);  
hd = design(h,'lagrange','FilterStructure','farrowfd')
```

Design a cubic Lagrange fractional delay filter with filter order equal to 3.

```
Fs = 8000;          % Sampling frequency of 8 kHz.  
fdelay = 50e-6;    % Fractional delay of 50 microseconds.  
h = fdesign.fracdelay(fdelay,'N',3,Fs);  
hd = design(h,'lagrange','FilterStructure','farrowfd');
```

## liblinks

Check model for blocks from specific DSP System Toolbox libraries

### Syntax

```
liblinks(lib)  
liblinks(lib,sys)  
liblinks(lib,sys,c)
```

### Description

`liblinks(lib)` returns a cell array of character vectors that lists the blocks in the current model that are linked to the specified libraries. The input `lib` provides a cell array of character vectors with the library names. Use the library name visible in the title bar when you open a library model.

`liblinks(lib,sys)` acts on the named model `sys`.

`liblinks(lib,sys,c)` changes the foreground color of the returned blocks to the color `c`. Possible values of `c` are 'blue', 'green', 'red', 'cyan', 'magenta', 'yellow', or 'black'.

### Examples

Check for blocks from the Sources library in the specified model:

```
rlsdemo  
liblinks('dspsrcs4',gcs)
```

# limitcycle

Response of single-rate, fixed-point IIR filter

## Syntax

```
report = limitcycle(hd)
report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)
```

## Description

`report = limitcycle(hd)` returns the structure `report` that contains information about how filter `hd` responds to a zero-valued input vector. By default, the input vector has length equal to twice the impulse response length of the filter.

`limitcycle` returns a structure whose elements contain the details about the limit cycle testing. As shown in this table, the `report` includes the following details.

| Output Object Property      | Description   |
|-----------------------------|---|
| <code>LimitCycleType</code> | Contains one of the following results: <ul style="list-style-type: none"> <li><code>Granular</code> — indicates that a granular overflow occurred.</li> <li><code>Overflow</code> — indicates that an overflow limit cycle occurred.</li> <li><code>None</code> — indicates that the test did not find any limit cycles.</li> </ul> |
| <code>Zi</code>             | Contains the initial condition value(s) that caused the detected limit cycle to occur.  |
| <code>Output</code>         | Contains the output of the filter in the steady state.  |
| <code>Trial</code>          | Returns the number of the Monte Carlo trial on which the limit cycle testing stopped. For example, <code>Trial = 10</code> indicates that testing stopped on the tenth Monte Carlo trial.   |

Using an input vector longer than the filter impulse response ensures that the filter is in steady-state operation during the limit cycle testing. `limitcycle` ignores output that occurs before the filter reaches the steady state. For example, if the filter impulse length is 500 samples, `limitcycle` ignores the filter output from the first 500 input samples.

To perform limit cycle testing on your IIR filter, you must set the filter `Arithmetic` property to `fixed` and `hd` must be a fixed-point IIR filter of one of the following forms:

- `df1` — direct-form I
- `df1t` — direct-form I transposed
- `df1sos` — direct-form I with second-order sections
- `df1tsos` — direct-form I transposed with second-order sections
- `df2` — direct-form II
- `df2t` — direct-form II transposed
- `df2sos` — direct-form II with second-order sections

- `df2tsos` — direct-form II transposed with second-order sections

When you use `limitcycle` without optional input arguments, the default settings are

- Run 20 Monte Carlo trials
- Use an input vector twice the length of the filter impulse response
- Stop testing if the simulation process encounters either a granular or overflow limit cycle

To determine the length of the filter impulse response, use `impzlength`:

```
impzlength(hd)
```

During limit cycle testing, if the simulation runs reveal both overflow and granular limit cycles, the overflow limit cycle takes precedence and is the limit cycle that appears in the report.

Each time you run `limitcycle`, it uses a different sequence of random initial conditions, so the results can differ from run to run.

Each Monte Carlo trial uses a new set of randomly determined initial states for the filter. Test processing stops when `limitcycle` detects a zero-input limit cycle in filter `hd`.

`report = limitcycle(hd,ntrials,inputlengthfactor,stopcriterion)` returns a report of how filter `hd` responds to a zero-valued input vector, using the following optional input arguments:

- `ntrials` — Number of Monte Carlo trials (default is 20).
- `inputlengthfactor` — integer factor used to calculate the length of the input vector. The length of the input vector comes from  $(\text{impzlength}(\text{hd}) * \text{inputlengthfactor})$ , where `inputlengthfactor = 2` is the default value.
- `stopcriterion` — the criterion for stopping the Monte Carlo trial processing. `stopcriterion` can be set to **either** (the default), **granular**, **overflow**. This table describes the results of each stop criterion.

| stopcriterion Setting | Description   |
|-----------------------|---|
| <b>either</b>         | Stop the Monte Carlo trials when <code>limitcycle</code> detects either a granular or overflow limit cycle. |
| <b>granular</b>       | Stop the Monte Carlo trials when <code>limitcycle</code> detects a granular limit cycle.                    |
| <b>overflow</b>       | Stop the Monte Carlo trials when <code>limitcycle</code> detects an overflow limit cycle.                   |

**Note** An important feature is that if you specify a specific limit cycle stop criterion, such as **overflow**, the Monte Carlo trials do not stop when testing encounters a granular limit cycle. You receive a warning that no **overflow** limit cycle occurred, but consider that a **granular** limit cycle might have occurred.

## Examples

In this example, there is a region of initial conditions in which no limit cycles occur and a region where they do. If no limit cycles are detected before the Monte Carlo trials are over, the state sequence converges to zero. When a limit cycle is found, the states do not end at zero. Each time you

run this example, it uses a different sequence of random initial conditions, so the plot you get can differ from the one displayed in the following figure.

```
s = [1 0 0 1 0.9606 0.9849];
hd = dfilt.df2sos(s);
hd.arithmetic = 'fixed';
greport = limitcycle(hd,20,2,'granular')
oreport = limitcycle(hd,20,2,'overflow')
figure,
subplot(211),plot(greport.Output(1:20)), title('Granular Limit Cycle');
subplot(212),plot(oreport.Output(1:20)), title('Overflow Limit Cycle');

greport =
    LimitCycle: 'granular'
              Zi: [2x1 double]
              Output: [1303x1 embedded.fi]
              Trial: 1

oreport =
    LimitCycle: 'overflow'
              Zi: [2x1 double]
              Output: [1303x1 embedded.fi]
              Trial: 2
```

The plots shown in this figure present both limit cycle types — the first displays the small amplitude granular limit cycle, the second the larger amplitude overflow limit cycle.

As you see from the plots, and as is generally true, overflow limit cycles are much greater magnitude than granular limit cycles. This is why `limitcycle` favors overflow limit cycle detection and reporting.

# maxflat

Maxflat FIR filter

## Syntax

```
maxflatFilter = design(d,'maxflat','SystemObject',true)
maxflatFilter =
design(d,'maxflat','FilterStructure',structure,'SystemObject',true)
```

## Description

`maxflatFilter = design(d,'maxflat','SystemObject',true)` designs a maximally flat filter, `maxflatFilter`, from a filter specification object, `d`.

`maxflatFilter = design(d,'maxflat','FilterStructure',structure,'SystemObject',true)` designs a maximally flat filter where `structure` is one of the following:

- 'dffir', a discrete-time, direct-form FIR filter (the default value)
- 'dffirt', a discrete-time, direct-form FIR transposed filter
- 'dfsymfir', a discrete-time, direct-form symmetric FIR filter

## Examples

### Design a Lowpass Filter with a Maximally Flat FIR Structure

```
d = fdesign.lowpass('N,F3dB', 50, 0.3);
flatLowpass = design(d, 'maxflat','SystemObject',true);
fvtool(flatLowpass);
```

### Design a Highpass Filter With a Maximally Flat Symmetric FIR Structure

```
d = fdesign.highpass('N,F3dB', 50, 0.7);  
flatHighpass = design(d,'maxflat','FilterStructure','dfsymfir',...  
    'SystemObject',true);  
fvtool(flatHighpass)
```

## maxstep

**Package:** dsp

Maximum step size for LMS adaptive filter convergence

### Syntax

```
mumax = maxstep(lmsFilt,x)
[mumax,mumaxmse] = maxstep(lmsFilt,x)
```

### Description

`mumax = maxstep(lmsFilt,x)` predicts a bound on the step size to provide convergence of the mean values of the coefficients of the adaptive filter, `lmsFilt`.

`[mumax,mumaxmse] = maxstep(lmsFilt,x)` predicts a bound, in mean squared sense, on the adaptive filter step size to provide convergence of the adaptive filter coefficients.

### Examples

#### Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
for k = 1:size(x,2)
    x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
end
mu = 0.1;
LMSFilter = dsp.LMSFilter('Length',32,...
    'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)
```

```
mumax = 0.0625
```

```
mumaxmse = 0.0536
```

## Input Arguments

### **lmsfilt** — LMS adaptive filter System object

`dsp.LMSFilter` | `dsp.BlockLMSFilter`

LMS adaptive filter, specified as either a `dsp.LMSFilter` System object or a `dsp.BlockLMSFilter` System object.

### **x** — Input signal

scalar | column vector | matrix

Columns of the matrix `x` contain individual input signal sequences. The signal set is assumed to have zero mean or close to zero mean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`  
Complex Number Support: Yes

## Output Arguments

### **mumax** — Maximum step size

scalar

Maximum step size value, returned as a scalar. This is the step size you can specify for the adaptive filter without causing the filter to become unstable. For details on how this parameter is calculated, see “Algorithms” on page 5-1147.

Data Types: `double`

### **mumaxmse** — Maximum step size in mean squared sense

scalar

Maximum adaptive filter step size to provide convergence of the LMS adaptive filter coefficients in the mean squared sense, returned as a scalar. For details on how this parameter is calculated, see “Algorithms” on page 5-1147.

Data Types: `double`

## Algorithms

The step size of the adaptive filter must satisfy the following equation in order for the adaptive filter to be stable:

$$0 < \mu < \mu_{\max}$$

where,  $\mu_{\max}$  is the maximum step size.

The value of  $\mu_{\max}$  depends on the LMS filter System object and the adaptive filter algorithm the object uses.

### **dsp.LMSFilter**

#### **LMS**

When the `Method` property of the `dsp.LMSFilter` object is set to `'LMS'`, maximum step size  $\mu_{\max}$  is calculated using the following equation:

$$\mu_{\max} = \frac{2}{\text{mean}(xt \circ xt)L}$$

where,

- $xt$  -- Concatenated columns of the input matrix,  $x(:)$ .
- $xt \circ xt$  -- Hadamard or entrywise product of the two vectors.
- $L$  -- Length of the filter coefficients.

The maximum step size in mean-square sense,  $\mu_{\max\text{MSE}}$  is computed using the following equation:

$$\mu_{\max\text{MSE}} = \frac{2}{\lambda_{\max}(\text{Kurt} + 2) + \text{sum}(\lambda)}$$

where,

- $\text{sum}(\lambda)$  -- Sum of the eigenvalues of the input auto correlation matrix.
- $\lambda_{\max}$  -- Maximum eigenvalue of the input auto correlation matrix.
- $\text{Kurt}$  -- Average kurtosis value of eigenvector-filtered signals.

### Normalized LMS

When the Method property of the `dsp.LMSFilter` System object is set to 'Normalized LMS':

- Maximum step size,  $\mu_{\max} = 2$ .
- Maximum step size in mean-square sense,  $\mu_{\max\text{MSE}} = 2$ .

### For Other Methods

For all other methods such as Sign-Data LMS, Sign-Error LMS, and Sign-Sign LMS:

- $\mu_{\max} = \infty$ .
- $\mu_{\max\text{MSE}} = \infty$ .

### `dsp.BlockLMSFilter`

The maximum step size for `dsp.BlockLMSFilter` is computed using the following equation:

$$\mu_{\max} = \frac{2}{\text{mean}(xt \circ xt)L}$$

where,

- $xt$  -- Concatenated columns of the input matrix,  $x(:)$ .
- $xt \circ xt$  -- Hadamard or entrywise product of the two vectors.
- $L$  -- Length of the filter coefficients.

The maximum step size in mean-square sense,  $\mu_{\max\text{MSE}}$  is computed using the following equation:

$$\mu_{\max\text{MSE}} = \frac{\mu_{\max}}{3}$$

## maximizestopband

Maximize stopband attenuation of fixed-point filter

### Syntax

```
Hq = maximizestopband(Hd,Wordlength)
Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)
```

### Description

`Hq = maximizestopband(Hd,Wordlength)` quantizes the single-stage or multistage FIR filter `Hd` and returns the fixed-point filter `Hq` with wordlength `wordlength` that maximizes the stopband attenuation. `Hd` must be generated using `fdesign` and `design`. For multistage filters, `wordlength` can either be a scalar or vector. If `wordlength` is a scalar, the same wordlength is used for all stages. If `wordlength` is a vector, each stage uses the corresponding element in the vector. The vector length must equal the number of stages. `maximizestopband` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`

`Hq = maximizestopband(Hd,Wordlength,'Ntrials',N)` specifies the number of Monte Carlo trials to use in the maximization. `Hq` is the fixed-point filter with the largest stopband attenuation among the trials. The number of Monte Carlo trials `N` defaults to 1.

You must have the Fixed-Point Designer software installed to use this function.

### Examples

#### Maximize Stopband Attenuation

Maximize stopband attenuation for 16-bit fixed-point filter.

```
Hf = fdesign.lowpass('Fp,Fst,Ap,Ast',0.4,0.45,0.5,60);
Hd = design(Hf,'equiripple');
```

Use 16 bits to represent coefficients.

```
WL = 16;
Hq = maximizestopband(Hd,WL);
```

Compare stopband attenuation

```
md = measure(Hd)

md =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.41178
6-dB Point       : 0.41845
Stopband Edge    : 0.45
Passband Ripple  : 0.49369 dB
```

```
Stopband Atten. : 60.0697 dB
Transition Width : 0.05
```

```
mq = measure(Hq)
```

```
mq =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.41178
6-dB Point       : 0.41845
Stopband Edge    : 0.45
Passband Ripple  : 0.49773 dB
Stopband Atten.  : 59.9728 dB
Transition Width  : 0.05
```

```
hfvf=fvtool(Hd,Hq,'ShowReference','off');
legend(hfvf,'Floating-point Filter','Fixed-point Filter');
```

# measure

**Package:** dsp

Measure frequency response characteristics of filter System object

## Syntax

```
measure(sysobj)
M = measure(sysobj)
M = measure(sysobj, 'Arithmetic', arithType)
M = measure(sysobj, 'freqspec', freqspecvalue)
```

## Description

`measure(sysobj)` displays measurements of various quantities from the frequency response of the filter System object, `sysobj`. Measurements include the actual passband ripple, the minimum stopband attenuation, the frequency point at which the filter's gain is 3 dB below the nominal passband gain, etc. You must construct `sysobj` using `fdesign` and `design` with the name-value pair argument `'SystemObject', true`. You can optionally specify additional options by one or more `Name, Value` pair arguments.

`M = measure(sysobj)` returns the measurements, `M`, such that the measurements can be queried programmatically. For example, to query the 3 dB point, type `M.F3dB`. Type `get(M)` to see the full list of properties that can be queried. Note that different filter responses generate different measurements.

`M = measure(sysobj, 'Arithmetic', arithType)` analyzes the filter System object, `sysobj`, based on the arithmetic specified in the `arithType` input. `arithType` can be set to one of `'double'`, `'single'`, or `'fixed'`. When the arithmetic input is not specified and the filter System object is in an unlocked state, the analysis tool assumes a double precision filter.

`M = measure(sysobj, 'freqspec', freqspecvalue)` passes the frequency value as an input to `measure` in order to determine the corresponding magnitude measurements. For designs that do not specify some of the frequency constraints, you can determine the corresponding magnitude measurements using this option.

In the following example, the passband edge, passband ripple, and the transition width of the IIR filter are unknown.

```
designLowpass = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
chebFilter = design(designLowpass, 'cheby2');
measure(chebFilter)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : Unknown
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : Unknown
Stopband Atten.  : 79.9994 dB
Transition Width  : Unknown
```

Specify the passband edge to be 0.4, and measure the passband ripple and the transition width of this filter.

```
measure(chebFilter, 'Fpass', 0.4)

Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : 0.013644 dB
Stopband Atten. : 79.9994 dB
Transition Width : 0.28727
```

## Examples

### Measure the Filter Specifications

Create a lowpass filter and check whether the actual filter meets the specifications. For this case, use normalized frequency for  $F_s$ , the default setting.

```
desigLowpass = fdesign.lowpass('Fp,Fst,Ap,Ast',0.45,0.55,0.1,80)
```

```
desigLowpass =
  lowpass with properties:

      Response: 'Lowpass'
  Specification: 'Fp,Fst,Ap,Ast'
  Description: {4x1 cell}
  NormalizedFrequency: 1
      Fpass: 0.4500
      Fstop: 0.5500
      Apass: 0.1000
      Astop: 80
```

```
designmethods(desigLowpass, 'SystemObject', true)
```

Design Methods that support System objects for class `fdesign.lowpass (Fp,Fst,Ap,Ast)`:

```
butter
cheby1
cheby2
ellip
equiripple
ifir
kaiserwin
multistage
```

Use the default equiripple design method.

```
equiFilter = design(desigLowpass, 'SystemObject', true)
```

```
equiFilter =
  dsp.FIRFilter with properties:
```

```

        Structure: 'Direct form'
    NumeratorSource: 'Property'
        Numerator: [-1.0186e-05 -6.8148e-04 -0.0017 -0.0014 7.3963e-04 0.0016 -7.5529e-04 -0
InitialConditions: 0

```

Show all properties

Measure the specifications of the designed lowpass filter.

```
measure(equiFilter)
```

```

ans =
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.45
3-dB Point       : 0.47798
6-dB Point       : 0.48913
Stopband Edge    : 0.55
Passband Ripple  : 0.095021 dB
Stopband Atten.  : 80.1164 dB
Transition Width  : 0.1

```

Stopband Edge, Passband Edge, Passband Ripple, and Stopband Attenuation all meet the specifications.

Now, using  $F_s$  in linear frequency, create a bandpass filter, and measure the magnitude response characteristics.

```
designBandpass = fdesign.bandpass
```

```
designBandpass =
bandpass with properties:

```

```

        Response: 'Bandpass'
    Specification: 'Fst1,Fp1,Fp2,Fst2,Ast1,Ap,Ast2'
    Description: {7x1 cell}
NormalizedFrequency: 1
        Fstop1: 0.3500
        Fpass1: 0.4500
        Fpass2: 0.5500
        Fstop2: 0.6500
        Astop1: 60
        Apass: 1
        Astop2: 60

```

Convert to Linear Frequency.

```
normalizefreq(designBandpass,false,1.5e3)
```

```
bpFilter = design(designBandpass,'cheby2','SystemObject',true);
```

Measure the specifications of the designed bandpass filter.

```
measure(bpFilter)
```

```

ans =
Sample Rate      : 1.5 kHz

```

```
First Stopband Edge      : 262.5 Hz
First 6-dB Point        : 319.9585 Hz
First 3-dB Point        : 324.9744 Hz
First Passband Edge     : 337.5 Hz
Second Passband Edge    : 412.5 Hz
Second 3-dB Point       : 425.0256 Hz
Second 6-dB Point       : 430.0415 Hz
Second Stopband Edge    : 487.5 Hz
First Stopband Atten.   : 60 dB
Passband Ripple         : 0.17985 dB
Second Stopband Atten. : 60 dB
First Transition Width  : 75 Hz
Second Transition Width : 75 Hz
```

### Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
```

```
HPF =
    dsp.HighpassFilter with properties:
```

```
        FilterType: 'FIR'
    DesignForMinimumOrder: true
        StopbandFrequency: 8000
        PassbandFrequency: 12000
    StopbandAttenuation: 80
        PassbandRipple: 0.1000
    NormalizedFrequency: false
        SampleRate: 44100
```

```
Show all properties
```

```
HPFMeas = measure(HPF)
```

```
HPFMeas =
    Sample Rate      : 44.1 kHz
    Stopband Edge    : 8 kHz
    6-dB Point       : 10.418 kHz
    3-dB Point       : 10.8594 kHz
    Passband Edge    : 12 kHz
    Stopband Atten.  : 81.8558 dB
    Passband Ripple  : 0.08066 dB
    Transition Width : 4 kHz
```

## Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter
```

```
LPF =
```

```
  dsp.LowpassFilter with properties:
```

```
          FilterType: 'FIR'
  DesignForMinimumOrder: true
    PassbandFrequency: 8000
    StopbandFrequency: 12000
      PassbandRipple: 0.1000
  StopbandAttenuation: 80
  NormalizedFrequency: false
        SampleRate: 44100
```

```
Show all properties
```

```
LPFMeas = measure(LPFF)
```

```
LPFMeas =
```

```
Sample Rate      : 44.1 kHz
Passband Edge    : 8 kHz
3-dB Point       : 9.1311 kHz
6-dB Point       : 9.5723 kHz
Stopband Edge    : 12 kHz
Passband Ripple  : 0.08289 dB
Stopband Atten.  : 81.6141 dB
Transition Width  : 4 kHz
```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.HighpassFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`

When `sysobj` is a generic discrete-time filter, for example, a single-rate lowpass filter, `measure(sysobj)` returns the following filter specifications.

| Lowpass Filter Specification | Description  |
|------------------------------|--|
| Sample Rate                  | Filter sampling frequency.   |
| Passband Edge                | Location of the edge of the passband as it enters transition.  |
| 3-dB Point                   | Location of the -3 dB point on the response curve.   |
| 6-dB Point                   | Location of the -6 dB point on the response curve.   |
| Stopband Edge                | Location of the edge of the transition band as it enters the stopband.   |
| Passband Ripple              | Ripple in the passband.  |
| Stopband Atten               | Attenuation in the stopband.   |
| Transition Width             | Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ . |

When `sysobj` is a bandstop filter, `measure(sysobj)` returns these specifications for the resulting bandstop filter.

| Bandstop Filter Specification | Description  |
|-------------------------------|--|
| Sample Rate                   | Filter sampling frequency.   |
| First Passband Edge           | Location of the edge of the first passband.                                      |
| First 3-dB Point              | Location of the edge of the -3 dB point in the first transition band.            |
| First 6-dB Point              | Location of the edge of the -6 dB point in the first transition band.            |
| First Stopband Edge           | Location of the start of the stopband.   |
| Second Stopband Edge          | Location of the end of the stopband.   |
| Second 6-dB Point             | Location of the edge of the -6 dB point in the second transition band.           |
| Second 3-dB Point             | Location of the edge of the -3 dB point in the second transition band.           |
| Second Passband Edge          | Location of the start of the second passband.                                    |
| First Passband Ripple         | Ripple in the first passband.  |
| Stopband Atten                | Attenuation in the stopband.   |
| Second Passband Ripple        | Ripple in the second passband.   |
| First Transition Width        | Width of the first transition region. Measured between the -3 and -6 dB points.  |
| Second Transition Width       | Width of the second transition region. Measured between the -6 and -3 dB points. |

When `sysobj` is an interpolator, decimator, or a rate converter, `measure(sysobj)` returns these specifications for the resulting filter.

| Interpolator Filter Specification | Description                |
|-----------------------------------|----------------------------|
| Sample Rate                       | Filter sampling frequency. |

| Interpolator Filter Specification | Description  |
|-----------------------------------|--|
| First Passband Edge               | Location of the edge of the passband as it enters transition.  |
| 3-dB Point                        | Location of the -3 dB point on the response curve.   |
| 6-dB Point                        | Location of the -6 dB point on the response curve.   |
| Stopband Edge                     | Location of the edge of the transition band as it enters the stopband.   |
| Passband Ripple                   | Ripple in the passband.  |
| Stopband Atten                    | Attenuation in the stopband.   |
| Transition Width                  | Width of the transition between the passband and stopband, in normalized frequency or absolute frequency. Measured between $F_{pass}$ and $F_{stop}$ . |

### arithType – Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

### freqspecvalue – Frequency specifications

scalar

Frequency specifications are input to `measure` in order to determine the corresponding magnitude measurements. For designs that do not specify some of the frequency constraints, you can determine the corresponding magnitude measurements using this option.

In the following example, the passband edge, passband ripple, and the transition width of the IIR filter are unknown.

```
designLowpass = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);
chebFilter = design(designLowpass,'cheby2');
measure(chebFilter)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : Unknown
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : Unknown
Stopband Atten.  : 79.9994 dB
Transition Width  : Unknown
```

Specify the passband edge to be 0.4, and measure the passband ripple and the transition width of this filter.

```
measure(chebFilter,'Fpass',0.4)
```

```
Sample Rate      : N/A (normalized frequency)
Passband Edge    : 0.4
3-dB Point       : 0.5
6-dB Point       : 0.51823
Stopband Edge    : 0.68727
Passband Ripple  : 0.013644 dB
Stopband Atten.  : 79.9994 dB
Transition Width  : 0.28727
```

## Output Arguments

### M — Measurements

`fdesign` object

Measurements object, returned as an `fdesign` object. Here is a list of supported input filter objects with their corresponding `fdesign` measurements objects:

- `dsp.CICCompensationDecimator` -- `fdesign.isinclpmeas`.
- `dsp.CICCompensationInterpolator` -- `fdesign.isinclpmeas`
- `dsp.FIRHalfbandDecimator` -- `fdesign.lowpassmeas`
- `dsp.FIRHalfbandInterpolator` -- `fdesign.lowpassmeas`
- `dsp.HighpassFilter` -- `fdesign.highpassmeas`
- `dsp.IIRHalfbandDecimator` -- `fdesign.lowpassmeas`
- `dsp.IIRHalfbandInterpolator` -- `fdesign.lowpassmeas`
- `dsp.LowpassFilter` -- `fdesign.lowpassmeas`

The measurements, *M* can be queried programmatically. For example, to query the 3 dB point, type `M.F3dB`. Type `get(M)` to see the full list of properties that can be queried. Note that different filter responses generate different measurements.

## Tips

For designs that do not specify some of the frequency constraints, the function may not be able to determine corresponding magnitude measurements. In these cases, a constraint can be passed in to `measure` to determine such measurements. For example:

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);  
H = design(f,'cheby2','SystemObject',true);  
measure(H)
```

returns values of Unknown for the passband edge, passband ripple, and transition width measurements, but

```
f = fdesign.lowpass('N,F3dB,Ast',8,0.5,80);  
H = design(f,'cheby2','SystemObject',true);  
measure(H,'Fpass',0.4)
```

provides measurements for all returned values.

## mfilt

(To be removed) Multirate filter

### Compatibility

`mfilt` will be removed in a future release. See `dsp.CICDecimator`, `dsp.CICInterpolator`, `dsp.FIRDecimator`, `dsp.FIRInterpolator`, `dsp.FilterCascade`, `dsp.FarrowRateConverter`, `dsp.FIRRateConverter`, `dsp.IIRHalfbandDecimator`, or `dsp.IIRHalfbandInterpolator` instead.

### Syntax

```
hm = mfilt.structure(input1,input2,...)
```

### Description

`hm = mfilt.structure(input1,input2,...)` returns the object `hm` of type *structure*. As with `dfilt` objects, you must include the *structure* to construct a multirate filter object. You can, however, construct a default multirate filter object of a given structure by not including input arguments in your calling syntax.

Multirate filters include decimators and interpolators, and fractional decimators and fractional interpolators where the resulting interpolation or decimation factor is not an integer.

### Structures

Each of the following multirate filter structures has a reference page of its own.

| Filter Structure                | Description of Resulting Multirate Filter        | Coefficient Mapping Support in <code>realizemdl</code> |
|---------------------------------|--|--|
| <code>mfilt.cascade</code>      | Cascade multirate filters to form another filter | Supported  |
| <code>mfilt.cicdecim</code>     | Cascaded integrator-comb decimator               | Not supported  |
| <code>mfilt.cicinterp</code>    | Cascaded integrator-comb interpolator            | Not supported  |
| <code>mfilt.farrowsrc</code>    | Multirate Farrow filter                          | Supported.   |
| <code>mfilt.fftfirinterp</code> | Overlap-add FIR polyphase interpolator           | Not supported  |
| <code>mfilt.firdecim</code>     | Direct-form FIR polyphase decimator              | Supported  |
| <code>mfilt.firinterp</code>    | Direct-form FIR polyphase interpolator           | Supported  |
| <code>mfilt.firsrc</code>       | Direct-form FIR polyphase sample rate converter  | Supported  |

| Filter Structure                | Description of Resulting Multirate Filter      | Coefficient Mapping Support in <code>realizemdl</code> |
|---------------------------------|--|--|
| <code>mfilt.firtdecim</code>    | Direct-form transposed FIR polyphase decimator | Supported  |
| <code>mfilt.holdinterp</code>   | FIR hold interpolator                          | Not supported  |
| <code>mfilt.iirdecim</code>     | IIR decimator                                  | Supported  |
| <code>mfilt.iirinterp</code>    | IIR interpolator                               | Supported  |
| <code>mfilt.linearinterp</code> | FIR Linear interpolator                        | Supported  |
| <code>mfilt.iirwdfdecim</code>  | IIR wave digital filter decimator              | Supported  |
| <code>mfilt.iirwdfinterp</code> | IIR wave digital filter interpolator           | Supported  |

### Copying mfilt Objects

To create a copy of an `mfilt` object, use the `copy` method.

```
h2 = copy(hd)
```

---

**Note** The syntax `hd2 = hd` copies only the object handle. It does not create a new object. `hd2` and `hd` are not independent. If you change the property value for one of the two, such as `hd2`, you are changing the property for both.

---

### Examples

Decimation by a factor of two. Convert input sampled at 48 kHz to 24 kHz:

```
Fs = 4.8e4;
t = 0:1/Fs:1-(1/Fs);
x = cos(2*pi*4000*t);
Hm = mfilt.firdecim(2);
% Note cutoff frequency of 1/2 normalized frequency
fvtool(Hm);
% Note the group delay of 34 samples
fvtool(Hm, 'analysis', 'grpdelay');
y = filter(Hm, x);
% Note delay in output is consistent with 36/2
stem(y(1:48), 'markerfacecolor', [0 0 1]);
```

Using existing coefficients to decimate a signal by a factor of two:

```
M = 2; % Decimation factor
b = firhalfband('minorder', .45, 0.0001);
Hm = mfilt.firdecim(M, b);
% Decimate a signal which consists of the sum of 2 sinusoids.
N = 160;
x = sin(2*pi*.05*[0:N-1]+pi/3) + cos(2*pi*.03*[0:N-1]+pi/3);
y = filter(Hm, x);
```

---

**Note** Multirate filters can also have complex coefficients. For example, you can specify complex coefficients in the argument `num` passed to the filter structure. This works for all multirate filter structures.

```
m = 2;
num = [0.5 0.5+1j*0.2];
```

```
Hm = mfilt.firdecim(m, num);  
y = filter(Hm, [1:10]);
```

---

## **Version History**

**Introduced in R2011a**

# mfilt.cascade

Cascade filter objects

---

**Note** `mfilt.cascade` will be removed in a future release. Use `dsp.FilterCascade` instead.

---

## Syntax

```
hm = cascade(hm1,hm2,...,hmn)
```

## Description

`hm = cascade(hm1,hm2,...,hmn)` creates filter object `hm` by cascading (connecting in series) the individual filter objects `hm1`, `hm2`, and so on to `hmn`.

In block diagram form, the cascade looks like this, with `x` as the input to the filter `hm` and `y` the output from the cascade filter `hm`:

`mfilt.cascade` accepts any combination of `mfilt` and `dfilt` objects (discrete time filters) to cascade, as well as Farrow filter objects.

## Examples

Create a variety of `mfilt` objects and cascade them together.

```

hm(1) = mfilt.firdecim(12);
hm(2) = mfilt.firdecim(4);
h1 = mfilt.cascade(hm(1),hm(2));
hm(3) = mfilt.firinterp(4);
hm(4) = mfilt.firinterp(12);
h2 = mfilt.cascade(hm(3),hm(4));
% Cascade h1 and h2 together
h3 = mfilt.cascade(h1,h2,9600);
  
```

## Version History

Introduced in R2011a

`dfilt.cascade`

## mfilt.cicdecim

Fixed-point CIC decimator

---

**Note** `mfilt.cicdecim` will be removed in a future release. Use `dsp.CICDecimator` instead.

---

### Syntax

```
hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)
```

### Description

`hm = mfilt.cicdecim(r,m,n,iwl,owl,wlps)` returns a cascaded integrator-comb (CIC) decimation filter object.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

| Input Arguments  | Description   |
|------------------|---|
| <code>r</code>   | Decimation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. <code>r</code> must be an integer value greater than or equal to 1. The default value is 2.   |
| <code>m</code>   | Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing <code>m</code> increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. <code>m</code> must be an integer value greater than or equal to 1. The default value is 1. |
| <code>n</code>   | Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. 2 is the default value.   |
| <code>iwl</code> | Word length of the input signal. Use any integer number of bits. The default value is 16 bits.  |
| <code>owl</code> | Word length of the output signal. It can be any positive integer number of bits. By default, <code>owl</code> is 16 bits.   |

| Input Arguments | Description  |
|-----------------|--|
| wlps            | <p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter wlps as a scalar or vector of length 2*n, where n is the number of sections. When wlps is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.</p> <p>When you elect to specify wlps as an input argument, the FilterInternals property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p> |

### Constraints and Word Length Considerations

CIC decimators have the following constraint — the word lengths of the filter section must be monotonically decreasing. The word length of each filter section must be the same size as, or smaller than, the word length of the previous filter section.

The formula for  $B_{max}$ , the most significant bit at the filter output, is given in the Hogenauer paper in the References on page 5-1176 below.

$$B_{max} = (N \log_2 RM + B_{in} - 1)$$

where  $B_{in}$  is the number of bits of the input.

The cast operations shown in the diagram in “Algorithms” on page 5-1176 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints above, the constructor returns an error.

When you specify the word lengths correctly, the most significant bit  $B_{max}$  stays the same throughout the filter, while the word length of each section either decreases or stays the same. This can cause the fraction length to change throughout the filter as least significant bits are truncated to decrease the word length, as shown in “Algorithms” on page 5-1176.

### Properties of the Object

Objects have properties that control the way the object behaves. This table lists all the properties for the filter, with a description of each.

| Name              | Values               | Default | Description  |
|-------------------|----------------------|---------|--|
| Arithmetic        | fixed                | fixed   | Reports the kind of arithmetic the filter uses. CIC decimators are always fixed-point filters. |
| DecimationFactor  | Any positive integer | 2       | Amount to reduce the input sampling rate.  |
| DifferentialDelay | Any positive integer | 1       | Sets the differential delay for the filter. Usually a value of one or two is appropriate.      |

| Name             | Values   | Default       | Description  |
|------------------|--|---------------|--|
| FilterStructure  | mfilt structure  | None          | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of mfilt objects.  |
| FilterInternals  | FullPrecision,<br>MinWordLengths,<br>SpecifyPrecision,<br>SpecifyWordLengths | FullPrecision | Set the usage mode for the filter. Refer to “Usage Modes” on page 5-1170 below for details.  |
| InputFracLength  | Any positive integer   | 15            | The number of bits applied to the fraction length to interpret the input data to the filter.   |
| InputOffset      | Integers in the range<br>$0 \leq \text{InputOffset} \leq r-1$                | 0             | Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.<br><br>The InputOffset property applies only when you set the PersistentMemory property to true. See “InputOffset” on page 6-9 for more information. |
| InputWordLength  | Any positive integer   | 16            | The number of bits applied to the word length to interpret the input data to the filter.   |
| NumberOfSections | Any positive integer   | 2             | Number of sections used in the decimator. Generally called $n$ . Reflects either the number of decimator or comb sections, not the total number of sections in the filter.   |
| OutputFracLength | Any positive integer   | 15            | The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.   |
| OutputWordLength | Any positive integer   | 16            | The number of bits applied to the word length to interpret the output data from the filter.  |

| Name             | Values        | Default | Description  |
|------------------|---------------|---------|--|
| PersistentMemory | false or true | false   | Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When PersistentMemory is false, you cannot access the filter states. Setting PersistentMemory to true reveals the States property so you can modify the filter states. |

| Name               | Values                                 | Default | Description   |
|--------------------|--|---------|---|
| SectionWordLengths | Any integer or a vector of length 2*n. | 16      | Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length 2*n, where n is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the decimator. Available when FilterInternals is 'SpecifyWordLengths'. |

| Name   | Values                             | Default  | Description  |
|--------|------------------------------------|--|--|
| States | <code>filtstates.cic</code> object | $m+1$ -by- $n$ matrix of zeros, after you call function <code>int</code> . | Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. $m$ is the differential delay of the comb section and $n$ is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when <code>PersistentMemory</code> is true. Refer to the <code>filtstates</code> object in Signal Processing Toolbox documentation for more general information about the <code>filtstates</code> object. |

### Usage Modes

There are four modes of usage for this which are set using the `FilterInternals` property

- `FullPrecision` — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [3]. Full Precision is the default setting.
- `MinWordLengths` — Automatically set the sections for minimum word lengths.
- `SpecifyWordLengths` — Specify the word lengths for each section.
- `SpecifyPrecision` — Specify precision by providing values for the word and fraction lengths for each section.

Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'FullPrecision'
```

#### Minimum Wordlengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [1]) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output wordlength for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15
```

```
FilterInternals: 'MinWordLengths'
```

```
OutputWordLength: 16
```

#### Specify word lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2*(NumberOfSections)$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'SpecifyWordLengths'
```

```
SectionWordLengths: [19 18 18 17]
```

```
OutputWordLength: 16
```

Specify precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the SpecifyPrecision mode, you must enter a vector of length  $2*(NumberOfSections)$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{accum}$ , `mfilt.cicdecim` expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(NumberOfSections)$  with elements that represent the fraction length for each section as well. When you enter a scalar such as  $B_{accum}$ , `mfilt.cicdecim` applies scalar expansion as done for the word lengths.

Here is the SpecifyPrecision display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'SpecifyPrecision'
```

```
SectionWordLengths: [19 18 18 17]  
SectionFracLengths: [14 13 13 12]
```

```
OutputWordLength: 16  
OutputFracLength: 11
```

## About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m + 1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use `int` to assign the states to a variable in MATLAB. As an example, here are the states for a CIC decimator `hm` before and after filtering a data set.

```
x = fi(ones(1,10),true,16,0); % Fixed-point input data.
hm = mfilt.cicdecim(2,1,2,16,16,16);
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified.
y=filter(hm,x);
sts=int(hm.states)
```

STS is an integer matrix that `int` returns from the contents of the `filtstates.cic` object in `hm`.

## Design Considerations

When you design your CIC decimation filter, remember the following general points:

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3,\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop (or rolloff) in the filter passband. Using an appropriate FIR filter in series after the CIC decimation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the decimation factor. Raising the decimation factor increases the DC gain.

## Examples

This example applies a decimation factor  $r$  equal to 8 to a 160-point impulse signal. The signal output from the filter has  $160/r$ , or 20, points or samples. Choosing 10 bits for the word length represents a fairly common setting for analog to digital converters. The plot shown after the code presents the stem plot of the decimated signal, with 20 samples remaining after decimation:

```
m = 2; % Differential delays in the filter.
n = 4; % Filter sections
r = 8; % Decimation factor
x = int16(zeros(160,1)); x(1) = 1; % Create a 160-point
% impulse signal.
hm = mfilt.cicdecim(r,m,n); % Expects 16-bit input
% by default.
y = filter(hm,x);
stem(double(y)); % Plot output as a stem plot.
xlabel('Samples'); ylabel('Amplitude');
title('Decimated Signal');
```

The next example demonstrates one way to compute the filter frequency response, using a 4-section decimation filter with the decimation factor set to 7:

```
hm = mfilt.cicdecim(7,1,4);  
fvtool(hm)
```

FVTool provides ways for you to change the title and x labels to match the figure shown. Here's the frequency response plot for the filter. For details about the transfer function used to produce the frequency response, refer to [1] in the References on page 5-1176 section.

This final example demonstrates the decimator for converting from 44.1 kHz audio to 22.05 kHz — decimation by two. To overlay the before and after signals, scale the output and plot the signals on a stem plot.

```

r = 2; % Decimation factor.
hm = mfilt.cicdecim(r); % Use default NumberOfSections &
% DifferentialDelay property values.
fs = 44.1e3; % Original sampling frequency: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay the stem plots.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:44)/fs,x(2:45)); hold on; % Plot original signal
% sampled at 44.1kHz.
stem(n(1:22)/(fs/r),y(3:24),'r','filled'); % Plot decimated
% signal (22.05kHz)
% in red.
xlabel('Time (seconds)');ylabel('Signal Value');

```

## Algorithms

To show how the CIC decimation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC decimation filter ( $n = 2$ ).  $fs$  is the high sampling rate, the input to the decimation process.

For details about the bits that are removed in the Comb section, refer to [1] in References.

`mfilt.cicdecim` calculates the fraction length at each section of the decimator to avoid overflows at the output of the filter.

## Version History

Introduced in R2011a

## mfilt.cicinterp

(Removed) Fixed-point CIC interpolator

---

**Note** `mfilt.cicinterp` has been removed. Use `dsp.CICInterpolator` instead. For more details, see “Compatibility Considerations”.

---

### Syntax

```
hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)
hm = mfilt.cicinterp
hm = mfilt.cicinterp(R,...)
```

### Description

`hm = mfilt.cicinterp(R,M,N,ILW,OWL,WLPS)` constructs a cascaded integrator-comb (CIC) interpolation filter object that uses fixed-point arithmetic.

All of the input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The following table describes the input arguments for creating `hm`.

| Input Arguments | Description   |
|-----------------|---|
| R               | Interpolation factor applied to the input signal. Sharpens the response curve to let you change the shape of the response. R must be an integer value greater than or equal to 1. The default value is 2.   |
| M               | Differential delay. Changes the shape, number, and location of nulls in the filter response. Increasing M increases the sharpness of the nulls and the response between nulls. In practice, differential delay values of 1 or 2 are the most common. M must be an integer value greater than or equal to 1. The default value is 1. |
| N               | Number of sections. Deepens the nulls in the response curve. Note that this is the number of either comb or integrator sections, not the total section count. By default, the filter has two sections.  |
| ILW             | Word length of the input signal. Use any integer number of bits. The default value is 16 bits.  |
| OWL             | Word length of the output signal. It can be any positive integer number of bits. By default, OWL is 16 bits.  |

| Input Arguments | Description   |
|-----------------|---|
| WLPS            | <p>Defines the number of bits per word in each filter section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter WLPS as a scalar or vector of length <math>2*N</math>, where <math>N</math> is the number of sections. When WLPS is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the integrator.</p> <p>When you elect to specify <code>wlps</code> as an input argument, the <code>FilterInternals</code> property automatically switches from the default value of 'FullPrecision' to 'SpecifyWordLengths'.</p> |

`hm = mfilt.cicinterp` constructs the CIC interpolator using the default values for the optional input arguments.

`hm = mfilt.cicinterp(R, ...)` constructs the CIC interpolator applying the values you provide for `R` and any other values you specify as input arguments.

### Constraints and Conversions

In Hogenauer [1], the author describes the constraints on CIC interpolator filters. `mfilt.cicinterp` enforces a constraint—the word lengths of the filter sections must be non-decreasing. That is, the word length of each filter section must be the same size as, or greater than, the word length of the previous filter section.

The formula for  $W_j$ , the minimum register width, is derived in [1]. The formula for  $W_j$  is given by

$$W_j = \text{ceil}(B_{in} + \log_2 G_j)$$

where  $G_j$ , the maximum register growth up to the  $j$ th section, is given by

$$G_j = \begin{cases} 2^j, & j = 1, 2, \dots, N \\ \frac{2^{2N-j}(RM)^{j-N}}{R}, & j = N + 1, \dots, 2N \end{cases}$$

When the differential delay,  $M$ , is 1, there is also a special condition for the register width of the last comb,  $W_N$ , that is given by

$$W_N = B_{in} + N - 1 \text{ if } M = 1$$

The conversions denoted by the cast blocks in the integrator diagrams in “Algorithms” on page 5-1184 perform the changes between the word lengths of each section. When you specify word lengths that do not follow the constraints described in this section, `mfilt.cicinterp` returns an error.

The fraction lengths and scalings of the filter sections do not change. At each section the word length is either staying the same or increasing. The signal scaling can change at the output after the final filter section if you choose the output word length to be less than the word length of the final filter section.

### Properties of the Object

The following table lists the properties for the filter with a description of each.

| Name                | Values   | Default       | Description   |
|---------------------|--|---------------|---|
| Arithmetic          | fixed  | fixed         | Reports the kind of arithmetic the filter uses. CIC interpolators are always fixed-point filters.   |
| InterpolationFactor | Any positive integer   | 2             | Amount to increase the input sampling rate.   |
| DifferentialDelay   | Any positive integer   | 1             | Sets the differential delay for the filter. Usually a value of one or two is appropriate.   |
| FilterStructure     | mfilt structure  | None          | Reports the type of filter object, such as an interpolator or fractional integrator. You cannot set this property — it is always read only and results from your choice of mfilt objects. |
| FilterInternals     | FullPrecision,<br>MinWordLengths,<br>SpecifyWordLengths,<br>SpecifyPrecision | FullPrecision | Set the usage mode for the filter. Refer to “Usage Modes” on page 5-1182 below for details.   |
| InputFracLength     | Any positive integer   | 16            | The number of bits applied as the fraction length to interpret the input data to the filter.  |
| InputWordLength     | Any positive integer   | 16            | The number of bits applied to the word length to interpret the input data to the filter.  |
| NumberOfSections    | Any positive integer   | 2             | Number of sections used in the interpolator. Generally called <i>n</i> . Reflects either the number of interpolator or comb sections, not the total number of sections in the filter.     |
| OutputFracLength    | Any positive integer   | 15            | The number of bits applied to the fraction length to interpret the output data from the filter. Read-only.  |
| OutputWordLength    | Any positive integer   | 16            | The number of bits applied to the word length to interpret the output data from the filter.   |

| Name               | Values   | Default | Description   |
|--------------------|--|---------|---|
| PersistentMemory   | false or true  | false   | <p>Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it.</p> <p>PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. When PersistentMemory is false, you cannot access the filter states. Setting PersistentMemory to true reveals the States property so you can modify the filter states.</p>                                |
| SectionWordLengths | <p>Any integer or a vector of length <math>2^N</math>, where <math>N</math> is a positive integer.</p> <p>This property only applies when the FilterInternals is SpecifyWordLengths.</p> | 16      | <p>Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter SectionWordLengths as a scalar or vector of length <math>2*n</math>, where <math>n</math> is the number of sections. When SectionWordLengths is a scalar, the scalar value is applied to each filter section. When SectionWordLengths is a vector of values, the values apply to the sections in order. The default is 16 for each section in the interpolator. Available when FilterInternals is 'SpecifyWordLengths'.</p> |

| Name   | Values                             | Default  | Description  |
|--------|------------------------------------|--|--|
| States | <code>filtstates.cic</code> object | $m+1$ -by- $n$ matrix of zeros, after you call function <code>int</code> . | Stored conditions for the filter, including values for the integrator and comb sections before and after filtering. $m$ is the differential delay of the comb section and $n$ is the number of sections in the filter. The integrator states are stored in the first matrix row. States for the comb section fill the remaining rows in the matrix. Available for modification when <code>PersistentMemory</code> is true. Refer to the <code>filtstates</code> object in Signal Processing Toolbox documentation for more general information about the <code>filtstates</code> object. |

### Usage Modes

There are usage modes which are set using the `FilterInternals` property:

- **FullPrecision** — In this mode, the word and fraction lengths of the filter sections and outputs are automatically selected for you. The output and last section word lengths are set to:
 
$$\text{wordlength} = \text{ceil}(\log_2((RM)^N/R)) + I,$$
 where  $R$  is the interpolation factor,  $M$  is the differential delay,  $N$  is the number of filter sections, and  $I$  denotes the input word length.
- **MinWordLengths** — In this mode, you specify the word length of the filter output in the `OutputWordLength` property. The word lengths of the filter sections are automatically set in the same way as in the `FullPrecision` mode. The section fraction lengths are set to the input fraction length. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- **SpecifyWordLengths** — In this mode, you specify the word lengths of the filter sections and output in the `SectionWordLengths` and `OutputWordLength` properties. The fraction lengths of the filter sections are set such that the spread between word length and fraction length is the same as in full-precision mode. The output fraction length is set to the input fraction length minus the difference between the last section and output word lengths.
- **SpecifyPrecision** — In this mode, you specify the word and fraction lengths of the filter sections and output in the `SectionWordLengths`, `SectionFracLengths`, `OutputWordLength`, and `OutputFracLength` properties.

### About the States of the Filter

In the `states` property you find the states for both the integrator and comb portions of the filter. `states` is a matrix of dimensions  $m+1$ -by- $n$ , with the states apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.

- States for the comb portion fill the remaining rows in the state matrix.

To review the states of a CIC filter, use the `int` method to assign the states. As an example, here are the states for a CIC interpolator `hm` before and after filtering data:

```
x = fi(cos(pi/4*[0:99]),true,16,0); % Fixed-point input data
hm = mfilt.cicinterp(2,1,2,16,16,16);
% get initial states-all zero
sts=int(hm.states)
set(hm,'InputFracLength',0); % Integer input specified
y=filter(hm,x);
sts=int(hm.states)
%sts =
%
%      -1      -1
%      -1      -1
```

## Design Considerations

When you design your CIC interpolation filter, remember the following general points:

- The filter output spectrum has nulls at  $\omega = k * 2\pi/rm$  radians,  $k = 1,2,3,\dots$
- Aliasing and imaging occur in the vicinity of the nulls.
- $n$ , the number of sections in the filter, determines the passband attenuation. Increasing  $n$  improves the filter ability to reject aliasing and imaging, but it also increases the droop or rolloff in the filter passband. Using an appropriate FIR filter in series after the CIC interpolation filter can help you compensate for the induced droop.
- The DC gain for the filter is a function of the interpolation factor. Raising the interpolation factor increases the DC gain.

## Examples

Demonstrate interpolation by a factor of two, in this case from 22.05 kHz to 44.1 kHz. Note the scaling required to see the results in the stem plot and to use the full range of the `int16` data type.

```
R = 2; % Interpolation factor.
hm = mfilt.cicinterp(R); % Use default NumberOfSections and
% DifferentialDelay property values.
fs = 22.05e3; % Original sample frequency:22.05 kHz.
n = 0:5119; % 5120 samples, .232 second long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.

y_fi = filter(hm,x); % 5120 samples, still 0.232 seconds.

% Scale the output to overlay stem plots correctly.
x = double(x);
y = double(y_fi);
y = y/max(abs(y));
stem(n(1:22)/fs,x(1:22),'filled'); % Plot original signal sampled
% at 22.05 kHz.

hold on;
stem(n(1:44)/(fs*R),y(4:47),'r'); % Plot interpolated signal
% (44.1 kHz) in red.
xlabel('Time (sec)');ylabel('Signal Value');
```

As you expect, the plot shows that the interpolated signal matches the input sine shape, with additional samples between each original sample.

Use the filter visualization tool (FVTool) to plot the response of the interpolator object. For example, to plot the response of an interpolator with an interpolation factor of 7, 4 sections, and 1 differential delay, do something like the following:

```
hm = mfilt.cicinterp(7,1,4)
fvtool(hm)
```

## Algorithms

To show how the CIC interpolation filter is constructed, the following figure presents a block diagram of the filter structure for a two-section CIC interpolation filter ( $n = 2$ ).  $fs$  is the high sampling rate, the output from the interpolation process.

For details about the bits that are removed in the integrator section, refer to [1] in References.

When you select `MinWordLengths`, the filter section word lengths are automatically set to the minimum number of bits possible in a valid CIC interpolator. `mfilt.cicinterp` computes the wordlength for each section so the roundoff noise introduced by all sections is less than the roundoff noise introduced by the quantization at the output.

## Version History

### Introduced in R2011a

**R2022a: mfilt.cicinterp has been removed**

Errors starting in R2022a

mfilt.cicinterp has been removed. Use dsp.CICInterpolator instead.

**Update Code**

This table shows how the mfilt.cicinterp object is typically used and explains how to update existing code to use the dsp.CICInterpolator object.

| Discouraged Usage  | Recommended Replacement   |
|--|---|
| <p>Initialize the object. Set the interpolation factor to 2. ## mfilt.farrowsrc

(Removed) Sample rate converter with arbitrary conversion factor

### Compatibility

`mfilt.farrowsrc` has been removed. Use `dsp.FarrowRateConverter` instead. For more details, see “Compatibility Considerations” on page 5-1188.

### Syntax

```
hm = mfilt.farrowsrc(L,M,C)
hm = mfilt.farrowsrc
hm = mfilt.farrowsrc(l,...)
```

### Description

`hm = mfilt.farrowsrc(L,M,C)` returns a filter object that is a natural extension of `dfilt.farrowfd` with a time-varying fractional delay. It provides a economical implementation of a sample rate converter with an arbitrary conversion factor. This filter works well in the interpolation case, but may exhibit poor anti-aliasing properties in the decimation case.

---

**Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.farrowsrc`.

---

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument | Description   |
|----------------|---|
| <code>l</code> | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. The default value of <code>l</code> is 3. |
| <code>m</code> | Decimation factor for the filter. <code>m</code> specifies the amount to decrease the input sampling rate. The default value for <code>m</code> is 2.   |
| <code>c</code> | Coefficients for the filter. When no input arguments are specified, the default coefficients are <code>[-1 1; 1, 0]</code>                              |

`hm = mfilt.farrowsrc` constructs the filter using the default values for `l`, `m`, and `c`.

`hm = mfilt.farrowsrc(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

### mfilt.farrowsrc Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.farrowsrc` objects. The next table describes each property for an `mfilt.farrowsrc` filter object.

| Name                | Values           | Description  |
|---------------------|------------------|--|
| FilterStructure     | Character vector | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.  |
| Arithmetic          | Character vector | Reports the arithmetic precision used by the filter.   |
| Coefficients        | Vector           | Vector containing the coefficients of the FIR lowpass filter   |
| InterpolationFactor | Integer          | Interpolation factor for the filter. It specifies the amount to increase the input sampling rate.  |
| DecimationFactor    | Integer          | Decimation factor for the filter. It specifies the amount to increase the input sampling rate.   |
| PersistentMemory    | false or true    | Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. |

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```
[L,M] = rat(48/44.1);
Hm = mfilt.farrowsrc(L,M);           % We use the default filter
Fs = 44.1e3;                         % Original sampling frequency
n = 0:9407;                           % 9408 samples, 0.213 seconds long
x = sin(2*pi*1e3/Fs*n);               % Original signal, sinusoid at 1kHz
y = filter(Hm,x);                     % 10241 samples, still 0.213 seconds
stem(n(1:45)/Fs,x(1:45))              % Plot original sampled at 44.1kHz
hold on
% Plot fractionally interpolated signal (48kHz) in red
stem((n(2:50)-1)/(Fs*L/M),y(2:50),'r','filled')
xlabel('Time (sec)');ylabel('Signal value')
legend('44.1 kHz sample rate','48kHz sample rate')
```

The results of the example are shown in the following figure:

## Version History

## mfilt.fftfirinterp

(Removed) Overlap-add FIR polyphase interpolator

---

**Note** `mfilt.fftfirinterp` has been removed. Use `dsp.FIRInterpolator` instead. For more details, see “Compatibility Considerations”.

---

### Syntax

```
hm = mfilt.fftfirinterp(l,num,bl)
hm = mfilt.fftfirinterp
hm = mfilt.fftfirinterp(l,...)
```

### Description

`hm = mfilt.fftfirinterp(l,num,bl)` returns a discrete-time FIR filter object that uses the overlap-add method for filtering input data.

The input arguments are optional. To enter any optional value, you must include all optional values to the left of your desired value.

When you omit one or more input options, the omitted option applies the default values shown in the table below.

The number of FFT points is given by  $[bl + \text{ceil}(\text{length}(\text{num})/l) - 1]$ . It is to your advantage to choose `bl` such that the number of FFT points is a power of two—using powers of two can improve the efficiency of the FFT and the associated interpolation process.

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument   | Description   |
|------------------|---|
| <code>l</code>   | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.   |
| <code>num</code> | Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>fftfirinterp</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/l$ by default. |
| <code>bl</code>  | Length of each block of input data used in the filtering. <code>bl</code> must be an integer. When you omit input <code>bl</code> , it defaults to 100.   |

`hm = mfilt.fftfirinterp` constructs the filter using the default values for `l`, `num`, and `bl`.

`hm = mfilt.fftfirinterp(l,...)` constructs the filter using the input arguments you provide and defaults for the argument you omit.

## mfilt.fffirinterp Object Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.fffirinterp` objects. The next table describes each property for an `mfilt.fffirinterp` filter object.

| Name                | Values        | Description  |
|---------------------|---------------|--|
| FilterStructure     |               | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.  |
| Numerator           |               | Vector containing the coefficients of the FIR lowpass filter used for interpolation.   |
| InterpolationFactor |               | Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer.   |
| BlockLength         |               | Length of each block of input data used in the filtering.  |
| PersistentMemory    | false or true | Determines whether the filter states are restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. |
| States              |               | Stored conditions for the filter, including values for the interpolator states.  |

## Examples

Interpolation by a factor of 8. This object removes the spectral replicas in the signal after interpolation.

```

l = 8; % Interpolation factor
hm = mfilt.fffirinterp(l); % We use the default filter
n = 8192; % Number of points
hm.blocklength = n; % Set block length to number of points
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:n-1; % 0.1858 secs of data
x = sin(2*pi*n*22e3/fs); % Original signal, sinusoid at 22 kHz
y = filter(hm,x); % Interpolated sinusoid
xu = l*upsample(x,8); % Upsample to compare--the spectrum
% does not change
[px,f]=periodogram(xu,[],65536,l*fs); % Power spectrum of original
% signal
[py,f]=periodogram(y,[],65536,l*fs); % Power spectrum of
% interpolated signal
plot(f,10*log10([fs*px,l*fs*py]))
legend('22 kHz sinusoid sampled at 44.1 kHz',...
'22 kHz sinusoid sampled at 352.8 kHz')
xlabel('Frequency (Hz)'); ylabel('Power Spectrum');

```

To see the results of the example, look at this figure.

## Version History

Introduced in R2011a

**R2022a: `mfilt.fftfirminterp` has been removed**

*Errors starting in R2022a*

`mfilt.fftfirminterp` has been removed. Use `dsp.FIRInterpolator` instead.

### Update Code

This table shows how the `mfilt.fftfirminterp` object is typically used and explains how to update existing code to use the `dsp.FIRInterpolator` object.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| <p>Initialize the object. Set the interpolation factor to 8.</p> <pre>L = 8; hm = mfilter.fftfirminterp(L);</pre> <p>Create sinusoidal data and pass the data through the object.</p> <pre>% Number of points n = 8192; % Set block length to number of points hm.blocklength = n; % Original sample rate fs = 44.1e3; % 0.1858 secs of data n = (0:n-1)'; % Original signal, sinusoid at 22 kHz x = sin(2*pi*n*22e3/fs); y_mfilter = filter(hm,x);</pre> | <p>Initialize the object. Set the interpolation factor to 8.</p> <pre>L = 8; firI = dsp.FIRInterpolator(L)</pre> <p>Create sinusoidal data and pass the data through the object.</p> <pre>% Number of points n = 8192; % Original sample rate fs = 44.1e3; % 0.1858 secs of data n = (0:n-1)'; % Original signal, sinusoid at 22 kHz x = sin(2*pi*n*22e3/fs); y = firI(x);</pre> |

## mfilt.firdecim

Direct-form FIR polyphase decimator

---

**Note** `mfilt.firdecim` will be removed in a future release. Use `dsp.FIRDecimator` instead.

---

### Syntax

```
hm = mfilt.firdecim(m)
hm = mfilt.firdecim(m,num)
```

### Description

`hm = mfilt.firdecim(m)` returns a direct-form FIR polyphase decimator object `hm` with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is designed by default. This filter allows some aliasing in the transition band but it very efficient because the first polyphase component is a pure delay.

`hm = mfilt.firdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. This lets you specify more completely the FIR filter to use for the decimator.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter
 

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hm,'arithmetic','fixed');
```

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument   | Description   |
|------------------|---|
| <code>m</code>   | Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> it defaults to 2.  |
| <code>num</code> | Vector containing the coefficients of the FIR lowpass filter used for decimation. When <code>num</code> is not provided as an input, <code>mfilt.firdecim</code> constructs a lowpass Nyquist filter with gain of 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24. |

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firdecim` objects. The next table describes each property for an `mfilt.firdecim` filter object.

| Name             | Values                | Description  |
|------------------|-----------------------|--|
| Arithmetic       | Double, single, fixed | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.   |
| DecimationFactor | Integer               | Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer.  |
| FilterStructure  | Character vector      | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.   |
| InputOffset      | Integers              | Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where <code>nx</code> is the number of input samples that have been processed so far and <code>m</code> is the decimation factor.  |
| Numerator        | Vector                | Vector containing the coefficients of the FIR lowpass filter used for decimation.  |
| PersistentMemory | false, true           | Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties. |

| Name           | Values  | Description  |
|----------------|---|--|
| PolyphaseAccum | 0 in double, single, or fixed for the different filter arithmetic settings. | Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision. |
| States         | Double, single, or fi matching the filter arithmetic setting.               | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. Double is the default setting for floating-point filters in double arithmetic.                       |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the filter. You see one or more of these properties when you set Arithmetic to fixed. Some of the properties have different default values when they refer fixed point filters. One example is the property PolyphaseAccum which stores data as doubles when you use your filter in double-precision mode, but stores a fi object in fixed-point mode.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use `info(hm)` where hm is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

| Name            | Values   | Description  |
|-----------------|--|--|
| AccumFracLength | Any positive or negative integer number of bits [32] | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.   |
| AccumWordLength | Any integer number of bits [39]                      | Sets the word length used to store data in the accumulator.  |
| Arithmetic      | fixed for fixed-point filters                        | Setting this to fixed allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale  | [true], false  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to false enables you to change the NumFracLength property value to specify the precision used. |
| CoeffWordLength | Any integer number of bits [16]                      | Specifies the word length to apply to filter coefficients.   |

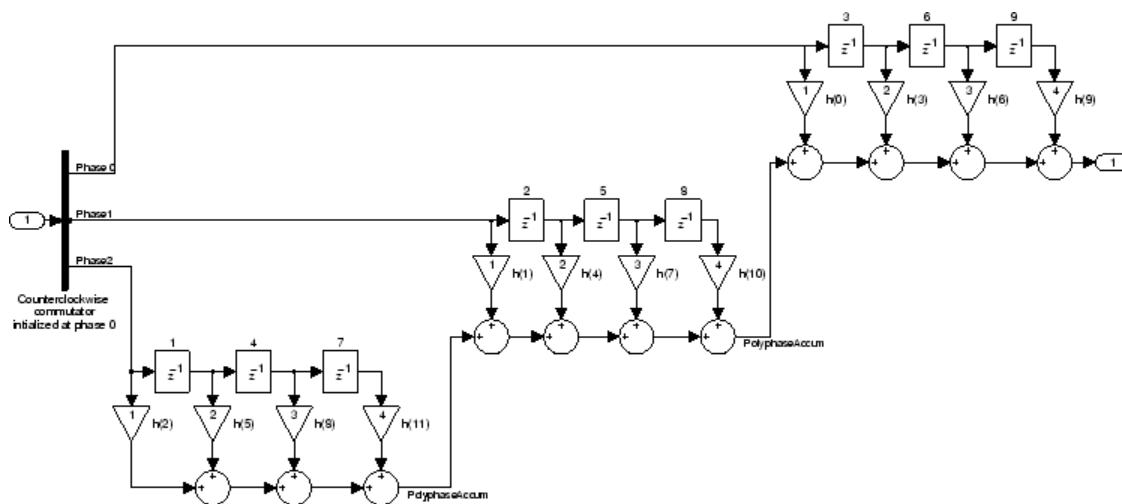

| Name             | Values   | Description  |
|------------------|--|--|
| FilterInternals  | [FullPrecision],<br>SpecifyPrecision                 | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, FullPrecision, sets automatic word and fraction length determination by the filter. SpecifyPrecision makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength  | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength  | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data.   |
| OutputFracLength | Any positive or negative integer number of bits [32] | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.  |
| OutputWordLength | Any integer number of bits [39]                      | Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.   |
| OverflowMode     | saturate, [wrap]                                     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision. |

| Name      | Values   | Description   |
|-----------|--|---|
| RoundMode | [convergent], ceil, fix, floor, nearest, round | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed    | [true], false                                  | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States    | fi object                                      | This property contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.  |

## Filter Structure

To provide decimation, `mfilt.firdecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firdecim`.

Notice the order of the states in the filter flow diagram. States 1 through 9 appear in the diagram above each delay element. State 1 applies to the first delay element in phase 2. State 2 applies to the first delay element in phase 1. State 3 applies to the first delay element in phase 0. State 4 applies to the second delay in phase 2, and so on. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:9];
```

## Examples

Convert an input signal from 44.1 kHz to 22.05 kHz using decimation by a factor of 2. In the figure that appears after the example code, you see the results of the decimation.

```
m = 2; % Decimation factor.
hm = mfilter.firdecim(m); % Use the default filter.
fs = 44.1e3; % Original sample freq: 44.1kHz.
n = 0:10239; % 10240 samples, 0.232 second long
% signal.
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1kHz.
y = filter(hm,x); % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
hold on % Plot decimated signal (22.05 kHz)
% in red.
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')
```

## Version History

# mfilt.firinterp

(Removed) FIR filter-based interpolator

## Compatibility

`mfilt.firinterp` has been removed. Use `dsp.FIRInterpolator` instead. For more details, see “Compatibility Considerations” on page 5-1206.

## Syntax

```
Hm = mfilt.firinterp(L)
Hm = mfilt.firinterp(L,num)
```

## Description

`Hm = mfilt.firinterp(L)` returns a FIR polyphase interpolator object `Hm` with an interpolation factor of `L` and gain equal to `L`. `L` defaults to 2 if unspecified.

`Hm = mfilt.firinterp(L,num)` uses the values in the vector `num` as the coefficients of the interpolation filter.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `Hm` as follows:

- To change to single-precision filtering, enter
 

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument   | Description  |
|------------------|--|
| <code>l</code>   | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2.  |
| <code>num</code> | Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>firinterp</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/l$ by default. The default length for the Nyquist filter is $24 \cdot l$ . Therefore, each polyphase filter component has length 24. |

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firinterp` objects. The next table describes each property for an `mfilt.firinterp` filter object.

| Name                | Values  | Description   |
|---------------------|---|---|
| Arithmetic          | Double, single, fixed                                   | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.  |
| FilterStructure     | Character vector  | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.  |
| InterpolationFactor | Integer   | Interpolation factor for the filter. <code>1</code> specifies the amount to increase the sampling rate of the input signal. It must be an integer.  |
| Numerator           | Vector  | Vector containing the coefficients of the FIR lowpass filter used for decimation.   |
| PersistentMemory    | [false], true   | Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> property. |
| States              | Double, single, matching the filter arithmetic setting. | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.   |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firinterp` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

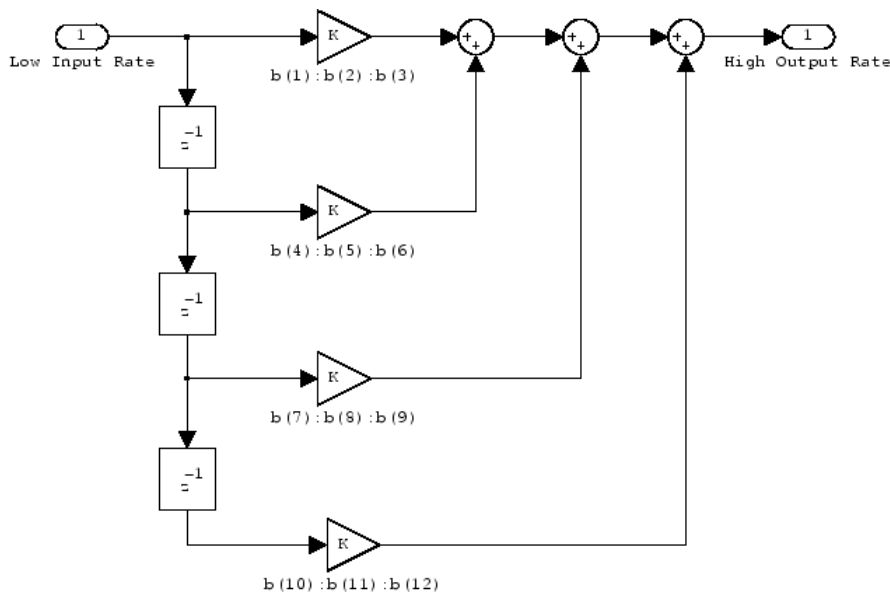

| Name             | Values  | Description   |
|------------------|---|---|
| AccumFracLength  | Any positive or negative integer number of bits. [32] | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.  |
| AccumWordLength  | Any integer number of bits [39]                       | Sets the word length used to store data in the accumulator.   |
| Arithmetic       | fixed for fixed-point filters                         | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale   | [true], false   | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.  |
| CoeffWordLength  | Any integer number of bits [16]                       | Specifies the word length to apply to filter coefficients.  |
| FilterInternals  | [FullPrecision], SpecifyPrecision                     | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength  | Any positive or negative integer number of bits [15]  | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength  | Any integer number of bits [16]                       | Specifies the word length applied to interpret input data.  |
| NumFracLength    | Any positive or negative integer number of bits [14]  | Sets the fraction length used to interpret the numerator coefficients.  |
| OutputFracLength | Any positive or negative integer number of bits [32]  | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |
| OutputWordLength | Any integer number of bits [39]                       | Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |

| Name         | Values  | Description   |
|--------------|---|---|
| OverflowMode | saturate, [wrap]                                  | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <b>saturate</b> (limit the output to the largest positive or negative representable value) or <b>wrap</b> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.  |
| RoundMode    | [convergent], ceil, fix, floor, nearest, round    | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> <li>• <b>floor</b> - Round toward negative infinity.</li> <li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed       | [true], false                                     | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States       | fi object to match the filter arithmetic setting. | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <b>fi</b> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation.   |

## Filter Structure

To provide interpolation, `mfilt.firinterp` uses the following structure.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firinterp`. In the figure, the delay line updates happen at the lower input rate. The remainder of the filter — the sums and coefficients — operate at the higher output rate.

## Examples

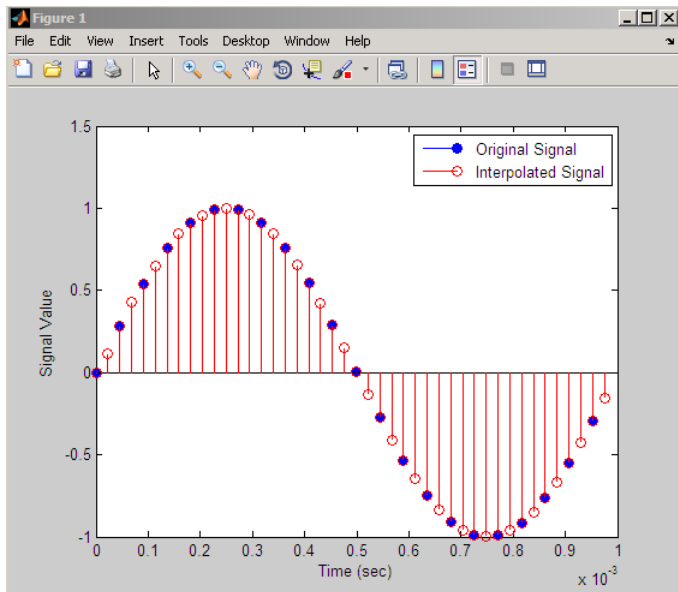

This example uses `mfilt.firinterp` to double the sample rate of a 22.05 kHz input signal. The output signal ends up at 44.1 kHz. Although `l` is set explicitly to 2, this represents the default interpolation value for `mfilt.firinterp` objects.

```
L = 2; % Interpolation factor.
Hm = mfilt.firinterp(L); % Use the default filter.
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232s long signal.
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz.
y = filter(Hm,x); % 10240 samples, still 0.232s.
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz.

hold on;

% Plot interpolated signal (44.1 kHz) in red
stem(n(1:44)/(fs*L),y(25:68),'r')
xlabel('Time (sec)');ylabel('Signal Value')
legend('Original Signal','Interpolated Signal');
```

With interpolation by 2, the resulting signal perfectly matches the original, but with twice as many samples — one between each original sample, as shown in the following figure.

## Version History

Introduced in R2011a

**R2022a: `mfilt.firinterp` has been removed**

*Errors starting in R2022a*

`mfilt.firinterp` has been removed. Use `dsp.FIRInterpolator` instead.

### Update Code

This table shows how the `mfilt.firinterp` object is typically used and explains how to update existing code to use the `dsp.FIRInterpolator` object.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| Initialize the object. Set the interpolation factor to 8. <pre>L = 8; hm = mfilt.firinterp(L);</pre>  | Initialize the object. Set the interpolation factor to 8. <pre>L = 8; firI = dsp.FIRInterpolator(L)</pre>  |
| Create sinusoidal data and pass the data through the object. <pre>% Original sample rate is 22.05 kHz. fs = 22.05e3; % 5120 samples, 0.232s long signal. n = (0:5119)'; x = sin(2*pi*1e3/fs*n); y_mfilt = filter(hm,x);</pre> | Create sinusoidal data and pass the data through the object. <pre>% Original sample rate is 22.05 kHz. fs = 22.05e3; % 5120 samples, 0.232s long signal. n = (0:5119)'; x = sin(2*pi*1e3/fs*n); y = firI(x);</pre> |

`dsp.FIRInterpolator`

## mfilt.firsrc

Direct-form FIR polyphase sample rate converter

---

**Note** `mfilt.firsrc` will be removed in a future release. Use `dsp.FIRRateConverter` instead.

---

### Syntax

```
hm = mfilt.firsrc(l,m,num)
```

### Description

`hm = mfilt.firsrc(l,m,num)` returns a direct-form FIR polyphase sample rate converter. `l` specifies the interpolation factor. It must be an integer and when omitted in the calling syntax, it defaults to 2.

`m` is the decimation factor. It must be an integer. If not specified, `m` defaults to 1. If `l` is also not specified, `m` defaults to 3 and the overall rate change factor is 2/3.

You specify the coefficients of the FIR lowpass filter used for sample rate conversion in `num`. If omitted, a lowpass Nyquist filter with gain `l` and cutoff frequency of  $\pi/\max(l,m)$  is the default.

Combining an interpolation factor and a decimation factor lets you use `mfilt.firsrc` to perform fractional interpolation or decimation on an input signal. Using an `mfilt.firsrc` object applies a rate change factor defined by  $l/m$  to the input signal. For proper rate changing to occur, `l` and `m` must be relatively prime — meaning the ratio  $l/m$  cannot be reduced to a ratio of smaller integers.

When you are doing sample-rate conversion with large values of `l` or `m`, such as `l` or `m` greater than 20, using the `mfilt.firsrc` structure is the most effective approach.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter

```
set(hm,'arithmetic','fixed');
```

---

**Note** You can use the `realizemdl` method to create a Simulink block of a filter created using `mfilt.firsrc`.

---

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument   | Description   |
|------------------|---|
| <code>l</code>   | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> , it defaults to 2.   |
| <code>num</code> | Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>mfilt.firsrc</code> uses a lowpass Nyquist filter with gain equal to <code>l</code> and cutoff frequency equal to $\pi/\max(l, m)$ by default. The default length for the Nyquist filter is $24*\max(1, m)$ . Therefore, each polyphase filter component has length 24. |
| <code>m</code>   | Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> , it defaults to 1. When <code>l</code> is unspecified as well, <code>m</code> defaults to 3.  |

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firsrc` objects. The next table describes each property for an `mfilt.firsrc` filter object.

| Name             | Values                  | Description  |
|------------------|-------------------------|--|
| Arithmetic       | [Double], single, fixed | Defines the arithmetic the filter uses. Gives you the options <code>double</code> , <code>single</code> , and <code>fixed</code> . In short, this property defines the operation mode for your filter.   |
| FilterStructure  | Character vector        | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Describes the signal flow for the filter object.   |
| InputOffset      | Integers                | Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where <code>nx</code> is the number of input samples and <code>m</code> is the decimation factor.  |
| Numerator        | Vector                  | Vector containing the coefficients of the FIR lowpass filter used for decimation.  |
| PersistentMemory | false, true             | Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties. |

| Name              | Values  | Description  |
|-------------------|---|--|
| RateChangeFactors | Positive integers. [2 3]                                | Specifies the interpolation and decimation factors [l m] (the rate change factors ) for changing the input sample rate by nonintegral amounts. |
| States            | Double, single, matching the filter arithmetic setting. | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.        |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firsrc` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

`info(hm)`

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

| Name            | Values  | Description  |
|-----------------|---|--|
| AccumFracLength | Any positive or negative integer number of bits. [32] | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters.   |
| AccumWordLength | Any integer number of bits [39]                       | Sets the word length used to store data in the accumulator.  |
| Arithmetic      | fixed for fixed-point filters                         | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.  |
| CoeffAutoScale  | [true], false   | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used. |
| CoeffWordLength | Any integer number of bits [16]                       | Specifies the word length to apply to filter coefficients.   |

| Name              | Values   | Description   |
|-------------------|--|---|
| FilterInternals   | [FullPrecision],<br>SpecifyPrecision                 | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength   | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength   | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data.  |
| NumFracLength     | Any positive or negative integer number of bits [14] | Sets the fraction length used to interpret the numerator coefficients.  |
| OutputFracLength  | Any positive or negative integer number of bits [32] | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |
| OutputWordLength  | Any integer number of bits [39]                      | Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |
| OverflowMode      | saturate, [wrap]                                     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.  |
| RateChangeFactors | Positive integers [2 3]                              | Specifies the interpolation and decimation factors [l m] (the rate change factors) for changing the input sample rate by nonintegral amounts.   |

| Name      | Values   | Description   |
|-----------|--|---|
| RoundMode | [convergent], ceil, fix, floor, nearest, round | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <b>ceil</b> - Round toward positive infinity.</li> <li>• <b>convergent</b> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <b>fix</b> - Round toward zero.</li> <li>• <b>floor</b> - Round toward negative infinity.</li> <li>• <b>nearest</b> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <b>round</b> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed    | [true], false                                  | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States    | fi object                                      | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section.  |

## Examples

This is an example of a common audio rate change process — changing the sample rate of a high end audio (48 kHz) signal to the compact disc sample rate (44.1 kHz). This conversion requires a rate change factor of 0.91875, or  $l = 147$  and  $m = 160$ .

```

l = 147; m = 160;           % Interpolation/decimation factors.
hm = mfilt.firsrc(l,m);    % Use the default FIR filter.
fs = 48e3;                 % Original sample freq: 48 kHz.
n = 0:10239;               % 10240 samples, 0.213 seconds long.
x = sin(2*pi*1e3/fs*n);    % Original signal, sinusoid at 1 kHz.
y = filter(hm,x);          % 9408 samples, still 0.213 seconds.
stem(n(1:49)/fs,x(1:49))  % Plot original sampled at 48 kHz.
hold on

% Plot fractionally decimated signal (44.1 kHz) in red
stem(n(1:45)/(fs*l/m),y(13:57),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value')

```

Fractional decimation provides you the flexibility to pick and choose the sample rates you want by carefully selecting  $l$  and  $m$ , the interpolation and decimation factors, that result in the final fractional decimation. The following figure shows the signal after applying the rate change filter `hm` to the original signal.

## Version History

Introduced in R2011a

## mfilt.firtdecim

Direct-form transposed FIR filter

---

**Note** `mfilt.firtdecim` will be removed in a future release. Use `dsp.FIRDecimator` instead.

---

### Syntax

```
hm = mfilt.firtdecim(m)
hm = mfilt.firtdecim(m,num)
```

### Description

`hm = mfilt.firtdecim(m)` returns a polyphase decimator `mfilt` object `hm` based on a direct-form transposed FIR structure with a decimation factor of  $m$ . A lowpass Nyquist filter of gain 1 and cutoff frequency of  $\pi/m$  is the default.

`hm = mfilt.firtdecim(m,num)` uses the coefficients specified by `num` for the decimation filter. `num` is a vector containing the coefficients of the transposed FIR lowpass filter used for decimation. If omitted, a lowpass Nyquist filter with gain of 1 and cutoff frequency of  $\pi/m$  is the default.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter
 

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hm,'arithmetic','fixed');
```

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument   | Description   |
|------------------|---|
| <code>num</code> | Vector containing the coefficients of the FIR lowpass filter used for interpolation. When <code>num</code> is not provided as an input, <code>firtdecim</code> uses a lowpass Nyquist filter with gain equal to 1 and cutoff frequency equal to $\pi/m$ by default. The default length for the Nyquist filter is $24*m$ . Therefore, each polyphase filter component has length 24. |
| <code>m</code>   | Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer. When you do not specify a value for <code>m</code> it defaults to 2.  |

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.firtdecim` objects. The next table describes each property for an `mfilt.firtdecim` filter object.

| Name             | Values   | Description  |
|------------------|--|--|
| Arithmetic       | Double, single, fixed                                  | Specifies the arithmetic the filter uses to process data while filtering.  |
| DecimationFactor | Integer  | Decimation factor for the filter. <code>m</code> specifies the amount to reduce the sampling rate of the input signal. It must be an integer.  |
| FilterStructure  | Character vector                                       | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object. Also describes the signal flow for the filter object.  |
| InputOffset      | Integers   | Contains a value derived from the number of input samples and the decimation factor — $\text{InputOffset} = \text{mod}(\text{length}(nx), m)$ where <code>nx</code> is the number of input samples that have been processed so far and <code>m</code> is the decimation factor.  |
| Numerator        | Vector   | Vector containing the coefficients of the FIR lowpass filter used for decimation.  |
| PersistentMemory | [false], true  | Determines whether the filter states get restored to zeros for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. <code>PersistentMemory</code> set to <code>false</code> returns filter states to the default values after filtering. States that the filter does not change are not affected. Setting this to <code>true</code> allows you to modify the <code>States</code> , <code>InputOffset</code> , and <code>PolyphaseAccum</code> properties. |
| PolyphaseAccum   | Double, single [0]                                     | The idea behind having both <code>PolyphaseAccum</code> and <code>Accum</code> is to differentiate between the adders in the filter that work in full precision at all times ( <code>PolyphaseAccum</code> ) from the adders in the filter that the user controls and that may introduce quantization effects when <code>FilterInternals</code> is set to <code>SpecifyPrecision</code> .  |
| States           | Double, single matching the filter arithmetic setting. | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions.  |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.firtdecim` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

| Name            | Values  | Description   |
|-----------------|---|---|
| AccumFracLength | Any positive or negative integer number of bits. [32] | Specifies the fraction length used to interpret data output by the accumulator. This is a property of FIR filters and lattice filters. IIR filters have two similar properties — <code>DenAccumFracLength</code> and <code>NumAccumFracLength</code> — that let you set the precision for numerator and denominator operations separately.  |
| AccumWordLength | Any integer number of bits [39]                       | Sets the word length used to store data in the accumulator.   |
| Arithmetic      | fixed for fixed-point filters                         | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale  | [true], false   | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.  |
| CoeffWordLength | Any integer number of bits [16]                       | Specifies the word length to apply to filter coefficients.  |
| FilterInternals | [FullPrecision], SpecifyPrecision                     | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength | Any positive or negative integer number of bits [15]  | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength | Any integer number of bits [16]                       | Specifies the word length applied to interpret input data.  |

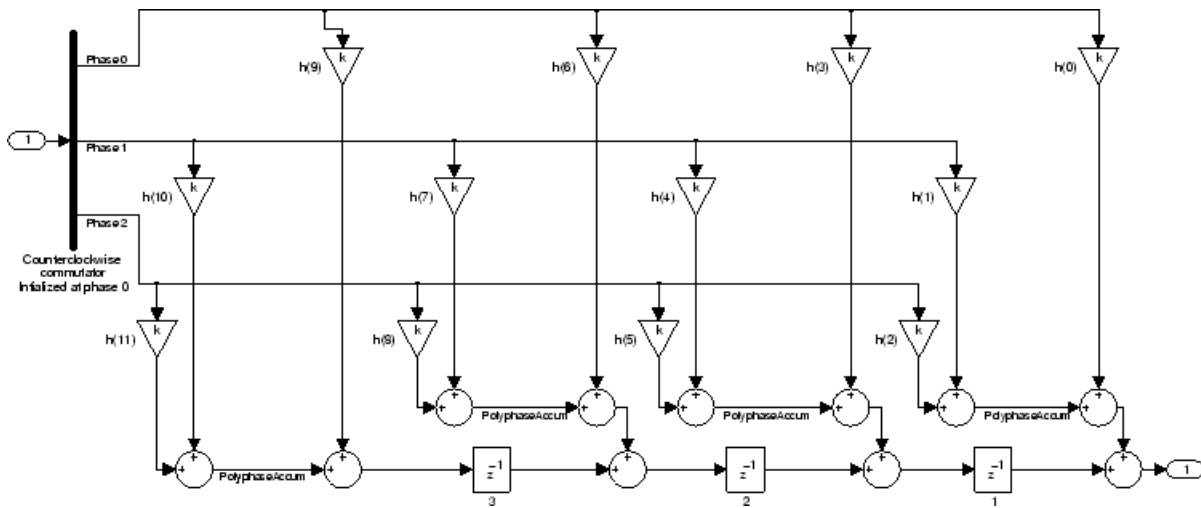

| Name             | Values   | Description   |
|------------------|--|---|
| NumFracLength    | Any positive or negative integer number of bits [14] | Sets the fraction length used to interpret the numerator coefficients.  |
| OutputFracLength | Any positive or negative integer number of bits [32] | Determines how the filter interprets the filter output data. You can change the value of OutputFracLength when you set FilterInternals to SpecifyPrecision.   |
| OutputWordLength | Any integer number of bits [39]                      | Determines the word length used for the output data. You make this property editable by setting FilterInternals to SpecifyPrecision.  |
| OverflowMode     | saturate, [wrap]                                     | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.  |
| PolyphaseAccum   | fi object with zeros to start                        | Differentiates between the adders in the filter that work in full precision at all times (PolyphaseAccum) and the adders in the filter that the user controls and that may introduce quantization effects when FilterInternals is set to SpecifyPrecision.  |
| RoundMode        | [convergent],<br>ceil, fix, floor,<br>nearest, round | <p>Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths).</p> <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |

| Name   | Values        | Description   |
|--------|---------------|---|
| Signed | [true], false | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.   |
| States | fi object     | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use fi objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure section. |

### Filter Structure

To provide sample rate changes, `mfilt.firtddecim` uses the following structure. At the input you see a commutator that operates counterclockwise, moving from position 0 to position 2, position 1, and back to position 0 as input samples enter the filter. To keep track of the position of the commutator, the `mfilt` object uses the property `InputOffset` which reports the current position of the commutator in the filter.

The following figure details the signal flow for the direct form FIR filter implemented by `mfilt.firtddecim`.

Notice the order of the states in the filter flow diagram. States 1 through 3 appear in the following diagram at each delay element. State 1 applies to the third delay element in phase 2. State 2 applies to the second delay element in phase 2. State 3 applies to the first delay element in phase 2. When you provide the states for the filter as a vector to the `States` property, the above description explains how the filter assigns the states you specify.

In property value form, the states for a filter `hm` are

```
hm.states=[1:3];
```

## Examples

Demonstrate decimating an input signal by a factor of 2, in this case converting from 44.1 kHz down to 22.05 kHz. In the figure shown following the code, you see the results of decimating the signal.

```
m = 2; % Decimation factor.
hm = mfilter.firtdecim(m); % Use the default filter coeffs.
fs = 44.1e3; % Original sample freq: 44.1 kHz.
n = 0:10239; % 10240 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal--sinusoid at 1 kHz.
y = filter(hm,x); % 5120 samples, 0.232 seconds.
stem(n(1:44)/fs,x(1:44)) % Plot original sampled at 44.1 kHz.
axis([0 0.001 -1.2 1.2]);
hold on % Plot decimated signal (22.05 kHz) in red
stem(n(1:22)/(fs/m),y(13:34),'r','filled')
xlabel('Time (sec)');ylabel('Signal Value');
legend('Original signal','Decimated signal','location','best');
```

## Version History

Introduced in R2011a

## mfilt.holdinterp

(Removed) FIR hold interpolator

---

**Note** `mfilt.holdinterp` has been removed. Use `dsp.FIRInterpolator(L,'ZOH')` instead. For more details, see “Compatibility Considerations”.

---

### Syntax

```
hm = mfilt.holdinterp(l)
```

### Description

`hm = mfilt.holdinterp(l)` returns the object `hm` that represents a hold interpolator with the interpolation factor `l`. To work, `l` must be an integer. When you do not include `l` in the calling syntax, it defaults to 2. To perform interpolation by noninteger amounts, use one of the fractional interpolator objects, such as `mfilt.firsrc`.

When you use this hold interpolator, each sample added to the input signal between existing samples has the value of the most recent sample from the original signal. Thus you see something like a staircase profile where the interpolated samples form a plateau between the previous and next original samples. The example demonstrates this profile clearly. Compare this to the interpolation process for other interpolators in the toolbox, such as `mfilt.linearinterp`.

Make this filter a fixed-point or single-precision filter by changing the value of the `Arithmetic` property for the filter `hm` as follows:

- To change to single-precision filtering, enter
 

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hm,'arithmetic','fixed');
```

### Input Arguments

The following table describes the input arguments for creating `hm`.

| Input Argument | Description   |
|----------------|---|
| <code>l</code> | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2. |

### Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.holdinterp` objects. The next table describes each property for an `mfilt.interp` filter object.

| Name                | Values                 | Description   |
|---------------------|------------------------|---|
| Arithmetic          | Double, single, fixed  | Specifies the arithmetic the filter uses to process data while filtering.   |
| FilterStructure     | Character vector       | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.   |
| InterpolationFactor | Integer                | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.  |
| PersistentMemory    | 'false' or 'true'      | Determines whether the filter states are restored to zero for each filtering operation.   |
| States              | Double or single array | Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates</code> ( <code>hm</code> ). Always available, but visible in the display only when <code>PersistentMemory</code> is true. |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

---

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

---

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

| Name       | Values                | Description   |
|------------|-----------------------|---|
| Arithmetic | Double, single, fixed | Specifies the arithmetic the filter uses to process data while filtering. |

| Name                | Values   | Description  |
|---------------------|--|--|
| FilterStructure     | Character vector                                     | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.  |
| InputFracLength     | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data.   |
| InputWordLength     | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data.   |
| InterpolationFactor | Integer  | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.   |
| PersistentMemory    | 'false' or 'true'                                    | Determine whether the filter states get restored to zero for each filtering operation  |
| States              | <code>fi</code> object                               | Contains the filter states before, during, and after filter operations. For hold interpolators, the states are always empty — hold interpolators do not have states. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. |

## Filter Structure

Hold interpolators do not have filter coefficients and their filter structure is trivial.

## Examples

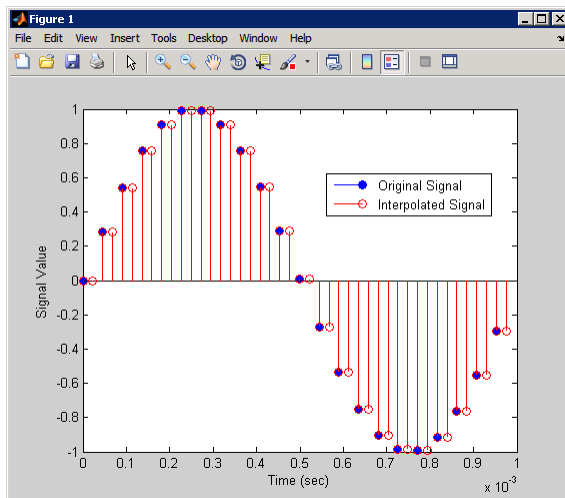

To see the effects of hold-based interpolation, interpolate an input sine wave from 22.05 to 44.1 kHz. Note that each added sample retains the value of the most recent original sample.

```

l = 2; % Interpolation factor
hm = mfilt.holdinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz
hold on % Plot interpolated signal (44.1 kHz)
stem(n(1:44)/(fs*l),y(1:44),'r')
legend('Original Signal','Interpolated Signal','Location','best');
xlabel('Time (sec)');ylabel('Signal Value')

```

The following figure shows clearly the step nature of the signal that comes from interpolating the signal using the hold algorithm approach. Compare the output to the linear interpolation used in `mfilt.linearinterp`.

`dsp.FIRInterpolator`

## mfilt.iirdecim

IIR decimator

### Compatibility

---

**Note** `mfilt.iirdecim` will be removed in a future release. Use `dsp.IIRHalfbandDecimator` instead.

---

### Syntax

```
hm = mfilt.iirdecim(c1,c2,...)
```

### Description

`hm = mfilt.iirdecim(c1,c2,...)` constructs an IIR decimator filter given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The resulting IIR decimator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR decimators.

Although the first example shows how to construct an IIR decimators explicitly, one usually constructs an IIR decimators filter as a result of designing an decimators, as shown in the subsequent examples.

### Examples

When the coefficients are known, you can construct the IIR decimator directly using `mfilt.iirdecim`. For example, if the filter's coefficients are [0.6 0.5] for the first phase in the first stage, 0.7 for the second phase in the first stage and 0.8 for the third phase in the first stage; as well as 0.5 for the first phase in the second stage and 0.4 for the second phase in the second stage, construct the filter as shown here.

```
Hm = mfilt.iirdecim({[0.6 0.5] 0.7 0.8},{0.5 0.4})
```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of the “IIR Polyphase Filter Design” example, “IIR Halfband Stages in Multistage Filter Design” example.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband decimator with a decimation factor of 2. The example specifies the optional sampling frequency argument.

```

tw = 100; % Transition width of filter.
ast = 80; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of signal to filter.
m = 2; % Decimation factor.
hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);

```

hm contains the specifications for a decimator defined by tw, ast, m, and fs.

Use the specification object hm to design a `mfilt.iirdecim` filter object.

```

d = design(hm,'ellip','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d) % Build model of the filter.

```

Designing a linear phase decimator is similar to the previous example. In this case, design a halfband linear phase decimator with decimation factor of 2.

```

tw = 100; % Transition width of filter.
ast = 60; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of signal to filter.
m = 2; % Decimation factor.

```

Create a specification object for the decimator.

```

hm = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);

```

Finally, design the filter d.

```

d = design(hm,'iirlinphase','filterstructure','iirdecim');
% Note that realizemdl requires Simulink
realizemdl(d) % Build model of the filter.

```

The filter implementation appears in this model, generated by `realizemdl` and Simulink.

Given the design specifications shown here

the first phase is a delay section with 0s and a 1 for coefficients and the second phase is a linear phase decimator, shown in the next models.

## mfilt.iirinterp

(Removed) IIR interpolator

### Compatibility

---

**Note** `mfilt.iirinterp` has been removed. Use `dsp.IIRHalfbandInterpolator` instead. For more details, see “Compatibility Considerations” on page 5-1230.

---

### Syntax

```
hm = mfilt.iirinterp(c1,c2,...)
```

### Description

`hm = mfilt.iirinterp(c1,c2,...)` constructs an IIR interpolator filter given the coefficients specified in the cell arrays `C1`, `C2`, etc.

The IIR interpolator is a polyphase IIR filter where each phase is a cascade allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadeallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirdecim` interprets them same way as `mfilt.cascadeallpass`.

The following exception applies to interpreting the contents of a cell array—if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and a unique element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadeallpass` section. This exception case occurs with quasi-linear phase IIR interpolators.

Although the first example shows how to construct an IIR interpolator explicitly, one usually constructs an IIR interpolator filter as a result of designing an interpolator, as shown in the subsequent examples.

### Examples

When the coefficients are known, you can construct the IIR interpolator directly using `mfilt.iirinterp`. In the following example, a cascaded polyphase IIR interpolator filter is constructed using 2 phases for each of three stages. The coefficients are given below:

```
Phase1Sect1=0.0603;Phase1Sect2=0.4126; Phase1Sect3=0.7727;
Phase2Sect1=0.2160; Phase2Sect2=0.6044; Phase2Sect3=0.9239;
```

Next the filter is implemented by passing the above coefficients to `mfilt.iirinterp` as cell arrays, where each cell array represents a different phase.

```
Hm = mfilt.iirinterp({Phase1Sect1,Phase1Sect2,Phase1Sect3},...
{Phase2Sect1,Phase2Sect2,Phase2Sect3})
```

```

Hm =
    FilterStructure: 'IIR Polyphase Interpolator'
    Polyphase: Phase1: Section1: 0.0603
                Section2: 0.4126
                Section3: 0.7727
                Phase2: Section1: 0.216
                    Section2: 0.6044
                    Section3: 0.9239
    InterpolationFactor: 2
    PersistentMemory: false

```

Also refer to the “Quasi-Linear Phase Halfband and Dyadic Halfband Designs” section of “IIR Halfband Stages in Multistage Filter Design”.

When the coefficients are not known, use the approach given by the following set of examples. Start by designing an elliptic halfband interpolator with a interpolation factor of 2.

```

tw = 100; % Transition width of filter.
ast = 80; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);

```

Specification object `d` stores the interpolator design specifics. With the details in `d`, design the filter, returning `hm`, an `mfilt.iirinterp` object. Use `hm` to realize the filter if you have Simulink installed.

```

hm = design(d,'ellip','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.

```

Designing a linear phase halfband interpolator follows the same pattern.

```

tw = 100; % Transition width of filter.
ast= 60; % Stopband attenuation of filter.
fs = 2000; % Sampling frequency of filter.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);

```

`fdesign.interpolator` returns a specification object that stores the design features for an interpolator.

Now perform the actual design that results in an `mfilt.iirinterp` filter, `hm`.

```

hm = design(d,'iirlinphase','filterstructure','iirinterp');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.

```

The toolbox creates a Simulink model for `hm`, shown here. `Phase1`, `Phase2`, and `InterpCommutator` are all subsystem blocks.

`dsp.IIRHalfbandInterpolator`

## mfilt.iirwdfdecim

IIR wave digital filter decimator

---

**Note** `mfilt.iirwdfdecim` will be removed in a future release. Use `dsp.IIRHalfbandDecimator` instead.

---

### Syntax

```
hm = mfilt.iirwdfdecim(c1,c2,...)
```

### Description

`hm = mfilt.iirwdfdecim(c1,c2,...)` constructs an IIR wave digital decimator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR decimator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfdecim` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR decimators.

Usually you do not construct IIR wave digital filter decimators explicitly. Instead, you obtain an IIR wave digital filter decimator as a result of designing a halfband decimator. The first example in the following section illustrates this case.

### Examples

Design an elliptic halfband decimator with a decimation factor equal to 2. Both examples use the `iirwdfdecim` filter structure (an input argument to the `design` method) to design the final decimator.

The first portion of this example generates a filter specification object `d` that stores the specifications for the decimator.

```
tw = 100; % Transition width of filter to design, 100 Hz.  
ast = 80; % Stopband attenuation of filter 80 dB.  
fs = 2000; % Sampling frequency of the input signal.  
m = 2; % Decimation factor.  
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design using `d`. Filter object `hm` is an `mfilt.iirwdfdecim` filter.

```
Hm = design(d,'ellip','FilterStructure','iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

Design a linear phase halfband decimator for decimating a signal by a factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 60; % Filter stopband attenuation = 80 dB
fs = 2000; % Input signal sampling frequency.
m = 2; % Decimation factor.
d = fdesign.decimator(m,'halfband','tw,ast',tw,ast,fs);
```

Use d to design the final filter hm, an `mfilt.iirwdfdecim` object.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfdecim');
% Note that realizemdl requires Simulink
realizemdl(hm) % Build model of the filter.
```

The models that `realizemdl` returns for each example appear below. At this level, the realizations of the filters are identical. The differences appear in the subsystem blocks Phase1 and Phase2.

This is the Phase1 subsystem from the halfband model.

Phase1 subsystem from the linear phase model is less revealing—an allpass filter.

# mfilt.iirwdfinterp

IIR wave digital filter interpolator

---

**Note** `mfilt.iirwdfinterp` will be removed in a future release. Use `dsp.IIRHalfbandInterpolator` instead.

---

## Syntax

```
hm = mfilt.iirwdfinterp(c1,c2,...)
```

## Description

`hm = mfilt.iirwdfinterp(c1,c2,...)` constructs an IIR wave digital interpolator given the coefficients specified in the cell arrays `c1`, `c2`, and so on. The IIR interpolator `hm` is a polyphase IIR filter where each phase is a cascade wave digital allpass IIR filter.

Each cell array `ci` contains a set of vectors representing a cascade of allpass sections. Each element in one cell array is one section. For more information about the contents of each cell array, refer to `dfilt.cascadewdfallpass`. The contents of the cell arrays are the same for both filter constructors and `mfilt.iirwdfinterp` interprets them same way as `mfilt.cascadewdfallpass`.

The following exception applies to interpreting the contents of a cell array — if one of the cell arrays `ci` contains only one vector, and that vector comprises a series of 0s and one element equal to 1, that cell array represents a `dfilt.delay` section with latency equal to the number of zeros, rather than a `dfilt.cascadewdfallpass` section. This exception occurs with quasi-linear phase IIR interpolators.

Usually you do not construct IIR wave digital filter interpolators explicitly. Rather, you obtain an IIR wave digital interpolator as a result of designing a halfband interpolator. The first example in the following section illustrates this case.

## Examples

Design an elliptic halfband interpolator with interpolation factor equal to 2. At the end of the design process, `hm` is an IIR wave digital filter interpolator.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency after interpolation.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

The specification object `d` stores the interpolator design requirements. Now use `d` to design the actual filter `hm`.

```
hm = design(d,'ellip','filterstructure','iirwdfinterp');
```

If you have Simulink installed, you can realize your filter as a model built from DSP System Toolbox blocks.

```
% Note that realizemdl requires Simulink
realizemdl(hm)      % Build model of the filter.
```

For variety, design a linear phase halfband interpolator with an interpolation factor of 2.

```
tw = 100; % Transition width of filter, 100 Hz.
ast = 80; % Stopband attenuation of filter, 80 dB.
fs = 2000; % Sampling frequency after interpolation.
l = 2; % Interpolation factor.
d = fdesign.interpolator(l,'halfband','tw,ast',tw,ast,fs);
```

Now perform the actual design process with `d`. Filter `hm` is an IIR wave digital filter interpolator. As in the previous example, `realizemdl` returns a Simulink model of the filter if you have Simulink installed.

```
hm = design(d,'iirlinphase','filterstructure',...
'iirwdfinterp');
% Note that realizemdl requires Simulink
realizemdl(hm)      % Build model of the filter.
```

## Version History

`mfilt.iirinterp` | `mfilt.iirwdfdecim`

# mfilt.linearinterp

(Removed) Linear interpolator

---

**Note** `mfilt.linearinterp` has been removed. Use `dsp.FIRInterpolator(L,'Linear')` instead. For more details, see “Compatibility Considerations”.

---

## Syntax

```
hm = mfilt.linearinterp(l)
```

## Description

`hm = mfilt.linearinterp(l)` returns an FIR linear interpolator `hm` with an integer interpolation factor `l`. Provide `l` as a positive integer. The default value for the interpolation factor is 2 when you do not include the input argument `l`.

When you use this linear interpolator, the samples added to the input signal have values between the values of adjacent samples in the original signal. Thus you see something like a smooth profile where the interpolated samples continue a line between the previous and next original samples. The example demonstrates this smooth profile clearly. Compare this to the interpolation process for `mfilt.holdinterp`, which creates a staircase profile.

Make this filter a fixed-point or single-precision filter by changing the value of the **Arithmetic** property for the filter `hm` as follows:

- To change to single-precision filtering, enter
 

```
set(hm,'arithmetic','single');
```
- To change to fixed-point filtering, enter
 

```
set(hm,'arithmetic','fixed');
```

## Input Arguments

The following table describes the input argument for `mfilt.linearinterp`.

| Input Argument | Description   |
|----------------|---|
| <code>l</code> | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer. When you do not specify a value for <code>l</code> it defaults to 2. |

## Object Properties

This section describes the properties for both floating-point filters (double-precision and single-precision) and fixed-point filters.

### Floating-Point Filter Properties

Every multirate filter object has properties that govern the way it behaves when you use it. Note that many of the properties are also input arguments for creating `mfilt.linearinterp` objects. The next table describes each property for an `mfilt.linearinterp` filter object.

| Name                | Values                 | Description  |
|---------------------|------------------------|--|
| Arithmetic          | Double, single, fixed  | Specifies the arithmetic the filter uses to process data while filtering.  |
| FilterStructure     | Character vector       | Reports the type of filter object. You cannot set this property — it is always read only and results from your choice of <code>mfilt</code> object.  |
| InterpolationFactor | Integer                | Interpolation factor for the filter. <code>l</code> specifies the amount to increase the input sampling rate. It must be an integer.   |
| PersistentMemory    | 'false' or 'true'      | Determine whether the filter states get restored to zero for each filtering operation  |
| States              | Double or single array | Filter states. <code>states</code> defaults to a vector of zeros that has length equal to <code>nstates(hm)</code> . Always available, but visible in the display only when <code>PersistentMemory</code> is true. |

### Fixed-Point Filter Properties

This table shows the properties associated with the fixed-point implementation of the `mfilt.holdinterp` filter.

**Note** The table lists all of the properties that a fixed-point filter can have. Many of the properties listed are dynamic, meaning they exist only in response to the settings of other properties. To view all of the characteristics for a filter at any time, use

```
info(hm)
```

where `hm` is a filter.

For further information about the properties of this filter or any `mfilt` object, refer to “Multirate Filter Properties” on page 6-2.

| Name            | Values   | Description   |
|-----------------|--|---|
| AccumFracLength | Any positive or negative integer number of bits. Depends on <code>L</code> . [29 when <code>L=2</code> ] | Specifies the fraction length used to interpret data output by the accumulator. |
| AccumWordLength | Any integer number of bits [33]  | Sets the word length used to store data in the accumulator.                     |

| Name             | Values   | Description   |
|------------------|--|---|
| Arithmetic       | fixed for fixed-point filters                        | Setting this to <code>fixed</code> allows you to modify other filter properties to customize your fixed-point filter.   |
| CoeffAutoScale   | [true], false  | Specifies whether the filter automatically chooses the proper fraction length to represent filter coefficients without overflowing. Turning this off by setting the value to <code>false</code> enables you to change the <code>NumFracLength</code> property value to specify the precision used.  |
| CoeffWordLength  | Any integer number of bits [16]                      | Specifies the word length to apply to filter coefficients.  |
| FilterInternals  | [FullPrecision], SpecifyPrecision                    | Controls whether the filter automatically sets the output word and fraction lengths, product word and fraction lengths, and the accumulator word and fraction lengths to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> makes the output and accumulator-related properties available so you can set your own word and fraction lengths for them. |
| InputFracLength  | Any positive or negative integer number of bits [15] | Specifies the fraction length the filter uses to interpret input data.  |
| InputWordLength  | Any integer number of bits [16]                      | Specifies the word length applied to interpret input data.  |
| NumFracLength    | Any positive or negative integer number of bits [14] | Sets the fraction length used to interpret the numerator coefficients.  |
| OutputFracLength | Any positive or negative integer number of bits [29] | Determines how the filter interprets the filter output data. You can change the value of <code>OutputFracLength</code> when you set <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |
| OutputWordLength | Any integer number of bits [33]                      | Determines the word length used for the output data. You make this property editable by setting <code>FilterInternals</code> to <code>SpecifyPrecision</code> .   |

| Name         | Values  | Description  |
|--------------|---|--|
| OverflowMode | saturate, [wrap]  | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either <code>saturate</code> (limit the output to the largest positive or negative representable value) or <code>wrap</code> (set overflowing values to the nearest representable value using modular arithmetic.) The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision.   |
| RoundMode    | [convergent], <code>ceil</code> , <code>fix</code> , <code>floor</code> , <code>nearest</code> , <code>round</code> | Sets the mode the filter uses to quantize numeric values when the values lie between representable values for the data format (word and fraction lengths). <ul style="list-style-type: none"> <li>• <code>ceil</code> - Round toward positive infinity.</li> <li>• <code>convergent</code> - Round to the closest representable integer. Ties round to the nearest even stored integer. This is the least biased of the methods available in this software.</li> <li>• <code>fix</code> - Round toward zero.</li> <li>• <code>floor</code> - Round toward negative infinity.</li> <li>• <code>nearest</code> - Round toward nearest. Ties round toward positive infinity.</li> <li>• <code>round</code> - Round toward nearest. Ties round toward negative infinity for negative numbers, and toward positive infinity for positive numbers.</li> </ul> <p>The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always round. Finally, products never overflow — they maintain full precision.</p> |
| Signed       | [true], false   | Specifies whether the filter uses signed or unsigned fixed-point coefficients. Only coefficients reflect this property setting.  |
| States       | <code>fi</code> object  | Contains the filter states before, during, and after filter operations. States act as filter memory between filtering runs or sessions. The states use <code>fi</code> objects, with the associated properties from those objects. For details, refer to fixed-point objects in Fixed-Point Designer documentation. For information about the ordering of the states, refer to the filter structure in the following section.  |

## Filter Structure

Linear interpolator structures depend on the FIR filter you use to implement the filter. By default, the structure is direct-form FIR.

## Examples

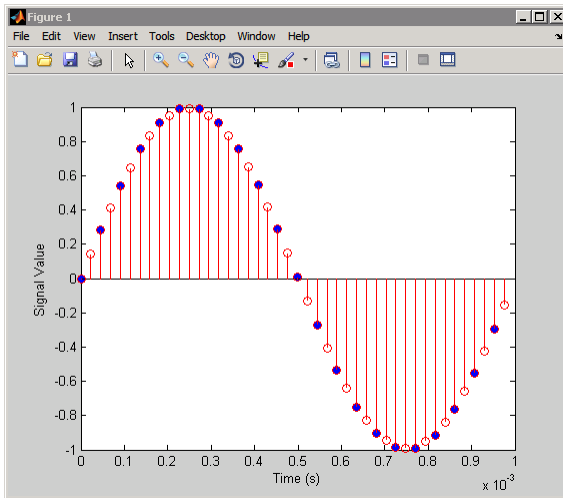

Interpolation by a factor of 2 (used to convert the input signal sampling rate from 22.05 kHz to 44.1 kHz).

```

l = 2; % Interpolation factor
hm = mfilt.linearinterp(l);
fs = 22.05e3; % Original sample freq: 22.05 kHz.
n = 0:5119; % 5120 samples, 0.232 second long signal
x = sin(2*pi*1e3/fs*n); % Original signal, sinusoid at 1 kHz
y = filter(hm,x); % 10240 samples, still 0.232 seconds
stem(n(1:22)/fs,x(1:22),'filled') % Plot original sampled at
% 22.05 kHz
hold on % Plot interpolated signal (44.1
% kHz) in red
stem(n(1:44)/(fs*l),y(2:45),'r')
xlabel('Time (s)');ylabel('Signal Value')

```

Using linear interpolation, as compared to the hold approach of `mfilt.holdinterp`, provides greater fidelity to the original signal.

## Version History

Introduced in R2011a

### R2022a: `mfilt.linearinterp` has been removed

Errors starting in R2022a

`mfilt.linearinterp` has been removed. Use `dsp.FIRInterpolator(L, 'Linear')` instead.

### Update Code

This table shows how the `mfilt.linearinterp` object is typically used and explains how to update existing code to use the `dsp.FIRInterpolator` object.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <p>Initialize the object. Set the interpolation factor to 2.</p> <pre>L = 2; hm = mfilt.linearinterp(L)</pre> <p>Pass the data through the object.</p> <pre>% Input sample rate fs = 22.05e3; % 5120 samples, 0.232 second long signal n = (0:5119)'; % Original signal, sinusoid at 1 kHz x = sin(2*pi*1e3/fs*n); y_mfilt = filter(hm,x);</pre> | <p>Initialize the object. Set the interpolation factor to 2.</p> <pre>L = 2; firI = dsp.FIRInterpolator(L, 'linear')</pre> <p>Pass the data through the object.</p> <p>Note that System objects operate column-wise on data while <code>mfilt</code> objects are agnostic to the dimension. Therefore, pass the data vector as a column vector to the object algorithm.</p> <pre>% Input sample rate fs = 22.05e3; % 5120 samples, 0.232 second long signal n = (0:5119)'; % Original signal, sinusoid at 1 kHz x = sin(2*pi*1e3/fs*n); y = firI(x);</pre> |

`dsp.FIRInterpolator`

## minimizecoeffwl

Minimum word length fixed-point filter

### Syntax

```
Hq = minimizecoeffwl(Hd)
Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)
Hq = minimizecoeffwl(Hd,...,'NTrials',N)
Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol)
Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)
Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)
```

### Description

`Hq = minimizecoeffwl(Hd)` returns the minimum word length fixed-point filter object `Hq` that meets the design specifications of the single-stage or multistage FIR filter object `Hd`. `Hd` must be generated using `fdesign` and `design`. If `Hd` is a multistage filter object, the procedure minimizes the word length for each stage separately. `minimizecoeffwl` uses a stochastic noise-shaping procedure by default to minimize the wordlength. To obtain repeatable results on successive function calls, initialize the uniform random number generator `rand`.

`Hq = minimizecoeffwl(Hd,...,'NoiseShaping',NSFlag)` enables or disables the stochastic noise-shaping procedure in the minimization of the word length. By default `NSFlag` is `true`. Setting `NSFlag` to `false` minimizes the word length without using noise-shaping.

`Hq = minimizecoeffwl(Hd,...,'NTrials',N)` specifies the number of Monte Carlo trials to use in the minimization. `Hq` is the filter with the minimum word length among the `N` trials that meets the specifications in `Hd`. `'NTrials'` defaults to one.

`Hq = minimizecoeffwl(Hd,...,'Apasstol',Apasstol)` specifies the passband ripple tolerance in dB. `'Apasstol'` defaults to `1e-4`.

`Hq = minimizecoeffwl(Hd,...,'Astoptol',Astoptol)` specifies the stopband tolerance in dB. `'Astoptol'` defaults to `1e-2`.

`Hq = minimizecoeffwl(Hd,...,'MatchrefFilter',RefFiltFlag)` determines whether the fixed-point filter matches the filter order and transition width of the floating-point design. Setting `'MatchRefFilter'` to `true` returns a fixed-point filter with the same order and transition width as `Hd`. The `'MatchRefFilter'` property defaults to `false` and the resulting fixed-point filter may have a different order and transition width than the floating-point design `Hd`.

You must have the Fixed-Point Designer software installed to use this function.

### Examples

Minimize word length for lowpass FIR equiripple filter:

```
f=fdesign.lowpass('Fp,Fst,Ap,Ast',0.2,0.3,1,60);
% Design filter with double-precision floating point
Hd=design(f,'equiripple');
```

```

% Find minimum wordlength fixed-point filter
% with 0.15 dB stopband tolerance
Hq=minimizecoeffwl(Hd,'MatchRefFilter',true,'Astoptol',0.15);
Hq1=minimizecoeffwl(Hd,'Astoptol',0.15);
% Hq.coeffwordlength is 14 bits.
% Hq1.coeffwordlength is 11 bits
hfvf=fvtool(Hd,Hq,Hq1,'showreference','off');
legend(hfvf,'44 coefficients floating-point',...
'44 coefficients 14 bits','48 coefficients 11 bits');

```

# modifyCursor

**Package:** dsp

Modify properties of Logic Analyzer cursor

## Syntax

```
modifyCursor(scope, tag)  
modifyCursor(scope, tag, Name, Value)
```

## Description

`modifyCursor(scope, tag)` modifies the properties of the Logic Analyzer cursor specified by the input tag.

`modifyCursor(scope, tag, Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

## Examples

### Modify Logic Analyzer Cursors Programmatically

This example shows how to use functions to create, manipulate, and delete cursors in a `dsp.LogicAnalyzer` object.

### Create Logic Analyzer and Signals

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

### Add Cursor

Add a cursor at 15 seconds and show the cursor information.

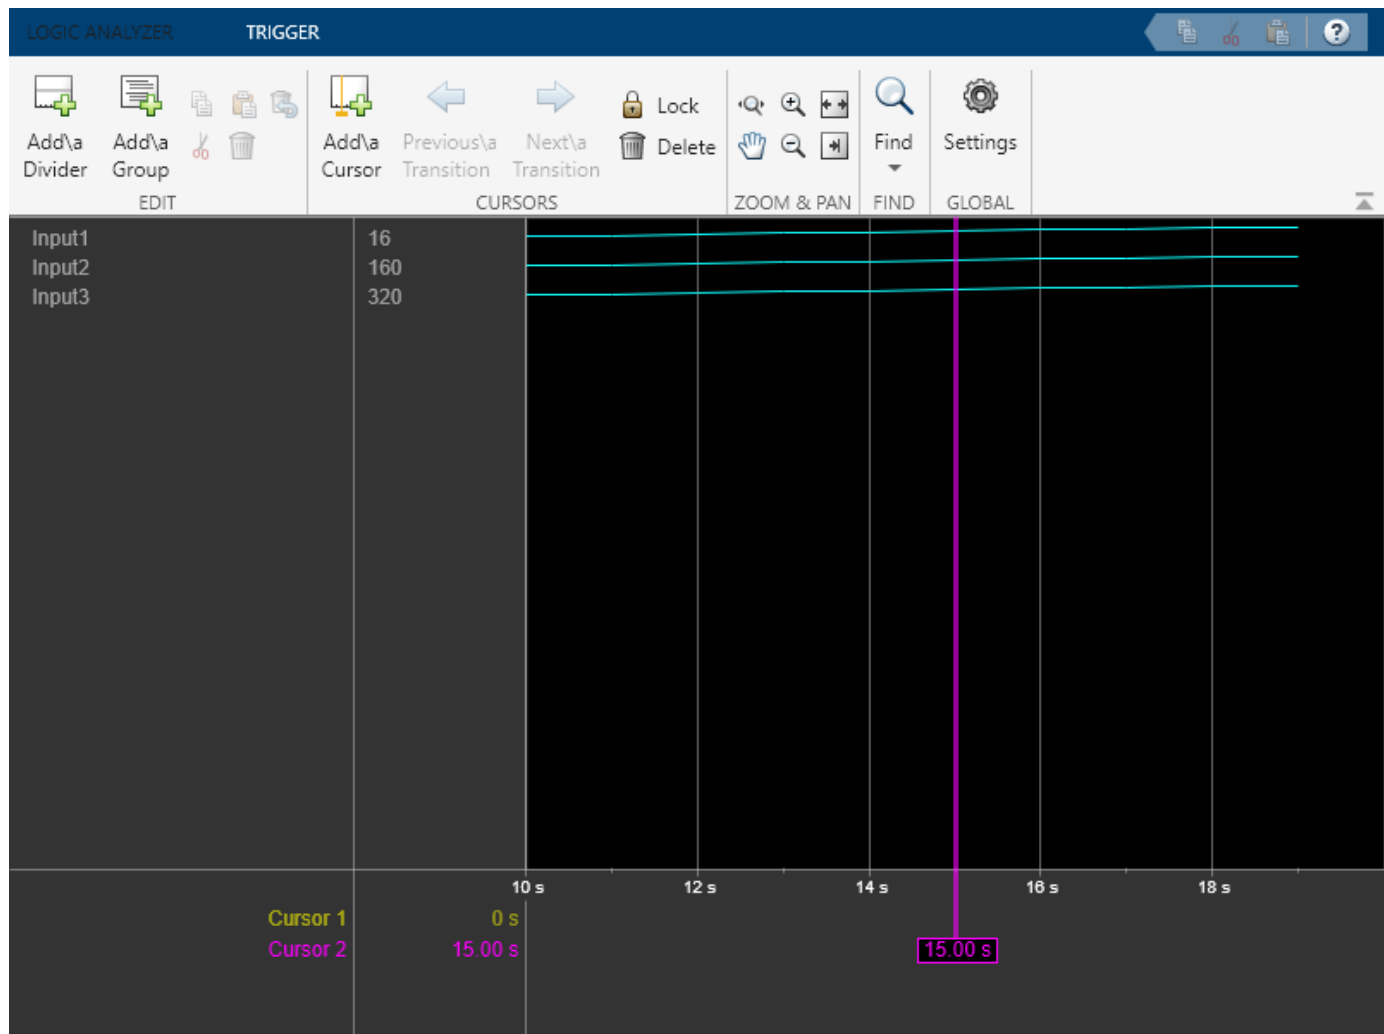

```
cursor = addCursor(scope, 'Location', 15, 'Color', 'Cyan');
getCursorInfo(scope, cursor)
```

```
ans = struct with fields:
    Location: 15
    Color: [0 1 1]
    Locked: 0
    Tag: 'C2'
```

### Modify Cursor

Change the cursor color to magenta.

```
hide(scope)
modifyCursor(scope, cursor, 'Color', 'Magenta')
show(scope)
```

### Remove Cursor

Delete the yellow cursor at 0 seconds.

```
hide(scope)
tags = getCursorTags(scope);
deleteCursor(scope, tags{1});
show(scope)
```

## Input Arguments

**scope** — The Logic Analyzer object for which you want to modify a cursor

`dsp.LogicAnalyzer` object

The Logic Analyzer object for which you want to modify a cursor specified, as a handle to the `dsp.LogicAnalyzer` object.

**tag** — The tag identifying which cursor to modify

character vector | string scalar

The tag identifying which cursor to modify specified.

Example: `modifyCursor(scope, 'C4')` modifies a cursor in Logic Analyzer.

Example: `modifyCursor(scope, "C4")` modifies a cursor in Logic Analyzer.

Data Types: `char` | `string`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

### Color — Color of the cursor

`'Yellow'` (default) | character vector | three element numeric vector | string scalar

Color of the cursor, specified as a `[R G B]` number value, color name, or color short name:

| Color Name | Short Name | RGB Triplet | Appearance  |
|------------|------------|-------------|---|
| "red"      | "r"        | [1 0 0]     |    |
| "green"    | "g"        | [0 1 0]     |    |
| "blue"     | "b"        | [0 0 1]     |    |
| "cyan"     | "c"        | [0 1 1]     |    |
| "magenta"  | "m"        | [1 0 1]     |    |
| "yellow"   | "y"        | [1 1 0]     |    |
| "black"    | "k"        | [0 0 0]     |  |
| "white"    | "w"        | [1 1 1]     |  |

Example: `'Color','blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `string` | `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### Location — Location of the cursor

`0` (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: `'Location',1`

Data Types: `double`

### Locked — Locked status of the cursor

`false` (default) | `true`

Locked status of the cursor, specified as `false` or `true`.

- `true` — the cursor location cannot be changed. Logic Analyzer denotes the locked cursor by assigning a default color of gray. This color cannot be changed.
- `false` — the cursor location can be changed. Logic Analyzer denotes the unlocked cursor by assigning a default color of yellow.

Example: `'Locked',true`

# modifyDisplayChannel

**Package:** dsp

Modify properties of Logic Analyzer display channel

## Syntax

```
modifyDisplayChannel(scope, tag, Name, Value)
```

## Description

`modifyDisplayChannel(scope, tag, Name, Value)` modifies the properties of `tag` using properties specified by one or more name-value pairs. Enclose each property name in single quotes.

## Examples

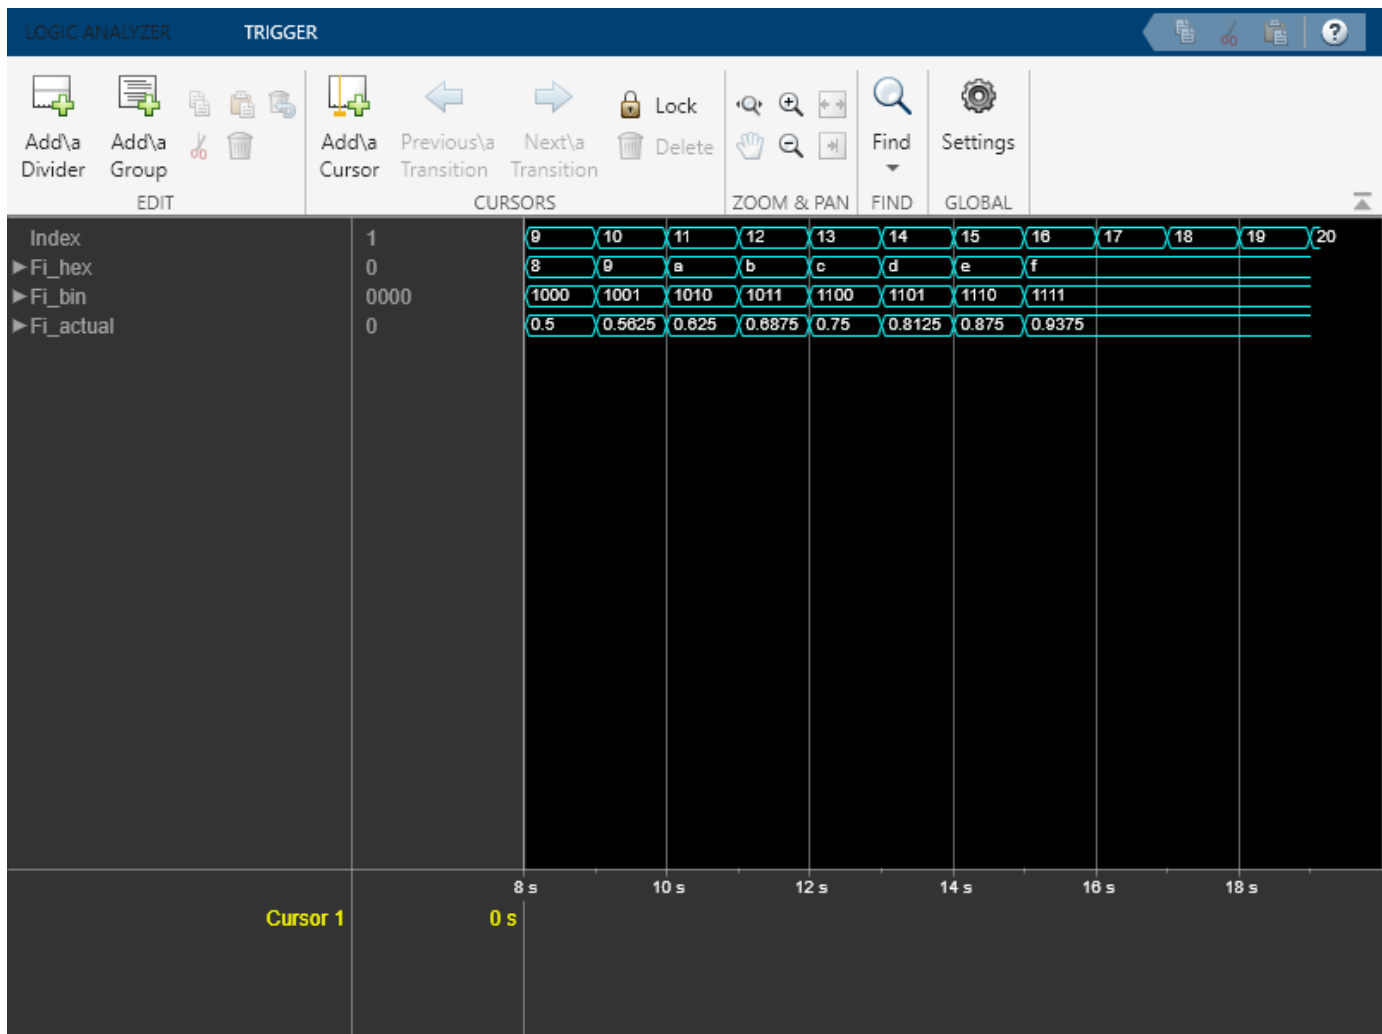

### Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;

modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');

for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```

## Manipulate Logic Analyzer Programatically

Use functions to construct and manipulate a dsp.LogicAnalyzer System object.

### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

**scope** — Logic Analyzer object for which you want to modify a display channel

dsp.LogicAnalyzer object

The Logic Analyzer object for which you want to modify a display channel, specified as a handle to the dsp.LogicAnalyzer object.

**tag** — which display channel to modify

character vector | string scalar

The tag identifying which display channel to modify.

Example: `modifyDisplayChannel(scope,tag)`

Example: `modifyDisplayChannel(scope,'W4')`

Data Types: `char` | `string`

The first section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a wave. The second section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a divider.

### **Wave Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `'InputChannel',2,'Color','Blue'` specifies that a wave should be added to input channel 1 and colored blue.

### **Color — Color of the wave**

`'Default'` (default) | character vector | three element numeric vector | string scalar

Color of the wave, specified as an [R G B] value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Default'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

When you choose `'Default'`, the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `string` | `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **DisplayChannel — Channel on the display that shows this wave**

`NumInputPorts` (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **FontSize — Font size for values in the wave**

`0` (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: `'FontSize',8`

Data Types: `double`

### **Format — Display format for the wave**

`'Default'` (default) | `'Analog'` | `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: `'Format','Digital'`

Data Types: `char` | `string`

### **Height — Height of the wave**

0 (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

### **InputChannel — Input channel that corresponds to this wave**

1 (default) | scalar integer in the range (1,NumInputPorts)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **Name — Name or label for the wave**

`''` (default) | character vector | string scalar

Specify the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types: `char` | `string`

### **Radix — Radix for the wave**

`'Default'` (default) | `'Binary'` | `'Hexadecimal'` | `'Octal'` | `'Signed decimal'` | `'Unsigned decimal'`

When the input signals are of class `double`, `single`, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Data Types: `char` | `string`

### **Divider Name-Value Pair Arguments**

Specify optional pairs of arguments as `Name1=Value1, . . . ,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.*

Example: `'DisplayChannel',2,'Name','MyDivider'` specifies that a divider should be added to display channel 2 and named "MyDivider".

### **DisplayChannel — Channel on the display that shows this divider**

`NumInputPorts` (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

### **Height — Height of the divider**

`0` (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8-200. If you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

### **Name — The name or label for the divider**

`''` (default) | character vector | string scalar

Specify the name that you would like to set for the new divider.

Example: `'Name','MyDivider'`

Data Types: `char` | `string`

## **Version History**

# moveDisplayChannel

**Package:** dsp

Move position of Logic Analyzer display channel

## Syntax

```
moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)
```

## Description

`moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)` moves the display channel, either a wave or a divider, specified by the input `tag`, to the new location specified by the input `displayChannelValue`.

## Examples

### Manipulate Logic Analyzer Programmatically

Use functions to construct and manipulate a `dsp.LogicAnalyzer` System object.

#### Display Waves on Logic Analyzer scope.

```
scope = dsp.LogicAnalyzer('NumInputPorts',2);

stop = 30;
for count = 1:stop
    sinValVec = sin(count/stop*2*pi);
    cosValVec = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);

    scope([count (count-(stop/2))],[sinValVec cosValVec cosValVecOffset])
end
```

### Reorganize Display

```
hide(scope)
digitalDividerTag = addDivider(scope, 'Name', 'Digital', 'Height', 20);
analogDividerTag = addDivider(scope, 'Name', 'Analog', 'Height', 40);

tags = getDisplayChannelTags(scope);

modifyDisplayChannel(scope, tags{1}, 'InputChannel', 1, ...
    'Name', 'Ramp Digital', 'Height', 40);
modifyDisplayChannel(scope, tags{2}, 'InputChannel', 2, ...
    'Name', 'Waves Analog', 'Format', 'Analog', 'Height', 80);

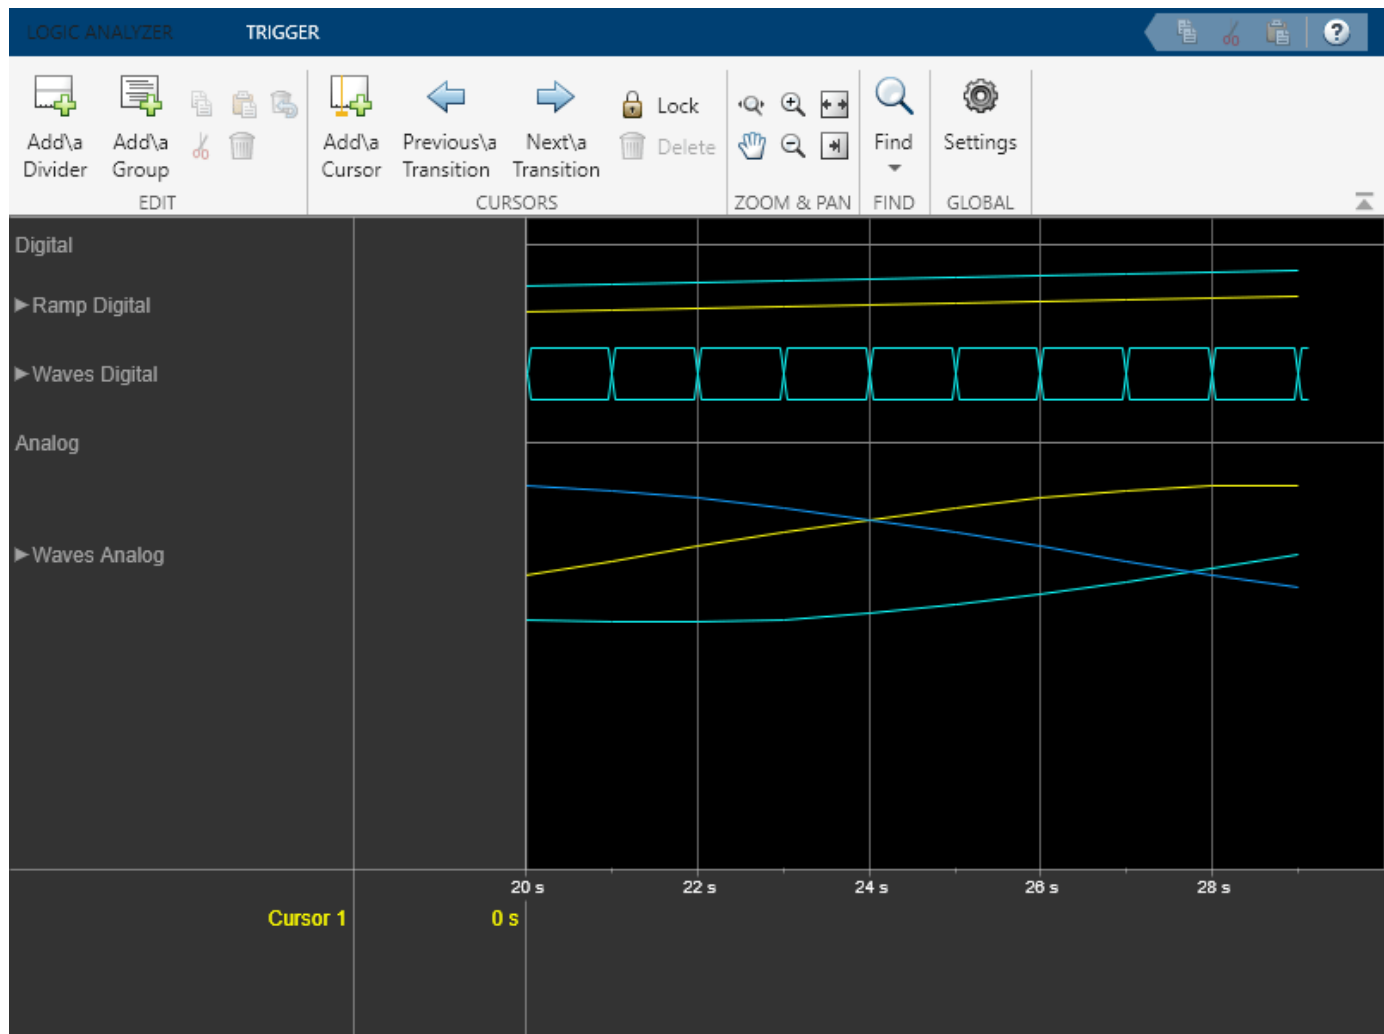

moveDisplayChannel(scope, digitalDividerTag, 'DisplayChannel', 1)
moveDisplayChannel(scope, tags{2}, 'DisplayChannel', length(tags))

show(scope)
```

### Duplicate Wave and Check Information

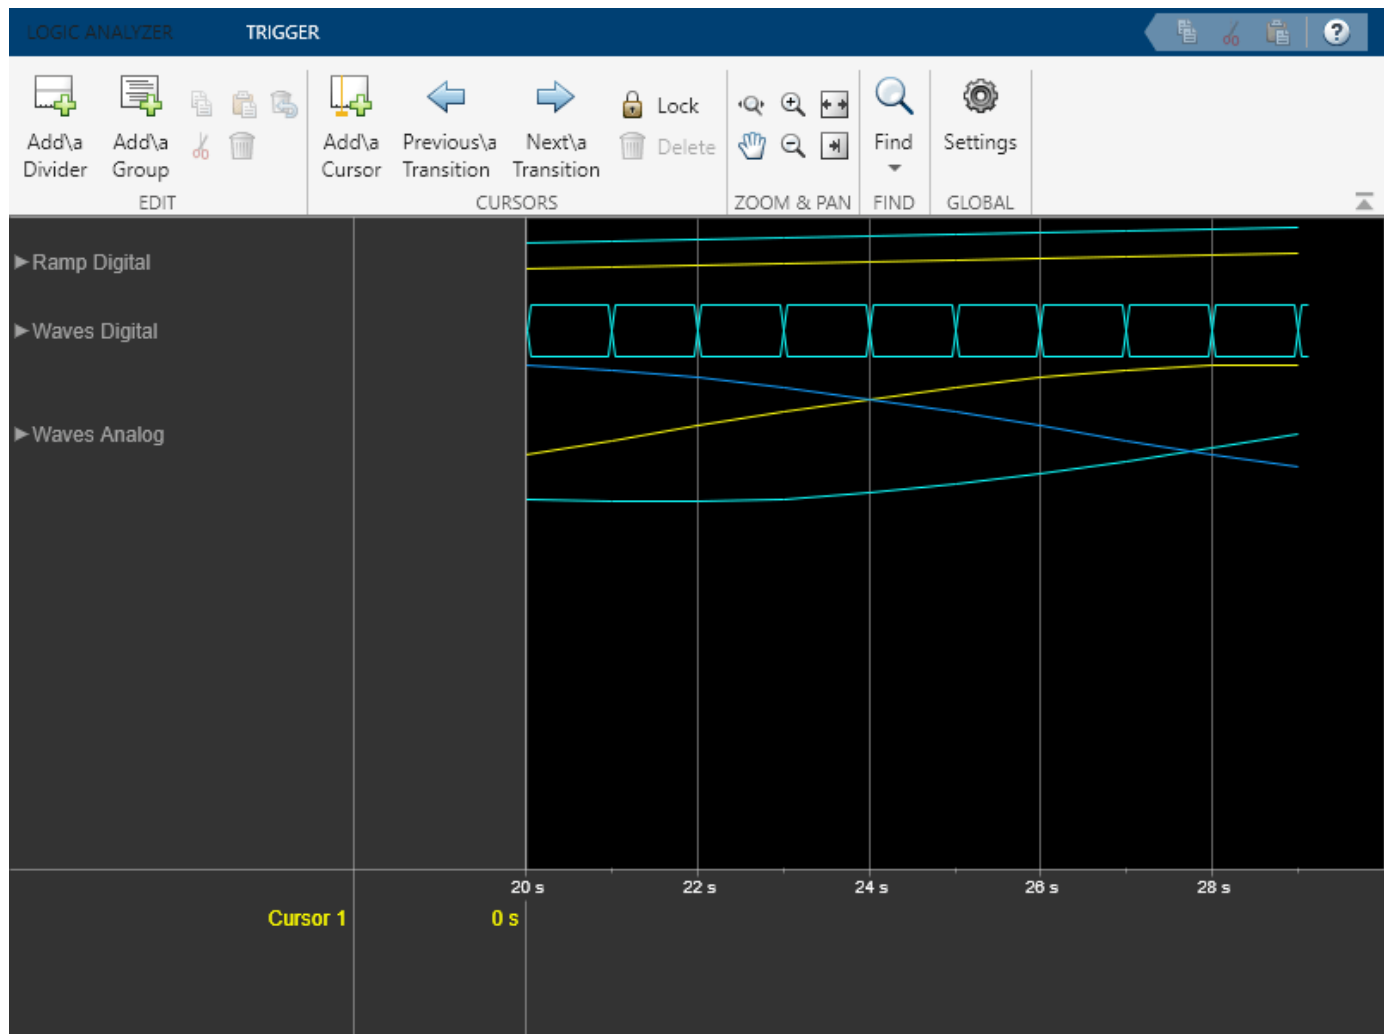

```
hide(scope)
addWave(scope, 'InputChannel', 2, 'Name', 'Waves Digital', 'Format', 'Digital', ...
'Height', 30, 'DisplayChannel', 3);
show(scope)
```

### Remove Dividers

```
hide(scope)
deleteDisplayChannel(scope,digitalDividerTag)
deleteDisplayChannel(scope,analogDividerTag)
show(scope)
```

### Clear variables

```
clear analogDividerTag cosValVec cosValVecOffset count digitalDividerTag duplicateWave scope sin
```

## Input Arguments

### scope — Logic Analyzer object

dsp.LogicAnalyzer object

The Logic Analyzer object in which you want to move a display channel, specified as a handle to the dsp.LogicAnalyzer object.

### tag — The tag identifying which display channel to move

character vector | string scalar

The tag identifying which display channel to move.

Example: 'W1'

Data Types: char | string

**displayChannelValue** – The location identifying where the display channel should be moved

scalar integer

The location identifying where the display channel should be moved, specified as a scalar integer.

Example: 'DisplayChannel',2

Data Types: double

## Version History

# msepred

**Package:** dsp

Predicted mean squared error for LMS adaptive filter

## Syntax

```
[mmseemse] = msepred(lmsFilt,x,d)
[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d)
[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d,m)
```

## Description

[mmseemse] = msepred(lmsFilt,x,d) predicts the steady-state values at convergence of the minimum mean squared error, mmse, and the excess mean squared error, emse, given the input and the desired response signal sequences in x and d and the quantities in the dsp.LMSFilter System object, lmsFilt.

[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d) also computes meanw, the sequence of means of the coefficient vectors, mse, sequence of mean-squared errors, and tracek, the sequence of total coefficient error powers.

[mmseemse,meanw,mse,tracek] = msepred(lmsFilt,x,d,m) specifies an optional decimation factor for computing meanw, mse, and tracek. If  $m > 1$ , every  $m^{\text{th}}$  predicted value of each of these sequences is saved. If omitted, the value of m is the default, which is one.

## Examples

### Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the msepred and msesim functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

### Initialization

Create a dsp.FIRFilter System object™ that represents the unknown system. Pass the signal, x, to the FIR filter. The output of the unknown system is the desired signal, d, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, n.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
```

```
n = 0.1*randn(size(x));
d = fir(x) + n;
```

### LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;
```

```
lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

### Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

### Plot the Coefficient Trajectories

meanWsim is the mean value of the simulated coefficients given by msesim. meanW is the mean value of the predicted coefficients given by msepred.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}

```

```
PlotTitle = 2x1 cell
            {'Average Coefficient Trajectories for'
            'W(12), W(13), W(14), and W(15)'}

```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')

```

In steady state, both the trajectories converge.

### Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')

## Input Arguments

### **lmsFilt** — LMS adaptive filter System object

`dsp.LMSFilter`

LMS adaptive filter, specified as a `dsp.LMSFilter` System object.

### **x** — Input signal

scalar | column vector | matrix

Input signal, specified as a scalar, column vector, or matrix. Columns of the matrix `x` contain individual input signal sequences. The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity.

Data Types: `single` | `double`

### **d** — Desired signal

scalar | column vector | matrix

Desired response signal, specified as a scalar, column vector, or matrix. Columns of the matrix `d` contain individual desired signal sequences. The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity.

Data Types: `single` | `double`

### **m** — Decimation factor

1 (default) | positive scalar

Decimation factor, specified as a positive scalar. Every  $m$ th predicted value of the 3rd, 4th, and 5th predicted sequences output is saved into the corresponding output arguments, `meanw`, `mse`, and `tracek`. If  $m$  equals 1, every value of these sequences is saved.

$m$  must be a factor of the input frame size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

### **mmse** — Minimum mean squared error

scalar

Minimum mean squared error (mmse), returned as a scalar. This parameter is estimated using a Wiener filter. The Wiener filter minimizes the mean squared error between the desired signal and the input signal filtered by the Wiener filter. A large value of the mean squared error indicates that the adaptive filter cannot accurately track the desired signal. The minimal value of the mean squared error ensures that the adaptive filter is optimal. The minimum mean squared error between a particular frame of the desired signal and the filtered signal is computed as the variance between the two frames of signals. The `msepred` function outputs the average of the mmse values for all the frames. For more details on how this parameter is calculated, see “Algorithms” on page 5-1273.

Data Types: `single` | `double`

### **emse** — Steady state excess mean squared error

scalar

Excess mean squared error, returned as a scalar. This error is the difference between the mean squared error introduced by adaptive filters and the minimum mean squared error produced by corresponding Wiener filter. For details on how this parameter is calculated, see “Algorithms” on page 5-1273.

Data Types: `single` | `double`

### **meanw** — Sequence of coefficient vector means

matrix

Sequence of coefficient vector means of the adaptive filter at each time instant, returned as a matrix. The columns of this matrix contain predictions of the mean values of the LMS adaptive filter coefficients at each time instant. If the decimation factor,  $m$  equals 1, the dimensions of `meanw` is  $M$ -by- $N$ .  $M$  is the frame size (number of rows) of the input signal,  $x$ .  $N$  is the length of the FIR filter weights vector, specified by the `Length` property of the `lmsFilt` System object. If  $m > 1$ , the dimensions of `meanw` is  $M/m$ -by- $N$ .

For details on how this parameter is calculated, see “Algorithms” on page 5-1273.

Data Types: `double`

### **mse** — Sequence of mean squared errors

column vector

Predictions of the mean squared error of the LMS adaptive filter at each time instant, returned as a column vector. If the decimation factor,  $m$  equals 1, the length of `mse` equals the frame size (number of rows) of the input signal,  $M$ . If  $m > 1$ , the length of `mse` equals  $M/m$ .

For details on how this parameter is calculated, see “Algorithms” on page 5-1273.

Data Types: `double`

### **tracek — Sequence of total coefficient error powers**

column vector

Predictions of the total coefficient error power of the LMS adaptive filter at each time instant, returned as a column vector. If the decimation factor,  $m$  equals 1, the length of `tracek` equals the frame size (number of rows) of the input signal, given by `size(x,1)`. If  $m > 1$ , the length of `tracek` equals the ratio of input frame size and the decimation factor,  $m$ .

For details on how this parameter is calculated, see “Algorithms” on page 5-1273.

Data Types: `double`

## **Algorithms**

### **Minimum Mean Squared Error (mmse)**

The `msepred` function computes the minimum mean-squared error (mmse) using the following equation:

$$mmse = \frac{\sum_{i=1}^N \text{var}(d_i - W(x_i))}{N}$$

where,

- $N$  -- Number of frames in the input signal,  $x$ .
- $d_i$  --  $i$ th frame (column) of the desired signal.
- $x_i$  --  $i$ th frame (column) of the input signal.
- $W(x_i)$  -- Output of the Wiener filter.
- `var` -- Variance

### **Excess Mean Squared Error (emse)**

The `msepred` function computes the steady-state excess mean squared error using the following equations:

$$\begin{aligned} emse &= K\lambda, \\ K &= \frac{B}{I(L) - A}, \\ B &= \mu^2 \cdot mmse \cdot \lambda', \\ A &= I(L) - 2\mu Lam + \mu^2(Lam^2(kurt + 2) + \lambda\lambda'). \end{aligned}$$

where,

- $K$  -- Final values of transformed coefficient variances.
- $\lambda$  -- Column vector containing the eigenvalues of the input autocorrelation matrix.
- $\lambda'$  -- Transpose of  $\lambda$ .

- $B$  -- MSE analysis driving term.
- $L$  -- Length of the FIR adaptive filter, given by `lmsFilt.Length`.
- $I(L)$  --  $L$ -by- $L$  identity matrix.
- $A$  -- MSE analysis transition matrix.
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- $Lam$  -- Diagonal matrix containing the eigenvalues.
- $kurt$  -- Average kurtosis value of eigenvector-filtered signals.

### Coefficient Vector Means (`meanw`)

The `msepred` function computes each element of the sequence of coefficient vector means using the following equations:

$$\begin{aligned} meanw &= meanw \cdot T \cdot D, \\ T &= I(L) - \mu R, \\ D &= \mu P. \end{aligned}$$

where,

- $meanw$  -- The initial value of  $meanw$  is given by `lmsFilt.InitialConditions`.
- $T$  -- Transition matrix for mean coefficient analysis.
- $I(L)$  --  $L$ -by- $L$  identity matrix.
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- $R$  -- Input autocorrelation matrix of size  $L$ -by- $L$ .
- $D$  -- Driving term for mean coefficient analysis.
- $P$  -- Cross correlation vector of size 1-by- $L$ .
- $kurt$  -- Average kurtosis value of eigenvector-filtered signals.

### Mean Squared Errors (`mse`)

The `msepred` function computes each element of the sequence of the mean squared errors using the following equations:

$$\begin{aligned} mse &= mmse + dk \cdot \lambda, \\ dk &= dk \circ diagA + mse \cdot D, \\ diagA &= (1 - 2\mu\lambda + \mu^2(kurt + 2)\lambda^2), \\ D &= \mu^2\lambda'. \end{aligned}$$

where,

- $mmse$  -- Minimum mean squared error.
- $dk$  -- Diagonal entries of coefficient covariance matrix. The initial value of  $dk$  is given by  $dk = ((meanw - W_{opt})Q)^2$ .
- $meanw$  -- Coefficient vector means given by `lmsFilt.InitialConditions`.
- $W_{opt}$  -- Optimal Wiener filter coefficients.
- $Q$  --  $L$ -by- $L$  matrix whose columns are the eigenvectors of the input autocorrelation matrix,  $R$ , so that  $RQ = QLam$ .  $Lam$  is the diagonal matrix containing the corresponding eigen values.

- *diagA* -- Portion of MSE analysis transition matrix.
- *dk* ◦ *diagA* -- Hadamard or entrywise product of *dk* and *diagA*.
- $\lambda$  -- Column vector containing the eigenvalues of the input autocorrelation matrix, *R*.
- $\mu$  -- Step size given by `lmsFilt.StepSize`.
- *kurt* -- Average kurtosis value of eigenvector filtered signals.
- $\lambda^2$  -- Hadamard or entrywise power of the column vector containing the eigenvalues.
- *D* -- Driving term for MSE analysis.

### Total Coefficient Error Powers (tracek)

The `msepred` function computes each element of the sequence of the total coefficient error powers. These values are given by the trace of the coefficient covariance matrix. The diagonal entries of the coefficient covariance matrix are given by *dk* in the following equations:

$$\begin{aligned}mse &= mmse + dk \cdot \lambda, \\dk &= dk \circ diagA + mse \cdot D, \\diagA &= (1 - 2\mu\lambda + \mu^2(kurt + 2)\lambda^2), \\D &= \mu^2\lambda' .\end{aligned}$$

The trace of the coefficient covariance matrix is given by the following equation:

$$tracek = sum(dk).$$

## Version History

## msesim

**Package:** dsp

Estimated mean squared error for adaptive filters

### Syntax

```
mse = msesim(adaptFilt,x,d)
[mse,meanw,w,tracek] = msesim(adaptFilt,x,d)
[ ___ ] = msesim(adaptFilt,x,m)
```

### Description

`mse = msesim(adaptFilt,x,d)` estimates the mean squared error of the adaptive filter at each time instant given the input and the desired response signal sequences in `x` and `d`.

`[mse,meanw,w,tracek] = msesim(adaptFilt,x,d)` also calculates the sequences of coefficient vector means, `meanw`, adaptive filter coefficients, `w`, and the total coefficient error powers, `tracek`, corresponding to the simulated behavior of the adaptive filter.

`[ ___ ] = msesim(adaptFilt,x,m)` specifies an optional decimation factor for computing `mse`, `meanw`, and `tracek`. If `m > 1`, every `m`th value of each of these sequences is saved. If omitted, the value of `m` defaults to 1.

### Examples

#### Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the `msepred` and `msesim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

#### Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

## LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

## Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

### Plot the Coefficient Trajectories

`meanWsim` is the mean value of the simulated coefficients given by `mseSim`. `meanW` is the mean value of the predicted coefficients given by `msePred`.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'}

```

```
PlotTitle = 2x1 cell
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}

```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')

```

In steady state, both the trajectories converge.

### Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `mresim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

### System Identification of FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-x LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

#### Initialization

Create a `dsp.FIRFilter` System object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

#### Adaptive Filter

Create a `dsp.FilteredXLMSFilter` System object to create an adaptive filter that uses the filtered-x LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the

decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```

l = 32;
mu = 0.008;
m = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = mlesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
% Plot the learning curve for filtered-x LMS filter
% used in system identification
title('Learning curve')

```

With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

### System Identification of FIR Filter Using Adaptive Lattice Filter

```

ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));

```

```

% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Decimation factor for analysis
% and simulation results
m = 5;
ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration');
ylabel('MSE (dB)');
% Plot the learning curve used for
% adaptive lattice filter used in system identification
title('Learning curve')

```

### System Identification of FIR Filter Using Block LMS Filter

```

fir = fir1(31,0.5);
% FIR system to be identified
firFilter = dsp.FIRFilter('Numerator',fir);
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);

```

```

x = iirFilter(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = firFilter(x)+n;
% Filter length
l = 32;
% Block LMS Step size
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 32;
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = mlesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
% Plot the learning curve for
% block LMS filter used in system identification
title('Learning curve')

```

### System Identification of FIR Filter Using Affine Projection Filter

```

ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);

```

```
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...  
    'Denominator',[1 -0.5]);  
x = iir(sign(randn(2000,25)));  
% Observation noise signal  
n = 0.1*randn(size(x));  
% Desired signal  
d = fir(x)+n;  
% Filter length  
l = 32;  
% Affine Projection filter Step size.  
mu = 0.008;  
% Decimation factor for analysis  
% and simulation results  
m = 5;  
  
apf = dsp.AffineProjectionFilter(l, 'StepSize',mu);  
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);  
plot(m*(1:length(simmse)),10*log10(simmse));  
xlabel('Iteration'); ylabel('MSE (dB)');  
% Plot the learning curve for affine projection filter  
% used in system identification  
title('Learning curve')
```

## Input Arguments

### **adaptFilt** — Adaptive filter System object

adaptive filter System object

Adaptive filter, specified as one of the following System objects:

- `dsp.LMSFilter`
- `dsp.BlockLMSFilter`
- `dsp.AdaptiveLatticeFilter`
- `dsp.AffineProjectionFilter`
- `dsp.FastTransversalFilter`
- `dsp.FilteredXLMSFilter`
- `dsp.RLSFilter`

### **x** — Input signal

scalar | column vector | matrix

Input signal, specified as a scalar, column vector, or matrix. Columns of the matrix `x` contain individual input signal sequences. The input, `x`, and the desired signal, `d`, must have the same size and data type.

If `adaptFilt` is a `dsp.BlockLMSFilter` object, the input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double`

### **d** — Desired signal

scalar | column vector | matrix

Desired response signal, specified as a scalar, column vector, or matrix. Columns of the matrix `d` contain individual desired signal sequences. The input, `x`, and the desired signal, `d`, must have the same size and the data type.

If `adaptFilt` is a `dsp.BlockLMSFilter` System object, the desired signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double`

### **m** — Decimation factor

1 (default) | positive scalar

Decimation factor, specified as a positive scalar. Every `m`th value of the estimated sequences is saved into the corresponding output arguments, `mse`, `meanw`, `w`, and `tracek`. If `m` equals 1, every value of these sequences is saved.

If `adaptFilt` is a `dsp.BlockLMSFilter` System object, the decimation factor must be a multiple of the value you specify in the `BlockSize` property of the object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

### mse — Sequence of mean squared errors

column vector

Estimates of the mean squared error of the adaptive filter at each time instant, returned as a column vector.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor `m` is specified, length of `mse` equals  $\text{floor}(M/m)$ .  $M$  is the frame size (number of rows) of the input signal, `x`. If `m` is not specified, the length of `mse` equals  $\text{floor}(M/B)$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, if the decimation factor,  $m = 1$ , the length of `mse` equals the frame size of the input signal. If  $m > 1$ , the length of `mse` equals  $\text{floor}(M/m)$ .

Data Types: `double`

### meanw — Sequence of coefficient vector means

matrix

Sequence of coefficient vector means of the adaptive filter at each time instant, estimated as a matrix. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor `m` is specified, the dimensions of `meanw` is  $\text{floor}(M/m)\text{-by-}N$ .  $M$  is the frame size (number of rows) of the input signal, `x`.  $N$  is the length of the filter weights vector, specified by the `Length` property of the adaptive filter. If `m` is not specified, the dimensions of `meanw` is  $\text{floor}(M/B)\text{-by-}N$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, If the decimation factor,  $m = 1$ , the dimensions of `meanw` is  $M\text{-by-}N$ . If  $m > 1$ , the dimensions of `meanw` is  $\text{floor}(M/m)\text{-by-}N$ .

Data Types: `double`

### w — Final values of adaptive filter coefficients

row vector

Final values of the adaptive filter coefficients for the algorithm corresponding to `adaptFilt`, returned as a row vector. The length of the row vector equals the value you specify in the `Length` property of the object.

Data Types: `single` | `double`

### tracek — Sequence of total coefficient error powers

column vector

Sequence of total coefficient error powers, estimated as a column vector. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant.

If the adaptive filter is `dsp.BlockLMSFilter` and the decimation factor `m` is specified, length of `tracek` equals  $\text{floor}(M/m)$ .  $M$  is the frame size (number of rows) of the input signal, `x`. If `m` is not

specified, the length of `tracek` equals  $\text{floor}(M/B)$ , where  $B$  is the value you specify in the `BlockSize` property of the object. The input signal frame size must be greater than or equal to the value you specify in the `BlockSize` property of the object. The decimation factor, if specified, must be a multiple of the `BlockSize` property.

For the other adaptive filters, if the decimation factor,  $m = 1$ , the length of `tracek` equals the frame size of the input signal. If  $m > 1$ , the length of `tracek` equals  $\text{floor}(M/m)$ .

Data Types: `double`

## multistage

Multistage filter from specification object

---

**Note** Support for multistage filter design using the `fdesign.interpolator` and `fdesign.decimator` objects will be removed in a future release. Use the `designMultistageInterpolator` and the `designMultistageDecimator` functions, respectively.

Multistage filter design using the `fdesign.lowpass` object and the `design` function now requires you to set the `SystemObject` flag to `true` unless the resulting design is a single-stage filter and not a cascade.

For more information on how to replace your existing code, see “Compatibility Considerations”.

---

### Syntax

```
msFilter = design(d, 'multistage', SystemObject=true)
msFilter = design(..., filterstructure=structure, SystemObject=true)
msFilter = design(..., nstages=nstages, SystemObject=true)
msFilter = design(..., usehalfbands=hb, SystemObject=true)
```

### Description

`msFilter = design(d, 'multistage', SystemObject=true)` designs a multistage filter whose response you specified by the filter specification object `d`.

`msFilter = design(..., filterstructure=structure, SystemObject=true)` returns a filter with the structure specified by `structure`. Input argument `structure` is `dffir` by default and can also be one of the following options.

| structure              | Valid with These Responses  |
|------------------------|-----------------------------|
| <code>firdecim</code>  | Lowpass or Nyquist response |
| <code>firtdecim</code> | Lowpass or Nyquist response |
| <code>firinterp</code> | Lowpass or Nyquist response |
| <code>lowpass</code>   | Default lowpass only        |

Multistage design applies to the default lowpass filter specification object and to decimators and interpolators that use either lowpass or Nyquist responses.

`msFilter = design(..., nstages=nstages, SystemObject=true)` specifies `nstages`, the number of stages to be used in the design. `nstages` must be an integer or `auto`. To allow the design algorithm to use the optimal number of stages while minimizing the cost of using the resulting filter, `nstages` is `auto` by default. When you specify an integer for `nstages`, the design algorithm minimizes the cost for the number of stages you specify.

`msFilter = design(..., usehalfbands=hb, SystemObject=true)` uses halfband filters when you set `hb` to `true`. The default value for `hb` is `false`.

---

**Note** To see a list of the design methods available for your filter, use `designmethods(hd)`.

---

## Examples

### Design a Multistage Interpolator

This example designs a minimum order, multistage Nyquist interpolator.

```
l = 15; % Interpolation factor. Also the Nyquist band.
tw = 0.05; % Normalized transition width
ast = 40; % Minimum stopband attenuation in dB
msMinInterp = designMultistageInterpolator(l,2,tw,ast)
```

```
msMinInterp =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRInterpolator]
    Stage2: [1x1 dsp.FIRInterpolator]
    CloneStages: false
```

```
fvtool(msMinInterp);
```

Design a multistage lowpass interpolator with an interpolation factor of 8 using the `designMultistageInterpolator` function.

```
m = 8;
msInterp = designMultistageInterpolator(m,2);
fvtool(msInterp);
```

## Version History

Introduced in R2011a

**R2022b: Support for multistage design in `fdesign.interpolator` and `fdesign.decimator` will be removed**

*Warns starting in R2022b*

Support for multistage filter design using the `fdesign.interpolator` and `fdesign.decimator` objects will be removed in a future release. Use the `designMultistageInterpolator` and the `designMultistageDecimator` functions, respectively.

### Update Code

This table shows how to update your code to use the equivalent functions.

| Discouraged Usage   | Recommended Replacement  |
|---|--|
| Using the design function and passing the 'multistage' flag as an input.<br><br><pre>L = 12; % Interpolation factor TW = 2205; % Transition width Astop = 80; % Stopband attenuation Fs = 44100; % Output sample rate filtSpec = fdesign.interpolator(L, 'nyquist', L, TW, Astop, Fs) filtObj = design(filtSpec, 'multistage', SystemObject=true)</pre> | When you set the cost method to 'design', the function designs an optimal number of stages so that the overall implementation cost is low.<br><br><pre>filtObj = designMultistageInterpolator(L, Fs, TW, Astop, CostMethod='design') filtObj = design(filtSpec, 'multistage', SystemObject=true)</pre> |
| Using the multistage function directly.<br><br><pre>filtObj = multistage(filtSpec, SystemObject=true)</pre>   |  |
| Using the design function and passing the 'multistage' flag as an input.<br><br><pre>D = 9; % Decimation factor TW = 2205; % Transition width Astop = 80; % Stopband attenuation Fs = 44100; % Input sample rate filtSpec = fdesign.decimator(D, 'nyquist', D, TW, Astop, Fs) filtObj = design(filtSpec, 'multistage', SystemObject=true)</pre>         | When you set the cost method to 'design', the function designs an optimal number of stages so that the overall implementation cost is low.<br><br><pre>filtObj = designMultistageDecimator(D, Fs, TW, Astop, CostMethod='design') filtObj = design(filtSpec, 'multistage', SystemObject=true)</pre>    |
| Using the multistage function directly.<br><br><pre>filtObj = multistage(filtSpec, SystemObject=true)</pre>   |  |

## R2022b: Support for designing `mfilt.cascade` object using the `fdesign.lowpass` object has been removed

Errors starting in R2022b

Multistage filter design using the `fdesign.lowpass` object and the `design` function now requires you to set the `SystemObject` flag to `true` unless the resulting design is single-stage filter and not a cascade. This setting generates a `dsp.FilterCascade` object instead of the `mfilt.cascade` object.

```
fdesignObj = fdesign.lowpass('Fp,Fst,Ap,Ast', ...
0.1,0.12,0.1,1e-4, 'linear');
FIRInterpObj = multistage(fdesignObj, SystemObject=true)
```

FIRInterpObj =

dsp.FilterCascade with properties:

```
Stage1: [1x1 dsp.FIRDecimator]
Stage2: [1x1 dsp.FIRDecimator]
Stage3: [1x1 dsp.FIRDecimator]
Stage4: [1x1 dsp.FIRInterpolator]
Stage5: [1x1 dsp.FIRInterpolator]
Stage6: [1x1 dsp.FIRInterpolator]
CloneStages: true
```

## noisepsd

**Package:** dsp

Power spectral density of filter output due to roundoff noise

### Syntax

```
noisepsdOut = noisepsd(sysobj,L)
noisepsdOut = noisepsd( ____,Name,Value)
noisepsdOut = noisepsd(sysobj,L,opts)
noisepsdOut = noisepsd(sysobj,'Arithmetic',arithType)
noisepsd(sysobj, ____)
```

### Description

`noisepsdOut = noisepsd(sysobj,L)` computes the power spectral density (PSD) of filter output occurring because of roundoff noise. The roundoff noise is produced by quantization errors within the filter. The PSD is computed as an average over the `L` trials.

`noisepsdOut = noisepsd( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

`noisepsdOut = noisepsd(sysobj,L,opts)` uses an options object to specify the optional input parameters in lieu of specifying name-value pairs.

`noisepsdOut = noisepsd(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in the `arithType` input.

`noisepsd(sysobj, ____)` with no output argument launches FVTool and shows the noise PSD estimate of the filter System object.

### Examples

#### Compute the PSD of Output Noise

Compute the PSD of the output noise caused by the quantization processes in a fixed-point, direct-form FIR filter. The input signal has fixed-point data type. The `noisepsd` function performs the analysis based on the data type of the locked input.

```
b = firgr(27,[0 .4 .6 1],[1 1 0 0]);
firfilt = dsp.FIRFilter('Numerator',b); % Create the filter object.
data = fi(randn(15,16),1,16,3);
output = firfilt(data);
```

Quantize the filter to fixed-point. Plot the `hpsd` data. This is the data resulting from the noise PSD calculation. You can review the data in `hpsd.data`.

```
hpsd = noisepsd(firfilt,'Arithmetic','fixed');
plot(hpsd)
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FIRFilter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`

- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **L — Number of trials**

10 | positive integer

Number of trials used to compute the average, specified as a positive integer. The larger you specify *L*, the more accurate is the estimate of power spectral density but at the expense of longer computation time. When you do not specify *L*, the function sets *L* to the default value of 10 trials.

Data Types: `single` | `double`

### **opts — Options object**

options object

Options object to specify the optional input parameters in lieu of specifying name-value pairs.

Create an `opts` object with

```
opts = noisepsdopts(sysobj);
```

`opts` then takes the `noisepsd` settings from `sysobj`.

Because `opts` is an object, use the `set` function to change the parameter values in `opts` before using it with the `noisepsd` function. For example, you could specify a new sample rate with

```
set(opts, 'NormalizedFrequency', false, 'Fs', 48e3);
```

### **arithType — Arithmetic type**

'double' | 'single' | 'fixed'

Arithmetic used in the analysis, specified as 'double', 'single', or 'Fixed'. You cannot use the 'Arithmetic' argument unless you know the data type of the input. If you do not specify the 'Arithmetic' argument, that is, you use the syntax `noisepsdOut = noisepsd(sysobj)`, then the `noisepsd` function applies these rules:

- If the System object is Unlocked — The `noisepsd` function performs double-precision analysis.
- If the System object is Locked — The `noisepsd` function performs the analysis based on the data type of the locked input.

If you do specify the 'Arithmetic' argument, that is, you use the syntax `noisepsdOut = noisepsd(sysobj, 'Arithmetic', arithType)`, the `noisepsd` function applies these rules depending on the value you set for `arithType`.

| Value                | System Object State | Rule   |
|----------------------|---------------------|--|
| arithType = 'double' | Unlocked            | noisepsd performs double-precision analysis. |
|                      | Locked              | noisepsd performs double-precision analysis. |
| arithType = 'single' | Unlocked            | noisepsd performs single-precision analysis. |
|                      | Locked              | noisepsd performs single-precision analysis. |

| Value               | System Object State | Rule   |
|---------------------|---------------------|--|
| arithType = 'fixed' | Unlocked            | noisepsd produces an error because data type of the fixed-point input is unknown.  |
|                     | Locked              | When the input data type is double or single, then noisepsd produces an error because data type of the fixed-point input is unknown. |
|                     |                     | When the input data is of fixed-point type, noisepsd performs analysis based on the data type of the locked input.                   |

### Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

```
Example: b = firgr(27,[0 .4 .6 1],[1 1 0 0]); firfilt =
dsp.FIRFilter('Numerator',b); noisepsdOut = noisepsd(firfilt);
```

### NFFT — Number of FFT points

512 (default) | positive integer

Number of FFT points used in calculating the PSD, specified as a positive integer. This value determines the length of the PSD data vector shown in the Data field of the noisepsdOut structure. When 'NFFT' is set to an:

- Odd integer -- The length of the PSD data is given by  $(NFFT+1)/2$ .
- Even integer -- The length of the PSD data is given by  $(NFFT/2)+1$ .

When not specified, NFFT defaults to 512.

---

**Note** If the spectrum data you specify is calculated over half the Nyquist interval and you do not specify a corresponding frequency vector, the default frequency vector assumes that the number of points in the whole FFT is even. Also, the plot option to convert to a whole or two-sided spectrum assumes the original whole FFT length is even.

---

Data Types: single | double

### NormalizedFrequency — Use normalized frequency

true (default) | false

Indicate whether to use normalized frequency or linear frequency, specified as either:

- true -- Use normalized frequency. When not specified, the function defaults to true.

- `false` -- Use linear frequency. When you specify `false`, you must supply the sampling frequency `Fs`.

### **Fs — Sampling frequency**

'Normalized' | positive scalar

Sampling frequency to be specified in Hz when 'NormalizedFrequency' is set to `false`. When 'NormalizedFrequency' is set to `true`, 'Fs' is set to 'Normalized'.

Data Types: `single` | `double`

### **SpectrumType — Spectrum type**

'Onesided' (default) | 'Twosided'

Spectrum type of the generated PSD data, specified as:

- 'Onesided' -- Converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.
- 'Twosided' -- Converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically. If you choose a two-sided computation, you can also choose 'CenterDC' as `true`. Otherwise, 'CenterDC' must be `false`.

### **CenterDC — Set center of spectrum to DC**

`false` (default) | `true`

Shift the zero-frequency component to the center of a two-sided spectrum.

- When you set 'SpectrumType' to 'Onesided', it is changed to 'Twosided' and the data is converted to a two-sided spectrum.
- Setting 'CenterDC' to `false` shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not affect the 'SpectrumType' property setting.

## **Output Arguments**

### **noisepsdOut — PSD data object**

psd data object

Data object containing the PSD data, returned as a `psd` object. To extract the PSD vector from `noisepsdOut`, enter the following in the MATLAB command prompt:

```
get(noisepsdOut, 'data')
```

Plot the PSD data with `plot(noisepsdOut)`. The average power of the output noise (the integral of the PSD) can be computed with `avgpower`, a method of `dspdata` objects:

```
avgpwr = avgpower(hpsd)
```

`filter` | `noisepsopts` | `reorder` | `scale`

## noisepsdopts

**Package:** dsp

Create an options object for output noise PSD computation

### Syntax

```
opts = noisepsdopts(sysobj)
```

### Description

`opts = noisepsdopts(sysobj)` uses the current settings in the filter System object to create an options object that contains specified options for computing the output noise power spectral density. You can pass the `opts` object as an input argument to the `noisepsd` function.

### Examples

#### Set the Noise PSD Options

Use the `noisepsdopts` function to set options to compute the output noise PSD. `filt1` and `filt2` are lowpass filters that use different design methods. The `opts` object makes it easier to set the same conditions for the noise PSD computation in the `noisepsd` function.

```
d = fdesign.lowpass
```

```
d =
```

```
lowpass with properties:
```

```

    Response: 'Lowpass'
  Specification: 'Fp,Fst,Ap,Ast'
  Description: {4x1 cell}
  NormalizedFrequency: 1
                Fpass: 0.4500
                Fstop: 0.5500
                Apass: 1
                Astop: 60
```

```
filt1 = design(d,'butter','Systemobject',true)
```

```
filt1 =
```

```
dsp.SOSFilter with properties:
```

```

    Structure: 'Direct form II'
  CoefficientSource: 'Property'
    Numerator: [13x3 double]
  Denominator: [13x3 double]
  HasScaleValues: true
    ScaleValues: [0.4151 0.3718 0.3374 0.3099 0.2878 0.2701 0.2558 0.2445 0.2358 0.2293 0.2245 0.2193 0.2145]
```

```
Show all properties
```

```
filt2 = design(d, 'cheby2', 'Systemobject', true)
filt2 =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II'
        CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
        HasScaleValues: true
        ScaleValues: [0.7003 0.5771 0.4734 0.3925 0.3466 1]
```

Show all properties

```
opts = noisepsdopts(filt1)
```

```
opts =
    struct with fields:
        FreqPoints: 'All'
        NFFT: 512
        NormalizedFrequency: true
        Fs: 'Normalized'
        SpectrumType: 'Onesided'
        CenterDC: false
        ConfLevel: 'Not Specified'
        ConfInterval: []
```

```
opts.NFFT = 256; % Same as set(opts, 'nfft', 256).
opts.NormalizedFrequency = false;
opts.Fs = 1.5e3;
opts.CenterDC = true
```

```
opts =
    struct with fields:
        FreqPoints: 'All'
        NFFT: 256
        NormalizedFrequency: false
        Fs: 1500
        SpectrumType: 'Twosided'
        CenterDC: true
        ConfLevel: 'Not Specified'
        ConfInterval: []
```

With `opts` configured as needed, use it as an input argument for the `noisepsd` function.

```
npsd = noisepsd(filt1, 20, opts);
plot(npsd)
title("Round-off Noise Power Spectrum")
```

```
npsd = noisepsd(filt2,20,opts);  
plot(npsd)  
title("Round-off Noise Power Spectrum")
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FIRFilter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`

- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

### **opts** — Options object

spectrum object

Options object which contains the options for computing the output noise PSD, returned as a spectrum object. You pass the `opts` object as an input argument to the `noisepsd` function to specify values for the input parameters.

Using `opts`, you can set the following properties for `noisepsd`:

| Property Name       | Default Value | Description and Valid Entries  |
|---------------------|---------------|--|
| NFFT                | 512           | Specify the number of FFT points to use to calculate the PSD.  |
| NormalizedFrequency | true          | Determine whether to use normalized frequency. Enter a logical value of the logical <code>true</code> or <code>false</code> . Because this property is a logical value, do not enclose with single quotation marks.  |
| Fs                  | 'Normalized'  | Specify the sampling frequency to use when you set <code>NormalizedFrequency</code> to <code>false</code> . Use any integer value greater than 1. Enter the value in Hz.   |
| SpectrumType        | 'Onesided'    | Specify how <code>noisepsd</code> should generate the PSD. Options are 'Onesided' or 'Twosided'. If you choose a two-sided computation, you can also choose <code>CenterDC = true</code> . Otherwise, <code>CenterDC</code> must be <code>false</code> . <ul style="list-style-type: none"> <li>• 'Onesided' converts the type to a spectrum that is calculated over half the Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> <li>• 'Twosided' converts the type to a spectrum that is calculated over the whole Nyquist interval. All properties affected by the new frequency range are adjusted automatically.</li> </ul> |

| Property Name | Default Value | Description and Valid Entries   |
|---------------|---------------|---|
| CenterDC      | false         | <p>Shift the zero-frequency component to the center of a two-sided spectrum.</p> <ul style="list-style-type: none"> <li>When you set <code>SpectrumType</code> to 'Onesided', it is changed to 'Twosided' and the data is converted to a two-sided spectrum.</li> <li>Setting <code>CenterDC</code> to false shifts the data and the frequency values in the object so that DC is in the left edge of the spectrum. This operation does not effect the <code>SpectrumType</code> property setting.</li> </ul> |
| Arithmetic    | arithType     | <p>Analyze the filter System object, based on the arithmetic specified in the <code>arithType</code> input. <code>arithType</code> can be set to 'double', 'single', or 'fixed'. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.</p>   |

### Functions

noisepsd | freqrespest

## norm

P-norm of filter

### Syntax

```
l = norm(hd)
l = norm(hd, pnorm)
```

### Description

All of the variants of `norm` return the filter p-norm for the object in the syntax, a digital filter. When you omit the `pnorm` argument, `norm` returns the L2-norm for the object.

Note that by Parseval's theorem, the L2-norm of a filter is equal to the `l2` norm. This equality is not true for the other norm variants.

#### For `dfilt` Objects

`l = norm(hd)` returns the L2-norm of a discrete-time filter.

`l = norm(hd, pnorm)` includes input argument `pnorm` that lets you specify the norm returned. `pnorm` can be either

- Frequency-domain norms specified by one of `L1`, `L2`, or `Linf`
- Discrete-time domain norms specified by one of `l1`, `l2`, or `linf`

By Parseval's theorem, the L2-norm of a filter is equal to the `l2` norm. This equality is not true for the other norm variants.

IIR filters respond slightly differently to `norm`. When you compute the `l2`, `linf`, `L1`, and `L2` norms for an IIR filter, `norm(..., L2, tol)` lets you specify the tolerance for the accuracy in the computation. For `l1`, `l2`, `L2`, and `linf`, `norm` uses the tolerance to truncate the infinite impulse response that it uses to calculate the norm. For `L1`, `norm` passes the tolerance to the numerical integration algorithm. Refer to Examples on page 5-0 to see this in use. You cannot specify `Linf` for the norm and include the `tol` option.

## Examples

### Norm of an IIR Filter

This example shows how to compute the L2 norm of an IIR filter. A tolerance of 1e-10 is used.

```
spec = fdesign.lowpass('n,fc',5,0.4);
filter = butter(spec);
filternorm = norm(filter, 'l2', 1e-10)
```

```
filternorm = 0.6336
```

## **Version History**

**Introduced in R2011a**

### **See Also**

reorder | scale | scalecheck

## normalize

Normalize filter numerator or feed-forward coefficients

### Syntax

```
normalize(hq)  
g = normalize(hd)
```

### Description

`normalize(hq)` normalizes the filter numerator coefficients for a quantized filter to have values between -1 and 1. The coefficients of `hq` change — `normalize` does not copy `hq` and return the copy. To restore the coefficients of `hq` to the original values, use `denormalize`.

Note that for lattice filters, the feed-forward coefficients stored in the property `lattice` are normalized.

`g = normalize(hd)` normalizes the numerator coefficients for the filter `hq` to between -1 and 1 and returns the gain `g` due to the normalization operation. Calling `normalize` again does not change the coefficients. `g` always returns the gain returned by the first call to `normalize` the filter.

### Examples

#### Normalize the Coefficients of a Direct Form II Filter

Create a direct form II quantized filter that uses second-order sections. Then use `normalize` to maximize the use of the range of representable coefficients.

```
d = fdesign.lowpass('n,fp,ap,ast',8,.5,2,40);  
hd = design(d,'ellip');  
hd.arithmetic = 'fixed';
```

Check the filter coefficients. Note that `InitialSOSMatrix(3,2)>1`

```
InitialSOSMatrix = hd.sosMatrix;
```

Use `normalize` to modify the coefficients into the range between -1 and 1. The output `g` contains the gains applied to each section of the SOS filter.

```
g = normalize(hd);
```

None of the numerator coefficients exceed -1 or 1.

## Version History

Introduced in R2011a

# normalizefreq

Switch filter specification between normalized frequency and absolute frequency

## Syntax

```
normalizefreq(d)  
normalizefreq(d, flag)  
normalizefreq(d, false, fs)
```

## Description

`normalizefreq(d)` normalizes the frequency specifications in filter specifications object `d`. By default, the `NormalizedFrequency` property is set to `true` when you create a design object. You provide the design specifications in normalized frequency units. `normalizefreq` does not affect filters that already use normalized frequency.

If you use this syntax when `d` does not use normalized frequency specifications, all of the frequency specifications are normalized by  $fs/2$  so they lie between 0 and 1, where `fs` is specified in the object. Included in the normalization are the filter properties that define the filter pass and stopband edge locations by frequency:

- `F3 dB` — Used by IIR filter specifications objects to describe the passband cutoff frequency
- `Fcutoff` — Used by FIR filter specifications objects to describe the passband cutoff frequency
- `Fpass` — Describes the passband edges
- `Fstop` — Describes the stopband edges

In this syntax, `normalizefreq(d)` assumes you specified `fs` when you created `d` or changed `d` to use absolute frequency specifications.

`normalizefreq(d, flag)` where `flag` is either **true** or **false**, specifies whether the `NormalizedFrequency` property value is `true` or `false` and therefore whether the filter normalizes the sampling frequency `fs` and other related frequency specifications. `fs` defaults to 1 for this syntax.

When you do not provide the input argument `flag`, it defaults to `true`. If you set `flag` to `false`, affected frequency specifications are multiplied by  $fs/2$  to remove the normalization. Use this syntax to switch your filter between using normalized frequency specifications and not using normalized frequency specifications.

`normalizefreq(d, false, fs)` lets you specify a new sampling frequency `fs` when you set the `NormalizedFrequency` property to `false`.

## Examples

### Normalize the Frequency Specifications of a Filter

These examples demonstrate using `normalizefreq` in both of the major syntax applications—setting the design object frequency specifications to use absolute frequency (`normalizefreq(hd,false,fs)`) and resetting a design object to using normalized frequencies (`normalizefreq(d)`).

Construct a highpass filter specifications object by specifying the passband and stopband edges and the desired attenuations in the bands. By default, provide the frequency specifications in normalized values between 0 and 1.

```
d = fdesign.highpass(0.35, 0.45, 60, 40);
```

`Fstop` and `Fpass` are in normalized form, and the property `NormalizedFrequency` is true.

Now use `normalizedfreq` to convert to absolute frequency specifications, with a sampling frequency of 1000 Hz.

```
normalizefreq(d,false,1e3);
```

Both of the attenuation specifications remain the same. The passband and stopband edge definitions now appear in Hz, where the new value represents the normalized values multiplied by  $F_s/2$ , or 500 Hz.

Converting to using normalized frequencies consists of using `normalizefreq` with the design object `d`.

```
normalizefreq(d)
```

For bandstop, bandpass, and multiple band filter specifications objects, `normalizefreq` works the same way for all band edge definitions. When you do not provide the sampling frequency  $F_s$  as an input argument and you are converting to absolute frequency specifications, `normalizefreq` sets  $F_s$  to 1, as shown in this example.

```
d=fdesign.bandstop(0.25,0.35,0.55,0.65,50,60);  
normalizefreq(d,false)
```

# nstates

Number of filter states

## Syntax

```
n = nstates(hd)
```

## Description

### Discrete-Time Filters

`n = nstates(hd)` returns the number of states `n` in the discrete-time filter `hd`. The number of states depends on the filter structure and the coefficients.

## Examples

### Number of States of a Filter

Determine the number of states of a direct form FIR filter.

```
FIRFilter = firls(30,[0 .1 .2 .5]*2,[1 1 0 0]);  
DiscFilter = dfilt.dffir(FIRFilter);  
NstateDF = nstates(DiscFilter)
```

```
NstateDF = 30
```

## Version History

Introduced in R2011a

## order

**Package:** dsp

Order of discrete-time filter System object

### Syntax

```
n = order(sysobj)
```

### Description

`n = order(sysobj)` returns the order `n` of the filter System object. The order depends on the filter structure and the reference double-precision floating-point coefficients.

### Examples

#### Determine Filter Order

Design a compensation decimator for a CIC decimator using the `dsp.FilterCascade` object. Determine the order of the overall filter.

```
cicdecim = dsp.CICDecimator('DecimationFactor', 6, ...  
    'NumSections', 6);  
  
fs = 16e3;    % Sampling frequency of input of compensation decimator  
fPass = 4e3; % Passband frequency  
fStop = 4.5e3; % Stopband frequency  
ciccomp = dsp.CICCompensationDecimator(cicdecim, ...  
    'DecimationFactor', 2, ...  
    'PassbandFrequency', fPass, ...  
    'StopbandFrequency', fStop, ...  
    'SampleRate', fs);  
  
filtchain = dsp.FilterCascade(cicdecim, ciccomp);  
  
order(filtchain)  
  
ans = 648
```

### Input Arguments

#### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`

- `dsp.BiquadFilter`
- `dsp.Channelizer`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

## Output Arguments

### **n** — Filter order

scalar

Filter order, returned as a scalar. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Data Types: `double`

## Version History

Introduced in R2011a

## See Also

`info`

## outputDelay

**Package:** dsp

Determine output delay of single-rate or multirate filter

### Syntax

```
D = outputDelay(sysobj)
[D,FsOut] = outputDelay(sysobj)
[D,FsOut,B] = outputDelay(sysobj)
[ ___ ] = outputDelay(sysobj,Name=Value)
```

### Description

`D = outputDelay(sysobj)` returns the system output delay of the single-rate or multirate filter object. A multirate filter is any cascade combining upsampling, downsampling, and convolution filters (FIR or IIR). Single-rate filters are special cases of multirate filters with a rate conversion factor of 1. The delay  $D$  results from the group delay of the convolution stages within the filter.

Use this syntax when `sysobj` is a linear-phase single-rate filter. To determine if a filter object has linear phase, use the `islinphase` function.

`[D,FsOut] = outputDelay(sysobj)` also returns the output sample rate. Use this syntax when `sysobj` is a linear-phase multirate filter.

`[D,FsOut,B] = outputDelay(sysobj)` also returns the input frequency band  $B$  over which the delay value is within the default tolerance of 5% (in input sample units) of  $D$ . That is,  $|D(f) - D| \leq 0.05/FsIn$ , where  $f$  is a frequency in the band  $B$ .

Use this syntax when `sysobj` has filter stages that have a nonlinear phase.

`[ ___ ] = outputDelay(sysobj,Name=Value)` specifies options using one or more name-value arguments in addition to the input arguments in previous syntaxes. For example, `outputDelay(sysobj, Tol=0.01)` estimates the band of input frequencies over which the delay value is within the tolerance of 1%.

Use this syntax to specify `FsIn`, `Fc`, `Tol`, and `FFTLength`.

## Examples

### Compute Output Delay of Filter Cascade

Compute the output delay of a cascade of `dsp.FIRRateConverter` objects. Use this delay value to plot the input and resampled signals on the same plot in a time scope.

### Resample Input Signal

First, let us inspect the delay and scaling that occurs in filtering. To do that, create a sinusoidal input signal. Initialize a cascade of `dsp.FIRRateConverter` objects to resample the input signal.

```
n = (0:7*17-1)';
u = cos(6*pi*n/147);

src = cascade(dsp.FIRRateConverter(13,17), dsp.FIRRateConverter(18,7))

src =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRRateConverter]
    Stage2: [1x1 dsp.FIRRateConverter]
    CloneStages: true
```

Resample the input signal by passing the signal through the cascade of `dsp.FIRRateConverter` objects.

```
y = src(u);
```

### Plot the Input and Output Signals

Initialize a time scope using the `timescope` object to visualize the input and the resampled signals.

```
tsnosync = timescope(NumInputPorts=2,...
    ChannelNames={'Input', 'Output'});
```

Plot the input and the resampled signals on the same plot in the time scope. You can see that the two signals are out of sync with respect to each other by a certain amount of delay and stretch over a different time scale

```
tsnosync(u,y);
```

### Using `outputDelay` to Synchronize Signals

To plot the input and resampled signals on the same plot, you need to account for the output delay of the filter. To compute the output delay, use the `outputDelay` function. The value of this delay depends on the filter structure and order, the rate conversion factor, and the signal input to the filter. In addition to the output delay, the rate conversion operation of the filter introduces scaling on the time domain. You must account for the output delay and the scaling.

Use the `outputDelay` function to compute the delay and the output sample rate introduced by the multirate filter. You can optionally specify the input sample rate to the function. Apply the delay value to the output signal through the `TimeDisplayOffset` property of the time scope.

To account for the scaling, specify the input and output sample rates through the `SampleRate` property of the time scope. The inverse of the input and output sample rates vector determines the x-axis (time axis) spacing between points in the input signal and the output signal, respectively.

Initialize the time scope to use the updated `TimeDisplayOffset` and `SampleRate` properties. Visualize the input and the resampled signals on the time scope. With the delay and scaling accounted for, you can see that signals are synchronized and have no delay with respect to each other.

```
FsIn = 44.1e2;
[D,FsOut] = outputDelay(src,FsIn=FsIn);

tssync = timescope(NumInputPorts=2,...
    SampleRate=[FsIn FsOut], ...
```

```

TimeDisplayOffset=[0, -D],...
ChannelNames={'Input', 'Output'});
tssync(u,y);

```

### Compute Output Delay for Farrow Rate Converter

Compute the output delay for a farrow rate converter, and use this delay value to plot the input sinusoidal signal and the rate converted signal on the same plot.

Create an input sinusoidal signal using the `sin` function. Initialize the `dsp.FarrowRateConverter` object to model the farrow rate converter.

```

u = sin(6*pi*(1:50)'/200);
FsIn = 48000;
frc = dsp.FarrowRateConverter(FsIn, 44100);

```

Compute the output delay of the rate converter using the `outputDelay` function.

```
[D, FsOut] = outputDelay(frc)
```

```
D = 4.1667e-05
```

```
FsOut = 44100
```

Resample the input using the farrow rate converter. Visualize the input signal and the resampled signal on the time scope. To account for the time delay and the scaling, set the `TimeDisplayOffset` and `SampleRate` properties of the time scope to `[0 -D]` and `[FsIn FsOut]`, respectively.

```
y = frc(u);
ts = timescope(NumInputPorts = 2, SampleRate = [FsIn FsOut], ...
    TimeDisplayOffset = [0, -D], ...
    ChannelNames = {'Input', 'Output'}, ...
    TimeSpan = length(y)*1.1/FsIn, ...
    PlotType = 'stem');
ts(u, y);
```

### Calculate Frequency Band for Nonlinear Phase Filters

Nonlinear phase filters have a group delay that depends on the input frequency. Due to the nonlinear phase nature, such filters distort input signals. Therefore, the output of these filters cannot be obtained by shifting and scaling the input on the time domain. To use the `outputDelay` function to compute the output delay of such filters, the filters must have a relatively constant group delay over the input signal band.

Start by calculating the frequency band of two nonlinear fractional delay FIR filters with partially flat group delay. One filter has a higher bandwidth compared to the other filter. Note the effect of the higher bandwidth on the output delay and the input frequency band over which the function computes the delay.

Then, consider a multirate filter cascade that has a highly nonlinear group delay response over a given band but has a relatively flat group delay over other frequency bands. Increase the tolerance value that you specify to the `outputDelay` function and see the effect on the input frequency band that the function returns.

### Fractional Delay FIR Filter with Nonlinear Phase and Partially Flat Group Delay

Since the fractional delay FIR filter has a nonlinear phase response, specify a center frequency around which the `outputDelay` function should compute the delay. When you specify the center frequency, the function returns an interval of frequencies (as the third output argument) over which the delay value is within the specified tolerance.

Design a fractional delay filter using the `designFracDelayFIR` function. Specify the filter to have a fractional delay of  $1.25e-3$  seconds and a passband coverage of 50%.

```
FsIn = 20;
Fc = 1;
FD = 1.25e-3;
```

```
n1PhaseFilterObj1 = dsp.FIRFilter(designFracDelayFIR(FD*FsIn, 0.5));
```

Using the `outputDelay` function, calculate the output delay around the center frequency of 1 Hz. Specify the input sample rate to 20 Hz and the tolerance to 0.01 (1%). In addition to the output delay, the function returns the input band over which the deviation in delay is upto 1% of `D1`.

```
[D1,~,B1] = outputDelay(n1PhaseFilterObj1,FsIn=FsIn,Fc=Fc,Tol=0.01)
```

```
D1 = 0.1513
```

```
B1 = 1×2
```

```
    -6.3794    6.3794
```

Use the `grpdelay` function to compute the group delay  $G$  of the filter and the frequencies  $W$  (in Hz) at which the group delay is evaluated. Specify the FFT length to 8192, and the sample rate to be the same as the input sample rate.

Plot the overall filter group delay. On the same figure, plot the input frequency band and the output delay value at the center frequency. The input frequency band indeed contains the center frequency.

```
[G1,W1] = n1PhaseFilterObj1.grpdelay(8192, FsIn); % Use 8192 FFT points to calculate the group delay
I1 = W1>=B1(1) & W1<=B1(2); % Mask applicable frequencies
```

```
plot(W1,G1/FsIn);
hold on
plot(W1(I1), G1(I1)/FsIn, 'r', LineWidth=2);
plot(Fc, D1, 'ro');
yline(D1+0.01/FsIn*[-1 1], 'k:');
```

```
title(sprintf('Applicable Band (FsIn=%iHz, Fc=%1.1fHz)',FsIn,Fc))
```

```
legend('Output delay (in sample time units)',...
```

```
    'Applicable input frequencies band',...
```

```
    'Output delay for Fc',...
```

```
    'Tolerance around the nominal delay', Location='best')
```

```
ylabel('Delay (sec)')
```

```
xlabel('Frequency (Hz)')
```

```
hold off
```

### Comparing with Higher Bandwidth Design

Compare the previous design with a higher bandwidth fractional delay design. For more information on the bandwidth of a fractional-delay FIR filter, see `designFracDelayFIR`.

Design a fractional-delay FIR filter with the same fractional delay ( $1.25e-3$  seconds) as the previous design but with a 70% bandwidth coverage.

```
n1PhaseFilterObj2 = dsp.FIRFilter(designFracDelayFIR(FD*FsIn, 0.7));
```

Measure the output delay of this alternative design. The output delay  $D2$  is larger due to the longer FIR length, but the input band is also larger, allowing signals up to 7.2 Hz (compared with only 6.4 Hz in the previous design).

```
[D2,~,B2] = outputDelay(n1PhaseFilterObj2,FsIn=FsIn,Fc=Fc,Tol=0.01)
```

```
D2 = 0.2512
```

```
B2 = 1×2
```

```
    -7.2217    7.2217
```

```
[G2,W2] = n1PhaseFilterObj2.grpdelay(8192, FsIn);
```

Plot the group delay response of the alternative design against the design with a 50% coverage.

```
I2 = W2>=B2(1) & W2<=B2(2); % Mask applicable frequencies
```

```

plot(W1,G1/FsIn);
hold on
plot(W2,G2/FsIn);
plot(W1(I1), G1(I1)/FsIn, 'r', LineWidth=2);
plot(W2(I2), G2(I2)/FsIn, 'm', LineWidth=2);
title(sprintf('Applicable Band (FsIn=%iHz, Fc=%1.1fHz)',FsIn,Fc))
legend('Output delay (in sample time units) of design 1',...
      'Output delay (in sample time units) of design 2',...
      'Applicable input frequencies band of design 1',...
      'Applicable input frequencies band of design 2', ...
      Location='best')
ylabel('Delay (sec)')
xlabel('Frequency (Hz)')
hold off

```

### Multirate Filter Cascade with Nonlinear Phase

Design a two-stage filter cascade that contains a stable IIR lowpass (which has a nonlinear phase) followed by an FIR decimator with a rate conversion factor of 2.

```

FsIn = 10;
Fc = 1.5;
LP = dsp.LowpassFilter(FilterType='IIR', SampleRate=FsIn, PassbandFrequency=2.3, StopbandFrequency=2.5);
nlPhaseCascadeObj = cascade(LP, dsp.FIRDecimator(2));

```

Measure the output delay, output sample rate, and the input frequency band for this cascade using a narrowband input signal with a carrier frequency of 1.5Hz. Set the tolerance to 0.001 samples. The

function returns an output sample rate of 5 Hz (which is half the input sample rate of 10 Hz, owing to the half-rate decimator).

```
[D,FsOut,B] = outputDelay(nlPhaseCascadeObj, Fc=Fc, Tol=0.001)
D = 2.9209
FsOut = 5
B = 1×2
    1.5000    1.5000
```

The band the function returns is a trivial band. That is, it contains a single point (the left and right boundaries are the same). This means that a tolerance value of 0.001 is too small.

To fix that, increase the tolerance to 0.05 seconds (0.5 of the input sample time). While the delay and the output sample rate do not change, the band is now nontrivial, and it contains the center frequency. The band is also relatively narrow due to the highly nonlinear phase nature of the IIR design.

```
[D1,FsOut1,B1] = outputDelay(nlPhaseCascadeObj, Fc=Fc, Tol=0.5)
D1 = 2.9209
FsOut1 = 5
B1 = 1×2
    1.3562    1.5967
```

Increase the tolerance value to 2. The band now increases even more as you have specified a more lax tolerance.

```
[D2,FsOut2,B2] = outputDelay(nlPhaseCascadeObj, Fc=Fc, Tol=2)
D2 = 2.9209
FsOut2 = 5
B2 = 1×2
    0.4565    1.7786
```

```
[G,W] = nlPhaseCascadeObj.grpdelay(8192, FsIn);
I1 = W>=B1(1) & W<=B1(2); % Mask applicable frequencies
I2 = W>=B2(1) & W<=B2(2); % Mask applicable frequencies

plot(W,G/FsIn);
hold on
plot(W(I2), G(I2)/FsIn, Color=[0.6 0.1 0.6], LineWidth=2);
plot(W(I1), G(I1)/FsIn, Color=[0 0.7 0.7], LineWidth=4);
plot(Fc, D1, 'ro');
title(sprintf('Applicable Band (FsIn=%iHz, Fc=%1.1fHz)',FsIn,Fc))
legend('Output delay (in sample time units)',...
       'Applicable input frequencies band with Tol=1',...)
```

```

    'Applicable input frequencies band with Tol=0.5',...
    'Output delay for Fc',...
    Location='best')
ylabel('Delay (sec)')
xlabel('Frequency (Hz)')
hold off

```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.Differentiator`

- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `FsIn=48000, Fc=-10.3, Tol=0.01, FFTLength=100`

### **FsIn** — Input sample rate

1 (default) | positive scalar

Input sample rate of the filter object `sysobj`, specified as a positive scalar.

If you do not specify `FsIn`, the function uses the input sample rate specified in the built-in input sample rate property of the filter object if it exists, otherwise the function uses the default rate of 1.

Specify `FsIn` when you want to override the input sample rate specified in the filter object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Fc** — Carrier frequency

0 (default) | real scalar

Carrier frequency from which the function derives the group delay of the convolution stages, specified as a real scalar. Specify `Fc` when the filter object `sysobj` has stages with a nonlinear phase.

For filters with a nonlinear phase (a varying group delay), the delay value `D` the `outputDelay` function returns depends on the input frequency. For more details, see “Linear and Nonlinear Phase Filters” on page 5-1326. For an example, see “Calculate Frequency Band for Nonlinear Phase Filters” on page 5-1316.

If you do not specify  $F_c$ , the function uses the default center frequency of 0 for most filters except the bandpass and highpass filters. Make sure that the absolute value of the carrier frequency is not larger than the Nyquist frequency. That is,  $|f_c| \leq F_{sIn}/2$ , where  $F_{sIn}$  is the input sample rate of the filter object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Tol — Tolerance of estimated delay**

0.05 (default) | real scalar

Tolerance of the estimated delay value  $D$ , specified as a real scalar. Specify `Tol` when you want to calculate the input band  $B$ .

When you specify a tolerance `Tol`, the function can estimate a band of input frequencies  $B$  for which the delay is close to  $D$  up to a given tolerance `Tol`. That is,  $|D(f) - D| \leq Tol/F_{sIn}$ , where  $f$  is a frequency in the band given by the  $B$  vector.

When you use the following signature, the function uses the default 5% tolerance (in input sample units) of  $D$ .

```
[D, FsOut, B] = outputDelay(sysobj, Fc=fc)
```

Alternatively, you can specify the tolerance value using the `Tol` argument.

```
[D, FsOut, B] = outputDelay(sysobj, Fc=fc, Tol=T)
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **FFTLength — FFT length**

8192 (default) | nonnegative integer

FFT length, specified as a nonnegative integer. Specify `FFTLength` when you want to calculate the input band  $B$ .

This value determines the frequency resolution with which the function estimates the input frequency band  $B$ . Higher the FFT length, the higher is the frequency resolution and accuracy of  $B$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Output Arguments**

### **D — Output delay**

nonnegative scalar

Output or resampling delay of the multirate filter on page 5-1324, returned as a nonnegative scalar.

The delay value  $D$  is determined by the group delay of the convolution filter stages, and the value depends on the filter structure, filter order, and rate conversion factors. When the filter has a nonlinear phase, the delay value also depends on the input signal.

For filters with a linear phase (that is, a flat group delay), the value of  $D$  applies to all inputs. For filters with a nonlinear phase (that is, a varying group delay), the delay value  $D$  depends on the input frequencies.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**FsOut — Output sample rate**

positive scalar

Output sample rate of the multirate filter object for the given input sample rate `FsIn`, returned as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**B — Estimated input frequency band**

two-element row vector

Estimated input frequency band  $[f_1 \ f_2]$  over which the delay value is within tolerance `Tol` (in input sample units) of `D`, returned as a two-element row vector. If you do not specify `Tol`, the function uses a tolerance value of 0.05 (or 5%).

The frequency band stretches from  $f_1$  counterclockwise to  $f_2$ . That is, if  $f_2 > f_1$ , then the band is  $\{f_1 < f < f_2\}$ . If  $f_2 < f_1$ , then the band wraps around the Nyquist frequency, that is the union of  $\{-FsIn/2 < f < f_2\}$  and  $\{f_1 < f < FsIn/2\}$ . If  $f_1 = f_2$ , then the band has a single frequency due to the FFT resolution being too coarse. In such cases, increase the value of `FFTLength` or the tolerance `Tol`.

Band measurement is available only for systems that can be reduced to a rational rate converter. For a linear phase system, the band `B` is always full,  $B = [-FsIn/2, \ FsIn/2]$  and the delay `D` is applicable for all input frequencies (flat group delay).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**More About****Multirate Filters**

A multirate filter is any cascade combining upsampling, downsampling, and convolution filters (FIR or IIR).

Most filter System objects in DSP System Toolbox are multirate filters. For example, `dsp.FIRDecimator(5)` is the multirate filter  $H(z)$  followed by a downsampler that has a downsampling ratio of 5.

Single-rate filters are special cases of multirate filters with a rate conversion factor of 1. Single-stage filters are special cases of cascades of multirate filters. For example, `dsp.LowpassFilter` is a single-rate, single-stage filter of the form  $H(z)$ .

**Multirate Filters as Resampling Systems**

The `outputDelay` function assumes that the multirate filter `sysobj` models a resampling system. The output of the resampling system is a filtered and resampled version of the input, and hence has a different rate compared to the input.

A resampling system interpolates the input  $u(n)$  to a continuous domain function  $f(t)$  that approximates the input.

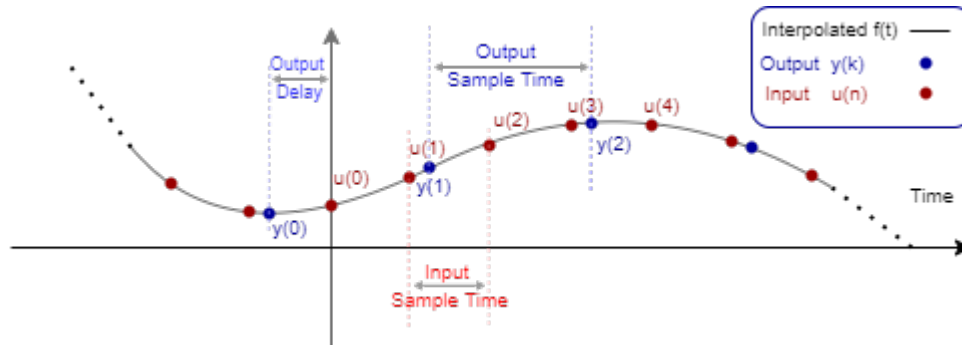

$$u(n) \approx f(n/FsIn)$$

The output is then sampled from  $f(t)$  on a different time scale.

$$y(k) = f(k/FsOut - D)$$

The values  $FsIn$  and  $FsOut$  are the input and output sample rates, respectively, and  $D$  is the resampling or output delay.

This graph overlays the input and output sequences on the same plot, shows the input and output sample times, and also shows the output delay that the function returns.

For examples that demonstrate the effect of the resampling delay and scaling in multirate filters, see “Compute Output Delay of Filter Cascade” on page 5-1312 and “Time Delay and Scaling in Multirate DSP Filters”.

### Output Delay and Group Delay

The output delay and the group delay are related to each other.

The output or resampling delay is the delay of the signal in time units as it goes through a convolution filter (FIR or IIR). For a single-rate filter, the output delay ( $D$ ) and the group delay ( $\tau_g$ ) are scaled by the sample rate,  $D = \tau_g/FsIn$ . If the filter has a linear phase, both the output delay and the group delay do not depend on the input frequency. However, if the filter has nonlinear phase, then the group delay and the output delay depend on the input frequency.

This figure shows the impulse response of a symmetric 24-tap FIR filter. You can see that the output delay and the group delay are equivalent quantities in different scales.

If the filter is a multirate filter, the output delay is the total delay that the filter accumulates on all stages of the cascade. The output sample rate  $F_{SOut}$  of each stage becomes the input sample rate  $F_{SIn}$  of the subsequent stage. The function scales the delay values accumulated over each stage by the rate conversion factors of the individual stages.

The group delay is defined only for single-rate filters while the output delay is defined for both single-rate and multirate filters.

The group delay refers to the average delay of the convolution filter (FIR or IIR) as a function of frequency. It is computed as the negative first derivative of the phase response of the filter. If the frequency response of a filter is  $H(e^{j\omega})$ , then the group delay is

$$\tau_g(\omega) = -\frac{d\theta(\omega)}{d\omega},$$

where  $\theta(\omega)$  is the phase, or argument, of  $H(e^{j\omega})$ .

If the filter is a linear phase filter, the group delay response is flat. The output delay  $D$  does not depend on input frequency. If the filter is a nonlinear phase filter, the group delay response varies with frequency and the delay value  $D$  is valid only for bandlimited inputs around a carrier frequency  $F_c$ . The function determines the edges of the frequency band  $B$  such that the group delay over this frequency region is approximately constant. For more information, see “Linear and Nonlinear Phase Filters” on page 5-1326. For an example, see “Time Delay and Scaling in Multirate DSP Filters”.

### Linear and Nonlinear Phase Filters

Depending on the group delay of the filter stages (whether flat or varies with frequency), the `outputDelay` function can operate in two modes.

If all the filter stages have a linear phase (flat group delay), then the `outputDelay` function operates in the full band mode on page 5-1327. If the individual filter stages have a nonlinear phase but can be reordered through noble identity operations such that the equivalent stage has a linear phase, then the `outputDelay` function operates in the full band mode and you do not need to specify the carrier frequency  $F_c$ .

For an example of nonlinear filter stages having a linear phase equivalent, see “A Nonlinear Phase Multirate Filter with Linear Phase Equivalent” on page 5-1328.

If one or more stages have a nonlinear phase, and the filter does not have a linear phase equivalent, then the `outputDelay` function operates in the bandlimited mode on page 5-1327. In the bandlimited mode, the function requires you to specify the input center frequency  $F_c$  in order to compute the delay.

### Full-Band Mode in Linear Phase Filters

In the full band mode, the delay value  $D$  applies to all inputs. All symmetric filter designs work in this mode.

The `outputDelay` function uses the group delay of the filter stages to calculate the overall output delay. When the filters have a linear phase, the group delay of the filter does not vary with frequency. The band  $B$  is always full (flat group delay).

For symmetric filters, the output delay ( $D$ ) can be thought of as the center of mass of the impulse response ( $h[k]$ ), which can be obtained by the weighted sum:

$$D = \frac{1}{FsIn} \cdot \tau_g,$$

$$D = \frac{1}{FsIn} \cdot \frac{\sum_{k=0}^{L-1} k \cdot h[k]}{\sum_{j=0}^{L-1} h[j]}$$

where  $\tau_g$  is the group delay of the filter, and  $L$  is the length of the filter.

The function obtains the output delay by scaling the center of mass with the sample time. For an example, see “Time Delay and Scaling in Multirate DSP Filters”.

This center-of-mass delay formulation can be generalized for asymmetric filters, where it takes the form of group delay. Symmetric and anti-symmetric filters have a linear phase response, hence their group delay response is constant and does not depend on frequency. Filters with a varying group delay (nonlinear phase filters) can exhibit distortion on the time domain.

### Bandlimited Mode for Nonlinear Phase Filters

In the bandlimited mode, the `outputDelay` function calculates the delay  $D$  for the input frequency  $F_c$ . The function uses this mode with filters that have nonlinear phase stages. Many causal and stable rational IIR filters have a nonlinear phase, and therefore have a varying group delay. Generally, those filters distort input signals, which breaks the resampling model described in “Multirate Filters” on page 5-1324. In such cases, the resampling model and the delay value  $D$  are valid only for bandlimited inputs around  $F_c$ . The function determines the width of the frequency band  $B$  such that the group delay over this frequency region is approximately constant. Use the `grpdelay` function to inspect the flatness of the group delay of the filter stages.

Assume that the input is a narrowband signal centered around some carrier frequency  $\omega_c = 2\pi F_c$ . The resampling model is slightly different in this case, where the input is

$$u(n) \approx f(n/FsIn) \cdot \cos(\omega_c n),$$

and the output is given by

$$y(k) \approx f(k/FsOut - D) \cdot \cos(\omega_c(k/FsOut - D_p)).$$

The baseband is delayed by output delay  $D$ , which is calculated using the group delay specific to the input frequency. The carrier, however, experiences a different delay,  $D_p$ , which is obtained by the phase delay of the filter rather than its group delay.

You can specify the input carrier frequency through the input argument  $F_c$ . The `outputDelay` function can also calculate the interval of input frequencies  $B$  that the value of  $D$  is applicable up to a certain tolerance. This band is returned as the third return value of the function (with the second one being the output sample rate  $F_sOut$ ). The tolerance (in sample time units) can be specified using the `Tol` argument.

To determine if a filter object is linear, use the `islinphase` function.

### A Nonlinear Phase Multirate Filter with Linear Phase Equivalent

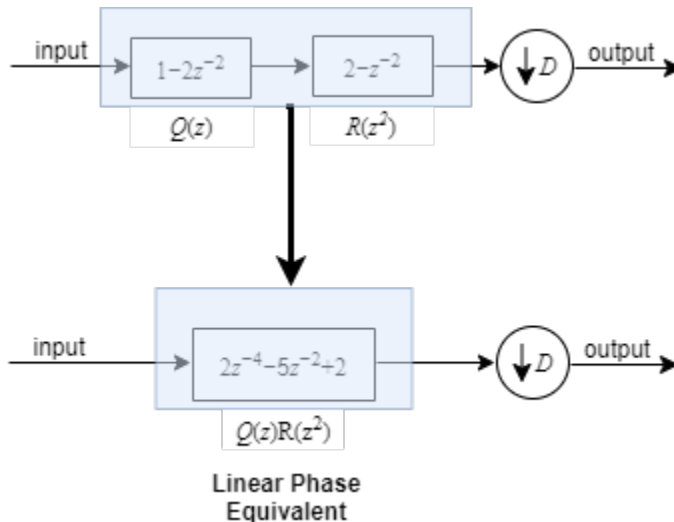

Consider the multirate filter cascade below with nonlinear phase filter stages  $Q(z)$  and  $R(z)$ .

The noble identity for decimation is given by:

Apply the noble identity for decimation on  $R(z)$ . The product  $Q(z)R(z^2)$  is a linear phase system.

Even though the individual filter stages have a nonlinear phase, the combined equivalent filter after applying the noble identity has a linear phase. The `outputDelay` function treats this filter as a linear phase filter.

All combinations of nonlinear phase stages cannot be reordered to form linear phase equivalents. The function treats such filters as nonlinear filters and operates in the bandlimited mode.

# phasedelay

**Package:** dsp

Phase delay response of discrete-time filter System object

## Syntax

```
[phi,w] = phasedelay(sysobj)
[phi,w] = phasedelay(sysobj,n)
[phi,w] = phasedelay(sysobj,n,fs)
[phi,w] = phasedelay( ____, 'Arithmetic', arithType)
phasedelay(sysobj)
```

## Description

`[phi,w] = phasedelay(sysobj)` returns the phase delay response vector, `phi`, and the corresponding frequency vector, `w`, in radians/sample of the filter System object based on the current filter coefficients.

`[phi,w] = phasedelay(sysobj,n)` returns the `n`-point phase delay response vector and the corresponding `n`-point frequency vector in radians/sample of the filter System object.

`[phi,w] = phasedelay(sysobj,n,fs)` uses `fs` to calculate the delay response. When you specify this syntax without any output arguments, the function launches `fvtool` and plots the response to `fs/2`.

`[phi,w] = phasedelay( ____, 'Arithmetic', arithType)` analyzes the filter System object, based on the arithmetic specified in `arithType` using anyone of the previous syntaxes.

`phasedelay(sysobj)` launches `fvtool` and shows the phase delay response of the filter System object.

For more input options, see `phasedelay` in Signal Processing Toolbox.

## Examples

### Phase Delay of Discrete-Time Filter

Design an FIR filter.

```
Fs = 8000; Fcutoff = 2000;
FIRfilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
```

The `phasedelay` function computes the phase delay of the filter and displays it using `FVTool`.

```
phasedelay(FIRfilt)
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.Channelizer`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`

- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**n — Number of points over which phase response is evaluated**

8192 (default) | positive integer

Number of points over which the phase response is evaluated around the upper half of the unit circle. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

Data Types: `double`

**fs — Sampling frequency**

1 (default) | positive scalar

Sampling frequency used in computing the phase delay response, specified as a positive scalar.

Data Types: `single` | `double`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- `unlocked` -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

- **locked** -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **phi** — Phase delay response vector

vector

Phase delay response vector, evaluated at  $n$  equally-spaced points around the upper half of the unit circle, returned as a vector. If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

### **w** — Frequency vector

vector

Frequency vector of length  $n$  in radians/sample.  $w$  consists of  $n$  equally-spaced points around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

# phasez

**Package:** dsp

Phase response of discrete-time filter System object (unwrapped)

## Syntax

```
[phi,w] = phasez(sysobj)
[phi,w] = phasez(sysobj,n)
[phi,w] = phasez( ____, 'Arithmetic',arithType)
phasez(sysobj)
```

## Description

`[phi,w] = phasez(sysobj)` returns the unwrapped phase response `phi` of the filter System object, `sysobj`, based on the current filter coefficients. The vector `w` contains the frequencies (in radians) at which the function evaluates the phase response. The phase response is evaluated at 8192 points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez(sysobj,n)` returns the phase response of the filter System object and the corresponding frequencies at `n` points equally spaced around the upper half of the unit circle.

`[phi,w] = phasez( ____, 'Arithmetic',arithType)` analyzes the filter System object, based on the arithmetic specified in `arithType`, using either of the previous syntaxes.

`phasez(sysobj)` displays the phase response of the filter System object `sysobj` in the `fvtool`.

For more input options, see `phasez` in Signal Processing Toolbox.

## Examples

### Unwrapped Phase Response of a Discrete-Time Filter

```
Fs = 8000; Fcutoff = 2000;
FIRfilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
```

`phasez` computes the unwrapped phase response of the filter and displays it using `fvtool`

```
phasez(FIRfilt);
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`

- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**n — Number of points over which the frequency response is computed**

8192 (default) | positive integer

Number of points over which the frequency response is computed. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- **unlocked** -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- **locked** -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **phi** — Phase response

vector

Phase response vector of length  $n$ . If  $n$  is not specified, the function uses a default value of 8192. The phase response is evaluated at  $n$  points equally spaced around the upper half of the unit circle.

### **w** — frequencies

vector

Frequency vector of length  $n$ , in radians/sample.  $w$  consists of  $n$  points equally spaced around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

## plot

**Package:** dsp

(To be removed) Plot pulse signal and metrics

---

**Note** `dsp.PulseMetrics` and `dsp.TransitionMetrics` objects will be removed in a future release. Use the functions from “Pulse and Transition Metrics” instead. To plot the metrics, call the functions with no output arguments. For more information, see “Compatibility Considerations”.

---

### Syntax

```
plot(pm)
```

### Description

`plot(pm)` plots the signal and metrics resulting from the last call of the object algorithm.

By default `plot` displays:

- the low- and high-state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the `TransitionOutputPort` property of the object is set to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the lower- and upper-state boundaries over the specified seek duration are plotted.

### Examples

#### Slew Rates for 2.3 V Digital Clock

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

```
load('pulseex.mat','x','t');
```

Construct the `dsp.PulseMetrics` object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

```
pm = dsp.PulseMetrics('SampleRate',4e6, ...
    'TransitionOutputPort', true, ...
    'StateLevelsSource', 'Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse,transition] = pm(x);  
plot(pm);
```

## Input Arguments

**pm** — Signal and metrics object

`dsp.PulseMetrics` | `dsp.TransitionMetrics`

Signal and metrics object, specified as one of the following:

- `dsp.PulseMetrics`
- `dsp.TransitionMetrics`

## Version History

**Introduced in R2012a**

**R2021b: `dsp.PulseMetrics` and `dsp.TransitionMetrics` System objects will be removed**

*Warns starting in R2021b*

`dsp.PulseMetrics` and `dsp.TransitionMetrics` System objects will be removed in a future release. Use the functions from “Pulse and Transition Metrics” instead. To plot the metrics, call these functions with no output arguments.

### Update Code

This table shows typical usage of the System object and explains how to update existing code to use these functions.

| Discouraged Usage  | Recommended Replacement  |
|--|--|
| <pre>load('clockx.mat','x','t'); pm = dsp.PulseMetrics('SampleRate',4e6,...     'TransitionOutputPort',true,...     'StateLevelsSource','Auto',... ## plot

**Package:** dsp

(To be removed) Plot signal, state levels, and histogram

---

**Note** `dsp.StateLevels` will be removed in a future release. Use `statelevels` instead. To plot the state levels, call the `statelevels` function with no output arguments. For more information, see “Compatibility Considerations”.

---

### Syntax

```
plot(sl)
```

### Description

`plot(sl)` plots the signal and state levels computed in the last call to the algorithm. If the `Method` property of the state levels object is set to 'Histogram mode' or 'Histogram Mean', the histogram is plotted in a subplot below the signal.

### Examples

#### State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock. Load the clock data in the variable, `x`, and the sampling instants in the variable `t`.

```
load('clockex.mat','x','t');
```

Estimate the state levels.

```
sl = dsp.StateLevels;  
levels = sl(x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(sl)
```

### Input Arguments

**sl** — State levels object

`dsp.StateLevels`

State levels object, specified as a `dsp.StateLevels` System object.

### Version History

Introduced in R2012a

**R2021b: dsp.StateLevels System object will be removed**

*Warns starting in R2021b*

`dsp.StateLevels` System object will be removed in a future release. To plot the state levels, call the `statelevels` function with no output arguments.

**Update Code**

This table shows typical usage of the System object and explains how to update existing code to use the `statelevels` function.

| Discouraged Usage   | Recommended Replacement   |
|---|---|
| <pre>load('clockex.mat', 'x', 't');<br/>slevel = dsp.StateLevels;</pre> <p><b>Plot state levels and the corresponding histogram</b></p> <pre>figure;<br/>plot(slevel)</pre> | <p><b>Plot state levels and the corresponding histogram</b></p> <pre>figure;<br/>statelevels(x)</pre> |

# polyphase

**Package:** dsp

Polyphase decomposition of multirate filter

## Syntax

```
p = polyphase(sysobj)
p = polyphase(sysobj, 'Arithmetic', arithType)
polyphase(sysobj)
```

## Description

`p = polyphase(sysobj)` returns the polyphase matrix `p` of the multirate filter System object `sysobj`. Each row in the matrix corresponds to a polyphase branch. The number of columns in `p` corresponds to the number of filter taps per polyphase branch.

`p = polyphase(sysobj, 'Arithmetic', arithType)` returns the polyphase matrix `p` in the precision set by the `arithType`.

`polyphase(sysobj)` launches the Filter Visualization Tool (`fvtool`) with all the polyphase subfilters to allow you to analyze each component subfilter individually.

## Examples

### Polyphase Matrix of an FIR Interpolator

When you create a multirate filter that uses polyphase decomposition, `polyphase` lets you analyze the component filters individually by returning the components as rows in a matrix. First, create an interpolate-by-three filter.

```
hs = dsp.FIRInterpolator
```

```
hs =
  dsp.FIRInterpolator with properties:
    InterpolationFactor: 3
    NumeratorSource: 'Property'
    Numerator: [0 -1.2906e-04 -2.2804e-04 0 5.5461e-04 8.0261e-04 0 -0.0015 -0.0020 0 0]
    Show all properties
```

In this syntax, the matrix `p` contains all of the subfilters for `hm`, one filter per matrix row.

```
p = polyphase(hs)
```

```
p = 3×24
```

```

      0      0      0      0      0      0      0      0      0
-0.0001  0.0006 -0.0015  0.0034 -0.0067  0.0121 -0.0205  0.0332 -0.0530  0.0732  0.0928  0.1119  0.1305  0.1486  0.1662  0.1834  0.2001  0.2164  0.2322  0.2476  0.2626  0.2772  0.2914  0.3052  0.3186  0.3316  0.3442  0.3564  0.3682  0.3796  0.3906  0.4012  0.4114  0.4212  0.4306  0.4396  0.4482  0.4564  0.4642  0.4716  0.4786  0.4852  0.4914  0.4972  0.5026  0.5076  0.5122  0.5168  0.5212  0.5252  0.5288  0.5322  0.5352  0.5378  0.5402  0.5422  0.5438  0.5452  0.5462  0.5468  0.5472  0.5476  0.5478  0.5478  0.5476  0.5472  0.5468  0.5462  0.5452  0.5438  0.5422  0.5402  0.5378  0.5352  0.5322  0.5288  0.5252  0.5212  0.5168  0.5122  0.5076  0.5026  0.4972  0.4914  0.4852  0.4786  0.4716  0.4642  0.4564  0.4482  0.4396  0.4306  0.4212  0.4114  0.4012  0.3906  0.3796  0.3682  0.3564  0.3442  0.3316  0.3186  0.3052  0.2914  0.2772  0.2626  0.2476  0.2322  0.2164  0.2001  0.1834  0.1662  0.1486  0.1305  0.1119  0.0928  0.0732  0.0530  0.0332  0.0121  0.0067  0.0034  0.0015  0.0006  0.0001  0
```

-0.0002    0.0008    -0.0020    0.0043    -0.0083    0.0145    -0.0241    0.0388    -0.0620    0.1

Finally, using `polyphase` without an output argument opens the Filter Visualization Tool, ready for you to use the analysis capabilities of the tool to investigate the interpolator `hm`.

`polyphase(hs)`

The `fvtool` shows the coefficients of the subfilters. To see the magnitude response of the subfilters, click on the **Magnitude Response** button on the `fvtool` toolstrip.

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as as one of the following filter System objects:

- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.FIRDecimator`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`

- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Specify the arithmetic used in computing the polyphase matrix. When you specify 'double' or 'single', the function performs double- or single-precision analysis. When you specify 'fixed', the arithmetic changes depending on the setting of the `CoefficientDataType` property and whether the System object is locked or unlocked.

#### **Details for Fixed-Point Arithmetic**

| <b>System Object State</b> | <b>Coefficient Data Type</b> | <b>Rule</b>  |
|----------------------------|------------------------------|--|
| Unlocked                   | 'Same as input'              | The function assumes that the coefficient data type is signed, 16 bit, and autoscaled. The function performs fixed-point analysis based on this assumption.  |
| Unlocked                   | 'Custom'                     | The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.   |
| Locked                     | 'Same as input'              | When the input data type is 'double' or 'fixed', the function assumes that the coefficient data type is signed, 16-bit, and autoscaled. The function performs fixed-point analysis based on this assumption. |
| Locked                     | 'Custom'                     | The function performs fixed-point analysis based on the setting of the <code>CustomCoefficientsDataType</code> property.   |

When you do not specify the arithmetic for non-CIC structures, the function uses double-precision arithmetic if the filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. CIC structures only support fixed-point arithmetic.

## **Output Arguments**

**p — polyphase matrix**

matrix

Polyphase matrix  $p$  of the multirate filter. Each row in the matrix corresponds to a polyphase branch. The first row of matrix  $p$  represents the first polyphase branch, the second row the second polyphase branch, and so on to the last polyphase branch. The number of columns in  $p$  corresponds to the number of filter taps per polyphase branch.

## **Version History**

**Introduced in R2011a**

## **See Also**

“Analysis Methods for Filter System Objects” on page 3-2

# polyphase

**Package:** dsp

Return polyphase matrix

## Syntax

`p = polyphase(obj)`

## Description

`p = polyphase(obj)` returns the polyphase matrix used by the filter bank in `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each row in the matrix corresponds to a polyphase branch. The number of columns in `p` corresponds to the number of filter taps per branch.

## Examples

### Polyphase Matrix of Filter Bank

Compute the polyphase matrix of the filter bank used by the channelizer.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB.

```
channelizer = dsp.Channelizer;
p = polyphase(channelizer)
```

`p = 8×12`

|         |        |         |        |         |        |        |         |        |         |  |
|---------|--------|---------|--------|---------|--------|--------|---------|--------|---------|--|
|         | 0      | 0       | 0      | 0       | 0      | 0      | 0.1250  | 0      | 0       |  |
| -0.0000 | 0.0002 | -0.0007 | 0.0022 | -0.0056 | 0.0161 | 0.1216 | -0.0119 | 0.0045 | -0.0000 |  |
| -0.0000 | 0.0004 | -0.0015 | 0.0045 | -0.0117 | 0.0354 | 0.1118 | -0.0192 | 0.0073 | -0.0000 |  |
| -0.0001 | 0.0006 | -0.0023 | 0.0067 | -0.0172 | 0.0565 | 0.0966 | -0.0220 | 0.0085 | -0.0000 |  |
| -0.0001 | 0.0008 | -0.0029 | 0.0082 | -0.0210 | 0.0776 | 0.0776 | -0.0210 | 0.0082 | -0.0000 |  |
| -0.0001 | 0.0009 | -0.0031 | 0.0085 | -0.0220 | 0.0966 | 0.0565 | -0.0172 | 0.0067 | -0.0000 |  |
| -0.0001 | 0.0008 | -0.0027 | 0.0073 | -0.0192 | 0.1118 | 0.0354 | -0.0117 | 0.0045 | -0.0000 |  |
| -0.0001 | 0.0005 | -0.0017 | 0.0045 | -0.0119 | 0.1216 | 0.0161 | -0.0056 | 0.0022 | -0.0000 |  |

Each row in the matrix corresponds to a polyphase branch. The number of columns in the matrix corresponds to the number of filter taps per branch.

## Input Arguments

**obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer`

## Output Arguments

### **p** — Polyphase matrix

matrix

Polyphase matrix of the filter bank, returned as a matrix of size  $[NFBands, NTPerBand]$ . The dimensions of the matrix depend on the type of System object in the `obj` argument:

- `dsp.Channelizer` -- *NFBands* is the value you specify in the `NumFrequencyBands` property, and *NTPerBand* is the value you specify in the `NumTapsPerBand` property.
- `dsp.ChannelSynthesizer` -- *NFBands* is the number of narrowband signals or the number of columns in the input signal, and *NTPerBand* is the value you specify in the `NumTapsPerBand` property.

## qreport

Most recent fixed-point filtering operation report

### Syntax

```
rlog = qreport(h)
```

### Description

`rlog = qreport(h)` returns the logging report stored in the filter object `h` in the object `rlog`. The ability to log features of the filtering operation is integrated in the fixed-point filter object and the `filter` method.

Each time you filter a signal with `h`, new log data overwrites the results in the filter from the previous filtering operation. To save the log from a filtering simulation, change the name of the output argument for the operation before subsequent filtering runs.

---

**Note** `qreport` requires Fixed-Point Designer software and that filter `h` is a fixed-point filter. Data logging for `fi` operations is a preference you set for each MATLAB session. To learn more about logging, `LoggingMode`, and `fi` object preferences, refer to `fipref` in the Fixed-Point Designer documentation.

---

Also, you cannot use `qreport` to log the filtering operations from a fixed-point Farrow filter.

---

Enable logging during filtering by setting `LoggingMode` to `on` for `fi` objects for your MATLAB session. Trigger logging by setting the `Arithmetic` property for `h` to `fixed`, making `h` a fixed-point filter and filtering an input signal.

### Using Fixed-Point Filtering Logging

Filter operation logging with `qreport` requires some preparation in MATLAB. Complete these steps before you use `qreport`.

- 1 Set the fixed-point object preference for `LoggingMode` to `on` for your MATLAB session. This setting enables data logging.  

```
fipref('LoggingMode','on')
```
- 2 Create your fixed-point filter.
- 3 Filter a signal with the filter.
- 4 Use `qreport` to return the filtering information stored in the filter object.

`qreport` provides a way to instrument your fixed-point filters and the resulting data log offers insight into how the filter responds to a particular input data signal.

Report object `rlog` contains a filter-structure-specific list of internal signals for the filter. Each signal contains

- Minimum and maximum values that were recorded during the last simulation. Minimum and maximum values correspond to values before quantization.

- Representable numerical range of the word length and fraction length format
- Number of overflows during filtering for that signal.

## Examples

### View the Logging Report

This example shows how to use `qreport` to log the results of filtering a sinusoidal signal with a fixed-point direct-form FIR filter, `firfilt`. To use the `qreport`, set the `LoggingMode` of fixed-point objects to 'on'.

```
fipref('loggingmode','on');
hd = design(fdesign.lowpass,'equiripple');
hd.arithmetic = 'fixed';
hd.InputWordLength = 32;
fs = 1000;           % Input sampling frequency.
t = 0:1/fs:1.5;     % Signal length = 1501 samples.
x = sin(2*pi*10*t); % Amplitude = 1 sinusoid.
y = filter(hd,x);
rlog = qreport(hd)
```

rlog =

| Fixed-Point Report |             |            |         |        |
|--------------------|-------------|------------|---------|--------|
|                    | Min         | Max        | Range   | Number |
| Input:             | -1          | 1          | -65536  | 65536  |
| Output:            | -1.02325    | 1.02325    | -131072 | 131072 |
| Product:           | -0.48538208 | 0.48538208 | -32768  | 32768  |
| Accumulator:       | -1.0852075  | 1.0852075  | -131072 | 131072 |

Restore the default logging mode preference.

```
fipref('loggingmode','off');
```

## ccdf

Get coordinates of CCDF curves

### Syntax

```
[relpower,prob] = ccdf(meter)
```

### Description

[relpower,prob] = ccdf(meter) returns the coordinates of the CCDF curves.

### Examples

#### Plot Coordinates of CCDF Curves

Compute the average power measurement of the generated voltage signal.

```
x = complex(rand(15000,1)-0.2,rand(15000,1)-0.2);  
pm = powermeter(ComputeCCDF=true);  
averagePower = pm(x); % power in dB
```

Plot the computed coordinates of the CCDF curve.

```
[relpower,prob] = ccdf(pm);  
semilogy(relpower,prob)  
xlabel('Relative Power (dB)');  
ylabel('Probability (%)');  
ylim([0 125]);  
grid on;  
title('CCDF Measurement');
```

## Input Arguments

### meter — Power meter

powermeter system object

Power meter, specified as a powermeter System object.

## Output Arguments

### relpower — Relative power

$N$ -by- $M$  matrix

Relative power in dB, returned as an  $N$ -by- $M$  matrix.  $M$  equals the number of columns in the signals provided and  $N$  equals  $\text{ceil}(\text{PowerRange}/\text{PowerResolution}) + 1$ .

Data Types: double

### prob — Probability

matrix

Probability in percentage, returned as a matrix. The probability that the instantaneous signal power of the  $j^{\text{th}}$  channel is above its average signal power by  $\text{relpower}(i,j)$ , in dB, is  $\text{prob}(i)/100$ .

Data Types: double

# plotCCDF

Plot CCDF curves

## Syntax

```
H = plotCCDF(meter)
H = plotCCDF(meter,ax)
H = plotCCDF(meter,GaussianReference=true)
H = plotCCDF( ____,Name=Value)
```

## Description

`H = plotCCDF(meter)` plots CCDF measurements in the `powermeter` System object `meter` and returns the plot handles as an output `H`. The number of curves plotted equals the number of input channels.

`H = plotCCDF(meter,ax)` plots CCDF measurements using the axes object `axis`.

`H = plotCCDF(meter,GaussianReference=true)`, uses the optional name-value argument `GaussianReference=true` to add a Gaussian reference curve, representing the power of a complex white Gaussian noise calculated as a chi-squared distribution, on the CCDF plot. By default `GaussianReference=false`.

`H = plotCCDF( ____,Name=Value)`, additionally you can use the name-value arguments of the `plot` function to customize the configuration of the CCDF plot. For example, `plotCCDF(meter,LineWidth=2)` plots the CCDF curves with a line width of 2 points.

## Examples

### Find Relative Power for Specified Probability

Compute the average power measurement of the generated voltage signal.

```
x = complex(rand(10000,1)-0.5,rand(10000,1)-0.5);
pm = powermeter(ComputeCCDF=true);
averagePower = pm(x); % power in dB
```

Compute the probability that the instantaneous power of the signal is 3 dB above the average power.

```
prob = probability(pm,3) % probability in percentage
prob = 7.6009
```

Plot the CCDF curve.

```
plotCCDF(pm,GaussianReference=true)
```

Find the relative power for the given probability.

```
relativepwr = relativePower(pm,prob)
relativepwr = 3.0000
```

## Input Arguments

### meter — Power meter

powermeter system object

Power meter, specified as a powermeter System object.

### ax — Axes object

axes object

Target axes, specified as an axes object. If you do not specify the axes, MATLAB plots into the current axes. The x-axis represents the relative power in dB, the ratio of instantaneous signal power to the average signal power. The y-axis represents the probability, in percentage, that the relative power exceeds a specified dB level.

## Output Arguments

### H — Plot handle output

line object

Plot handle output, returned as a line object. For more information about plot handle properties, see Line Properties.

## Version History

Introduced in R2022a

**See Also****Objects**

powermeter

**Functions**

ccdf | probability | relativePower

## probability

Use CCDF to find probability for specified relative power

### Syntax

```
prob = probability(meter,relpower)
```

### Description

`prob = probability(meter,relpower)` finds the probability `prob` in percent that the instantaneous signal power is above the average signal power by `relpower` dB.

### Examples

#### Find Relative Power for Specified Probability

Compute the average power measurement of the generated voltage signal.

```
x = complex(rand(10000,1)-0.5,rand(10000,1)-0.5);
pm = powermeter(ComputeCCDF=true);
averagePower = pm(x); % power in dB
```

Compute the probability that the instantaneous power of the signal is 3 dB above the average power.

```
prob = probability(pm,3) % probability in percentage
prob = 7.6009
```

Plot the CCDF curve.

```
plotCCDF(pm,GaussianReference=true)
```

Find the relative power for the given probability.

```
relativepwr = relativePower(pm,prob)
```

```
relativepwr = 3.0000
```

## Input Arguments

### **meter** — Power meter

powermeter system object

Power meter, specified as a powermeter System object.

### **relpower** — Relative power

column vector

Relative power in dB, specified as a column vector.

Data Types: single | double

## Output Arguments

### **prob** — Probability

*N*-by-*M* matrix

Probability in percentage, returned as an *N*-by-*M* matrix. The probability that the instantaneous signal power of the *j*<sup>th</sup> channel is above its average signal power by `relpower(i,j)`, in dB, is `prob(i)/100`. *N* equals the number of rows in `relpower` and *M* equals the number of signals provided to the powermeter object.

If the `PowerRange` property is not set sufficiently large, the computed CCDF curve may not reach some relative power values in `relpower` and the corresponding values in `prob` is NaN.

Data Types: double

## Version History

Introduced in R2022a

### **Objects**

powermeter

### **Functions**

plotCCDF | ccdf | relativePower

## relativePower

Use CCDF to find relative power for specified probability

### Syntax

```
relpower = relativePower(meter,prob)
```

### Description

`relpower = relativePower(meter,prob)` computes the relative power `relpower` for a specified probability `prob`, such that the instantaneous signal power is above the average signal power by `relpower` dB with probability `prob/100`. To enable this syntax, set the `computeCCDF` property to `true` in the `powermeter` System object.

### Examples

#### Find Relative Power for Specified Probability

Compute the average power measurement of the generated voltage signal.

```
x = complex(rand(10000,1)-0.5,rand(10000,1)-0.5);  
pm = powermeter(ComputeCCDF=true);  
averagePower = pm(x); % power in dB
```

Compute the probability that the instantaneous power of the signal is 3 dB above the average power.

```
prob = probability(pm,3) % probability in percentage
```

```
prob = 7.6009
```

Plot the CCDF curve.

```
plotCCDF(pm,GaussianReference=true)
```

Find the relative power for the given probability.

```
relativepwr = relativePower(pm,prob)
relativepwr = 3.0000
```

## Input Arguments

### meter — Power meter

powermeter system object

Power meter, specified as a powermeter System object.

### prob — Probability

nonnegative column vector

Probability in percentage, specified as a nonnegative column vector. The probability that the instantaneous signal power of the  $j^{\text{th}}$  channel is above its average signal power by `relpower(i,j)`, in dB, is `prob(i)/100`.

If the `PowerRange` property is not set sufficiently large, the computed CCDF curve may not reach some probability values in `prob` and the corresponding values in `relpower` is NaN. If no `prob` value is provided, `relativePower` returns `relpower` for `prob = [10 1 0.1 0.01 0.001 0.0001]'`.

Data Types: single | double

## Output Arguments

### relpower — Relative power

$N$ -by- $M$  matrix

Relative power in dB, returned as an  $N$ -by- $M$  matrix.  $N$  equals the number of rows in `prob` and  $M$  equals the number of signals provided.

Data Types: double

# realizemdl

**Package:** dsp

Simulink subsystem block for filter

## Syntax

```
realizemdl(sysobj)
realizemdl(sysobj,Name,Value)
```

## Description

`realizemdl(sysobj)` generates a model of filter System object in a Simulink subsystem block using sum, gain, and delay blocks from Simulink. The properties and values of `sysobj` define the resulting subsystem block parameters.

`realizemdl` requires Simulink. To accurately realize models of quantized filters, use Fixed-Point Designer.

`realizemdl(sysobj,Name,Value)` generates the model for `sysobj` with additional options specified by one or more `Name,Value` pair arguments. Using name-value pair arguments lets you control more fully the way the block subsystem model gets built. You can specify such details as where the block goes, what the name is, or how to optimize the block structure.

## Examples

### Realize Simulink Model of a Lowpass Butterworth Filter

```
d = fdesign.lowpass('N,F3dB',4,0.25);
filterobject = design(d,'butter','systemobject',true);
```

Create a new model, `LPFilter.slx`, and realize the subsystem block in this model.

```
new_system('LPFilter');
realizemdl(filterobject);
```

View the block diagram by clicking on the subsystem block.

Create a new model, `LPFilterMapping.slx`, and realize the subsystem block, with coefficients mapped to ports, in this model.

```
new_system('LPFilterMapping');
realizemdl(filterobject, 'MapCoeffsToPorts', 'on');
```

View the block diagram by clicking on the subsystem block.

In this case, the filter is an IIR filter with a direct form II second-order sections structure. Setting `MapCoeffstoPorts` to 'on' exports the numerator coefficients, the denominator coefficients, and the gains to the MATLAB® workspace using the default variable names `Num`, `Den`, and `g`. Each column of `Num` and `Den` represents one second-order section. You can modify the filter coefficients directly in the MATLAB workspace providing tunability to the realized Simulink model.

## Input Arguments

### **sysobj** – Filter System object

filter System object

List of filter system objects that the function supports:

| Filter System objects                        |
|--|
| <code>dsp.AllpassFilter</code>               |
| <code>dsp.AllpoleFilter</code>               |
| <code>dsp.BiquadFilter</code>                |
| <code>dsp.CICCompensationDecimator</code>    |
| <code>dsp.CICCompensationInterpolator</code> |

| <b>Filter System objects</b> |
|------------------------------|
| dsp.CoupledAllpassFilter     |
| dsp.FarrowRateConverter      |
| dsp.FilterCascade            |
| dsp.FIRFilter                |
| dsp.FIRInterpolator          |
| dsp.FIRDecimator             |
| dsp.FIRRateConverter         |
| dsp.FIRHalfbandDecimator     |
| dsp.FIRHalfbandInterpolator  |
| dsp.FourthOrderSectionFilter |
| dsp.HighpassFilter           |
| dsp.IIRFilter                |
| dsp.IIRHalfbandDecimator     |
| dsp.IIRHalfbandInterpolator  |
| dsp.LowpassFilter            |
| dsp.NotchPeakFilter          |
| dsp.SOSFilter                |

### **Name-Value Pair Arguments**

```
Example: d = fdesign.lowpass('N,F3dB',4,0.25); filterobject =
design(d,'butter','systemobject',true);
realizemdl(filterobject,'MapCoeffsToPorts','on');
```

### **Destination – Destination choices**

'current' (default) | 'new' | character vector | string scalar

Specify whether to add the block to your current Simulink model or create a new model to contain the block. If you provide the name of a current subsystem as a character vector or a string scalar, the `realizemdl` function adds the new block to the specified subsystem.

### **BlockName – Name of the block**

'filter' (default) | character vector | string scalar

Provide the name for the new subsystem block. By default the block is named Filter.

### **MapCoeffsToPorts – Map coefficients**

'off' (default) | 'on'

Specify whether to map the coefficients of the filter to the ports of the block.

### **MapStates – Apply current filter states**

'off' (default) | 'on'

Specify whether to apply the current filter states to the realized model. Such specification allows you to save states from a filter object you may have used or configured in a specific way. The default

setting of 'off' means the states are not transferred to the model. Setting the property to 'on' preserves the current filter states in the realized model.

**OverwriteBlock — Overwrite existing block**

'off' (default) | 'on'

Specify whether to overwrite an existing block with the same name or create a new block.

**OptimizeZeros — Remove zero-gain blocks**

'off' (default) | 'on'

Specify whether to remove zero-gain blocks.

**OptimizeOnes — Replace unity-gain blocks**

'off' (default) | 'on'

Specify whether to replace unity-gain blocks with direct connections.

**OptimizeNegOnes — Replace negative unity-gain blocks**

'off' (default) | 'on'

Specify whether to replace negative unity-gain blocks with a sign change at the nearest sum block.

**OptimizeDelayChains — Replace delay chains**

'off' (default) | 'on'

Specify whether to replace delay chains made up of  $n$  unit delays with a single delay by  $n$ .

**CoeffNames — Names of coefficients**

{'Num'} (default FIR) | {'Num', 'Den'} (default direct form IIR) | {'Num', 'Den', 'g'} (default IIR SOS) | {'Num\_1', 'Num\_2', 'Num\_3' . . .} (default multistage) | {'K'} (default form lattice)

Specify the coefficient variable name as a cell array of character vectors. `MapCoeffsToPorts` must be set to 'on' for this property to apply.

**InputProcessing — Possible input processing options**

'columnsaschannels' | 'elementsaschannels'

Specify sample-based ('elementsaschannels') or frame-based ('columnsaschannels') processing.

**RateOption — Rate options**

'enforcesinglerate' (default) | 'allowmultirate'

Specify how the block adjusts the rate at the output to accommodate the reduced number of samples.

**Dependencies**

This parameter applies only when `InputProcessing` is 'columnsaschannels'.

**Arithmetic — Value types**

'double' | 'single'

The arithmetic for System object inputs must be 'double' or 'single'.

## Limitations

The destination must be a Simulink model. The function does not support a library file destination.

## rebuffer\_delay

Number of samples of delay introduced by buffering and unbuffering operations

### Syntax

```
d = rebuffer_delay(f,n,v)
d = rebuffer_delay(f,n,v,'mode')
```

### Description

`d = rebuffer_delay(f,n,v)` returns the delay, in samples, introduced by the Buffer or Unbuffer block in multitasking operations.

`d = rebuffer_delay(f,n,v,'mode')` returns the delay, in samples, introduced by the Buffer or Unbuffer block in the specified tasking mode.

### Input Arguments

**f**

Frame size of the input to the Buffer or Unbuffer block.

**n**

Size of the output buffer. Specify one of the following:

- The value of the **Output buffer size** parameter, if you are computing the delay introduced by a Buffer block.
- 1, if you are computing the delay introduced by an Unbuffer block.

**v**

Amount of buffer overlap. Specify one of the following:

- The value of the **Buffer overlap** parameter, if you are computing the delay introduced by a Buffer block.
- 0, if you are computing the delay introduced by an Unbuffer block.

**'mode'**

The tasking mode of the model. Specify one of the following options:

- 'singletasking'
- 'multitasking'

**Default:** 'multitasking'

### Examples

### Compute Delay Introduced by Buffer Block

Compute the delay introduced by a Buffer block in a multitasking model.

Open the `ex_buffer_tut4` model.

Copyright 2019 The Mathworks, Inc

**Note:** This model creates the workspace variables "sp\_examples\_src" and "sp\_examples\_yout". Closing the model clears both variables from your workspace.

Double-click the Buffer block to open the block mask. Verify that you have the following settings:

- **Output buffer size** = 3
- **Buffer overlap** = 1
- **Initial conditions** = 0

Based on these settings, two of the required inputs to the `rebuffer_delay` function are as follows:

- $n = 3$
- $v = 1$

To determine the frame size of the input signal to the Buffer block, open the Signal From Workspace block mask. Verify that you have the following settings:

- **Signal** = `sp_examples_src`
- **Sample time** = 1
- **Samples per frame** = 4

Because **Samples per frame** = 4, you know the `f` input to the `rebuffer_delay` function is 4. After you verify the values of all the inputs to the `rebuffer_delay` function, determine the delay that the Buffer block introduces in this multitasking model. To do so, type the following at the MATLAB command line:

```
rebuffer_delay(4,3,1)
```

```
ans =
```

```
8
```

### Compute Delay Introduced by Unbuffer Block

Compute the delay introduced by an Unbuffer block in a multitasking model.

Open the `ex_unbuffer_ref1` model.

### Unbuffer Example 1

In this example, the Unbuffer block unbuffers a frame-based signal with frame size 3 to a sample-based signal.

**Note:** This model creates workspace variables called "sp\_examples\_src" and "sp\_examples\_yout". Closing the model clears both variables from your workspace.

To determine the frame size of the input to the Buffer block, open the Signal From Workspace block mask by double-clicking the block in your model. Verify that you have the following settings:

- **Signal** = `sp_examples_src`
- **Sample time** = 1
- **Samples per frame** = 3

Because **Samples per frame** = 3, you know the `f` input to the `rebuffer_delay` function is 3. Use the `rebuffer_delay` function to determine the amount of delay that the Unbuffer block introduces in this multitasking model. To compute the delay introduced by the Unbuffer block, use `f = 3`, `n = 1` and `v = 0`.

```
rebuffer_delay(3,1,0)
```

```
ans =
```

```
3
```

## More About

### Multitasking

When you run a model in `MultiTasking` mode, Simulink processes groups of blocks with the same execution priority through each stage of simulation based on task priority. Multitasking mode helps to create valid models of real-world multitasking systems, where sections of your model represent concurrent tasks. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

## Singletasking

When you run a model in `SingleTasking` mode, Simulink processes all blocks through each stage of simulation together. The **Treat each discrete rate as a separate task** parameter on the Solver (Simulink) pane of the Configuration Parameters dialog box controls this setting.

## Version History

Introduced before R2006a

## Topics

“Buffer Delay and Initial Conditions”

## reffilter

Reference filter for fixed-point or single-precision filter

### Syntax

```
href = reffilter(hd)
```

### Description

`href = reffilter(hd)` returns a new filter `href` that has the same structure as `hd`, but uses the reference coefficients and has its arithmetic property set to `double`. Note that `hd` can be either a fixed-point filter (arithmetic property set to `'fixed'`), or a single-precision floating-point filter whose arithmetic property is `'single'`).

`reffilter(hd)` differs from `double(hd)` in that

- the filter `href` returned by `reffilter` has the reference coefficients of `hd`.
- `double(hd)` returns the quantized coefficients of `hd` represented in double-precision.

To check the performance of your fixed-point filter, use `href = reffilter(hd)` to quickly have the floating-point, double-precision version of `hd` available for comparison.

### Examples

#### Compare Fixed-point Quantizations of a Filter

Compare several fixed-point quantizations of a filter with the same double-precision floating-point version of the filter.

```
h = dfilt.dffir(firceqrip(87,.5,[1e-3,1e-6])); % Lowpass filter.
h1 = copy(h); h2 = copy(h); % Create copies of h.
h.arithmetic = 'fixed'; % Set h to filter using fixed-point...
                        % arithmetic.
h1.arithmetic = 'fixed'; % Same for h1.
h2.arithmetic = 'fixed'; % Same for h2.
h.CoeffWordLength = 16; % Use 16 bits to represent the...
                        % coefficients.
h1.CoeffWordLength = 12; % Use 12 bits to represent the...
                        % coefficients.
h2.CoeffWordLength = 8; % Use 8 bits to represent the...
                        % coefficients.

href = reffilter(h);
hfvt = fvtool(href,h,h1,h2);
set(hfvt,'ShowReference','off'); % Reference displayed once
                                % already.
legend(hfvt,'Reference filter','16-bits','12-bits','8-bits');
```

The fvtool shows href, the reference filter, and the effects of using three different word lengths to represent the coefficients.

## Version History

Introduced in R2011a

## reorder

**Package:** dsp

Reorder second-order sections of biquadratic filter System object

### Syntax

```
reorder(sysobj,order)
sysobjnew = reorder(sysobj,order)
reorder(sysobj,numorder,denorder)
reorder(sysobj,numorder,denorder,svorder)
reorder(sysobj,filter_type)
reorder(sysobj,dir_flag)
reorder(sysobj,dir_flag,sv)
reorder( __ , 'Arithmetic',arithType)
```

### Description

`reorder(sysobj,order)` rearranges the sections of the biquadratic filter object using the vector of indices provided in `order`.

`sysobjnew = reorder(sysobj,order)` generates a new biquadratic filter System object that contains the reordered sections. In this case, the original filter `sysobj` does not change.

`reorder(sysobj,numorder,denorder)` reorders the numerator and denominator of the filter separately using the vector of indices in `numorder` and `denorder`, respectively. These vectors must be of the same length.

`reorder(sysobj,numorder,denorder,svorder)` independently reorders the scale values of the biquadratic filter System object. If `svorder` is not specified, the scale values of the biquadratic filter are reordered in the same way as the numerator. The output scale value always remains at the end and `numorder` is used to reorder the scale values.

`reorder(sysobj,filter_type)` reorders `sysobj` in a way suitable for the specified filter type. This mode is intended for fixed-point implementations where the ordering of the sections can have a significant impact on the filter performance.

`reorder(sysobj,dir_flag)` rearranges the sections according to proximity to the origin of the poles of the sections.

`reorder(sysobj,dir_flag,sv)` reorders the scale values following the reordering of the poles when `sv` is set to 'poles', or following the reordering of the zeros when `sv` is set to 'zeros'. The scale values are not reordered when using the `dir_flag` option unless `sv` is specified.

`reorder( __ , 'Arithmetic',arithType)` assumes that the filter arithmetic is equal to `arithType`.

### Examples

## Reorder Biquadratic Filter

Being able to rearrange the order of the sections in a filter can be a powerful tool for controlling the filter design process. This example uses the `reorder` function to change the sections of a direct form II filter.

First use the automatic reordering option on a lowpass filter.

```
d = fdesign.lowpass('n,f3db',15,0.75);
sosFilt = design(d,'butter','SystemObject',true)
```

```
sosFilt =
  dsp.SOSFilter with properties:
    Structure: 'Direct form II'
    CoefficientSource: 'Property'
    Numerator: [8x3 double]
    Denominator: [8x3 double]
    HasScaleValues: true
    ScaleValues: [0.7948 0.7005 0.6306 0.5794 0.5430 0.5186 0.5046 0.7071 1]
```

Show all properties

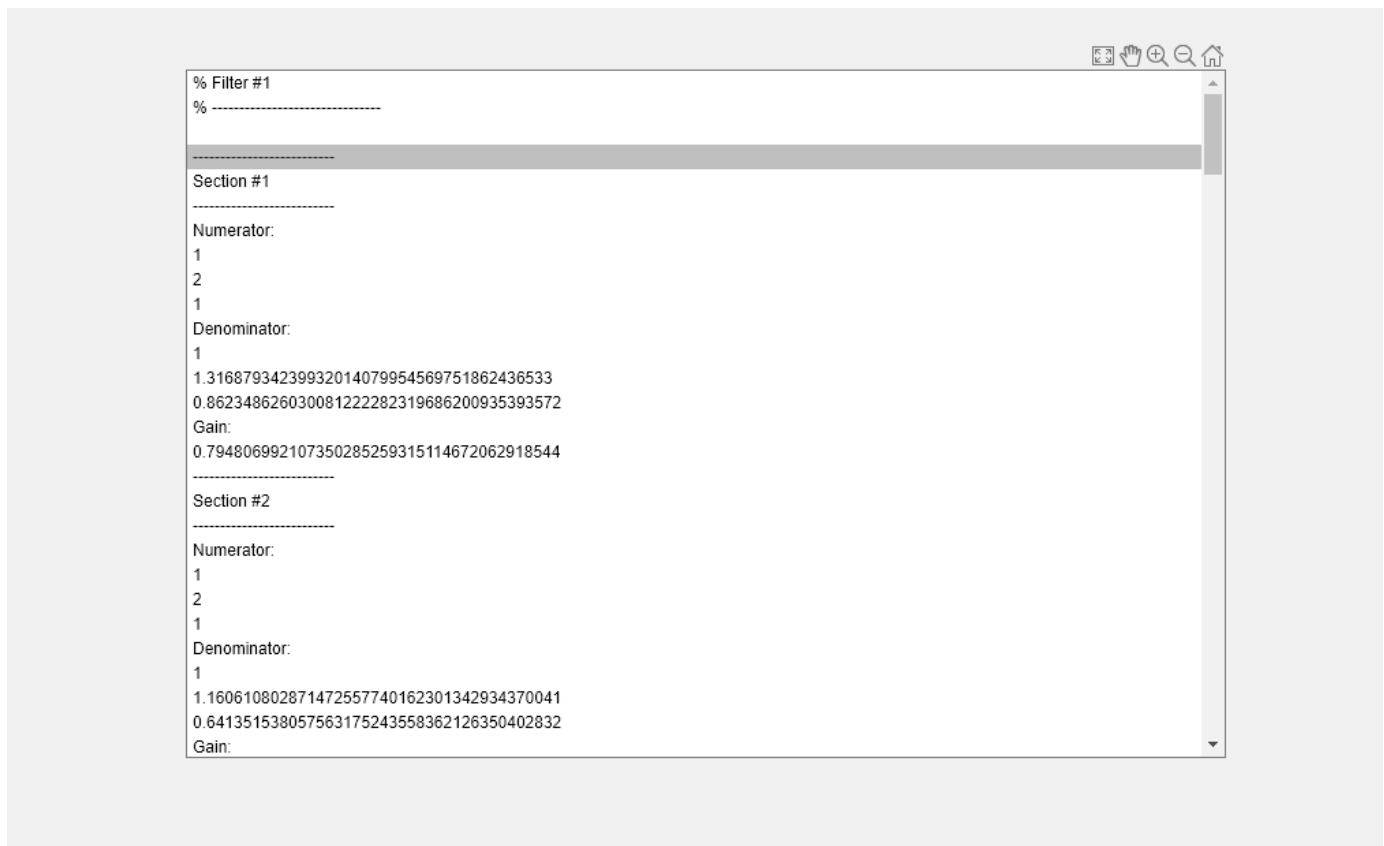

```
sosFiltreorder = reorder(sosFilt,'auto')
```

```
sosFiltreorder =
  dsp.SOSFilter with properties:
    Structure: 'Direct form II'
    CoefficientSource: 'Property'
    Numerator: [8x3 double]
    Denominator: [8x3 double]
    HasScaleValues: true
    ScaleValues: [0.6306 0.5046 0.5430 0.7948 0.5794 0.7071 0.5186 0.7005 1]
```

Show all properties

Now, use `reorder` to specify the new order for the sections.

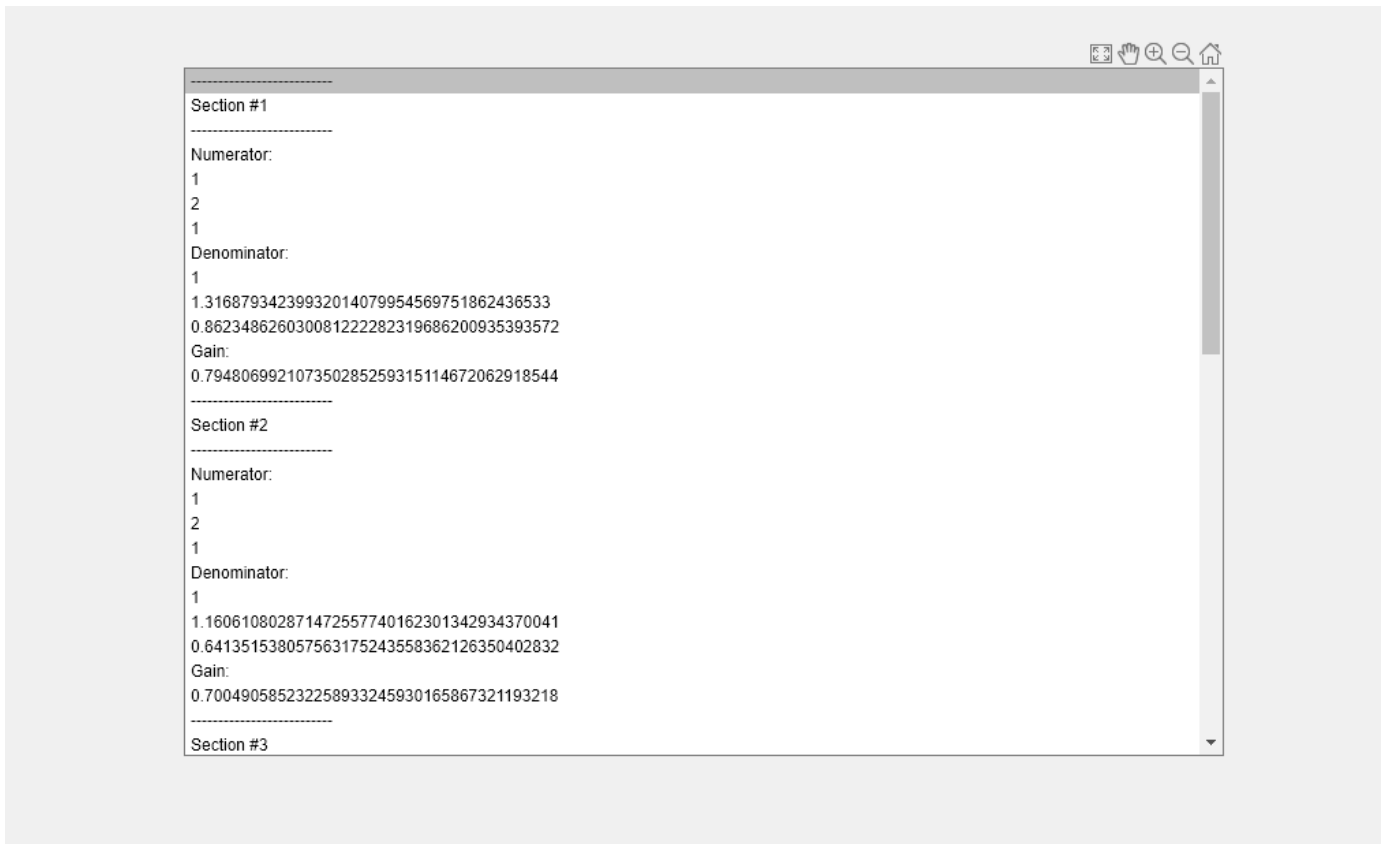

```
sosFiltspecifyreorder = reorder(sosFilt,[1 3:7 2 8]);
fvt = fvtool(sosFilt,sosFiltspecifyreorder,'analysis','coefficients');
```

Remove the third, fourth, and seventh sections.

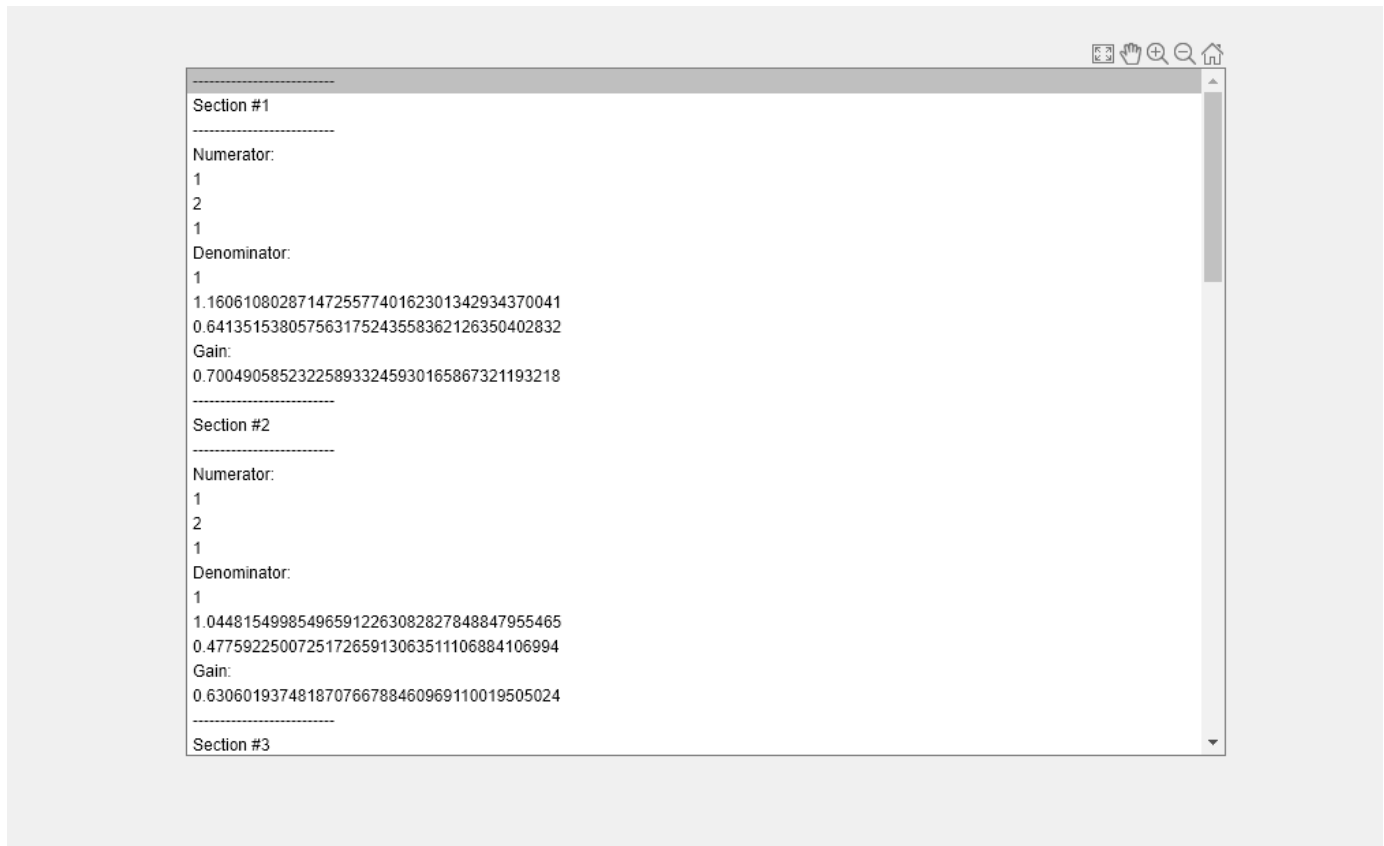

```
sosFiltclone1 = clone(sosFilt);
reorder(sosFiltclone1,logical([1 1 0 0 1 1 0 1]));
setfilter(fvt,sosFiltclone1);
```

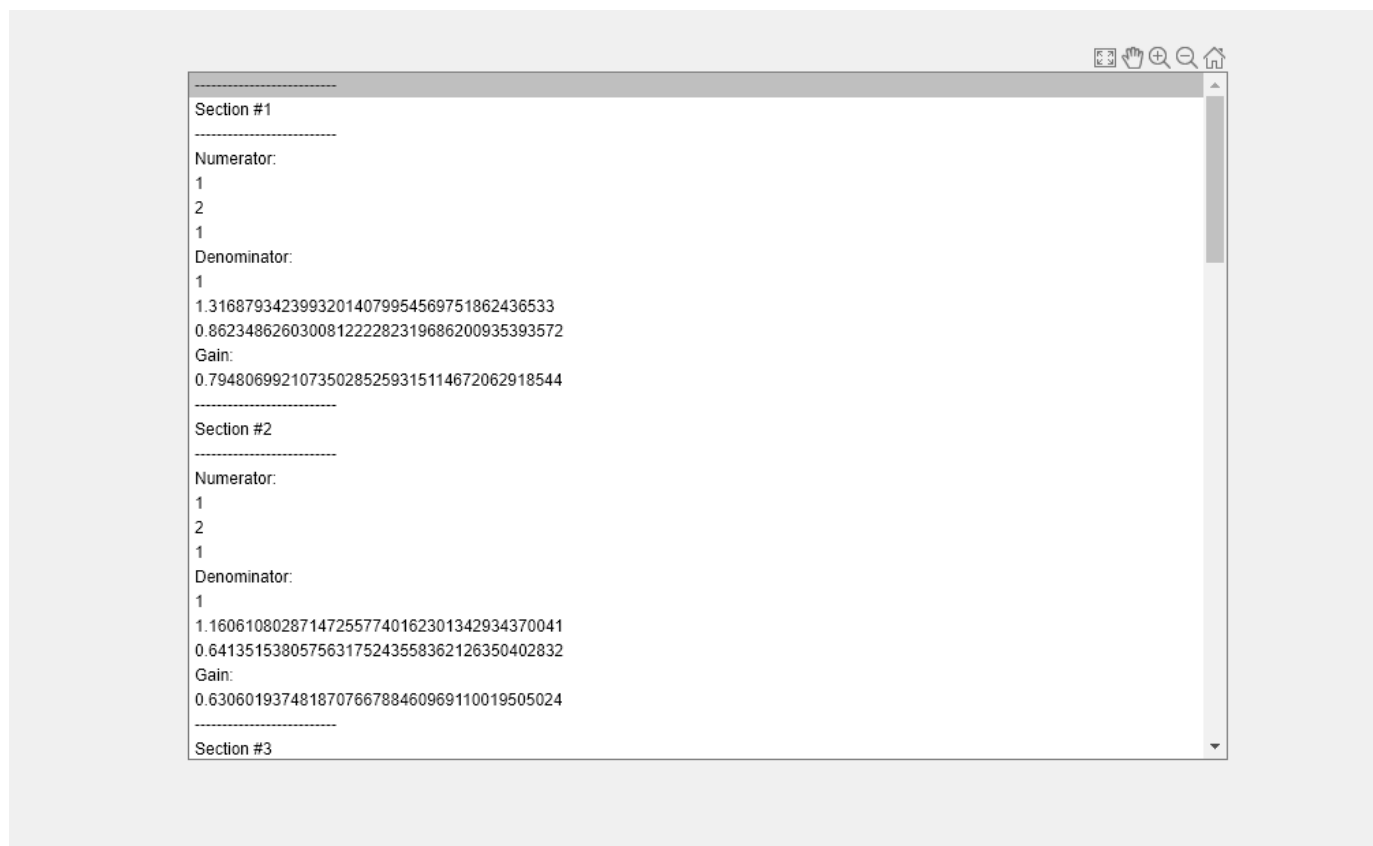

Move the first filter to the end and remove the eighth section.

```
sosFiltclone2 = clone(sosFilt);  
reorder(sosFiltclone2,[2:7 1]);  
setfilter(fvt,sosFiltclone2);
```

Move the numerator and denominator independently.

```
sosFiltclone3 = clone(sosFilt);  
reorder(sosFiltclone3, [1 3:8 2],(1:8));  
setfilter(fvt, sosFiltclone3);
```

## Input Arguments

### **sysobjj** — Biquadratic filter object

`dsp.BiquadFilter` System object | `dsp.SOSFilter` System object

Biquadratic filter object, specified as either `dsp.BiquadFilter` or `dsp.SOSFilter` objects.

### **order** — Vector of indices used to reorder filter sections

vector

Vector of indices used to reorder the filter sections. `order` does not need to contain all the indices of the filter. Omitting one or more filter section indices removes the omitted sections from the filter. You can use a logical array to remove sections from the filter, but not to reorder it.

When `order` is a vector of logicals, the function removes the sections of the filter that correspond to the index values where `order` is equal to `false`.

Data Types: `double` | `logical`

### **numorder** — Vector of indices used to reorder filter numerator

vector

Vector of indices used to reorder the numerator of the filter. The `numorder` and `denorder` vectors must be of the same length.

When `numorder` is a vector of logicals, the function removes the numerator coefficients that correspond to the index values where `numorder` is equal to `false`.

Data Types: `double` | `logical`

#### **denorder** — Vector of indices used to reorder filter denominator

vector

Vector of indices used to reorder the denominator of the filter. The `numorder` and `denorder` vectors must be of the same length.

When `denorder` is a vector of logicals, the function removes the denominator coefficients that correspond to the index values where `denorder` is equal to `false`.

Data Types: `double` | `logical`

#### **svorder** — Reorder scale values

vector

Independent reordering of scale values. When `svorder` is not specified, the scale values are reordered in the same way as the numerator. The output scale value always remains at the end when you use the argument `numorder` to reorder the scale values.

When `svorder` is a vector of logicals, the function removes the scale values that correspond to the index values where `svorder` is equal to `false`.

Data Types: `double` | `logical`

#### **filter\_type** — Filter type

'auto' | 'bandpass' | 'bandstop' | 'highpass' | 'lowpass'

Filter type. Automatic reordering only applies when `sysobj` was obtained using `fdesign`. With the 'auto' option as an input argument, `reorder` automatically rearranges the filter sections depending on the specification response type of the design (lowpass, highpass, etc).

#### **dir\_flag** — Pole direction flag

'down' | 'up'

Pole direction flag, specified as either:

- 'up' -- The first filter section contains the poles closest to the origin, and the last section contains the poles closest to the unit circle.
- 'down' -- The sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.

#### **sv** — Scale value options

'poles' | 'zeros'

Scale value options, specified as either:

- 'poles' -- Scale values are reordered following the reordering of the poles.
- 'zeros' -- Scale values are reordered following the reordering of the zeros.

The scale values are not reordered when using the `dir_flag` option unless `sv` is specified.

**arithType — Filter arithmetic**`'double' (default) | 'single' | 'fixed'`

Arithmetic type the `reorder` function assumes, specified as one of the following:

- `'double'` -- The function assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.
- `'single'` -- The function assumes a single precision filter.
- `'fixed'` -- The overflow action used in the reorder operation is set to the action specified in the filter System object.

**Output Arguments****sysobjnew — Reordered biquadratic filter object**`dsp.BiquadFilter System object | dsp.SOSFilter System object`

Biquadratic filter object with reordered second-order sections, returned as a `dsp.BiquadFilter` or a `dsp.SOSFilter` object. The SOS matrices and the corresponding scale values in the output object are as per the reorder arguments run on the input `sysobj`.

**Version History**

Introduced in R2011a

**See Also**

`scale` | `scalecheck` | `scaleopts` | `cumsec` | `sos`

## scale

**Package:** dsp

Scale second-order sections

### Syntax

```
scale(sysobj)
sysobjnew = scale(sysobj)
scale(sysobj,pnorm)
scale(sysobj,pnorm,opts)
scale(sysobj,pnorm,Name,Value)
```

### Description

`scale(sysobj)` scales the biquadratic System object, `sysobj`, using peak magnitude response scaling (L-infinity, 'Linf'). This scaling reduces the possibility of overflows when the filter object operates in fixed-point arithmetic mode.

`sysobjnew = scale(sysobj)` generates a new filter System object, `sysobjnew`, with scaled second-order sections. The original filter System object, `sysobj`, is not changed.

`scale(sysobj,pnorm)` specifies the norm used to scale the filter. The variable `pnorm` can be either a discrete-time-domain norm or a frequency-domain norm. Valid time-domain norms are 'l1', 'l2', and 'linf'. Valid frequency-domain norms are 'L1', 'L2', and 'Linf'. Note that L2-norm is equal to l2-norm (Parseval's theorem) but the same is not true for other norms.

The different norms can be ordered in terms of how stringent they are as follows: 'l1' >= 'Linf' >= 'L2' = 'l2' >= 'L1' >= 'linf'.

Using the most stringent scaling, 'l1', the filter is the least prone to overflow, but also has the worst signal-to-noise ratio. Linf-scaling is the most commonly used scaling in practice.

`scale(sysobj,pnorm,opts)` uses an options object to specify the optional scaling parameters in lieu of specifying parameter-value pairs. The `opts` object can be created using the `scalexts` function: `opts = scalexts(sysobj)`.

`scale(sysobj,pnorm,Name,Value)` specifies optional scaling parameters via by one or more `Name,Value` pair arguments.

### Examples

#### Linf-norm Scaling of a Biquadratic SOS Filter

Demonstrate the Linf-norm scaling of a biquadratic SOS filter using the `scale` function.

```
Fs = 8000;
Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2));
```

```
[sosMatrix,scaleValues] = zp2sos(z,p,k);
sosFilt = dsp.SOSFilter(Structure='Direct form I', ...
    Numerator=sosMatrix(:,1:3),Denominator=sosMatrix(:,4:6), ...
    HasScaleValues=true,ScaleValues=scaleValues)
```

```
sosFilt =
    dsp.SOSFilter with properties:

        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [0.0029 1 1 1 1 1]
```

Show all properties

```
scale(sosFilt,'linf',scalevalueconstraint='none',maxscalevalue=2)
```

## Input Arguments

### sysobj — Input filter

dsp.BiquadFilter System object | dsp.SOSFilter System object

Input filter, specified as one of the following System objects:

- dsp.BiquadFilter
- dsp.SOSFilter

Example: `biquad = dsp.BiquadFilter('Structure', 'Direct form I', ... 'SOSMatrix', s, 'ScaleValues', g);`

### pnorm — Discrete-time-domain norm or a frequency-domain norm

'Linf' (default) | 'L1' | 'L2' | 'l1' | 'l2' | 'linf'

Valid time-domain norm values for `pnorm` are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

Filter norms can be ordered in terms of how stringent they are, as follows from most stringent to least: 'l1', 'Linf', 'l2' ('L2'), 'linf'. Using 'l1', the most stringent scaling, produces a filter that is least likely to overflow, but has the worst signal-to-noise ratio performance. The default scaling 'Linf' (default) is the most commonly used scaling norm.

### opts — Scale options object

fdopts.sosscaling object

You can create an `fdopts.sosscaling` object, `opts`, using the `scalemopts` function.

The following table lists the properties of `opts`:

| Parameter            | Default    | Description and Valid Value  |
|----------------------|------------|--|
| sosReorder           | 'auto'     | Reorder section prior to scaling.<br>Valid options are 'auto' (default), 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', and 'bandstop'.  |
| MaxNumerator         | 2          | Maximum allowed value for numerator coefficients.  |
| NumeratorConstraint  | 'none'     | Specifies whether and how to constrain numerator coefficient values. Options are 'none' (default), 'unit', 'normalize', and 'po2'.   |
| OverflowMode         | 'wrap'     | Sets the way the filter handles arithmetic overflow situations during scaling. Valid options are 'wrap' (default), 'saturate', and 'satall'.   |
| ScaleValueConstraint | 'unit'     | Specify whether to constrain the filter scale values, and how to constrain them. Valid options are 'unit' (default), 'none', and 'po2'.  |
| MaxScaleValue        | 'Not used' | Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit. Setting MaxScaleValue to a numerical value automatically changes the ScaleValueConstraint setting to none. |

Example: `opts = scaleopts(biquad)`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

*Before R2021a, use commas to separate each name and value, and enclose Name in quotes.*

Example: `[z,p,k] = butter(10,2000/(8000/2)); [s,g] = zp2sos(z,p,k); biquad = dsp.BiquadFilter('Structure','Direct form I','SOSMatrix',s,'ScaleValues',g); scale(biquad,'linf','scalevalueconstraint','none','maxscalevalue',2)`

### Arithmetic – Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic type used during analysis, specified as one of 'double', 'single', or 'fixed'. The scale method assumes a double precision filter when the arithmetic input is not specified and the

filter System object is in an unlocked state. If the System object is locked, the function performs analysis based on the locked input data type. If 'Arithmetic' is 'double' or 'single', the default values are used for all scaling options that are not specified as an input to the `scale` function. If 'Arithmetic' is 'fixed', the values used for the scaling options are set according to the settings in the filter System object. However, if a scaling option is specified that differs from the settings in `sysobj`, this option is used for scaling purposes but does not change the setting in `sysobj`. For example, if you do not specify the 'OverflowMode' scaling option, the `scale` method assumes that the 'OverflowMode' is equal to the value in the `OverflowAction` property of the filter object. If you do specify an 'OverflowMode' scaling option, then the `scale` function uses this overflow mode value regardless of the value in the `OverflowAction` property of the System object.

### **sosReorder — Reorder section prior to scaling**

'auto' (default) | 'none' | 'up' | 'down' | 'lowpass' | 'highpass' | 'bandpass' | 'bandstop'

Reorder filter sections prior to applying scaling. Possible options:

- 'auto'
- 'none'
- 'up'
- 'down'
- 'lowpass'
- 'highpass'
- 'bandpass'
- 'bandstop'

Automatic reordering takes effect when `sysobj` is obtained as a result from a design using `fdesign`. The sections are automatically reordered depending on the response type of the design.

### **MaxNumerator — Maximum value for numerator coefficients**

2 (default) | positive scalar

Maximum allowed value for numerator coefficients, specified as a positive scalar.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **NumeratorConstraint — Method to constrain numerator coefficients**

'none' (default) | 'normalized' | 'po2' | 'unit'

Method to constrain numerator coefficient values, specified as one of the following:

- 'none'
- 'normalized'
- 'po2'
- 'unit'

### **OverflowMode — Overflow mode**

'wrap' (default) | 'saturate'

Sets the way the filter handles arithmetic overflow situations during scaling. If your device does not have guard bits available, and you are using saturation arithmetic for filtering, use 'sata11' instead of 'saturate'. The default is 'wrap'.

### **ScaleValueConstraint — Constrain scale values**

'unit' (default) | 'none' | 'po2'

Specify whether to constrain the filter scale values, and how to constrain them. Choosing 'unit' for the constraint disables the `MaxScaleValue` property setting. 'po2' constrains the scale values to be powers of 2, while 'none' removes any constraint on the scale values. 'unit' is the default value.

### **MaxScaleValue — Maximum value for scale values**

'Not Used' (default) | positive scalar

Maximum allowed scale values. The filter applies the `MaxScaleValue` limit only when you set `ScaleValueConstraint` to a value other than `unit` (the default setting). Setting `MaxScaleValue` to any numerical value automatically changes the `ScaleValueConstraint` setting to `none`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **Output Arguments**

### **sysobjnew — Scaled biquadratic filter object**

`dsp.BiquadFilter` System object | `dsp.SOSFilter` System object

Scaled biquadratic filter object, returned as one of the following System objects:

- `dsp.BiquadFilter`
- `dsp.SOSFilter`

The returned object contains the scaled second-order sections.

# scalecheck

**Package:** dsp

Check scaling of biquadratic filter

## Syntax

```
s = scalecheck(sysobj,pnorm)
s = scalecheck(sysobj,pnorm,'Arithmetic',arithType)
```

## Description

`s = scalecheck(sysobj,pnorm)` checks the scaling of the input filter System object.

`s = scalecheck(sysobj,pnorm,'Arithmetic',arithType)` checks the scaling of the filter object with the arithmetic specified in `arithType`.

## Examples

### Linf-norm scaling of a filter

This example shows how to check the Linf-norm scaling of a filter.

Design an elliptic sos filter in the direct form II structure with default specifications.

```
EllipII = design(fdesign.lowpass, 'ellip', 'FilterStructure', 'df2sos',...
    'SystemObject',true)
```

```
EllipII =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II'
        CoefficientSource: 'Property'
        Numerator: [3x3 double]
        Denominator: [3x3 double]
        HasScaleValues: true
        ScaleValues: [0.8629 2.0523 0.0127 1]
```

Show all properties

Check the scaling.

```
scalecheck(EllipII,'Linf')
ans = 2x3
    3.1678    15.0757    1.4974
    4.7360    52.6026    1.0000
```

Design an elliptic sos filter in the direct form I structure with default specifications.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20), 'ellip',...
    'FilterStructure', 'dfllsos','SystemObject',true)
```

```
EllipI =
    dsp.SOSFilter with properties:

        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [0.9442 1.0014 1.0170 1.6551 0.1398 1]
```

Show all properties

Check the scaling.

```
scalecheck(EllipI,'Linf')
```

```
ans = 1x5
```

```
    1.7078    2.0807    2.6084    7.1467    1.0000
```

## Input Arguments

### sysobj — Input filter object

dsp.BiquadFilter System object | dsp.SOSFilter System object

Input filter, specified as one of the following System objects:

- dsp.BiquadFilter
- dsp.SOSFilter

### pnorm — Different types of norm

'l1' | 'l2' | 'linf' | 'L1' | 'L2' | 'Linf'

Discrete-time-domain norm or a frequency-domain norm.

Valid time-domain norm values for pnorm are 'l1', 'l2', and 'linf'. Valid frequency-domain norm values are 'L1', 'L2', and 'Linf'. The 'L2' norm is equal to the 'l2' norm (by Parseval's theorem), but this equivalency does not hold for other norms — 'l1' is not the same as 'L1' and 'Linf' is not the same as 'linf'.

### arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic type used during analysis, specified as 'double', 'single', or 'fixed'. The function assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state.

## Output Arguments

### **s** — Filter scaling

scalar | row vector

Filter scaling for a given p-norm. An optimally scaled filter has partial norms equal to one. In such cases, **s** contains all ones.

For direct-form I (**df1sos**) and direct-form II transposed (**df2tsos**) filters, the function returns the p-norm of the filter computed from the filter input to the output of each second-order section. Therefore, the number of elements in **s** is one less than the number of sections in the filter. This p-norm computation does not include the trailing scale value of the filter, which you can find by entering `hd.scalevalue(end)` at the MATLAB prompt.

For direct-form II (**df2sos**) and direct-form I transposed (**df1tsos**) filters, the function returns a row vector whose elements contain the p-norm from the filter input to the input of the recursive part of each second-order section. This computation of the p-norm corresponds to the input to the multipliers in these filter structures. These inputs correspond to the locations in the signal flow where overflow should be avoided.

When **hd** has nontrivial scale values, that is, if any scale values are not equal to one, **s** is a two-row matrix, rather than a vector. The first row elements of **s** report the p-norm of the filter computed from the filter input to the output of each second-order section. The elements of the second row of **s** contain the p-norm computed from the input of the filter to the input of each scale value between the sections. For **df2sos** and **df1tsos** filter structures, the last numerator and the trailing scale value for the filter are not included when `scalecheck` checks the scaling.

Data Types: `double`

Create an options object for second-order section scaling

### Syntax

```
opts = scaleopts(sysobj)
opts = scaleopts(sysobj, 'Arithmetic', arithType)
```

### Description

`opts = scaleopts(sysobj)` uses the current settings in the filter System object to create an options object `opts` that contains specified scaling options for second-order section scaling. You can pass `opts` as an input to `scale` to apply scaling settings to a second-order filter.

`opts = scaleopts(sysobj, 'Arithmetic', arithType)` returns filter coefficients for the filter System object with the arithmetic specified in `arithType`.

### Examples

#### Options for scaling SOS filter

Create an options scaling object that contains the scaling options settings you require.

```
EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast',10,0.5,0.5,20),...
    'ellip',...
    'FilterStructure', 'df1sos',...
    'SystemObject',true)
```

```
EllipI =
    dsp.SOSFilter with properties:

        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [5x3 double]
        Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [0.9442 1.0014 1.0170 1.6551 0.1398 1]
```

Show all properties

```
opts = scaleopts(EllipI)

opts =

        sosReorder: 'auto'
    MaxNumerator: 2
    NumeratorConstraint: 'none'
    OverflowMode: 'wrap'
```

```
ScaleValueConstraint: 'unit'
MaxScaleValue: 'Not used'
```

## Input Arguments

### sysobj — Input filter

`dsp.BiquadFilter` System object | `dsp.SOSFilter` System object

Input filter, specified as one of the following System objects:

- `dsp.BiquadFilter`
- `dsp.SOSFilter`

Example: `biquad = dsp.BiquadFilter('Structure', 'Direct form I', ... 'SOSMatrix', s, 'ScaleValues', g);`

### arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic type used during analysis, specified as 'double', 'single', or 'fixed'. The function assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The `scaleopts` function chooses the default values of the scaling options according to the 'Arithmetic' value and the System object settings.

## Output Arguments

### opts — Scale options object

`fdopts.sosscaling` object

You can create an `fdopts.sosscaling` object, `opts`, using the `scaleopts` function.

The following table lists the properties of `opts`:

| Parameter                        | Default | Description and Valid Value   |
|----------------------------------|---------|---|
| <code>sosReorder</code>          | 'auto'  | Reorder section prior to scaling.<br><br>Valid options are 'auto' (default), 'none', 'up', 'down', 'lowpass', 'highpass', 'bandpass', and 'bandstop'. |
| <code>MaxNumerator</code>        | 2       | Maximum allowed value for numerator coefficients.   |
| <code>NumeratorConstraint</code> | 'none'  | Specifies whether and how to constrain numerator coefficient values. Options are 'none' (default), 'unit', 'normalize', and 'po2'.                    |

| Parameter            | Default    | Description and Valid Value  |
|----------------------|------------|--|
| OverflowMode         | 'wrap'     | Sets the way the filter handles arithmetic overflow situations during scaling. Valid options are 'wrap' (default), 'saturate', and 'satall'.   |
| ScaleValueConstraint | 'unit'     | Specify whether to constrain the filter scale values, and how to constrain them. Valid options are 'unit' (default), 'none', and 'po2'.  |
| MaxScaleValue        | 'Not used' | Maximum allowed scale values. The filter applies the MaxScaleValue limit only when you set ScaleValueConstraint to a value other than unit. Setting MaxScaleValue to a numerical value automatically changes the ScaleValueConstraint setting to none. |

Example: `opts = scaleopts(biquad)`

# setCursorDataLabels

Customize data labels for cursor measurements

## Syntax

```
setCursorDataLabels(obj,labels)
```

## Description

setCursorDataLabels(obj,labels) customizes the data labels that appear in the tool tip of cursor measurements in the dsp.MatrixViewer.

## Examples

### Set Cursor Labels on dsp.MatrixViewer

This example shows how to set the data labels for the cursor measurements on the dsp.MatrixViewer System object.

Display a chirp signal on the dsp.MatrixViewer scope.

```
Fs = 233e3;
frameSize = 20e3;
chirp = dsp.Chirp("SampleRate",Fs,"SamplesPerFrame",frameSize,...
    "InitialFrequency",11e3,"TargetFrequency",11e3+55e3,...
    "Type","Quadratic");
scope = dsp.MatrixViewer(...
    "ColorBarLabel","Power/Frequency (dB/Hz)",...
    "XLabel","Frequency (Hz)",...
    "YLabel","Time (secs)",...
    "Colormap","hsv",...
    "ColorLimits",[-100,-30]);
y = chirp() + 0.05*randn(frameSize,1);
[~,~,~,Ps] = spectrogram(y,128,120,128,1e3);
val = 10*log10(abs(Ps)'+eps);
scope(val);
```

Change the data labels for the cursor measurements to match the type of data in the matrix.

```
setCursorDataLabels(scope, ["Hz", "Sec", "db/Hz"])
```

Enable the cursor measurements by selecting the cursor button in the axes toolbar. When you hover over the cursor, the tooltip shows you the data values with the new data labels.

## Input Arguments

### obj — Matrix viewer

`dsp.MatrixViewer` System object

Matrix viewer whose data labels you want to customize.

### labels — Label customization vector

`["X", "Y", "Value"]` (default) | 3-by-1 string array

Specify the label names as a three-element string array. The first element corresponds to the x-data, the second element to the y-data, and the third element to the matrix value.

Example: `["freq", "time", "power"]`

Data Types: `char` | `string`

## set2int

Configure filter for integer filtering

### Syntax

```
set2int(h)
set2int(h,coeffwl)
set2int(...,inwl)
g = set2int(...)
```

### Description

This section applies to discrete-time (`dfilt`) filters.

`set2int(h)` scales the filter coefficients to integer values and sets the filter coefficient and input fraction lengths to zero.

`set2int(h,coeffwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients.

`set2int(...,inwl)` uses the number of bits specified by `coeffwl` as the word length it uses to represent the filter coefficients and the number of bits specified by `inwl` as the word length to represent the input data.

`g = set2int(...)` returns the gain `g` introduced into the filter by scaling the filter coefficients to integers. `g` is always calculated to be a power of 2.

---

**Note** `set2int` does not work with CIC decimators or interpolators because they do not have coefficients.

---

## Examples

### Configure an FIR Filter for Integer Filtering

Two parts comprise this example. Part 1 compares the step response of an FIR filter in both the fractional and integer filter modes. Fractional mode filtering is essentially the opposite of integer mode. Integer mode uses a filter which has coefficients represented by integers. Fractional mode filters have coefficients represented in fractional form (nonzero fraction length).

The second part of the example depends on the following - after you filter a set of data, the input data and output data cover the same range of values, unless the filter process introduces gain in the output. Converting your filter object to integer form, and then filtering a set of data, does introduce gain into the system. When the examples refer to resetting the output to the same range as the input, the examples are accounting for this added gain feature.

```
b = rcosdesign(.25,4,25,'sqrt');
hd = dfilt.dffir(b);
hd.Arithmetic = 'fixed';
```

```
hd.InputFracLength = 0; % Integer inputs.  
x = ones(100,1);  
yfrac = filter(hd,x); % Fractional mode output.  
g = set2int(hd); % Convert to integer coefficients.  
yint = filter(hd,x); % Integer mode output.
```

Note that `yint` and `yfrac` are `fi` objects. Later in this example, use the `fi` object properties `WordLength` and `FractionLength` to work with the output data. Now use the gain `g` to rescale the output from the integer mode filter operation. Verify that the scaled integer output is equal to the fractional output.

```
yints = double(yint)/g;
```

Verify that the scaled integer output is equal to the fractional output.

```
max(abs(yints-double(yfrac)))
```

```
ans = 0
```

In part two, the example reinterprets the output binary data, putting the input and the output on the same scale by weighting the most significant bits in the input and output data equally.

```
WL = yint.WordLength;  
FL = yint.FractionLength + log2(g);  
yints2 = fi(zeros(size(yint)),true,WL,FL);  
yints2.bin = yint.bin;  
max(abs(double(yints2)-double(yfrac)))
```

```
ans = 0
```

## Version History

Introduced in R2011a

## setspecs

Specifications for filter specification object

### Syntax

```
setspecs(D,specvalue1,specvalue2,...)
setspecs(D,Specification,specvalue1,specvalue2,...)
setspecs(...Fs)
setspecs(...,MAGUNITS)
```

### Description

`setspecs(D,specvalue1,specvalue2,...)` sets the specifications in filter specification object, `D`, in the same order they appear in the `Specification` property.

`setspecs(D,Specification,specvalue1,specvalue2,...)` changes the specifications for an existing filter specification object and sets values for the new `Specification` property.

`setspecs(...Fs)` specifies the sampling frequency, `Fs`, in Hz. The sampling frequency must be a scalar trailing all other specifications. Entering a sampling frequency causes all other frequency specifications to be in Hz.

`setspecs(...,MAGUNITS)` specifies the units for any magnitude specifications. `MAGUNITS` can be one of the following: 'linear', 'dB', or 'squared'. The default is 'dB'. The magnitude specifications are always converted and stored in dB regardless of how the units are specified.

Use `SET(D,'SPECIFICATION')` to get the list of all available specification types for the filter specification object, `D`.

### Examples

#### Set the Filter Order and Cutoff Frequency Using `setspecs`

Construct a lowpass filter with specifications for the filter order and cutoff frequency (-6 dB). Use `setspecs` after construction to set the values of the filter order and cutoff frequency. Display the values in the MATLAB® command window.

```
D = fdesign.lowpass('N,Fc');
setspecs(D,10,0.2);
```

```
D.FilterOrder
```

```
ans = 10
```

```
D.Fcutoff
```

```
ans = 0.2000
```

### **Set the Specifications of a Highpass Filter Using setspecs**

Construct a highpass filter with specifications for the numerator order, denominator order, and 3-dB frequency. Assume the sampling frequency is 1 kHz. Use `setspecs` to set the numerator and denominator orders to 6. Set the 3-dB frequency to 250 Hz. In order to use frequency specifications in Hz, specify the sampling frequency as a trailing scalar.

```
D = fdesign.highpass('Nb,Na,F3dB');  
setspecs(D,6,6,250,1000);
```

# show

## Package:

Display scope window

## Syntax

```
show(scope)
```

## Description

show(scope) shows the window of the scope.

## Examples

### Hide and Show Time Scope

Create a sine wave signal and view it in the scope.

```
Fs = 1000; % Sample rate
signal = dsp.SineWave(Frequency=50, SampleRate=Fs, ...
    SamplesPerFrame=100);
scope = timescope(SampleRate=Fs, TimeSpanSource="property", ...
    TimeSpan=0.25, YLimits=[-1 1]);
for ii = 1:2
    xsine = signal();
    scope(xsine)
end
```

Hide the scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clean up workspace variables.

```
clear scope Fs sine ii xsine
```

## Input Arguments

### scope — Scope object

scope object

Scope object, specified as one of the following:

- spectrumAnalyzer object
- dsp.ArrayPlot object
- dsp.LogicAnalyzer System object
- timescope object
- dsp.DynamicFilterVisualizer object

Example: myScope = spectrumAnalyzer; show(myScope)

## Version History

Introduced in R2011a

**R2022a: Support for `dsp.SpectrumAnalyzer` object will be removed**

*Not recommended starting in R2022a*

The `show` function will stop supporting the `dsp.SpectrumAnalyzer` object in a future release. Use the `spectrumAnalyzer` object instead.

**Update Code**

No updates to your code are required except replacing instances of `dsp.SpectrumAnalyzer` with `spectrumAnalyzer`.

This table shows how the `show` function typically uses the `dsp.SpectrumAnalyzer System` object and explains how to update existing code to use the `spectrumAnalyzer` object.

| Discouraged Usage  | Recommended Replacement                                |
|--|--|
| <code>scope = dsp.SpectrumAnalyzer;<br/>show(scope)</code> | <code>scope = spectrumAnalyzer;<br/>show(scope)</code> |

# showsignalblockdatatypetable

Launch DSP System Toolbox data type support table

## Syntax

```
showsignalblockdatatypetable
```

## Description

The `showsignalblockdatatypetable` function shows a table of characteristics for the DSP System Toolbox blocks. The table lists capabilities and limitations of code generation, variable size, and supported data types for each block.

If a cell has an:

- "X" -- The corresponding block supports the data type or capability indicated by the column heading.
- "s" or a "u" -- The block supports signed or unsigned varieties of that data type, respectively.
- (#) -- Refer to the numbered footnotes at the bottom of the table window for further details. The (#) is hyperlinked to the footnotes at the bottom.

## Examples

### Show Block Characteristics for DSP System Toolbox

The `showsignalblockdatatypetable` function returns a table of block characteristics for DSP System Toolbox™.

Run the function in the MATLAB™ command prompt. The table opens in a separate window.

```
showsignalblockdatatypetable
```

```
Loading DSP System Toolbox Library.
```

## SOS

**Package:** dsp

Convert to second order sections

### Syntax

```
sosFilt = sos(sysobj)
sosFilt = sos(sysobj,dir_flag)
```

### Description

`sosFilt = sos(sysobj)` converts a IIR discrete-time filter to a second-order section (SOS) filter. The `sosFilt` output is a `dsp.SOSFilter` System object.

`sosFilt = sos(sysobj,dir_flag)` rearranges the second-order sections according to proximity to the origin of the poles of the sections.

### Examples

#### Convert IIR Discrete-time Filter to SOS Form

Convert an IIR discrete-time filter object to an SOS filter object that contains the corresponding SOS sections.

Design a 10th order lowpass Butterworth filter using the `butter` function.

```
N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
```

Create a `dsp.IIRFilter` object and assign the designed coefficients to the `Numerator` and the `Denominator` properties of the object.

```
iir = dsp.IIRFilter(Numerator=b,Denominator=a)
```

```
iir =
  dsp.IIRFilter with properties:
    Structure: 'Direct form II transposed'
    Numerator: [4.9945e-04 0.0050 0.0225 0.0599 0.1049 0.1259 0.1049 0.0599 0.0225 0.0050]
    Denominator: [1 -1.9924 3.0195 -2.8185 2.0387 -1.0545 0.4144 -0.1157 0.0225 -0.0027 1.4]
    InitialConditions: 0
```

```
Show all properties
```

Use the `sos` function to convert the IIR filter object into an SOS filter that contains the corresponding SOS sections.

```
sosFilt = sos(iir)
```

```

sosFilt =
  dsp.SOSFilter with properties:

    Structure: 'Direct form II transposed'
    CoefficientSource: 'Property'
    Numerator: [5x3 double]
    Denominator: [5x3 double]
    HasScaleValues: true
    ScaleValues: [4.9945e-04 1 1 1 1 1]

```

Show all properties

You can obtain the SOS matrix and scale values from the SOS filter object.

```
sMatrix = [sosFilt.Numerator,sosFilt.Denominator]
```

```
sMatrix = 5x6
```

|        |        |        |        |         |        |
|--------|--------|--------|--------|---------|--------|
| 1.0000 | 2.0958 | 1.0984 | 1.0000 | -0.3187 | 0.0313 |
| 1.0000 | 2.0576 | 1.0602 | 1.0000 | -0.3345 | 0.0826 |
| 1.0000 | 1.9981 | 1.0005 | 1.0000 | -0.3695 | 0.1958 |
| 1.0000 | 1.9412 | 0.9436 | 1.0000 | -0.4317 | 0.3969 |
| 1.0000 | 1.9073 | 0.9097 | 1.0000 | -0.5380 | 0.7410 |

```
sValues = sosFilt.ScaleValues
```

```
sValues = 1x6
```

|        |        |        |        |        |        |
|--------|--------|--------|--------|--------|--------|
| 0.0005 | 1.0000 | 1.0000 | 1.0000 | 1.0000 | 1.0000 |
|--------|--------|--------|--------|--------|--------|

Compare these values to the values obtained using the `tf2sos` function and verify that they are the same.

```
[sMatrixfn,g] = tf2sos(b,a)
```

```
sMatrixfn = 5x6
```

|        |        |        |        |         |        |
|--------|--------|--------|--------|---------|--------|
| 1.0000 | 2.0958 | 1.0984 | 1.0000 | -0.3187 | 0.0313 |
| 1.0000 | 2.0576 | 1.0602 | 1.0000 | -0.3345 | 0.0826 |
| 1.0000 | 1.9981 | 1.0005 | 1.0000 | -0.3695 | 0.1958 |
| 1.0000 | 1.9412 | 0.9436 | 1.0000 | -0.4317 | 0.3969 |
| 1.0000 | 1.9073 | 0.9097 | 1.0000 | -0.5380 | 0.7410 |

```
g = 4.9945e-04
```

```
isequal(sMatrix,sMatrixfn)
```

```
ans = logical
     1
```

```
isequal(sValues(1),g)
```

```
ans = logical
     1
```

## Input Arguments

### **sysobj** — IIR discrete-time filter object

`dsp.IIRFilter` object

IIR discrete-time filter object, specified as a `dsp.IIRFilter` System object.

### **dir\_flag** — Pole direction flag

'up' | 'down'

Pole direction flag, specified as either:

- 'up' -- The first row contains the poles closest to the origin, and the last row contains the poles closest to the unit circle.
- 'down' -- The sections are ordered in the opposite direction. The zeros are always paired with the poles closest to them.

## Output Arguments

### **sosFilt** — Second order section filter object

`dsp.SOSFilter` object

Second order section filter object, returned as a `dsp.SOSFilter` System object. The `sos` function converts the input IIR filter numerator and denominator coefficients into SOS matrix and scale values, and assigns these values to the `dsp.SOSFilter` object.

## Version History

### Introduced in R2011a

### **R2022b: Designs `dsp.SOSFilter` object instead of `dsp.BiquadFilter` object**

*Behavior changed in R2022b*

The `sos` function now generates a `dsp.SOSFilter` object instead of the `dsp.BiquadFilter` object.

Initialize a `dsp.IIRFilter` object. Use the `sos` function to convert the IIR filter object into a biquadratic filter that contains the corresponding SOS sections. The output is a `dsp.SOSFilter` filter object.

```
iirFilt = dsp.IIRFilter
convFilt = sos(iirFilt)
```

```
convFilt =
    dsp.SOSFilter with properties:
        Structure: 'Direct form II transposed'
        CoefficientSource: 'Property'
        Numerator: [1 1 0]
        Denominator: [1 0.1000 0]
        HasScaleValues: false

    Show all properties
```

To design a `dsp.BiquadFilter` object instead of the `dsp.SOSFilter` object, you can use the `UseLegacyBiquadFilter` flag and set it to `true`.

```
convFilt = sos(iirFilt,UseLegacyBiquadFilter=true)
convFilt =
    dsp.BiquadFilter with properties:
        Structure: 'Direct form II transposed'
        SOSMatrixSource: 'Property'
        SOSMatrix: [1 1 0 1 0.1000 0]
        ScaleValues: [2x1 double]
        InitialConditions: 0
        OptimizeUnityScaleValues: true

Show all properties
```

## SS

**Package:** dsp

Convert discrete-time filter System object to state-space representation

### Syntax

```
[A,B,C,D] = ss(sysobj)
[A,B,C,D] = ss(sysobj,'Arithmetic',arithType)
```

### Description

`[A,B,C,D] = ss(sysobj)` converts a filter System object to state-space representation given by:

$$\begin{aligned}x(k+1) &= Ax(k) + Bu(k), \\ y(k) &= Cx(k) + Du(k),\end{aligned}$$

where  $x$  is the state vector,  $u$  is the input vector, and  $y$  is the output vector.

`[A,B,C,D] = ss(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

For more input options, see `ss` in Signal Processing Toolbox.

## Examples

### State-Space Representation of Biquad Filter

Design a fourth-order, lowpass SOS filter object with a normalized cutoff frequency of 0.4.

```
[z,p,k] = ellip(4,1,60,.4);    % Set up the filter
[sosMatrix,scaleValues] = zp2sos(z,p,k);
sosFilt = dsp.SOSFilter(Structure='Direct form I',...
    Numerator=sosMatrix(:,1:3),Denominator=sosMatrix(:,4:6),...
    HasScaleValues=true,ScaleValues=scaleValues)
```

```
sosFilt =
    dsp.SOSFilter with properties:
        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [2x3 double]
        Denominator: [2x3 double]
    HasScaleValues: true
        ScaleValues: [0.0351 1 1]
```

Show all properties

Convert the designed filter into state-space form using the `ss` function.

```
[A,B,C,D] = ss(sosFilt)
```

```
A = 8×8
```

```

    0         0         0         0         0         0         0         0
  1.0000     0         0         0         0         0         0         0

```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.BiquadFilter`
- `dsp.Differentiator`
- `dsp.FilterCascade`
- `dsp.FIRFilter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`

- `dsp.VariableBandwidthIIRFilter`

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## **Output Arguments**

### **A — State matrix**

matrix

State matrix, returned as an  $N$ -by- $N$  matrix, where  $N$  is the filter order.

Data Types: `double`

### **B — Input matrix**

column vector

Input matrix, returned as an  $N$ -by-1 column vector, indicating that the number of inputs to the linear system is 1.  $N$  is the filter order.

Data Types: `double`

### **C — Output matrix**

row vector

Output matrix, returned as a 1-by- $N$  row vector, indicating that the number of outputs of the linear system is 1.  $N$  is the filter order.

Data Types: `double`

**D — Feedthrough matrix**

scalar

Feedthrough matrix, returned as a scalar, indicating that the number of inputs and outputs of the linear system is 1.

Data Types: double

## step

**Package:** dsp

Display time-varying magnitude response

### Syntax

```
step(dfv, filt)
step(dfv, B, A)
```

### Description

`step(dfv, filt)` displays the time-varying magnitude response of the object filter, `filt`, in the Dynamic Filter Visualizer figure, as long as `filt` has a valid `freqz()` implementation.

`step(dfv, B, A)` displays the magnitude response for the digital filters with numerator and denominator polynomial coefficients stored in  $B_1$  and  $A_1$ ,  $B_2$  and  $A_2$ , ..., and  $B_N$  and  $A_N$ , respectively.

### Examples

#### Plot Time-Varying Magnitude and Phase Response of FIR Filter

Design an FIR filter with a time-varying magnitude and phase response. Plot this varying response on a dynamic filter visualizer in normalized frequency units.

Create a `dsp.DynamicFilterVisualizer` object. Set the `PlotAsMagnitudePhase` and the `NormalizedFrequency` properties to `true`.

```
dfv = dsp.DynamicFilterVisualizer(PlotAsMagnitudePhase=1, ...
    NormalizedFrequency=true, ShowLegend=true, ...
    Title='Magnitude and Phase Response', ...
    FilterNames="FIR Filter")
```

```
dfv =
    dsp.DynamicFilterVisualizer with properties:
```

```
        FFTLength: 2048
    NormalizedFrequency: 1
        FrequencyRange: [0 1]
            XScale: 'Linear'
    MagnitudeDisplay: 'Magnitude (dB)'
    PlotAsMagnitudePhase: 1
            PlotType: 'Line'
        AxesScaling: 'Auto'
```

Show all properties

Vary the cutoff frequency of the FIR filter  $k$  from 0.1 to 0.5 in increments of 0.001. View the varying magnitude and phase response using the dynamic filter visualizer.

```

for k = 0.1:0.001:0.5
    b = fir1(90,k);
    dfv(b,1);
end

```

### Plot Time-Varying Magnitude Response of Variable Bandwidth FIR Filter

Visualize the varying magnitude response of the variable bandwidth FIR filter using the dynamic filter visualizer.

Create a `dsp.DynamicFilterVisualizer` object.

```

dfv = dsp.DynamicFilterVisualizer(YLimits=[-160 10],...
    FilterNames="Variable Bandwidth FIR Filter")

```

`dfv =`  
`dsp.DynamicFilterVisualizer` with properties:

```

    FFTLength: 2048
  NormalizedFrequency: 0
    SampleRate: 44100
   FrequencyRange: [0 22050]
        XScale: 'Linear'
  MagnitudeDisplay: 'Magnitude (dB)'

```

```

PlotAsMagnitudePhase: 0
    PlotType: 'Line'
    AxesScaling: 'Manual'

```

Show all properties

Design a bandpass variable bandwidth FIR filter with a center frequency of 5 kHz and a bandwidth of 4 kHz.

```

Fs = 44100;
vbw = dsp.VariableBandwidthFIRFilter(FilterType='Bandpass',...
    FilterOrder=100,...
    SampleRate=Fs,...
    CenterFrequency=5e3,...
    Bandwidth=4e3);

```

Vary the center frequency of the filter. Visualize the varying magnitude response of the filter using the `dsp.DynamicFilterVisualizer` object.

```

for idx = 1:100
    dfv(vbw);
    vbw.CenterFrequency = vbw.CenterFrequency + 20;
end

```

## Input Arguments

### **dfv** — Dynamic filter visualizer

`dsp.DynamicFilterVisualizer` object

Dynamic filter visualizer, specified as a `dsp.DynamicFilterVisualizer` object.

### **filt** — Filter

filter System object

Filter System object with a valid `freqz()` implementation.

### **B** — Numerator polynomial coefficients

row vector

Numerator polynomial coefficients, specified as a row vector.

Data Types: `single` | `double`

### **A** — Denominator polynomial coefficients

scalar | row vector

Denominator polynomial coefficients, specified as a:

- scalar -- The filter is an FIR filter.
- row vector -- The filter is an IIR filter.

Data Types: `single` | `double`

### Objects

`dsp.DynamicFilterVisualizer`

# specifyall

**Package:** dsp

Fully specify fixed-point filter System object settings

## Syntax

```
specifyall(sysobj)
specifyall(sysobj,false)
specifyall(sysobj,true)
```

## Description

`specifyall(sysobj)` sets all the data type fixed-point properties of the filter System object to 'Custom' so that you can easily specify all the fixed-point settings. If the object has a `FullPrecisionOverride` property, its value is set to `false`. `specifyall` is intended as a shortcut to changing all the fixed-point properties.

`specifyall(sysobj, false)` sets all fixed-point properties of the filter System object to their default values and sets the filter to full-precision mode, if one is available.

`specifyall(sysobj, true)` is equivalent to `specifyall(sysobj)`.

## Examples

### Specify All Fixed-point Settings of FIRFilter

Use `specifyall` to access all the fixed-point settings of an FIR filter implemented with a direct-form structure. Using `specifyall` disables all automatic filter scaling and resets the mode values.

```
b = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],{'w' 'c'});
firFilter = dsp.FIRFilter('Numerator',b);
get(firFilter)
```

*ans = struct with fields:*

```

    Numerator: [0.0164 0.1031 -0.0632 -0.0907 0.0467 0.3139 0.4526 0.3139 -0.0907 -0.0632 -0.1031 -0.0164]
  ReflectionCoefficients: [0.5000 0.5000]
    InitialConditions: 0
    NumeratorSource: 'Property'
  ReflectionCoefficientsSource: 'Property'
        Structure: 'Direct form'
  FullPrecisionOverride: 1
    RoundingMethod: 'Floor'
    OverflowAction: 'Wrap'
    CoefficientsDataType: 'Same word length as input'
  ReflectionCoefficientsDataType: 'Same word length as input'
    CustomCoefficientsDataType: [1x1 embedded.numerictype]
  CustomReflectionCoefficientsDataType: [1x1 embedded.numerictype]
        ProductDataType: 'Full precision'
    CustomProductDataType: [1x1 embedded.numerictype]
```

```

        AccumulatorDataType: 'Full precision'

```

## Input Arguments

### **sysobj** — Input filter object

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`

- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.LowpassFilter`
- `dsp.SOSFilter`

## **Version History**

**Introduced in R2011a**

# stepz

**Package:** dsp

Step response of discrete-time filter System object

## Syntax

```
[stepResp,t] = stepz(sysobj)
[stepResp,t] = stepz(sysobj,n)
[stepResp,t] = stepz(sysobj,n,fs)
[stepResp,t] = stepz(sysobj,[],fs)
[___] = stepz( ___, 'Arithmetic',arithType)
stepz(sysobj)
```

## Description

`[stepResp,t] = stepz(sysobj)` computes the step response of the filter System object and returns the response in the column vector `stepResp`, and a vector of times (or sample intervals) in `t`, where `t = [0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[stepResp,t] = stepz(sysobj,n)` computes the step response at `floor(n)` 1-second intervals. The time vector `t` equals `(0:floor(n)-1)'`.

`[stepResp,t] = stepz(sysobj,n,fs)` computes the step response at `floor(n)` 1/fs-second intervals. The time vector `t` equals `(0:floor(n)-1)'/fs`.

`[stepResp,t] = stepz(sysobj,[],fs)` computes the step response at `k` 1/fs-second intervals, where `k` is the number of filter coefficients. The time vector `t` equals `(0:k-1)'/fs`.

`[___] = stepz( ___, 'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType` using any one of the previous syntaxes.

`stepz(sysobj)` launches `fvtool` and plots the step response of the filter System object.

For more input options, see `stepz` in Signal Processing Toolbox.

`stepz` works for both real and complex filters. When you omit the output arguments, the `stepz` function plots only the real part of the step response.

## Examples

### Step Response of Equiripple Lowpass FIR Filter

Design an equiripple lowpass FIR filter and compute the step response of the filter.

Use the `fdesign.lowpass` specification object to define the filter specifications. Run the `design` function on the specification object to create a `dsp.FIRFilter` object. Specify the passband frequency to be 20 kHz, stopband frequency to be 22.05 kHz, passband ripple to be 1 dB, and the stopband attenuation to be 80 dB. Specify the sampling frequency to be 96 kHz.

```
Fs = 96e3; filtSpecs = fdesign.lowpass(20e3,22.05e3,1,80,Fs);
firlp2 = design(filtSpecs,'equiripple','SystemObject',true)
```

```
firlp2 =
```

```
  dsp.FIRFilter with properties:
```

```
    Structure: 'Direct form'
```

```
  NumeratorSource: 'Property'
```

```
    Numerator: [4.2157e-04 9.7407e-04 3.1143e-04 -0.0031 -0.0082 -0.0111 -0.0081 -8.9652e-05]
  InitialConditions: 0
```

```
Show all properties
```

Compute the step response of the filter using the `stepz` function.

```
stepz(firlp2)
```

## Input Arguments

### **sysobj** – Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.Channelizer`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**n — Length of step response vector**

positive integer

Length of the step response vector, specified as a positive integer.

Data Types: `single` | `double`

**fs — Sampling frequency**

1 (default) | positive scalar

Sampling frequency used in computing the step response, specified as a positive scalar.

Data Types: `single` | `double`

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **stepResp** — Step response

vector

Step response, returned as an n-element vector. If n is not specified, the length of the step response vector equals the number of coefficients, k in the filter.

Data Types: double

### **t** — Time vector

vector

Time vector of length n in seconds. The vector t consists of n equally spaced points in the range  $(0 : \text{floor}(n) - 1) / fs$ . If n is not specified, the function uses the number of coefficients k in the filter.

Data Types: double

## Version History

Introduced in R2011a

## sysobj

Create filter System object from discrete-time filter

### Syntax

```
hs = sysobj(hfilt)
```

### Description

`hs = sysobj(hfilt)` creates a new filter System object `hs` from the `dfilt` object, `hfilt`.

The function supports a subset of `dfilt` objects. The following table lists supported filter structures for `hfilt` and the filter System object that the function creates.

| Single-rate   | Filter System object                  |
|---|---------------------------------------|
| Lattice AR( <code>dfilt.latticear</code> )  | <code>dsp.AllpoleFilter</code>        |
| Coupled-allpass, power-complementary lattice filter ( <code>dfilt.calatticepc</code> )        | <code>dsp.CoupledAllpassFilter</code> |
| Coupled-allpass, lattice filter ( <code>dfilt.calattice</code> )                              | <code>dsp.CoupledAllpassFilter</code> |
| Cascade of discrete time filters ( <code>dfilt.cascade</code> )                               | <code>dsp.CoupledAllpassFilter</code> |
| Direct Form I ( <code>dfilt.df1</code> )  | <code>dsp.IIRFilter</code>            |
| Direct Form I transposed ( <code>dfilt.df1t</code> )  | <code>dsp.IIRFilter</code>            |
| Direct Form II ( <code>dfilt.df2</code> )   | <code>dsp.IIRFilter</code>            |
| Direct Form II transposed ( <code>dfilt.df2t</code> )   | <code>dsp.IIRFilter</code>            |
| Direct-form FIR ( <code>dfilt.dffir</code> )  | <code>dsp.FIRFilter</code>            |
| Direct-form FIR transposed ( <code>dfilt.dffirt</code> )                                      | <code>dsp.FIRFilter</code>            |
| Direct-form symmetric FIR ( <code>dfilt.dfsymfir</code> )                                     | <code>dsp.FIRFilter</code>            |
| Direct-form antisymmetric FIR ( <code>dfilt.dfasymfir</code> )                                | <code>dsp.FIRFilter</code>            |
| Discrete-time, lattice, moving-average ( <code>dfilt.latticemamin</code> )                    | <code>dsp.FIRFilter</code>            |
| Discrete-time, second-order section, direct-form I ( <code>dfilt.df1sos</code> )              | <code>dsp.BiquadFilter</code>         |
| Discrete-time, second-order section, direct-form I transposed ( <code>dfilt.df1tsos</code> )  | <code>dsp.BiquadFilter</code>         |
| Discrete-time, second-order section, direct-form II ( <code>dfilt.df2sos</code> )             | <code>dsp.BiquadFilter</code>         |
| Discrete-time, second-order section, direct-form II transposed ( <code>dfilt.df2tsos</code> ) | <code>dsp.BiquadFilter</code>         |

## Input Arguments

### hfilt

Discrete-time filter (dfilt) object. The preceding table lists supported filter structures.

If hfilt is a discrete-time filter with the PersistentMemory property set to true, then the filter states are copied into the initial conditions properties of hs. Otherwise, initial conditions are ignored.

The function does not support some properties for SOS filter structures:

- If the CastBeforeSum property is set to false, the function issues a warning. dsp.BiquadFilter System objects always have a cast before a sum.
- If the Signed property is false, the function issues an error. dsp.BiquadFilter System objects do not support unsigned arithmetic.

## Output Arguments

### hs

Filter System object. The function maps almost all properties of hfilt into the filter System object. However, some properties are not mapped exactly:

- Filter System objects do not have a CoeffAutoScale property. The function specifies a word length and a fraction length regardless of whether the CoeffAutoScale property of hfilt is true or false.
- dsp.BiquadFilter System objects do not have a FullPrecisionOverride property. Full-precision values in hfilt are mapped to word and fraction lengths in hs. These settings correspond to the full-precision setting of the input data type.

## Examples

### Convert a discrete-time filter object to a System object

```
hfilt = dfilt.df1sos; %Direct-form I SOS
hs = sysobj(hfilt) %Biquadratic IIR filter

hs =
  dsp.BiquadFilter with properties:
      Structure: 'Direct form I'
  SOSMatrixSource: 'Property'
      SOSMatrix: [1 0 0 1 0 0]
      ScaleValues: [2x1 double]
  NumeratorInitialConditions: 0
  DenominatorInitialConditions: 0
  OptimizeUnityScaleValues: true
```

Show all properties

## **Version History**

**Introduced in R2012a**

## **tf**

**Package:** dsp

Return transfer function of overall prototype lowpass filter

### **Syntax**

```
[num,den] = tf(obj)
```

### **Description**

`[num,den] = tf(obj)` returns the vector of numerator coefficients, `num`, and the vector of denominator coefficients, `den`, for the overall prototype lowpass filter used for the filter bank in `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects.

### **Examples**

#### **Transfer Function of Prototype Lowpass Filter**

Determine the transfer function of the overall prototype lowpass filter used for the filter bank in the `dsp.Channelizer` System object.

Design a channelizer with the number of frequency bands or polyphase branches set to 8, the number of taps or coefficients per band set to 12, and stopband attenuation set to 80 dB. The function `tf` returns the transfer function of the prototype lowpass filter.

```
channelizer = dsp.Channelizer;  
[num,den] = tf(channelizer);
```

View the magnitude response of the prototype lowpass filter using `fvtool`.

```
fvtool(num,den);
```

## Input Arguments

### **obj** — Input filter System object

`dsp.Channelizer` | `dsp.ChannelSynthesizer`

Input filter, specified as either a `dsp.Channelizer` or a `dsp.ChannelSynthesizer` System object.

Example: `channelizer = dsp.Channelizer;`

Example: `channelizer = dsp.ChannelSynthesizer`

## Output Arguments

### **num** — Numerator coefficients

row vector

Numerator coefficients, returned as a row vector.

### **den** — Denominator coefficients

row vector

Denominator coefficients, returned as a row vector. For a finite Impulse response (FIR) filter, this value is 1.

## **Version History**

**Introduced in R2016b**

# tf

**Package:** dsp

Convert discrete-time filter System object to transfer function

## Syntax

```
[num,den] = tf(sysobj)
[num,den] = tf(sysobj,'Arithmetic',arithType)
```

## Description

`[num,den] = tf(sysobj)` converts the discrete-time filter System object to numerator and denominator coefficient vectors of the equivalent transfer function.

`[num,den] = tf(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

For more input options, see `tf` in Signal Processing Toolbox.

## Examples

### Transfer Function of SOS Filter

Compute the transfer function of an SOS filter using the `tf` function.

Create a fourth-order, lowpass SOS filter object with a normalized cutoff frequency of 0.4.

```
[z,p,k] = ellip(4,1,60,0.4); % Set up the filter
[sosMatrix,scaleValues] = zp2sos(z,p,k);
sosFilt = dsp.SOSFilter(Structure='Direct form I',...
    Numerator=sosMatrix(:,1:3),Denominator=sosMatrix(:,4:6),...
    HasScaleValues=true,ScaleValues=scaleValues)
```

```
sosFilt =
    dsp.SOSFilter with properties:
        Structure: 'Direct form I'
    CoefficientSource: 'Property'
        Numerator: [2x3 double]
        Denominator: [2x3 double]
    HasScaleValues: true
        ScaleValues: [0.0351 1 1]
```

Show all properties

Compute the transfer function of the designed SOS filter. The `tf` function returns the numerator and the denominator coefficient vectors of the filter.

```
[num,den] = tf(sosFilt)
```

```
num = 1×5
    0.0351    0.1038    0.1432    0.1038    0.0351

den = 1×5
    1.0000   -1.5676    1.7412   -1.0104    0.3093
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## **Output Arguments**

### **num — Numerator coefficients**

row vector

Numerator coefficients of the filter, returned as a row vector.

Data Types: `double`

### **den — Denominator coefficients**

scalar | row vector

Denominator coefficients of the filter, returned as a row vector.

Data Types: `double`

## **Version History**

Introduced in R2011a

### **Functions**

tf

**Topics**

“Analysis Methods for Filter System Objects” on page 3-2

## tf2ca

Transfer function to coupled allpass

### Syntax

```
[d1,d2] = tf2ca(b,a)
[d1,d2] = tf2ca(b,a)
[d1,d2,beta] = tf2ca(b,a)
```

### Description

`[d1,d2] = tf2ca(b,a)` where **b** is a real, symmetric vector of numerator coefficients and **a** is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors **d1** and **d2** containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

representing a coupled allpass decomposition.

`[d1,d2] = tf2ca(b,a)` where **b** is a real, antisymmetric vector of numerator coefficients and **a** is a real vector of denominator coefficients, corresponding to a stable digital filter, returns real vectors **d1** and **d2** containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$  such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

In some cases, the decomposition is not possible with real  $H1(z)$  and  $H2(z)$ . In those cases a generalized coupled allpass decomposition may be possible, as described in the following syntax.

`[d1,d2,beta] = tf2ca(b,a)` returns complex vectors **d1** and **d2** containing the denominator coefficients of the allpass filters  $H1(z)$  and  $H2(z)$ , and a complex scalar **beta**, satisfying  $|\text{beta}| = 1$ , such that

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)]$$

representing the generalized allpass decomposition.

In the above equations,  $H1(z)$  and  $H2(z)$  are real or complex allpass IIR filters given by

$$H1(z) = \frac{\text{fliplr}(\overline{D1(z)})}{D1(z)}, H2(z) = \frac{\text{fliplr}(\overline{D2(1)(z)})}{D2(1)(z)}$$

where  $D1(z)$  and  $D2(z)$  are polynomials whose coefficients are given by **d1** and **d2**.

---

**Note** A coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

---

## Examples

```
[b,a]=cheby1(9,.5,.4);  
[d1,d2]=tf2ca(b,a); % TF2CA returns denominators of the allpass.  
num = 0.5*conv(fliplr(d1),d2)+0.5*conv(fliplr(d2),d1);  
den = conv(d1,d2); % Reconstruct numerator and denominator.  
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed  
% numerator and denominators.
```

## Version History

Introduced in R2011a

## Extended Capabilities

### C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

All inputs must be constant. Expressions or variables are allowed if their values do not change.

## tf2cl

Transfer function to coupled allpass lattice

### Syntax

```
[k1,k2] = tf2cl(b,a)
[k1,k2] = tf2cl(b,a)
[k1,k2,beta] = tf2cl(b,a)
```

### Description

`[k1,k2] = tf2cl(b,a)` where `b` is a real, symmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, will perform the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) + H2(z)]$$

of a stable IIR filter  $H(z)$  and convert the allpass transfer functions  $H1(z)$  and  $H2(z)$  to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

`[k1,k2] = tf2cl(b,a)` where `b` is a real, antisymmetric vector of numerator coefficients and `a` is a real vector of denominator coefficients, corresponding to a stable digital filter, performs the coupled allpass decomposition

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[H1(z) - H2(z)]$$

of a stable IIR filter  $H(z)$  and converts the allpass transfer functions  $H1(z)$  and  $H2(z)$  to a coupled lattice allpass structure with coefficients given in vectors `k1` and `k2`.

In some cases, the decomposition is not possible with real  $H1(z)$  and  $H2(z)$ . In those cases, a generalized coupled allpass decomposition may be possible, using the syntax described below.

`[k1,k2,beta] = tf2cl(b,a)` performs the generalized allpass decomposition of a stable IIR filter  $H(z)$  and converts the complex allpass transfer functions  $H1(z)$  and  $H2(z)$  to corresponding lattice allpass filters

$$H(z) = \frac{B(z)}{A(z)} = \left(\frac{1}{2}\right)[\bar{\beta} \cdot H1(z) + \beta \cdot H2(z)]$$

where `beta` is a complex scalar of magnitude equal to 1.

---

**Note** Coupled allpass decomposition is not always possible. Nevertheless, Butterworth, Chebyshev, and Elliptic IIR filters, among others, can be factored in this manner. For details, refer to Signal Processing Toolbox User's Guide.

---

### Examples

```
[b,a]=cheby1(9,.5,.4);
[k1,k2]=tf2cl(b,a); % Get the reflection coeffs. for the lattices.
```

```
[num1,den1]=latc2tf(k1,'allpass'); % Convert each allpass lattice
[num2,den2]=latc2tf(k2,'allpass'); % back to transfer function.
num = 0.5*conv(num1,den2)+0.5*conv(num2,den1);
den = conv(den1,den2); % Reconstruct numerator and denominator.
MaxDiff=max([max(b-num),max(a-den)]); % Compare original and reconstructed
% numerator and denominators.
```

## Version History

# validstructures

Structures for specification object with design method

## Syntax

```
filtstruct = validstructures(designSpecs,'Systemobject',true)
filtstruct = validstructures(designSpecs,method,'Systemobject',true)
```

## Description

`filtstruct = validstructures(designSpecs,'Systemobject',true)` returns a structure of cell arrays, `filtstruct`, which contains a set of valid filter structures for the filter specification object `designSpecs`. When you set `'Systemobject'` to `true`, `validstructures` returns a list of structures that support filter System objects. Each field in `filtstruct` lists a set of filter structures for the design method specified.

`filtstruct = validstructures(designSpecs,method,'Systemobject',true)` returns the valid structures for the filter specification object, `designSpecs`, and the design method, `method`, in a cell array of character vectors.

## Examples

### Valid Filter Structures

Design a default lowpass filter specification object. Use the `validstructures` function to obtain valid design methods and structures in a structure array. Display the fieldnames to see all valid design methods. Display the valid filter structures for the `equiripple` field.

```
D = fdesign.lowpass;
filtstruct = validstructures(D,'SystemObject',true);
```

```
fn = fieldnames(filtstruct)
```

```
fn = 8x1 cell
    {'butter'   }
    {'cheby1'  }
    {'cheby2'  }
    {'ellip'   }
    {'equiripple'}
    {'ifir'    }
    {'multistage'}
    {'kaiserwin' }
```

```
strs = eval(['filtstruct.' fn{5}])
```

```
strs = 1x3 cell
    {'dffir'}    {'dffirt'}    {'dfsymfir'}
```

Create a highpass filter of order 50 with a 3-dB frequency of 0.2. Obtain the available structures for a Butterworth design.

```
D = fdesign.highpass('N,F3dB',50,0.2);
C = validstructures(D,'butter','SystemObject',true)

C = 1x6 cell
    {'df1sos'}    {'df2sos'}    {'df1tsos'}    {'df2tsos'}    {'cascadeallpass'}    {'cascadewdf'}
```

## Input Arguments

### **designSpecs** — Filter specification object

object

Filter specification object, specified as one of the `fdesign` functions.

### **method** — Design method

character vector

Design method, specified as a character vector. You can pick a design method from the available methods given by the `designmethods` function.

## Output Arguments

### **filtstruct** — Available filter structures

structure

Available filter structures, returned as a structure with the fields determined by the input filter specification object, `designSpecs`, and the chosen design method.

Data Types: `struct`

## Version History

Introduced in R2009a

# visualizeFilterStages

**Package:** dsp

Visualize filter stages

## Syntax

```
visualizeFilterStages(sysobj)
```

## Description

`visualizeFilterStages(sysobj)` shows the response of each individual filter stage of the filter System object using FVTool.

## Examples

### Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

#### Initialization

Create a `dsp.ComplexBandpassDecimator` System object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `spectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;
CF = 2000;
BW = 1000;
D = Fs/BW;
FrameLength = 1200;
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);

sa = spectrumAnalyzer('SampleRate',Fs/D,...
    'Method','welch',...
    'YLimits',[-120 40],...
    'FrequencyOffset',CF);

tones = [1625 2000 2125];
sin = dsp.SineWave('SampleRate',Fs,'Frequency',tones,...
    'SamplesPerFrame',FrameLength);
```

#### Visualize Filter Stages

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```

### Display Filter info

The `info` function displays information about the bandpass decimator.

```
fprintf('%s',info(bpdecim))
```

```
Overall Decimation Factor      : 48
Bandwidth                     : 1000 Hz
Number of Filters             : 5
Real multiplications per Input Sample: 14.708333
Real additions per Input Sample  : 13.833333
Number of Coefficients        : 89
Filters:
  Filter 1:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 2:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 3:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 4:
  dsp.FIRDecimator - Decimation Factor : 3
  Filter 5:
  dsp.FIRDecimator - Decimation Factor : 2
```

## Stream In and Filter Signal

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, sa.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4*randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400

bpdecim =
    dsp.ComplexBandpassDecimator with properties:

        CenterFrequency: 2400
        Specification: 'Decimation factor'
        DecimationFactor: 48
        StopbandAttenuation: 80
```

```

TransitionWidth: 100
MinimizeComplexCoefficients: true
SampleRate: 48000

```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900, 2900] Hz.

```

release(sa)
sa.FrequencyOffset = 2400;

```

Stream in the data and filter the signal.

```

for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end

```

The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

### Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

```
src = dsp.SampleRateConverter;
visualizeFilterStages(src)
```

## Input Arguments

### **sysobj** — Filter System object

filter System object

Filter System object, specified as one of the following:

- `dsp.ComplexBandpassDecimator`
- `dsp.SampleRateConverter`

## Version History

Introduced in R2012a

## visualizeFilterStages

**Package:** dsp

Display response of digital down converter or digital up converter filter cascade

### Syntax

```
visualizeFilterStages(Conv)
visualizeFilterStages(Conv,'Arithmetic',arithType)
fvt = visualizeFilterStages(Conv)
```

### Description

`visualizeFilterStages(Conv)` plots the magnitude response of the filter stages and the cascade response of a digital down converter or digital up converter, `Conv`. The function plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(Conv,'Arithmetic',arithType)` specifies the arithmetic type of the filter stages. Set input `arithType` to 'double', 'single', or 'fixed-point'. When the `Conv` object is in an unlocked state, you must specify the arithmetic type. When the `Conv` object is in a locked state, the object ignores the arithmetic input argument.

`fvt = visualizeFilterStages(Conv)` returns the handle to the `FVTool` object.

### Examples

#### Magnitude Response of Digital Down Converter

Plot the magnitude response of the digital down converter using the `fvtool` function and the `visualizeFilterStages` function.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `fvtool` function, plot the magnitude response of the overall filter cascade. The `visualizeFilterStages` function in addition plots the magnitude response of the individual filters stages.

```
dwnConv = dsp.DigitalDownConverter

dwnConv =
  dsp.DigitalDownConverter with properties:

    DecimationFactor: 100
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 30000000
```

Show all properties

## Using fvtool

If the System object is unlocked, you must specify the filter arithmetic through the 'Arithmetic' input of the fvtool function. If the System object is locked, the arithmetic input is ignored.

```
fvtool(dwnConv, 'Arithmetic', 'fixed-point')
```

## Using visualizeFilterStages

To view the magnitude response of the individual filter stages, call the visualizeFilterStages function.

```
visualizeFilterStages(dwnConv, 'Arithmetic', 'fixed-point')
```

## Input Arguments

### Conv — Digital down converter or digital up converter

`dsp.DigitalDownConverter` | `dsp.DigitalUpConverter`

Digital down converter or digital up converter, specified as a `dsp.DigitalDownConverter` or `dsp.DigitalUpConverter` System object.

### arithType — Arithmetic type

'double' (default) | 'single' | 'fixed-point'

Arithmetic type of the filter stages, specified as 'double', 'single', or 'fixed-point'. When the Conv object is in an unlocked state, you must specify the arithmetic type. When the Conv object is in a locked state, the object ignores the arithmetic input argument.

## wdf2allpass

Wave Digital Filter to allpass coefficient transformation

### Syntax

```
a = wdf2allpass(w)
A = wdf2allpass(W)
```

### Description

`a = wdf2allpass(w)` accepts a vector of transformed real allpass coefficients, `w`, and returns the conventional allpass polynomial version `a`. `w` is used by allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with `Structure` set to 'Wave Digital Filter'.

`A = wdf2allpass(W)` accepts the cell array of transformed allpass coefficient vectors `W`. Each cell of `W` contains the transformed real coefficients of a section of a cascade allpass filter. The output `A` is also a cell array, and each cell of `A` contains the conventional polynomial version of the corresponding cell of `W`. `W` is used by allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with `Structure` set to 'Wave Digital Filter'. Every cell of `W` must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. `W` can be a row or column vector of cells while `A` is always returned as column.

### Examples

#### Convert Wave Digital Filter Coefficients to Allpass Polynomial Coefficients

Create a second order allpass filter with wave digital filter coefficients `w = [0.5 0]`. Convert these coefficients into polynomial form using `wdf2allpass`. Assign the polynomial coefficients to an allpass filter using the 'Minimum multiplier' structure. Pass a random input to both these filters and compare the outputs.

```
w = [0.5 0];
allpasswdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter', ...
    'WDFCoefficients', w);
a = wdf2allpass(w);
allpass = dsp.AllpassFilter('AllpassCoefficients', a);
in = randn(512, 1);
outputallpasswdf = allpasswdf(in);
outputallpass = allpass(in);
plot(outputallpasswdf-outputallpass)
```

The difference between the two outputs is very small.

## Input Arguments

### **w** — Transformed Wave Digital Filter allpass coefficients

scalar | vector of real numbers

Numeric vector of transformed Wave Digital Filter allpass coefficients, specified as a real number. *w* can have only length equal to 1, 2, and 4. When the length is 4, the second and fourth components must both be zero. *w* can be a row or a column vector.

Example: `[0.3, -0.2]`

Data Types: `double` | `single`

### **W** — Transformed Wave Digital Filter allpass coefficients

scalar cell | vector of cells

Cascade of allpass filter coefficients in transformed Wave Digital Filter form, specified as a cell vector. Every cell of *W* must contain a real vector of length 1, 2, or 4. When the length is 4, the second and fourth components must both be zero. *W* can be a row or a column vector of cells.

Example: `{[0.3, -0.2]; 0.5}`

## Output Arguments

### **a** — allpass filter coefficients

vector of real numbers

Numeric vector of polynomial allpass coefficients, determined as a numeric row vector.

Data Types: `double` | `single`

### **A** — allpass filter coefficients

vector cell array

Cascade of allpass filter coefficient, determined as a column of cells, each containing a vector of length 1, 2, or 4.

Example: `{0.3 5.0 0.2}`

Data Types: `double` | `single`

## Algorithms

`wdf2allpass` provides the inverse operation of `allpass2wdf`, by transforming the transformed cascade of allpass coefficients  $W$  into their conventional polynomial representation  $A$ . Please refer to the reference page for `allpass2wdf` for more details about the two representations.

$W$  defines a multisection allpass filter, and `wdf2allpass` applies separately to each section, with the same transformation used in the single-section case. In this case, the numeric coefficients vector  $w$  can have order 1, 2, or 4.

The relations between the vector of section coefficients  $a$  and  $w$  respectively depend on the order, as follows:

*for order 1:*

$$a_1 = w_1$$

*for order 2:*

$$a_1 = w_2(1 + w_1)$$

$$a_2 = w_1$$

*for order 4:*

$$a_2 = w_3(1 + w_1)$$

$$a_4 = w_1$$

$$a_1 = a_3 = 0$$

## window

FIR filter using windowed impulse response

### Syntax

```
h = window(d,fcnhdl,fcnarg,'SystemObject',true)
h = window(d,win,'SystemObject',true)
```

### Description

`h = window(d,fcnhdl,fcnarg,'SystemObject',true)` designs a single-rate digital filter System object using the specifications in filter specification object `d`.

`fcnhdl` is a handle to a filter design function that returns a window vector, such as the `hamming` or `blackman` functions. `fcnarg` is an optional argument that returns a window. You pass the function to `window`.

`h = window(d,win,'SystemObject',true)` designs a filter using the vector you supply in `win`. The length of vector `win` must be the same as the impulse response of the filter, which is equal to the filter order plus one.

### Examples

#### Design a Nyquist Filter Using Kaiser Window

This example designs a filter using the two design techniques of specifying a function handle and passing a window vector as an input argument.

Use a window vector provided by the `kaiser` window function to design a Nyquist filter. The window length must be the filter order plus one.

```
d = fdesign.nyquist(5,'n',150);
% Kaiser window with beta parameter 2.5
nyqFilter = window(d,'window',kaiser(151,2.5),'SystemObject',true);
fvtool(nyqFilter)
```

## Version History

Introduced in R2011a

## zerophase

**Package:** dsp

Zero-phase response of discrete-time filter System object

### Syntax

```
[zphase,w] = zerophase(sysobj)
[zphase,w] = zerophase(sysobj,n)
[zphase,w] = zerophase( __ , 'Arithmetic',arithType)
zerophase(sysobj)
```

### Description

`[zphase,w] = zerophase(sysobj)` returns the zero-phase response vector, `zphase`, and the corresponding frequency vector, `w`, in radians/sample of the filter System object based on the current filter coefficients.

`[zphase,w] = zerophase(sysobj,n)` returns the `n`-point zero-phase response vector and the corresponding `n`-point frequency vector in radians/sample of the filter System object.

`[zphase,w] = zerophase( __ , 'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType` using either of the previous syntaxes.

`zerophase(sysobj)` launches `fvtool` and shows the zero-phase response of the filter System object.

For more input options, see `zerophase` in Signal Processing Toolbox.

### Examples

#### Zero-phase Response of Discrete-Time Filter

Create a `dsp.FIRFilter` System object™ and compute the zero-phase response of the filter.

```
Fs = 8000;
Fcutoff = 2000;
FIRfilt = dsp.FIRFilter('Numerator', fir1(130,Fcutoff/(Fs/2)));
```

The `zerophase` function computes the zero-phase response of the filter and displays the response using `fvtool`.

```
zerophase(FIRfilt)
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.Channelizer`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`

**n — Number of points over which zero-phase response is evaluated**

8192 (default) | positive integer

Number of points over which the zero-phase response is evaluated around the upper half of the unit circle. For an FIR filter where *n* is a power of two, the computation is done faster using FFTs.

Data Types: double

**arithType — Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **zphase** — Zero-phase response vector

vector

Zero-phase response vector, evaluated at  $n$  equally-spaced points around the upper half of the unit circle, returned as a vector. If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

### **w** — Frequency vector

vector

Frequency vector of length  $n$  in radians/sample.  $w$  consists of  $n$  equally-spaced points around the upper half of the unit circle (from 0 to  $\pi$  radians/sample). If  $n$  is not specified, the function uses a default value of 8192.

Data Types: double

## zpk

**Package:** dsp

Zero-pole-gain conversion of discrete-time filter System object

### Syntax

```
[z,p,k] = zpk(sysobj)
[z,p,k] = zpk(sysobj,'Arithmetic',arithType)
```

### Description

`[z,p,k] = zpk(sysobj)` returns the zeros, poles, and gain corresponding to the filter System object in vector `z`, vector `p`, and scalar `k`, respectively.

`[z,p,k] = zpk(sysobj,'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

For more input options, see `zpk` in Signal Processing Toolbox.

### Examples

#### Highpass Filter in Zero-Pole-Gain Form

Compute the zero-pole-gain form of the highpass filter using the `zpk` function.

Design a minimum order highpass FIR filter with a passband frequency of 75 kHz and passband ripple of 0.2 dB. Specify a sample rate of 200 kHz.

```
hFilt = dsp.HighpassFilter('PassbandFrequency',75e3,'PassbandRipple',0.2,'SampleRate',200e3)
```

```
hFilt =
  dsp.HighpassFilter with properties:
```

```
      FilterType: 'FIR'
  DesignForMinimumOrder: true
      StopbandFrequency: 8000
      PassbandFrequency: 75000
  StopbandAttenuation: 80
      PassbandRipple: 0.2000
  NormalizedFrequency: false
      SampleRate: 200000
```

Show all properties

Find the zeros, poles, and the gain of the designed filter using the `zpk` function.

```
[z,p,k] = zpk(hFilt)
```

```
z = 8×1 complex
```

```

```
k = -0.0023
```

## Input Arguments

### **sysobj** — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`
- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`

- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

### **arithType – Arithmetic type**

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When the 'Arithmetic' input argument is specified as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis depends on whether the System object is unlocked or locked.

- unlocked -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## **Output Arguments**

### **z – Zeros**

column vector

Zeros of the filter, returned as a column vector.

Data Types: `double`

### **p – Poles**

column vector

Poles of the filter, returned as a column vector.

Data Types: double  
Complex Number Support: Yes

**k — Gain**

real scalar

Gain of the filter, returned as a real scalar.

Data Types: double

## zpkbpc2bpc

Zero-pole-gain complex bandpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkbpc2bpc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the complex bandpass prototype by applying a first-order complex bandpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places two features of an original filter, located at frequencies  $W_{o1}$  and  $W_{o2}$ , at the required target frequency locations,  $W_{t1}$ , and  $W_{t2}$  respectively. It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle; e.g., in the adaptive system.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
```

Create a complex passband from 0.25 to 0.75:

```
[b, a] = iirlp2bpc(b,a,0.5,[0.25,0.75]);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpkbpc2bpc(z,p,k,[0.25, 0.75],[-0.75, -0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Comparing the filters in FVTool shows the example results. Use the features in FVTool to check the filter coefficients, or other filter analyses.

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter                       |
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## zpkftransf

Zero-pole-gain frequency transformation

### Syntax

```
[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)
```

### Description

`[Z2,P2,K2] = zpkftransf(Z,P,K,AllpassNum,AllpassDen)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the transformed lowpass digital filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ . If `AllpassDen` is not specified it will default to 1. If neither `AllpassNum` nor `AllpassDen` is specified, then the function returns the input filter.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
[AlpNum, AlpDen] = allpasslp2lp(0.5, 0.25);
[z2, p2, k2] = zpkftransf(roots(b),roots(a),b(1),AlpNum,AlpDen);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

After transforming the filter, you get the response shown in the figure, where the passband has been shifted towards zero.

## Arguments

| Variable | Description                                 |
|----------|---|
| $Z$      | Zeros of the prototype lowpass filter       |
| $P$      | Poles of the prototype lowpass filter       |
| $K$      | Gain factor of the prototype lowpass filter |
| $FTFNum$ | Numerator of the mapping filter             |
| $FTFDen$ | Denominator of the mapping filter           |
| $Z2$     | Zeros of the target filter                  |
| $P2$     | Poles of the target filter                  |
| $K2$     | Gain factor of the target filter            |

## zpklp2bp

Zero-pole-gain lowpass to bandpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandpass frequency mapping.

It also returns the numerator, `AllpassNum`, and the denominator `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Real lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be easily doubled and positioned at two distinct, desired frequencies.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[B,A] = ellip(3,0.1,30,0.409);
Z = roots(B);
P = roots(A);
K = B(1);
[Z2,P2,K2] = zpklp2bp(Z,P,K, 0.5, [0.2 0.3]);
hfvtool(B,A,K2*poly(Z2),poly(P2));
legend(hfvtool,'Prototype Lowpass Filter', 'Bandpass Filter');
axis([0 1 -70 10]);
```

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter                       |
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2bpc

Zero-pole-gain lowpass to complex bandpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bpc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bpc(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

| Variable     | Description  |
|--------------|--|
| $Z$          | Zeros of the prototype lowpass filter  |
| $P$          | Poles of the prototype lowpass filter  |
| $K$          | Gain factor of the prototype lowpass filter  |
| $W_o$        | Frequency value to be transformed from the prototype filter. It should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.   |
| $W_t$        | Desired frequency locations in the transformed target filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate. |
| $Z_2$        | Zeros of the target filter   |
| $P_2$        | Poles of the target filter   |
| $K_2$        | Gain factor of the target filter   |
| $AllpassNum$ | Numerator of the mapping filter  |
| $AllpassDen$ | Denominator of the mapping filter  |

## zpklp2bs

Zero-pole-gain lowpass to bandstop frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt)
```

### Description

[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bs(Z,P,K,Wo,Wt) returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a second-order real lowpass to real bandstop frequency mapping.

It also returns the numerator, AllpassNum, and the denominator, AllpassDen, of the allpass mapping filter. The prototype lowpass filter is given with zeros, Z, poles, P, and gain factor, K.

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ s.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bs(z, p, k, 0.5, [0.2 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Arguments

| Variable | Description                           |
|----------|---------------------------------------|
| Z        | Zeros of the prototype lowpass filter |

| Variable     | Description   |
|--------------|---|
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $W_o$        | Frequency value to be transformed from the prototype filter |
| $W_t$        | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2bsc

Zero-pole-gain lowpass to complex bandstop frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2bsc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to complex bandstop frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $-W_o$ , at the required target frequency location,  $W_{t1}$ , and the second feature, originally at  $+W_o$ , at the new location,  $W_{t2}$ . It is assumed that  $W_{t2}$  is greater than  $W_{t1}$ . Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2bsc(z, p, k, 0.5, [0.2, 0.3]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter   |
| $P$          | Poles of the prototype lowpass filter   |
| $K$          | Gain factor of the prototype lowpass filter   |
| $W_o$        | Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.     |
| $W_t$        | Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. |
| $Z_2$        | Zeros of the target filter  |
| $P_2$        | Poles of the target filter  |
| $K_2$        | Gain factor of the target filter  |
| $AllpassNum$ | Numerator of the mapping filter   |
| $AllpassDen$ | Denominator of the mapping filter   |

## zpklp2hp

Zero-pole-gain lowpass to highpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2hp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real highpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ , at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . After the transformation feature  $F_2$  will precede  $F_1$  in the target filter. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, or the deep minimum in the stopband, or other ones.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2hp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Arguments

| Variable | Description                           |
|----------|---------------------------------------|
| $Z$      | Zeros of the prototype lowpass filter |

| Variable     | Description   |
|--------------|---|
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $W_o$        | Frequency value to be transformed from the prototype filter |
| $W_t$        | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2lp

Zero-pole-gain lowpass to lowpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2lp(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order real lowpass to real lowpass frequency mapping. This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ .

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without designing them again.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3, 0.1, 30, 0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2lp(z, p, k, 0.5, 0.25);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Using `zpklp2lp` creates the desired half band IIR filter with the transformed features that you specify in the transformation function. This figure shows the results.

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter                       |
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassNum$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2mb

Zero-pole-gain lowpass to M-band frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to real multibandpass frequency mapping. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2mb(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'pass');
[z2,p2,k2] = zpklp2mb(z, p, k, 0.5, [2 4 6 8]/10, 'stop');
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

The resulting multiband filter that replicates features from the prototype appears in the figure shown. Note the accuracy of the replication process.

## Arguments

| Variable          | Description   |
|-------------------|---|
| $Z$               | Zeros of the prototype lowpass filter   |
| $P$               | Poles of the prototype lowpass filter   |
| $K$               | Gain factor of the prototype lowpass filter                                   |
| $w_0$             | Frequency value to be transformed from the prototype filter                   |
| $w_t$             | Desired frequency location in the transformed target filter                   |
| <i>Pass</i>       | Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default |
| $Z_2$             | Zeros of the target filter  |
| $P_2$             | Poles of the target filter  |
| $K_2$             | Gain factor of the target filter  |
| <i>AllpassNum</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter   |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpklp2mbc

Zero-pole-gain lowpass to complex M-band frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklpmbc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Mth-order real lowpass to complex multibandpass frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

This transformation effectively places one feature of an original filter, located at frequency  $W_o$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature, for example, the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., to replicate notch filters and resonators at any required location.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z1,p1,k1] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
[z2,p2,k2] = zpklp2mbc(z, p, k, 0.5, [2 4 6 8]/10);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k1*poly(z1), poly(p1), k2*poly(z2), poly(p2));
```

You could review the coefficients to compare the filters, but the graphical comparison shown here is quicker and easier.

However, looking at the coefficients in FVTool shows the complex nature desired.

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter   |
| $P$          | Poles of the prototype lowpass filter   |
| $K$          | Gain factor of the prototype lowpass filter   |
| $W_0$        | Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.     |
| $W_t$        | Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. |
| $Z_2$        | Zeros of the target filter  |
| $P_2$        | Poles of the target filter  |
| $K_2$        | Gain factor of the target filter  |
| $AllpassNum$ | Numerator of the mapping filter   |
| $AllpassDen$ | Denominator of the mapping filter   |

## zpklp2xc

Zero-pole-gain lowpass to complex N-point frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to complex multipoint frequency transformation.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Parameter  $N$  also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places  $N$  features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating  $N$  bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xc(z, p, k, [-0.5 0.5], [-0.25 0.25]);
```

Verify the result by comparing the prototype filter with the target filter:

```
fvtool(b, a, k2*poly(z2), poly(p2));
```

Plotting the filters on the same axes lets you compare the results graphically, shown here.

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter   |
| $P$          | Poles of the prototype lowpass filter   |
| $K$          | Gain factor of the prototype lowpass filter   |
| $W_o$        | Frequency values to be transformed from the prototype filter. They should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.  |
| $W_t$        | Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate. |
| $Z_2$        | Zeros of the target filter  |
| $P_2$        | Poles of the target filter  |
| $K_2$        | Gain factor of the target filter  |
| $AllpassNum$ | Numerator of the mapping filter   |
| $AllpassDen$ | Denominator of the mapping filter   |

## zpklp2xn

Zero-pole-gain lowpass to N-point frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)
[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying an Nth-order real lowpass to real multipoint frequency transformation, where N is the number of features being mapped. By default the DC feature is kept at its original location.

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpklp2xn(Z,P,K,Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility". In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is allowed to move.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Parameter N also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places N features of an original filter, located at frequencies  $W_{o1}, \dots, W_{oN}$ , at the required target frequency locations,  $W_{t1}, \dots, W_{tM}$ .

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation. For DC mobility feature  $F_2$  will precede  $F_1$  after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating N bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
```

```

p = roots(a);
k = b(1);
[z2,p2,k2] = zpklp2xn(z, p, k, [-0.5 0.5], [0 0.25], 'pass');
hfvt = fvtool(b, a, k2*poly(z2), poly(p2));
legend(hfvt, 'Original Filter', 'Half-band Filter');

```

As demonstrated by the figure, the target filter has the desired response shape and values replicated from the prototype.

## Arguments

| Variable          | Description   |
|-------------------|---|
| <i>Z</i>          | Zeros of the prototype lowpass filter   |
| <i>P</i>          | Poles of the prototype lowpass filter   |
| <i>K</i>          | Gain factor of the prototype lowpass filter                                   |
| <i>Wo</i>         | Frequency value to be transformed from the prototype filter                   |
| <i>Wt</i>         | Desired frequency location in the transformed target filter                   |
| <i>Pass</i>       | Choice ('pass' / 'stop') of passband/stopband at DC, 'pass' being the default |
| <i>Z2</i>         | Zeros of the target filter  |
| <i>P2</i>         | Poles of the target filter  |
| <i>K2</i>         | Gain factor of the target filter  |
| <i>AllpassDen</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter   |

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

## zpkrateup

Zero-pole-gain complex bandpass frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkrateup(Z,P,K,N)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter being transformed from any prototype by applying an  $N$ th-order rateup frequency transformation, where  $N$  is the upsample ratio. Transformation creates  $N$  equal replicas of the prototype filter frequency response.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The original lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and gain factor,  $K$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
% Upsample the prototype filter 4 times
[z2,p2,k2] = zpkrateup(z, p, k, 4);
% Compare prototype filter with target filter
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Arguments

| Variable | Description                                 |
|----------|---|
| $Z$      | Zeros of the prototype lowpass filter       |
| $P$      | Poles of the prototype lowpass filter       |
| $K$      | Gain factor of the prototype lowpass filter |
| $N$      | Integer upsampling ratio                    |
| $Z2$     | Zeros of the target filter                  |
| $P2$     | Poles of the target filter                  |
| $K2$     | Gain factor of the target filter            |

---

| Variable          | Description                       |
|-------------------|-----------------------------------|
| <i>AllpassNum</i> | Numerator of the mapping filter   |
| <i>AllpassDen</i> | Denominator of the mapping filter |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

## zpkshift

Zero-pole-gain real shift frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshift(Z,P,K,Wo,Wt)` returns the zeros,  $Z2$ , poles,  $P2$ , and gain factor,  $K2$ , of the target filter transformed from the zeros, poles, and gain factor of real lowpass prototype by applying a second-order real shift frequency mapping. It also returns the numerator,  $AllpassNum$ , and the denominator,  $AllpassDen$  of the allpass mapping filter.

This transformation places one selected feature of an original filter, located at frequency  $W_o$ , at the required target frequency location,  $W_t$ . This transformation implements the "DC Mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of  $W_o$  and  $W_t$ .

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter,  $F_1$  and  $F_2$ , with  $F_1$  preceding  $F_2$ . Feature  $F_1$  will still precede  $F_2$  after the transformation. However, the distance between  $F_1$  and  $F_2$  will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way without the need to design them again.

### Examples

Rotate frequency response by  $\pi/2$  radians/sample:

```
[B,A] = ellip(10,0.1,40,0.25);
% Elliptic lowpass filter with passband frequency 0.25*pi rad/sample
Z = roots(B); % get roots of numerator polynomial- filter zeros
P = roots(A); % get roots of denominator polynomial- filter poles
K = B(1);
[Z2,P2,K2] = zpkshift(Z,P,K,0.25,0.75); % shift by 0.25*pi rad/sample
Num = poly(Z2);
Den = poly(P2);
hfvtool(B,A,K2*Num,Den);
legend(hfvtool,'Original Filter','Rotate by \pi/2 radians/sample');
axis([0 1 -90 10]);
```

## zpkshifc

Zero-pole-gain complex shift frequency transformation

### Syntax

```
[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)
[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)
```

### Description

`[Z2,P2,K2,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,Wo,Wt)` returns zeros,  $Z_2$ , poles,  $P_2$ , and gain factor,  $K_2$ , of the target filter transformed from the real lowpass prototype by applying a first-order complex frequency shift transformation. This transformation rotates all the features of an original filter by the same amount specified by the location of the selected feature of the prototype filter, originally at  $W_o$ , placed at  $W_t$  in the target filter.

It also returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the allpass mapping filter. The prototype lowpass filter is given with zeros,  $Z$ , poles,  $P$ , and the gain factor,  $K$ .

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,0.5)` performs the Hilbert transformation, i.e. a 90 degree counterclockwise rotation of an original filter in the frequency domain.

`[Num,Den,AllpassNum,AllpassDen] = zpkshifc(Z,P,K,0,-0.5)` performs the inverse Hilbert transformation, i.e. a 90 degree clockwise rotation of an original filter in the frequency domain.

### Examples

Design a prototype real IIR halfband filter using a standard elliptic approach:

```
[b, a] = ellip(3,0.1,30,0.409);
z = roots(b);
p = roots(a);
k = b(1);
```

#### Rotation by $\pi/4$ Radians/Sample

Rotation by -0.25:

```
[z2,p2,k2] = zpkshifc(z, p, k, 0.5, 0.25);
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Rotation by $\pi/2$ Radians/Sample

```
[z2,p2,k2] = zpkshifc(z, p, k, 0, 0.5);
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Rotation by $-\pi/2$ Radians/Sample

```
[z2,p2,k2] = zpkshifc(z, p, k, 0, -0.5);
fvtool(b, a, k2*poly(z2), poly(p2));
```

### Result of Example 1

After performing the rotation, the resulting filter shows the features desired.

### Result of Example 2

Similar to the first example, performing the Hilbert transformation generates the desired target filter, shown here.

### Result of Example 3

Finally, using the inverse Hilbert transformation creates yet a third filter, as the figure shows.

## Arguments

| Variable     | Description   |
|--------------|---|
| $Z$          | Zeros of the prototype lowpass filter                       |
| $P$          | Poles of the prototype lowpass filter                       |
| $K$          | Gain factor of the prototype lowpass filter                 |
| $\omega_0$   | Frequency value to be transformed from the prototype filter |
| $\omega_t$   | Desired frequency location in the transformed target filter |
| $Z_2$        | Zeros of the target filter                                  |
| $P_2$        | Poles of the target filter                                  |
| $K_2$        | Gain factor of the target filter                            |
| $AllpassDen$ | Numerator of the mapping filter                             |
| $AllpassDen$ | Denominator of the mapping filter                           |

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

# zplane

**Package:** dsp

Z-plane zero-pole plot for discrete-time filter System object

## Syntax

```
zplane(sysobj)
zplane(sysobj,'Arithmetic',arithType)
[z,p,k] = zplane(sysobj)
```

## Description

`zplane(sysobj)` plots the zeros and poles of the filter System object, `sysobj`, with the unit circle for reference in the Filter Visualization Tool (FVTool). Each zero is represented with an 'o' and each pole with a 'x' on the plot. Multiple zeros and poles are indicated by the multiplicity number shown at the upper right of the zero or pole.

When you run the filter System object with a fixed-point input, the filter becomes a quantized fixed-point filter, `filtQuant`. When `filtQuant` is a quantized filter, `zplane(filtQuant)` plots the poles and zeros of the quantized and unquantized filters. The symbols  $\square$  and  $+$  represent the zeros and poles of the quantized filter `filtQuant`. The plot includes the unit circle for reference.

`zplane(sysobj,'Arithmetic',arithType)` also analyzes the filter System object, `sysobj`, based on the arithmetic specified in `arithType`.

`[z,p,k] = zplane(sysobj)` returns the zeros, poles, and the gain of the filter.

For more input options, see `zplane` in Signal Processing Toolbox.

## Examples

### Plot Poles and Zeros of Fourth-Order Filter

Create a fourth-order IIR digital filter with a cutoff frequency of 0.6. Plot the poles and zeros of this filter.

```
[b,a] = ellip(4,.5,20,.6);
zplane(b,a)
```

Quantize the filter by passing a fixed-point input through the filter algorithm. Plot the quantized and unquantized poles and zeros associated with this filter.

```
iirFilt = dsp.IIRFilter('Numerator',b,'Denominator',a);  
in = fi(randn(15,6),1,15,3);  
out = iirFilt(in);  
zplane(iirFilt)
```

## Input Arguments

### sysobj — Input filter

filter System object

Input filter, specified as one of the following filter System objects:

- `dsp.AllpassFilter`
- `dsp.AllpoleFilter`
- `dsp.BiquadFilter`
- `dsp.Channelizer`
- `dsp.CICCompensationDecimator`
- `dsp.CICCompensationInterpolator`
- `dsp.CICDecimator`
- `dsp.CICInterpolator`
- `dsp.CoupledAllpassFilter`
- `dsp.Differentiator`
- `dsp.FarrowRateConverter`
- `dsp.FilterCascade`

- `dsp.FIRDecimator`
- `dsp.FIRFilter`
- `dsp.FIRHalfbandDecimator`
- `dsp.FIRHalfbandInterpolator`
- `dsp.FIRInterpolator`
- `dsp.FIRRateConverter`
- `dsp.FourthOrderSectionFilter`
- `dsp.HighpassFilter`
- `dsp.IIRFilter`
- `dsp.IIRHalfbandDecimator`
- `dsp.IIRHalfbandInterpolator`
- `dsp.LowpassFilter`
- `dsp.NotchPeakFilter`
- `dsp.SOSFilter`
- `dsp.VariableBandwidthFIRFilter`
- `dsp.VariableBandwidthIIRFilter`

**arithType — Arithmetic type**

`'double'` (default) | `'single'` | `'Fixed'`

Arithmetic used in the filter analysis, specified as `'double'`, `'single'`, or `'Fixed'`. When the arithmetic input is not specified and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When the arithmetic input is not specified and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Fixed'` value applies to filter System objects with fixed-point properties only.

When the `'Arithmetic'` input argument is specified as `'Fixed'` and the filter object has the data type of the coefficients set to `'Same word length as input'`, the arithmetic analysis depends on whether the System object is unlocked or locked.

- `unlocked` -- The analysis object function cannot determine the coefficients data type. The function assumes that the coefficients data type is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.
- `locked` -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the coefficients data type. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is auto scaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When the arithmetic input is specified as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

## Output Arguments

### **z — Location of zeros**

vector

Location of zeros of the filter transfer function on the zplane, returned as a column vector. The zeros are the roots of the polynomial whose coefficients are given by the numerator coefficients of the filter System object.

In case there are no zeros, the vector `z` is set to an empty matrix `[]`.

Data Types: `double`

### **p — Location of poles**

vector

Location of poles of the filter transfer function on the zplane, returned as a column vector. The poles are the roots of the polynomial whose coefficients are given by the denominator coefficients of the filter System object.

In case there are no poles, the vector `p` is set to an empty matrix `[]`.

Data Types: `double`

### **k — Gain of filter**

real scalar

Gain of the filter, returned as a real scalar.

Data Types: `double`

## Multirate Filter Properties

### In this section...

“Compatibility” on page 6-2

“Property Summaries” on page 6-2

“Property Details for Multirate Filter Properties” on page 6-5

“References for Multirate Filters” on page 6-12

### Compatibility

`mfilt` objects will be removed in a future release. Refer to the reference page for a specific `mfilt` object to see its recommended replacement.

### Property Summaries

The following table summarizes the multirate filter properties and provides a brief description of each. Full descriptions of each property are given in the subsequent section.

| Name              | Values   | Default       | Description  |
|-------------------|--|---------------|--|
| BlockLength       | Positive integers  | 100           | Length of each block of data input to the FFT used in the filtering. <code>fftfirinterp</code> multirate filters include this property.  |
| DecimationFactor  | Any positive integer   | 2             | Amount to reduce the input sampling rate.  |
| DifferentialDelay | Any integer  | 1             | Sets the differential delay for the filter. Usually a value of one or two is appropriate.  |
| FilterInternals   | FullPrecision,<br>MinWordLengths,<br>SpecifyWordLengths,<br>SpecifyPrecision | FullPrecision | Controls whether the filter sets the output word and fraction lengths, and the accumulator word and fraction lengths automatically to maintain the best precision results during filtering. The default value, <code>FullPrecision</code> , sets automatic word and fraction length determination by the filter. <code>SpecifyPrecision</code> exposes the output and accumulator related properties so you can set your own word and fraction lengths for them. |

| Name                | Values                 | Default           | Description   |
|---------------------|------------------------|-------------------|---|
| FilterStructure     | mfilt structure        | None              | Describes the signal flow for the filter object, including all of the active elements that perform operations during filtering — gains, delays, sums, products, and input/output. You cannot set this property — it is always read only and results from your choice of mfilt object.   |
| InputOffset         | Integers               | 0                 | Contains the number of input data samples processed without generating an output sample.<br>InputOffset = $\text{mod}(\text{length}(nx), m)$ where $nx$ is the number of input samples that have been processed so far and $m$ is the decimation factor.  |
| InterpolationFactor | Positive integers      | 2                 | Interpolation factor for the filter. $l$ specifies the amount to increase the input sampling rate.  |
| NumberOfSections    | Any positive integer   | 2                 | Number of sections used in the decimator, or in the comb and integrator portions of CIC filters.  |
| Numerator           | Array of double values | No default values | Vector containing the coefficients of the FIR lowpass filter used for interpolation.  |
| OverflowMode        | saturate, [wrap]       | wrap              | Sets the mode used to respond to overflow conditions in fixed-point arithmetic. Choose from either saturate (limit the output to the largest positive or negative representable value) or wrap (set overflowing values to the nearest representable value using modular arithmetic. The choice you make affects only the accumulator and output arithmetic. Coefficient and input arithmetic always saturates. Finally, products never overflow — they maintain full precision. |

| Name               | Values   | Default               | Description   |
|--------------------|--|-----------------------|---|
| PolyphaseAccum     | Values depend on filter type. Either double, single, or fixed-point object | 0                     | Stores the value remaining in the accumulator after the filter processes the last input sample. The stored value for PolyphaseAccum affects the next output when PersistentMemory is true and InputOffset is not equal to 0. Always provides full precision values. Compare the AccumWordLength and AccumFracLength.  |
| PersistentMemory   | false or true  | false                 | Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. PersistentMemory returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. |
| RateChangeFactors  | [l,m]  | [2,3] or [3,2]        | Reports the decimation (m) and interpolation (l) factors for the filter object. Combining these factors results in the final rate change for the signal. The default changes depending on whether the filter decimates or interpolates.   |
| States             | Any m+1-by-n matrix of double values                                       | 2-by-2 matrix, int32  | Stored conditions for the filter, including values for the integrator and comb sections. n is the number of filter sections and m is the differential delay. Stored in a filtstates object.   |
| SpecifyWordLengths | Vector of integers   | [16 16 16 16]<br>bits |   |

| Name                 | Values                                  | Default | Description   |
|----------------------|---|---------|---|
| WordLengthPerSection | Any integer or a vector of length $2*n$ | 16      | Defines the word length used in each section while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using 'wrap' arithmetic). Enter <code>WordLengthPerSection</code> as a scalar or vector of length $2*n$ , where $n$ is the number of sections. When <code>WordLengthPerSection</code> is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator. |

The following sections provide details about the properties that govern the way multirate filter work. Creating any multirate filter object puts in place a number of these properties. The following pages list the `mfilt` object properties in alphabetical order.

## Property Details for Multirate Filter Properties

### BitsPerSection

Any integer or a vector of length  $2*n$ .

Defines the bits per section used while accumulating the data in the integrator sections or while subtracting the data during the comb sections (using `wrap` arithmetic). Enter `bps` as a scalar or vector of length  $2*n$ , where  $n$  is the number of sections. When `bps` is a scalar, the scalar value is applied to each filter section. The default is 16 for each section in the decimator.

### BlockLength

Length of each block of input data used in the filtering.

`mfilt.fftfirinterp` objects process data in blocks whose length is determined by the value you set for the `BlockLength` property. By default the property value is 100. When you set the `BlockLength` value, try choosing a value so that  $[\text{BlockLength} + \text{length}(\text{filter order})]$  is a power of two.

Larger block lengths generally reduce the computation time.

### DecimationFactor

Decimation factor for the filter. `m` specifies the amount to reduce the sampling rate of the input signal. It must be an integer. You can enter any integer value. The default value is 2.

### DifferentialDelay

Sets the differential delay for the filter. Usually a value of one or two is appropriate. While you can set any value, the default is one and the maximum is usually two.

## FilterInternals

Similar to the FilterInternals pane in **Filter Designer**, this property controls whether the filter sets the output word and fraction lengths automatically, and the accumulator word and fraction lengths automatically as well, to maintain the best precision results during filtering. The default value, `FullPrecision`, sets automatic word and fraction length determination by the filter. Setting `FilterInternals` to `SpecifyPrecision` exposes the output and accumulator related properties so you can set your own word and fraction lengths for them.

### About FilterInternals Mode

There are four usage modes for this that you set using the `FilterInternals` property in multirate filters.

- `FullPrecision` — All word and fraction lengths set to  $B_{max} + 1$ , called  $B_{accum}$  by Fred Harris in [2]. Full precision is the default setting.
- `MinWordLengths` — Minimum Word Lengths
- `SpecifyWordLengths` — Specify Word Lengths
- `SpecifyPrecision` — Specify Precision

### Full Precision

In full precision mode, the word lengths of all sections and the output are set to  $B_{accum}$  as defined by

$$B_{accum} = \text{ceil}(N_{secs}(\text{Log}_2(D \times M)) + \text{InputWordLength})$$

where  $N_{secs}$  is the number of filter sections.

Section fraction lengths and the fraction length of the output are set to the input fraction length.

Here is the display looks for this mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'  
Arithmetic: 'fixed'  
DifferentialDelay: 1  
NumberOfSections: 2  
DecimationFactor: 4  
PersistentMemory: false
```

```
InputWordLength: 16  
InputFracLength: 15
```

```
FilterInternals: 'FullPrecision'
```

### Minimum Word Lengths

In minimum word length mode, you control the output word length explicitly. When the output word length is less than  $B_{accum}$ , roundoff noise is introduced at the output of the filter. Hogenauer's bit pruning theory (refer to [3] in the following References section) states that one valid design criterion is to make the word lengths of the different sections of the filter smaller than  $B_{accum}$  as well, so that the roundoff noise introduced by all sections does not exceed the roundoff noise introduced at the output.

In this mode, the design calculates the word lengths of each section to meet the Hogenauer criterion. The algorithm subtracts the number of bits computed using eq. 21 in Hogenauer's paper from  $B_{accum}$  to determine the word length each section.

To compute the fraction lengths of the different sections, the algorithm notes that the bits thrown out for this word length criterion are least significant bits (LSB), therefore each bit thrown out at a particular section decrements the fraction length of that section by one bit compared to the input fraction length. Setting the output word length for the filter automatically sets the output fraction length as well.

Here is the display for this mode:

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'MinWordLengths'

OutputWordLength: 16
```

### Specify Word Lengths

In this mode, the design algorithm discards the LSBs, adjusting the fraction length so that unrecoverable overflow does not occur, always producing a reasonable output.

You can specify the word lengths for all sections and the output, but you cannot control the fraction lengths for those quantities.

To specify the word lengths, you enter a vector of length  $2*(NumberOfSections)$ , where each vector element represents the word length for a section. If you specify a scalar, such as  $B_{accum}$ , the full-precision output word length, the algorithm expands that scalar to a vector of the appropriate size, applying the scalar value to each section.

The CIC design does not check that the specified word lengths are monotonically decreasing. There are some cases where the word lengths are not necessarily monotonically decreasing, for example

```
hcic=mfilt.cicdecim;
hcic.FilterInternals='minwordlengths';
hcic.Outputwordlength=14;
```

which are valid CIC filters but the word lengths do not decrease monotonically across the sections.

Here is the display looks like for the SpecifyWordLengths mode.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false
```

```
InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyWordLengths'

SectionWordLengths: [19 18 18 17]

OutputWordLength: 16
```

### Specify Precision

In this mode, you have full control over the word length and fraction lengths of all sections and the filter output.

When you elect the `SpecifyPrecision` mode, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the word length for each section. When you enter a scalar such as  $B_{accum}$ , the CIC algorithm expands that scalar to a vector of the appropriate size and applies the scalar value to each section and the output. The design does not check that this vector is monotonically decreasing.

Also, you must enter a vector of length  $2*(\text{NumberOfSections})$  with elements that represent the fraction length for each section as well. When you enter a scalar such as  $B_{accum}$ , the design applies scalar expansion as done for the word lengths.

Here is the `SpecifyPrecision` display.

```
FilterStructure: 'Cascaded Integrator-Comb Decimator'
Arithmetic: 'fixed'
DifferentialDelay: 1
NumberOfSections: 2
DecimationFactor: 4
PersistentMemory: false

InputWordLength: 16
InputFracLength: 15

FilterInternals: 'SpecifyPrecision'

SectionWordLengths: [19 18 18 17]
SectionFracLengths: [14 13 13 12]

OutputWordLength: 16
OutputFracLength: 11
```

### FilterStructure

Reports the type of filter object, such as a decimator or fractional integrator. You cannot set this property — it is always read only and results from your choice of `mfilt` object.

```
hm = mfilt.firdecim
```

```
hm =
```

```
    FilterStructure: 'Direct-Form FIR Polyphase Decimator'
           Arithmetic: 'double'
           Numerator: [1x48 double]
    DecimationFactor: 2
    PersistentMemory: false
```

## InputOffset

When you decimate signals whose length is not a multiple of the decimation factor  $M$ , the last samples —  $(nM + 1)$  to  $[(n+1)M - 1]$ , where  $n$  is an integer — are processed and used to track where the filter stopped processing input data and when to expect the next output sample. If you think of the filtering process as generating an output for a block of input data, `InputOffset` contains a count of the number of samples in the last incomplete block of input data.

---

**Note** `InputOffset` applies only when you set `PersistentMemory` to `true`. Otherwise, `InputOffset` is not available for you to use.

---

Two different cases can arise when you decimate a signal:

- 1 The input signal is a multiple of the filter decimation factor. In this case, the filter processes the input samples and generates output samples for all inputs as determined by the decimation factor. For example, processing 99 input samples with a filter that decimates by three returns 33 output samples.
- 2 The input signal is not a multiple of the decimation factor. When this occurs, the filter processes all of the input samples, generates output samples as determined by the decimation factor, and has one or more input samples that were processed but did not generate an output sample.

For example, when you filter 100 input samples with a filter which has decimation factor of 3, you get 33 output samples, and 1 sample that did not generate an output. In this case, `InputOffset` stores the value 1 after the filter run.

`InputOffset` equal to 1 indicates that, if you divide your input signal into blocks of data with length equal to your filter decimation factor, the filter processed one sample from a new (incomplete) block of data. Subsequent inputs to the filter are concatenated with this single sample to form the next block of length  $m$ .

One way to define the value stored in `InputOffset` is

```
InputOffset = mod(length(nx),m)
```

where  $nx$  is the number of input samples in the data set and  $m$  is the decimation factor.

Storing `InputOffset` in the filter allows you to stop filtering a signal at any point and start over from there, provided that the `PersistentMemory` property is set to `true`. Being able to resume filtering after stopping a signal lets you break large data sets in to smaller pieces for filtering. With `PersistentMemory` set to `true` and the `InputOffset` property in the filter, breaking a signal into sections of arbitrary length and filtering the sections is equivalent to filtering the entire signal at once.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =
    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]
ysec =
    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### **InterpolationFactor**

Amount to increase the sampling rate. Interpolation factor for the filter. It specifies the amount to increase the input sampling rate. It must be an integer. Two is the default value. You may use any positive value.

### **NumberOfSections**

Number of sections used in the multirate filter. By default multirate filters use two sections, but any positive integer works.

### **OverflowMode**

The `OverflowMode` property is specified as one of the following two character vectors indicating how to respond to overflows in fixed-point arithmetic:

- `'saturate'` — saturate overflows.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the applicable word length and fraction length properties), these values are quantized to the value of either the largest or smallest representable value, depending on which is closest.

- `'wrap'` — wrap all overflows to the range of representable values.

When the values of data to be quantized lie outside of the range of the largest and smallest representable numbers (as specified by the data format properties), these values are wrapped back into that range using modular arithmetic relative to the smallest representable number. You can learn more about modular arithmetic in Fixed-Point Designer documentation.

These rules apply to the `OverflowMode` property.

- Applies to the accumulator and output data only.
- Does not apply to coefficients or input data. These always saturate the results.
- Does not apply to products. Products maintain full precision at all times. Your filters do not lose precision in the products.

### **Default value**

: `'saturate'`

---

**Note** Numbers in floating-point filters that extend beyond the dynamic range overflow to  $\pm\text{inf}$ .

---

### **PolyphaseAccum**

The idea behind `PolyphaseAccum` and `AccumWordLength/AccumFracLength` is to distinguish between the adders that always work in full precision (`PolyphaseAccum`) from the others [the adders that are controlled by the user (through `AccumWordLength` and `AccumFracLength`) and that may introduce quantization effects when you set property `FilterInternals` to `SpecifyPrecision`].

Given a product format determined by the input word and fraction lengths, and the coefficients word and fraction lengths, doing full precision accumulation means allowing enough guard bits to avoid overflows and underflows.

Property `PolyphaseAccum` stores the value that was in the accumulator the last time your filter ran out of input samples to process. The default value for `PolyphaseAccum` affects the next output only if `PersistentMemory` is `true` and `InputOffset` is not equal to 0.

`PolyphaseAccum` stores data in the format for the filter arithmetic. Double-precision filters store doubles in `PolyphaseAccum`. Single-precision filter store singles in `PolyphaseAccum`. Fixed-point filters store `fi` objects in `PolyphaseAccum`.

### PersistentMemory

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected.

Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter object. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true` — the filter retains memory about filtering operations from one to the next. Maintaining memory lets you filter large data sets as collections of smaller subsets and get the same result.

```
xtot=[x,x];
ytot=filter(hm1,xtot)
ytot =

    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
reset(hm1); % Clear history of the filter
hm1.PersistentMemory='true';
ysec=[filter(hm1,x) filter(hm1,x)]

ysec =

    0    -0.0003    0.0005   -0.0014    0.0028   -0.0054    0.0092
```

This test verifies that `ysec` (the signal filtered by sections) is equal to `ytot` (the entire signal filtered at once).

### RateChangeFactors

Reports the decimation (`m`) and interpolation (`l`) factors for the filter object when you create fractional integrators and decimators, although `m` and `l` are used as arguments to both decimators and integrators, applying the same meaning. Combining these factors as input arguments to the fractional decimator or integrator results in the final rate change for the signal.

For decimating filters, the default is [2,3]. For integrators, [3,2].

### States

Stored conditions for the filter, including values for the integrator and comb sections. `m` is the differential delay and `n` is the number of sections in the filter.

### About the States of Multirate Filters

In the `states` property you find the states for both the integrator and comb portions of the filter, stored in a `filtstates` object. `states` is a matrix of dimensions  $m+1$ -by- $n$ , with the states in CIC filters apportioned as follows:

- States for the integrator portion of the filter are stored in the first row of the state matrix.
- States for the comb portion fill the remaining rows in the state matrix.

In the state matrix, state values are specified and stored in `double` format.

`States` stores conditions for the delays between each interpolator phase, the filter states, and the states at the output of each phase in the filter, including values for the interpolator and comb states.

The number of states is  $(lh-1)*m+(l-1)*(lo+mo)$  where  $lh$  is the length of each subfilter, and  $l$  and  $m$  are the interpolation and decimation factors.  $lo$  and  $mo$ , the input and output delays between each interpolation phase, are integers from Euclid's theorem such that  $lo*l-mo*m = -1$  (refer to the reference for more details). Use `euclidfactors` to get  $lo$  and  $mo$  for an `mfilt.firfracdecim` object.

`States` defaults to a vector of zeros that has length equal to `nstates(hm)`
